acs_get_parent_partition

Creates a collection of designs that are compiled partitions containing the specified subdesign.

SYNTAX

```
string acs_get_parent_partition
      design_name
      [-hierarchy]
      [-list]
```

Data Types

design_name string

ARGUMENTS

design_name

Specifies the name of a subdesign.

-hierarchy

Causes the command to collect all parent partitions of the specified design. By default only the immediate parent partition is returned.

-list

Causes the command to return a list of names. Without this option a collection of design objects is returned.

DESCRIPTION

The **acs_get_parent_partition** command returns the lowest-level compile partition that contains the specified subdesign. If the specified subdesign is a compile partition, the command returns the subdesign. If the **-hierarchy** option is specified, all partitions that contain the subdesign are included in the collection. If the subdesign is in the subtree of a multiply instantiated design, all parent partitions of all instances of this multiply instantiated design are included in the result. The command creates a collection containing the design objects, unless the **-list** option is specified. In this case, the command returns a Tcl list with the names of the designs.

SEE ALSO

[set_compile_partitions\(2\)](#)

acs_read_hdl

Reads in the HDL source code of a design and generates the GTECH representation.

SYNTAX

```
status acs_read_hdl
[design_name]
[-hdl_source file_or_dir_list]
[-exclude_list file_or_dir_list]
[-format {verilog | vhdl}]
[-recurse]
[-no_dependency_check]
[-no_elaborate]
[-library design_lib_name]
[-verbose]
[-auto_update | -update file_list]
[-destination destination_dir]
[-sv_package_files file_list]
```

Data Types

<i>design_name</i>	string
<i>file_or_dir_list</i>	list
<i>design_lib_name</i>	string
<i>file_list</i>	list
<i>destination_dir</i>	string

ARGUMENTS

design_name

Specifies the name of the top-level design. Elaboration starts at the specified module and elaborates the entire design subtree under that module. This argument is required unless the **-no_elaborate** option is specified.

-hdl_source *file_or_dir_list*

Specifies a list of files or directories containing the source code of the design. The **acs_read_hdl** command analyzes the contents of all files in the list (and in the subdirectories if the **-recurse** option is set) according to the **acs_verilog_extensions**, **acs_vhdl_extensions**, **acs_exclude_list**, and **acs_exclude_extensions** variables.

If this option is not specified, the command uses the **acs_hdl_source** Tcl variable by default. If the **acs_hdl_source** variable is not defined, the **search_path** variable is used. The command-line argument overrides the variables. The names in the **-hdl_source** lists can contain wildcards. The command performs a Tcl glob-style expansion on each list item.

-exclude_list *file_or_dir_list*

Specifies a list of files and directories that are not to be analyzed. If the command expands an item from the **-hdl_source** list, it checks the file or directory against all entries of this list and ignores the file or directory if it is covered by at least one of the entries.

If this option is omitted, the command uses the **acs_exclude_list** Tcl variable. The command-line argument overrides the variable.

It is possible to apply Tcl's UNIX-like filename globbing features by using the *, ?, and [] in file and directory names in this list. Add a file name (wildcards are allowed) without a path to exclude all files with that name regardless of their location.

-format {verilog | vhdl}

Specifies that **acs_read_hdl** is to only look for files of the specified language with extensions from the corresponding extensions list for the **acs_verilog_extensions** or **acs_vhdl_extensions** variables. The default is that the command reads in all files it finds with Verilog extensions and VHDL extensions.

Use this option when you want to specify file names in the **-hdl_source** list that do not have one of the language-specific extensions.

-recurse

Specifies that the command is to look into subdirectories of directories specified in the **-hdl_source** list, and recursively collect source files from that location.

The default is that the command looks into the specified directories, but does not look in their subdirectories.

-no_dependency_check

Causes the command not to detect Verilog include files, not to determine VHDL libraries, and not to reorder the source file list. Instead, the command processes the HDL source file list from left to right and analyzes VHDL files into the current working library or the library specified with the **-library** option.

-no_elaborate

Prevents **acs_read_hdl** from performing the elaboration. The command stops after all source files are analyzed. Specify this option when you want to manually elaborate the design after the command finishes.

-library *design_lib_name*

Specifies the library that is used as the working library for all VHDL files.

-verbose

Prints out more messages.

-auto_update

Automatically determines the HDL files to update, puts them in order according to the dependency (unless the **-no_dependency_check** option is specified) and analyzes and elaborates the files. The designs defined in the specified HDL file(s) replace the corresponding designs in the unmapped design in the destination directory. The option also creates the tables of timestamps used by the subsequent **acs_read_hdl -auto_update**, **acs_read_hdl -update**, and **acs_merge_design -auto_update** commands.

This option is mutually exclusive with the **-update** option.

-update *file_list*

Analyzes and elaborates the specified HDL source files in the given order. The designs defined in the specified HDL file(s) replace the corresponding designs in the unmapped design in the destination directory. The option also creates the tables of timestamps used by the subsequent **acs_read_hdl -auto_update**, **acs_read_hdl -update**, and **acs_merge_design -auto_update** commands.

This option is mutually exclusive with the **-auto_update** option.

-destination *destination_dir*

Specifies the directory to which the unmapped design is written when either the **-update** or the **-auto_update** option is specified. The default is that the command writes the unmapped design and the timestamp tables to the elab/db directory.

DESCRIPTION

The **acs_read_hdl** command reads in the HDL source files of a design, analyzes them, and elaborates the design starting at the specified top-level module. It retains the resulting GTECH representation in memory.

To locate the source files, the command expands each item from the **-hdl_source** list. The list is either specified as an option with **-hdl_source** at the command line, or set as the value of the **acs_hdl_source** Tcl variable. If neither of these methods are used, then the **search_path** variable is used. The **acs_read_hdl** command performs a Tcl glob-style expansion on an item and checks if the result is excluded by the **acs_exclude_list** or the **acs_exclude_extensions** variable. If it is not excluded and a file ends with one of the extensions from the **acs_vhdl_extensions** variable extensions list, it is considered a VHDL source file. If the file ends with one of the **acs_verilog_extensions**, it is considered a Verilog source file.

If an expansion is a directory, the command collects the files from the directory, and recursively from its subdirectories if the **-recursive** option is set. The command then performs all extension checks on these files. If the **-format** option is set, only files with Verilog or VHDL extensions are collected (based on the value of the option).

After **acs_read_hdl** collects all of the source files, it performs the following dependency checks (unless the **-no_dependency_check** option is specified).

- Detects Verilog include files to verify that they are not analyzed as source code files.
- If a Verilog include file that appears only in the list of HDL source files is detected, but its directory does not appear in the global **search_path** variable, and it is included in the Verilog source code without giving the path, then **acs_read_hdl** appends the include file's directory to the **search_path**. This enables the **analyze** or **read_verilog** commands to locate the file. You are notified about the changes made.
- Detects Verilog macro usage and definition and reorders files accordingly to ensure that they are analyzed in the correct order. This might not always be possible, such as when a macro is defined several times in different files or when macros are defined in files included by other include files.
- Determines the target library for each VHDL file. However, if the **-library** option is specified, this step is skipped and all VHDL files are analyzed into the specified design library.
- Orders the VHDL source files to ensure that they are analyzed in the correct order.

After analyzing all source files, the design is elaborated from the top-level module, unless the **-no_elaborate** option is specified. The resulting GTECH representation is retained in memory.

If either the **-update** or the **-auto_update** option is specified, then the GTECH representation (unmapped design) is written to the specified destination directory. The default destination directory is elab/db.

When the **acs_read_hdl -auto_update** or **acs_read_hdl -update** command is called the first time, all of the source HDL files are analyzed and elaborated to create the unmapped design and the timestamp tables. Subsequent **acs_read_hdl -auto_update** commands only analyze and elaborate the updated HDL source files and subsequent **acs_read_hdl -update** commands only analyze and elaborate the specified HDL source files. The updated designs are replaced in the unmapped design. The first issuance of the **acs_read_hdl** command is determined by the presence of the unmapped design file and timestamp tables in the destination directory.

EXAMPLES

The following example assumes that the current directory is the source directory. It specifies the source file list at the command line and calls the command with the name of the top-level entity.

```
prompt> acs_read_hdl -hdl_source {.} -recurse E1
```

The next example specifies extensions for Verilog files that are different than the default (.v), sets the **-hdl_source** list and the **exclude_list** list, and calls the command with the name of the top-level module name, forcing it to only collect files with Verilog extensions.

```
prompt> set acs_verilog_extensions { .ve .VE }
prompt> set acs_hdl_source {mod1/src mod2/*/src}
prompt> set acs_exclude_list {mod1/src/incl mod2/*/src/incl}
prompt> acs_read_hdl -f verilog -no_dep TOP
```

Note that excluding include directories explicitly is only necessary if include files have the same extensions as source files and not all

include files are included in the source.

```
prompt> acs_read_hdl -hdl_source src/mixed -auto_update
```

The first time the above command is issued, all of the mixed (Verilog and VHDL) HDL files from the specified directory are analyzed and elaborated, and the resulting unmapped design is written to the default destination directory along with the timestamp tables. The timestamp tables are used by the **acs_merge_design -auto_update** command to determine which designs are new, so that the partitions which depend on the updated designs are recompiled by the **acs_compile_design -update** command. The subsequent calls to the above command only analyze and elaborate the updated HDL files, and the corresponding designs are replaced in the unmapped design in the destination directory.

acs_report_user_messages

Reports the number of error, warning, and information messages.

SYNTAX

```
status acs_report_user_messages
      [-total]
      [-errors]
      [-warnings]
      [-infos]
      [-reset]
```

ARGUMENTS

-total

Prints the total number of error messages that have occurred since the the current session began. The default is to print the number of error messages since the last call to the **acs_report_user_messages** command.

-errors

Prints the number of error messages that have occurred since the last call to **acs_report_user_messages**.

-warnings

Prints the number of warning messages that have occurred since the last call to **acs_report_user_messages**.

-infos

Prints the number of informational messages that have occurred since the last call to **acs_report_user_messages**.

-reset

Resets the counters for the errors, warnings, and informational messages. However, subsequent calls to **acs_report_user_messages** with the **-total** option prints the number of error, warning, and information messages since the start of the session.

DESCRIPTION

The **acs_report_user_messages** command reports the number of error, warning, and information messages.

You can use any combination of the **-errors**, **-warnings**, and **-infos** options with the command. If no options are specified, then the effect is the same as if all three of the options are specified; all three types of messages are printed. Note that the **-total** option is independent of these three options.

The ACS chip-level compile commands **acs_compile_design**, **acs_recompile_design**, and **acs_refine_design** issue the **acs_report_user_messages -reset** command when the commands begin.

EXAMPLES

The following example prints the number of error, warning, and information messages since the last call to **acs_report_user_messages**:

```
prompt> acs_report_user_messages
```

The following example prints the number of warning and error messages that have occurred since the last call to **acs_report_user_messages**:

```
prompt> acs_report_user_message -errors -warnings
```

The following example prints the number of errors since the start of the session:

```
prompt> acs_report_user_message -errors -total
```

add_module

Reads in a specified library file containing module functional information and uses it to update an existing technology library.

SYNTAX

```
status add_module
  [-overwrite]
  [-force]
  [-permanent]
  file_name
  library_name
  [-no_warnings]
```

Data Types

```
file_name    string
library_name  string
```

ARGUMENTS

-overwrite

Indicates that a group declared in *file_name* is to overwrite any group in *library_name* having the same name. Only groups added by **add_module** or **model** can be overwritten. Groups included in the original library and groups added with the **-permanent** option cannot be modified. If **-force** is specified, some library-level groups (wire_load, power_supply, and operating_conditions) included in the original library can be modified. The other groups included in the original library and groups added with **-permanent** cannot be modified.

-force

Indicates that some library-level groups and attributes declared in *file_name* can overwrite the same groups and attributes included in the original library. The library-level groups are as follows:

```
wire_load
power_supply
operating_conditions.
```

The library-level attributes are as follows:

```
<k_factors>
in_place_swap_mode
default_wire_load_mode
default_wire_load_selection
default_wire_load_capacitance
default_wire_load_resistance
default_wire_load_area
default_operating_conditions
```

-permanent

Indicates to store groups declared in *file_name* in the library in such a way that they cannot be overwritten.

file_name

Specifies the name of the file in which one or more new groups containing module functional information are listed. The syntax of this file is the same as that expected by **read_lib**, except that the file contains only library-level groups without the library() {} group definition.

library_name

Specifies the name of the library to update. The library must reside in memory. This option can be a simple filename with no directory specification and, therefore, no slash ("") (for example, test_db or library.db). Simple filenames must be found in a directory listed in the search_path. Alternatively, this option can be a complex filename, which has a directory specification (for example, ~synopsys/dc/test.lib). Complex filenames are not included in the search_path.

-no_warnings

Indicates that all warning messages are suppressed. The default is to issue all warning messages. Warning messages can identify serious library problems; use this option sparingly.

DESCRIPTION

This command reads in a library file and adds to the specified library only those groups with module functional information declared in the library file. Groups are added to the library as if they were entered at the end of the original text of the library. If the tool finds any errors while processing a group, it does not add that group to the library. You do not need a Library Compiler License to add groups with module functionality to a technology library.

For details on library file syntax, see the Library Compiler manuals.

EXAMPLES

The following example adds the library file *add_ram.lib*, which contains module information, (that is, a RAM group) to the library memory.

```
prompt> add_module add_ram.lib memory
```

The following example adds the library file *romgen.lib*, which contains a cell description of a ROM cell, to the cmos library. The **-permanent** option indicates that the new cell cannot be overwritten.

```
prompt> add_module -permanent romgen.lib cmos
```

SEE ALSO

read_lib(2)
update_lib(2)
write_lib(2)

add_parameter

Define parameters that can be overridden by apply_power_model.

SYNTAX

```
status add_parameter
  parameter_name
  [-default default_value]
  [-type type_name]
  [-description description text]
```

Data Types

parameter_name	string
default_value	string
type_name	buildtime, runtime, or rate
description	text string
text	description

ARGUMENTS

parameter_name

Specifies the name of the parameter to be defined inside a power model.

-default default_value

Specifies the default value of the parameter if there is no parameter mapping specified in the apply_power_model command.

-type type_name

When -type option is specified, the parameter defined is used for system-level IP power model. The parameter scope is within the power model only and power models and power functions cannot access parameters that are defined outside of the power model in which they are used.

Three types of parameters can be defined as follows:

1. Build time - for parameters that remain unchanged during run time
2. Run time - for parameters that can change during run time
3. Rate - for parameters that represent rate-based quantities that can change during run time

-description description text

Text description of the parameter.

DESCRIPTION

The add_parameter command is used to define parameters for use within a power model. A parameter can be used just like a regular Tcl variable by prepending the parameter name with the \$ keyword.

This command can only be defined within the define_power_model command and applied to a macro instance through the apply_power_model command. It is an error if this command is executed through the load_upf command.

The -parameters option of the apply_power_model command can change the value of a parameter during application of the power model on a macro instance. If the parameter is not found in the -parameter option, default value specified in add_parameter will be used.

A power model provides a self-contained environment for variables. Parameters defined outside a power model are not visible inside the power model. Parameters defined within a power model are only visible inside the power model.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
define_power_model MODEL -for {lib_cell} {
    add_parameter PD_NAME -default "PD" -description "power domain in model"
    add_parameter process -type buildtime -default 1.0
    add_parameter cache_miss -type rate -default 0.02
    create_supply_net VDD
    create_supply_net VSS
    create_supply_set SS -function {power VDD} -function {ground VSS}
    create_power_domain $PD_NAME -supply {primary SS} -include_scope
}
apply_power_model MODEL -parameters {{PD_NAME pd_macro}}
```

SEE ALSO

```
define_power_model(2)
apply_power_model(2)
report_power_model(2)
```

add_pg_pin_to_db

Converts a non-PG-pin-based logic library in compiled format (.db file) into a PG-pin-based logic library in .db format.

SYNTAX

```
status add_pg_pin_to_db
  input_db_filename
  -output pg_db_filename
  [-mw_library_name mw_lib_name]
  [-pg_map_file map_file]
  [-pg_map_template template_filename]
  [-expanded]
  [-fast]
  [-force_update]
  [-verbose]
```

Data Types

<i>input_db_filename</i>	string
<i>pg_db_filename</i>	string
<i>mw_lib_name</i>	list
<i>map_file</i>	string
<i>template_filename</i>	string

ARGUMENTS

input_db_filename

Specifies the name of the existing logic library in compiled format (.db file) that lacks PG pin data.

-output *pg_db_filename*

Specifies the name of the new PG-pin-based .db file generated by the conversion. This name must be different from the name of the input .db file unless the **-force_update** option is used.

-mw_library_name *mw_lib_name*

Specifies the names of one or more Milkyway libraries containing the FRAM views of the input .db library file. The FRAM views provide PG pin information used to update the library.

-pg_map_file *map_file*

Specifies the name of a text file that defines the mapping between non-PG-pin-based data and PG-pin-based data.

-pg_map_template *template_filename*

Specifies the file name a map template. If you use this option, the command generates only a map template file; it does not perform a library update. You can edit the generated template file and use it to specify the PG mapping for a subsequent **add_pg_pin_to_db** command.

-expanded

Generates an expanded rather than compressed PG map template. By default, when you use the **-pg_map_template** option, the command generates a compressed PG map template, using wildcards to specify multiple mappings where possible, to reduce the file size. Use this option to generate a PG map template with the wildcards expanded to individual names.

-fast

Generates a PG pin library from a non-PG pin library without using a PG map file. This option uses the information available in the Milkyway FRAM view, the input non-PG pin library, or a combination of both. It is recommended that you use the FRAM view, which helps identify the names of the cell's PG pins. If you omit the **-mw_library_name** option, the FRAM view is not used and the **-fast** option can only infer the PG pin names if they are specified in the logic library's Liberty (.lib file) attributes: **rail_connection**, **input_signal_level**, and **output_signal_level**.

-force_update

Forces the command to update the library data based on the input data and overwrite the existing data in the library. By default, the command writes out a new .db library and retains the existing library.

-verbose

Writes out all sections of the PG map data, whether generated automatically or expanded from a compressed PG map file.

DESCRIPTION

The **add_pg_pin_to_db** command converts a non-PG-pin-based logic library in compiled format (.db file) into a PG-pin-based logic library and writes out the new, updated library in .db format.

The command converts and updates a logic library automatically from the old **rail_connection** Liberty syntax or from a format that is not based on PG pin syntax to a library with PG pin syntax. You specify an existing logic library in .db format and the related physical libraries with Milkyway FRAM views, if available, and a PG map file.

The command gets information it needs to perform the conversion from the FRAM views in the Milkyway library or from the PG map file, or both. The PG map file is a text file that specifies the mapping between signal pins and their related power and ground pins, between PG pins and their corresponding voltage names, and between voltage names and voltage values.

You can use the **add_pg_pin_to_db** command with the **-pg_map_template** option to automatically generate a PG map template file, which you can then edit to provide the specific mapping information. When you use this option, the command only writes out the PG map template file and does not actually perform the library conversion. You first need to edit the template file, then use the command again with the **-pg_map_file** option to perform the library conversion.

The options you can use depend on whether a Milkyway library with FRAM views is available:

- With a complete Milkyway library

If all cells have single PG rail (one power rail and one ground rail), the **-pg_map_file** option is not required; use the **-mw_library_name** option to allow the command to derive the mapping from the Milkyway FRAM view. If some cells have multiple PG rails, the **-pg_map_file** option is required.

- Without a Milkyway library (.db library only)

If you specify only a logic library (.db file), without using the **-mw_library_name** option, you need to use the **-pg_map_file** option, whether the library uses single or multiple PG rails.

- With a partial Milkyway library

If some cells exist in both the logic library and the Milkyway library while others exist only in the logic library, you need to use the **-pg_map_file** option for the cells that are missing from the Milkyway library.

For more information, see "Adding PG Pin Syntax to Logic Libraries" in the "UPF Library Preparation Application Notes," available on SolvNet.

EXAMPLES

The following example writes out a PG map template file named "pg.map" using information from the compiled logic library "old.db" and the corresponding FRAM views in the Milkyway library named "mw_lib." This command does not convert the library; it only writes out the PG map template file, which you can edit and use later for library conversion.

```
prompt> add_pg_pin_to_db old.db -mw_library_name {mw_lib} \
-pg_map_template pg.map
```

The following example converts a non-PG-pin-based logic library named "old.db" into a PG-pin-based library named "pg.db."

```
prompt> add_pg_pin_to_db old.db -mw_library_name {mw_lib} \
-pg_map_file pg.map -output pg.db
```

SEE ALSO

[add_pg_pin_to_lib\(2\)](#)

add_pg_pin_to_lib

Converts a non-PG-pin based logic library in Liberty format (.lib file) into a PG-pin-based logic library in .lib format.

SYNTAX

```
status add_pg_pin_to_lib
  input_lib_filename
  -output pg_lib_filename
  [-mw_library_name mw_lib_name]
  [-pg_map_file map_file]
  [-pg_map_template template_filename]
  [-common_shell_path common_shell_path]
  [-expanded]
  [-fast]
  [-force_update]
  [-verbose]
```

Data Types

<i>input_lib_filename</i>	string
<i>pg_lib_filename</i>	string
<i>mw_lib_name</i>	list
<i>map_file</i>	string
<i>template_filename</i>	string
<i>common_shell_path</i>	string

ARGUMENTS

input_lib_filename

Specifies the name of the existing logic library in Liberty format (.lib file) that lacks PG pin data.

-output *pg_lib_filename*

Specifies the name of the new PG-pin-based .lib file generated by the conversion. This name must be different from the name of the input .lib file unless the **-force_update** option is used.

-mw_library_name *mw_lib_name*

Specifies the names of one or more Milkyway libraries containing the FRAM views of the input .lib library file. The FRAM views provide PG pin information used to update the library.

-pg_map_file *map_file*

Specifies the name of a text file that defines the mapping between non-PG-pin-based data and PG-pin-based data, including the power management attributes.

-pg_map_template *template_filename*

Specifies the file name a map template. If you use this option, the command generates only a map template file; it does not perform a library update. You can edit the generated template file and use it to specify the PG mapping for a subsequent

add_pg_pin_to_lib command.

-common_shell_path common_shell_path

Specifies a common shell path where **lc_shell** or **dc_shell** resides, to compile the input .lib using an older tool version. By default, the current Library Compiler or Design Compiler tool version is used. Use this option for older .lib files, when the latest utility version cannot compile the input .lib file due to new checking applied in the current version.

-expanded

Generates an expanded rather than compressed PG map template. By default, when you use the **-pg_map_template** option, the command generates a compressed PG map template, using wildcards to specify multiple mappings where possible, to reduce the file size. Use this option to generate a PG map template with the wildcards expanded to individual names.

-fast

Generates a PG pin library from a non-PG pin library without using a PG map file. This option uses the information available in the Milkyway FRAM view, the input non-PG pin library, or a combination of both. It is recommended that you use the FRAM view, which helps identify the names of the cell's PG pins. If you omit the **-mw_library_name** option, the FRAM view is not used and the **-fast** option can only infer the PG pin names if they are specified in the logic library's Liberty (.lib file) attributes: **rail_connection**, **input_signal_level**, and **output_signal_level**.

-force_update

Forces the command to update the library data based on the input data and overwrite the existing data in the library. By default, the command writes out a new .lib library and retains the existing library.

-verbose

Writes out all sections of the PG map data, whether generated automatically or expanded from a compressed PG map file.

DESCRIPTION

The **add_pg_pin_to_lib** command converts a non-PG-pin based logic library in Liberty format (.lib file) into a PG-pin-based logic library and writes out the new, updated library in .lib format.

The command converts and updates a logic library automatically from the old **rail_connection** Liberty syntax or from a format that is not based on PG pin syntax to a library with PG pin syntax. You specify an existing logic library in .lib format and the related physical libraries with Milkyway FRAM views, if available, and a PG map file.

The command gets information it needs to perform the conversion from the FRAM views in the Milkyway library or from the PG map file, or both. The PG map file is a text file that specifies the mapping between signal pins and their related power and ground pins, between PG pins and their corresponding voltage names, and between voltage names and voltage values.

You can use the **add_pg_pin_to_lib** command with the **-pg_map_template** option to automatically generate a PG map template file, which you can then edit to provide the specific mapping information. When you use this option, the command only writes out the PG map template file and does not actually perform the library conversion. You first need to edit the template file, then use the command again with the **-pg_map_file** option to perform the library conversion.

The options you can use depend on whether a Milkway library with FRAM views is available:

- With a complete Milkyway library

If all cells have single PG rail (one power rail and one ground rail), the **-pg_map_file** option is not required; use the **-mw_library_name** option to allow the command to derive the mapping from the Milkyway FRAM view. If some cells have multiple PG rails, the **-pg_map_file** option is required.

- Without a Milkyway library (.lib library only)

If you specify only a logic library (.lib file), without using the **-mw_library_name** option, you need to use the **-pg_map_file** option, whether the library uses single or multiple PG rails.

- With a partial Milkyway library

If some cells exist in both the logic library and the Milkyway library while others exist only in the logic library, you need to use the **-pg_map_file** option for the cells that are missing from the Milkyway library.

For more information, see "Adding PG Pin Syntax to Logic Libraries" in the "UPF Library Preparation Application Notes," available on SolvNet.

EXAMPLES

The following example writes out a PG map template file named "pg.map" using information from the Liberty logic library "old.lib" and the corresponding FRAM views in the Milkyway library named "mw_lib." This command does not convert the library; it only writes out the PG map template file, which you can edit and use later for library conversion.

```
prompt> add_pg_pin_to_lib old.lib -mw_library_name {mw_lib} \
    -pg_map_template pg.map
```

The following example converts a non-PG-pin-based logic library named "old.lib" into a PG-pin-based library named "pg.lib."

```
prompt> add_pg_pin_to_lib old.lib -mw_library_name {mw_lib} \
    -pg_map_file pg.map -output pg.lib
```

SEE ALSO

[add_pg_pin_to_db\(2\)](#)

add_port_state

Adds state information to a supply port.

SYNTAX

```
string add_port_state
  supply_port_name
  -state {state_name state_value}
```

Data Types

```
supply_port_name  string
state_name        string
state_value       string
```

ARGUMENTS

supply_port_name

Specifies the name of the supply port. Hierarchical names are allowed.

-state {state_name state_value}

Specifies the name and value of a state of the supply port. You can repeat this option. The state value can be one of the following:

- A single floating point number that represents the nominal voltage for the specified state. For example, to define a state called s88 with a nominal voltage of 0.88, use the following syntax:

```
-state {s88 0.88}
```

- Three floating point numbers that represent the minimum, nominal, and maximum voltages of the specified state, respectively. For example, to define a state called active_state with a minimum voltage of 0.88, a nominal voltage of 0.90, and a maximum voltage of 0.92, use the following syntax:

```
-state {active_state 0.88 0.90 0.92}
```

NOTE: It is an error if minimum voltage is greater than (>) the nominal voltage or the nominal voltage is greater than (>) the maximum voltage.

- The keyword **off**, which indicates an inactive state. For example, to define an inactive state called off_state, use the following syntax:

```
-state {off_state off}
```

DESCRIPTION

This command adds state information to a supply port. The first occurrence of the *supply_port_name* option is the default state of the supply port. You can use this to represent off-chip supply sources that are not driven by the testbench. This option defines the voltage level supplied to the chip. It provides a convenient shortcut to facilitate verification and analysis without requiring the creation of a power domain and a supply network within the verification environment. An error occurs if *supply_port_name* does not already exist before executing this command.

This command returns the fully-qualified name from the current scope of the created port or a null string if the port is not created.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the states and voltages of a supply port named VN1:

```
prompt> add_port_state VN1 \
           -state {active_state 0.88 0.90 0.92} \
           -state {off_state off}
```

SEE ALSO

[add_pst_state\(2\)](#)
[create_pst\(2\)](#)
[report_pst\(2\)](#)

add_power_state

Adds state information to a supply set or a group or a domain.

SYNTAX

```
status add_power_state
  [-supply | -group | -domain] object_name
  [-simstate {simstate}]
  [-update]
  [-state state_name {[ -supply_expr {supply_expression} ]
    [-logic_expr {logic_expression}]
    [-simstate {simstate}]
    [-illegal]}]*
```

Data Types

<i>object_name</i>	string
<i>simstate</i>	string
<i>state_name</i>	string
<i>supply_expression</i>	string
<i>logic_expression</i>	string

ARGUMENTS

-supply | -group | -domain *object_name*

Specifies the name of a supply set, or the name of a group created with the **create_power_state_group** command, or the name of a domain. The name should be a simple (nonhierarchical) name.

-state *state_name*

Specifies the name of the state of the supply set or the group or the domain. The name should be a simple (nonhierarchical) name. This option can be specified multiple times in the same command.

-supply_expr {*supply_expression*}

Specifies a Boolean expression in terms of nets and their netstates. This option can only be specified when the *object_name* is a supply set. The only operator allowed in the Boolean expression is && (AND operator). Each subexpression in the Boolean expression specifies the net and netstate definitions. Each subexpression must have the following syntax:

net == netstate

The *net* can be power or ground and the *netstate* syntax must be one of the following:

```
status
`{status}
`{status, nom}
`{status, min, max}
`{status, min, nom, max}
```

```
{status}
{status nom}
{status min max}
{status min nom max}
```

- *status* can be OFF or FULL_ON
- *min*, *nom*, and *max* are floating-point numbers representing the minimum, nominal, and maximum voltages of the specified state, respectively.

NOTE: It is an error if *min* is greater than (>) *nom* or if *nom* is greater than (>) *max*.

- If the *status* is FULL_ON, at least one voltage must be defined.

-logic_expr {logic_expression}

If the *object_name* is a supply set, then this option specifies a SystemVerilog Boolean expression in terms of logic nets and supply nets. The **-logic_expr** option does not affect implementation and is intended to be used by simulation tools, to read and write transparently.

If the *object_name* is a group or a domain, then this option specifies a Boolean expression in terms of supply sets/groups/domains/PSTs and their states. The only operator allowed in the Boolean expression is &&.

-simstate {simstate}

Specifies a simstate for the power states associated with a supply set. Valid values are NORMAL, CORRUPT_ON_ACTIVITY, CORRUPT, NOT_NORMAL, CORRUPT_STATE_ON_CHANGE, CORRUPT_STATE_ON_ACTIVITY and CORRUPT_ON_CHANGE. This option can only be specified when the *object_name* is a supply set. The **-simstate** option does not affect implementation and is intended to be used by simulation, so the tool reads and writes the information specified with this option transparently.

This option can be specified for every state that is defined with the **add_power_state** command:

```
add_power_state -state state_name {-simstate simstate_value}.
```

This option can also be specified globally for the entire **add_power_state** command:

```
add_power_state -simstate simstate_value -state state_name {...}
```

However, the UPF standard does not use the **-simstate** globally. It is retained only for backward compatibility purposes and will be obsolete in a future release.

-update

Specifies additional power states (supply set states or group states or domain states) to add to an object. Also specifies additional power state intent to add to an existing state.

For supply sets, this option can be used to add incremental information (**-logic_expr**, **-supply_expr**, **-simstate**) to an existing supply set state.

For groups and domains, this option can be used to add incremental information (**-logic_expr**) to an existing group or domain state.

-illegal

Indicates that the state defined (for a supply set or a group) is an illegal state.

DESCRIPTION

This command adds state information to a supply set or a group.

If the object specified is a supply set, then use this command to set power states on the nets of a supply set and then use them as supplies for the power state table. If the supply set does not already exist, this command issues an error.

If the object specified is a group, then use this command to create the power state table by using supply sets, other groups or PSTs in the **-logic_expr** option. The group should have been previously created using the **create_power_state_group** command. If the group does not already exist, this command issues an error. To add additional group states to a group, the **-update** option must be used.

EXAMPLES

The following example shows the states and voltages of a supply set, SS1:

```
prompt> add_power_state SS1 \
    -state HVp {-supply_expr {power == `{FULL_ON, 0.88, 0.90, 0.92}}}

prompt> add_power_state SS1 \
    -state HPg {-supply_expr {ground == `{OFF}}}
```

The following example defines LV state, but omitting the details on voltages for SS2 supply set:

```
prompt> add_power_state SS2 \
    -state LV {}
```

The following example defines a state ON for supply set SS1 where the supply_expression is a Boolean expression of power and ground.

```
prompt> add_power_state -supply SS1 \
    -state ON {-supply_expr {power == {FULL_ON 0.8} && ground == {FULL_ON 0}}}
```

The following example shows how power states can be added to a group. Here 'GROUP1' is a power state group that has previously been created with the **create_power_state_group** command. GS1 and GS2 are the names of the group states created. The system is in state GS1 when supply set SS1 is in state ON1, and group GROUP2 defined in scope MID1 is in state ON1, and the PST PST1 defined in scope MID2 is in state ON1.

```
prompt> add_power_state -group GROUP1 \
    -state GS1 {-logic_expr {SS1 == ON1 && MID1/GROUP2 == ON1 && MID2/PST1 == ON1}}
    -state GS2 {-logic_expr {SS1 == ON2 && MID1/GROUP2 == ON2 && MID2/PST1 == ON2}}
```

[create_supply_set\(2\)](#)
[report_pst\(2\)](#)

add_pst_state

Defines the states of each of the supply nets for one possible state of the design.

SYNTAX

```
status add_pst_state
  state_name
  -pst table_name
  -state supply_states
```

Data Types

<i>state_name</i>	string
<i>table_name</i>	string
<i>supply_states</i>	list

ARGUMENTS

state_name

Specifies the name of the power state.

-pst *table_name*

Specifies the power state table (PST) to which this state applies.

-state *supply_states*

Lists the supply net state names in the corresponding order of the **-supplies** option listing in the **create_pst** command.

DESCRIPTION

The **add_pst_state** command defines the states of each of the supply nets for one possible state of the design. It is an error if the number of supply state names is different from the number of supply nets within the power state table.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines the supply net state names for the s1, s2 and s3 power states:

```
create_pst pt -supplies { PN1 PN2 SOC/OTC/PN3 }
add_pst_state s1 -pst pt -state { s08 s08 s08 }
add_pst_state s2 -pst pt -state { s08 s08 off }
add_pst_state s3 -pst pt -state { s08 s09 off }
```

SEE ALSO

[add_port_state\(2\)](#)
[create_pst\(2\)](#)
[report_pst\(2\)](#)

add_row

Creates a list of rows in the design.

SYNTAX

```
status add_row
  -within {coordinates}
  [-direction horizontal | vertical]
  [-flip_first_row]
  [-no_double_back]
  [-minimal_channel_height channel_height]
  [-no_start_from_first_row]
  [-tile_name tile_name]
  [-snap_to_row_direction {wire_track | tile_width | none}]
  [-snap_to_orthogonal_row_direction {existing_row | wire_track | none}]
  [-left_offset left_offset]
  [-right_offset right_offset]
  [-top_offset top_offset]
  [-bottom_offset bottom_offset]
  [-allow_overlap]
```

Data Types

<i>coordinates</i>	list
<i>channel_height</i>	float
<i>tile_name</i>	string
<i>left_offset</i>	float
<i>right_offset</i>	float
<i>top_offset</i>	float
<i>bottom_offset</i>	float

ARGUMENTS

-within {coordinates}

Specifies the boundary within which to create rows. For a rectangular region, specify the coordinates for the lower-left and upper-right corners as `{ll_x ll_y} {ur_x ur_y}`. For a rectilinear region, specify a list of rectilinear coordinates in either clockwise or counterclockwise order.

-direction horizontal | vertical

Specifies the direction of rows to be created. By default, the direction of rows is the same as the direction of the base array where the rows are added.

-flip_first_row

Flips the bottom row in a horizontal core area or the leftmost row in a vertical core area. The `-flip_first_row` and `-no_double_back` options are mutually exclusive. By default, the first row is not flipped.

-no_double_back

Creates rows without flipping one row in each pair. The **-no_double_back** and **-flip_first_row** options are mutually exclusive. By default, the area can contain pairs of rows that are doubled back.

-minimal_channel_height *channel_height*

Specifies the amount of channel height to allocate for routing between rows. By default, the minimum channel height is 0.0.

-no_start_from_first_row

Specifies that the bottom row in a horizontal core area or the leftmost row in a vertical core area is not paired with the second row. By default, the first row can form a row pair with the second row.

-tile_name *tile_name*

Specifies the name of the unit tile to use in rows. By default, the tile name is **unit**.

-snap_to_row_direction {wire_track | tile_width | none}

Specifies the snapping type in the row direction.

If you specify a snapping type of **wire_track** for a design with horizontal rows, the tool aligns the vertical-layer wire tracks of the tile and the design. For a design with vertical rows, the tool aligns the horizontal-layer wire tracks of the tile and the design.

If you specify a snapping type of **tile_width** for a design with horizontal rows, the tool separates the left edge of the base array boundary and the starting left edge of the row by using a multiple of the tile width. For a design with vertical rows, the tool separates the bottom edge of the base array boundary and the bottom edge of the first row by using a multiple of the tile width.

If you specify a snapping type of **none** for a design with horizontal rows, the tool creates each new row from the left edge as specified by the **-within** option. For a design with vertical rows, the tool creates each new row from the bottom edge as specified by the **-within** option.

By default, the snapping type is **wire_track**.

-snap_to_orthogonal_row_direction {existing_row | wire_track | none}

Specifies the snapping type in the orthogonal row direction.

If you specify an orthogonal snapping type of **existing_row**, the tool attempts to align the new row with an existing row that is within one tile height of the specified location. The existing row must have the same tile pattern and orientation as the first new row. If the tool cannot find an existing row that meets the criteria, the tool snaps the new row to a wire track.

If you specify a snapping type of **wire_track** for a design with horizontal rows, the tool aligns the horizontal-layer wire track of the tile and the design. For a design with vertical rows, the tool aligns the vertical-layer wire tracks of the tile and the design.

If you specify a snapping type of **none** for a design with horizontal rows, the tool creates the first row at the bottom edge as specified by the **-within** option. For a design with vertical rows, the tool creates the first row at the left edge as specified by the **-within** option.

By default, the orthogonal row snap type is **existing_row**.

-left_offset *left_offset*

Specifies the minimum space between the new rows and the left boundary specified by the **-within** option. By default, the left offset is 0.

-right_offset *right_offset*

Specifies the minimum space between the new rows and the right boundary specified by the **-within** option. By default, the right offset is 0.

-top_offset *top_offset*

Specifies the minimum space between the new rows and the top boundary specified by the **-within** option. By default, the top offset is 0.

-bottom_offset *bottom_offset*

Specifies the minimum space between the new rows and the bottom boundary specified by the **-within** option. By default, the

bottom offset is 0.

-allow_overlap

Specifies that overlapped rows are allowed. By default, overlapped rows are not allowed, whether they are same height or not.

DESCRIPTION

This command adds rows to the specified area.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates rows in a rectangular region.

```
prompt> add_row -within {{100 100} {300 300}} -tile_name unit1  
info: created 6 rows.  
1
```

The following example creates rows in the specified rectilinear region.

```
prompt> add_row -within {{30.0 30.0} {30.0 50.0} \  
{40.0 50.0} {40.0 60.0} {50.0 60.0} {50.0 40.0} \  
{60.0 40.0} {60.0 30.0} {30.0 30.0}} -tile_name unit2
```

```
Info: 18 rows are added.  
1
```

The following example creates rows and sets left/right offset of 5 units and top/bottom offset of 10 units.

```
prompt> add_row -within {{100 100} {300 300}} \  
-left_offset 5 -right_offset 5 \  
-top_offset 10 -bottom_offset 10 \  

```

```
Info: 6 rows are added.  
1
```

The following example creates rows with a channel height of 3.69 units between the rows.

```
prompt> add_row -within {{30 148} {30 159}} \  
{645 159} {645 166} {817 166} \  
{817 159} {1432 159} {1432 148} \  
-minimal_channel_height 3.69
```

```
Info: created 4 rows.  
1
```

The following example creates rows that overlap with the existing rows in the region.

```
prompt> add_row -within {{30 148} {30 159}} \  
{645 159} {645 166} {817 166} \  
{817 159} {1432 159} {1432 148} \  
-allow_overlap
```

Warning: Existing row (id = 11279) found in the specified new row creation region. (MWUI-183)

Warning: Existing row (id = 11280) found in the specified new row creation region. (MWUI-183)

SEE ALSO

[cut_row\(2\)](#)
[write_floorplan\(2\)](#)

add_state_transition

Adds state transitions to an existing UPF object.

SYNTAX

```
status add_state_transition
  [-supply | -domain | -group]object_name
  [-update]
  [-transition transition_name {through_list}]]]*
```

[-complete]

Data Types

transition_name string

ARGUMENTS

-supply | -domain | -group *object_name*

Specifies the name of a supply set, power domain or power state group to which the transitions will be added.

-update

Used when updating an already existing transition.

-transition *transition_name*

Specifies the name of a transition to be added to the object. This option can be specified multiple times in the same command.

-complete

Indicates that the transition list is complete. Any new transitions defined after the command with -complete is given will result in an error.

DESCRIPTION

This command defines named state transitions between power states of an object. This is a UPF 3.0 command and it replaces the describe_state_transition command.

The allowed object types, in case no type is specified through options, are the following:

- Power Domain
- Supply Set
- Power State Group
- Power State Table
- Supply Port

- Supply Net
- Power Switch

If the specified doesn't exist or is not one of these types, the command issues an error.

Multiple transitions can be defined in the same command, and the initial and final states of each transition can be specified either using two separate **-from** and **-to** lists or a **-paired** list. If none of these are specified the command issues an error. Furthermore, the same state cannot be an initial and final state of the same transition, and specifying this will cause the command to return an error.

Synopsys has a specific extension consisted of the **-through** option, which is a list of intermediate states to the **-from** and **-to** lists. If this option is specified without the **-from** or **-to** option, the command issues an error.

Design Compiler does not preserve this command through hierarchical flow, a warning will be issued from characterize when this command is seen.

Design Compiler only parses and preserves this command.

EXAMPLES

Following examples show different usages of **add_state_transition** command and the outcome.

```
prompt> add_state_transition -supply MID_SS \
    -transition {turn_on -from [list OFF PWR_OFF] -to [list ON PWR_ON] -legal} \
    -transition {turn_off -from [list ON PWR_ON] -to [list OFF PWR_OFF] -legal} \
    -complete
1

prompt> add_state_transition -domain supply_set_1 \
    -transition {failed_transition -from OFF -to ON -legal}
Error: Object supply_set_1 isn't a defined power domain. (UPF-901)

prompt> add_state_transition MID_PD \
    -transition {failed_transition -from ON -through TRAN}
Error: State list -through can't be defined if -from or -to lists are empty. (UPF-897)

prompt> add_state_transition MID_SS -transition {failed_transition}
Error: State lists -from and -to can't be empty if -paired state list is not defined. (UPF-896)

prompt> add_state_transition MID3_SS -transition {failed_transition -from OFF -to ON}
Error: Object MID3_SS wasn't found (UPF-899)
```

SEE ALSO

[describe_state_transition\(2\)](#)

add_supply_state

Adds state information to a supply object.

SYNTAX

```
string add_supply_state
  supply_name
  -state {state_name state_value}
```

Data Types

```
supply_name  string
state_name   string
state_value  string
```

ARGUMENTS

supply_name

Specifies the name of the supply port, supply net or supply set function. Hierarchical names are allowed.

-state {state_name state_value}

Specifies the name and value of a state of the supply. You can repeat this option in the command to define multiple supply states.

The supply state value can be specified as one of the following:

- A single floating-point number that represents the nominal voltage for the named state:

```
-state {s88 0.88}
```

- The keyword off, which represents the inactive state:

```
-state {off_state off}
```

DESCRIPTION

The add_supply_state command adds state information to a supply object for a UPF power state table. The command specifies the name of the supply object and the possible states of the object. Each state is specified as a state name and the voltage level for that state.

You can specify the voltage level as a single nominal value, or the keyword off to indicate the off state.

Use the create_pst command first, then the add_supply_state command to specify the names and voltages of the possible states for each supply, and finally the add_pst_state command to specify the allowed combinations of supply states. Here is an example:

```
# Create power state table, specify supply ports or nets for table
```

```
create_pst MyPST -supplies { PN1 PN2 SOC/PN3 }

# Specify supply states and corresponding voltages
add_supply_state PN1 -state {sLO 0.88}
add_supply_state PN2 -state {sLO 0.88} -state {sHI 0.99}
add_supply_state SOC/PN3 -state {sLO 0.88} -state {PDOWN off}

# Specify power states (allowed combinations of supply states)
add_pst_state S1 -pst MyPST -state {sLO sLO sLO}
add_pst_state S2 -pst MyPST -state {sLO sLO PDOWN}
add_pst_state S3 -pst MyPST -state {sLO sHI PDOWN}
```

The power state table defines the legal combinations of states that can exist at any given time during the operation of the design. The supply states sLO, sHI, and PDOWN represent the low voltage, high voltage, and power-down states of the supplies. The power states S1, S2, and S3 each refer to a specific combination of supply states for the supplies listed in the create_pst command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the states and voltages of a supply set function named ss1.power:

```
prompt> add_supply_state ss1.power \
           -state {active_state 0.88} \
           -state {off_state off}
```

SEE ALSO

add_port_state(2)
add_pst_state(2)
create_pst(2)
report_pst(2)

add_to_collection

Adds objects to a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

```
collection add_to_collection
  [-unique]
  collection1
  object_spec
```

Data Types

```
collection1  collection
object_spec  list
```

ARGUMENTS

-unique

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

collection1

Specifies the base collection to which objects are to be added. This collection is copied to the result collection, and objects matching *object_spec* are added to the result collection. The *collection1* option can be the empty collection (empty string), subject to some constraints, as explained in the DESCRIPTION section.

object_spec

Specifies a list of named objects or collections to add.

If the base collection is heterogeneous, only collections can be added to it.

If the base collection is homogeneous, the object class of each element in this list must be the same as in the base collection. If it is not the same class, it is ignored. From heterogeneous collections in the *object_spec*, only objects of the same class of the base collection are added. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

The *object_spec* has some special rules when the base collection is empty, as explained in the DESCRIPTION section.

DESCRIPTION

The **add_to_collection** command allows you to add elements to a collection. The result is a new collection representing the objects in the *object_spec* added to the objects in the base collection.

Elements that exist in both the base collection and the *object_spec*, are duplicated in the resulting collection. Duplicates are not

removed unless you use the *-unique* option. If the *object_spec* is empty, the result is a copy of the base collection.

If the base collection is homogeneous, the command searches in the database for any elements of the *object_spec* that are not collections, using the object class of the base collection. If the base collection is heterogeneous, all implicit elements of the *object_spec* are ignored.

When the *collection1* argument is the empty collection, some special rules apply to the *object_spec*. If the *object_spec* is non-empty, there must be at least one homogeneous collection somewhere in the *object_spec* list (its position in the list does not matter). The first homogeneous collection in the *object_spec* list becomes the base collection and sets the object class for the function. The examples show the different errors and warnings that can be generated.

The **append_to_collection** command has similar semantics as the **add_to_collection** command; however, the **append_to_collection** command can be much more efficient in some cases. For more information about the command, see the man page.

For background on collections and querying of objects, see the **collections** man page.

EXAMPLES

The following example uses the **get_ports** command to get all of the ports beginning with 'mode' and then adds the "CLOCK" port.

```
prompt> set xports [get_ports mode*]
{mode[0] mode[1] mode[2]}
prompt> add_to_collection $xports [get_ports CLOCK]
{mode[0] mode[1] mode[2] CLOCK}
```

The following example adds the cell u1 to a collection containing the SCANOUT port.

```
prompt> set so [get_ports SCANOUT]
{SCANOUT}
prompt> set u1 [get_cells u1]
{u1}
prompt> set het [add_to_collection $so $u1]
{u1}
prompt> query_objects -verbose $het
{port SCANOUT} {cell u1}}
```

The following examples show how the **add_to_collection** command behaves when the base collection is empty. Adding two empty collections yields the empty collection. Adding an implicit list of only strings or heterogeneous collections to the empty collection generates an error message, because no homogeneous collections are present in the *object_spec* list. Finally, if one homogeneous collection is present in the *object_spec* list, the command succeeds, even though a warning message is generated. The example uses the variable settings from the previous example.

```
prompt> sizeof_collection [add_to_collection "" ""]
0

prompt> set A [add_to_collection "" [list a $het c]]
Error: At least one homogeneous collection required for argument 'object_spec'
      to add_to_collection when the 'collection' argument is empty (SEL-014)

prompt> add_to_collection "" [list a $het $sp]
Warning: Ignored all implicit elements in argument 'object_spec'
        to add_to_collection because the class of the base collection
        could not be determined (SEL-015)
{SCANOUT u1 SCANOUT}
```

SEE ALSO

```

remove_from_collection(2)
sizeof_collection(2)
```

add_to_rp_group

Adds a cell, hierarchical group, or keepout to an existing relative placement group.

SYNTAX for Leaf Cells

```
status add_to_rp_group
  rp_groups
  -leaf cell_names
  [-column integer]
  [-row integer]
  [-pin_align_name pin_name]
  [-orientation direction]
  [-alignment bottom-left | bottom-right]
  [-num_rows integer]
  [-num_columns integer]
  [-free_placement]
```

Data Types

<i>rp_groups</i>	list or collection
<i>cell_names</i>	cells
<i>pin_name</i>	string
<i>direction</i>	list of strings

SYNTAX for Hierarchical Groups

```
status add_to_rp_group
  rp_groups
  -hierarchy group_name
  [-instance instance_name]
  [-column integer]
  [-row integer]
  [-orientation direction]
  [-alignment bottom-left | bottom-right]
```

Data Types

<i>group_name</i>	list or collection
<i>instance_name</i>	cell

SYNTAX for Keepouts

```
status add_to_rp_group
  rp_groups
  -keepout keepout_name
```

[-column *integer*]
 [-row *integer*]
 [-width *integer*]
 [-height *integer*]
 [-type hard | soft | space]

Data Types

keepout_name string

ARGUMENTS

rp_groups

Specifies the relative placement groups in which to add an item. The groups must all be in the same design.

-leaf *cell_names*

Specifies the name of a cell to add to the relative placement groups in *rp_groups*. The specified cell must be in the design that contains the relative placement groups in *rp_groups*. Multiple cells are accepted when the **-free_placement** option is specified.

-column *integer*

Specifies the column position in which to add the item. If you do not specify the column position, the default is zero.

-row *integer*

Specifies the row position in which to add the item. If you do not specify the row position, the default is zero.

-pin_align_name *pin_name*

Specifies the name of the pin to use for pin alignment of this cell with other cells in a group. This overrides the default pin name specified for the relative placement group into which it is being added. This option can only be used when adding a leaf cell with the **-leaf** option.

-orientation *direction*

Specifies the placement orientation of the cell or relative placement group being added. The option functions differently for cells from for relative placement groups. For cells, specify the orientation with respect to the group to which the cell is being added. You can specify a list of possible orientations, and the tool chooses the first legal orientation for the cell. For relative placement groups, the orientation you specify overrides any group orientation that was specified.

You can specify the direction using DEF syntax:

DEF syntax:
 N, W, S, E, FN, FW, FS, FE

This option can only be used to add a leaf cell with the **-leaf** option or hierarchical instance with the **-hierarchy** and **-instance** options.

-alignment *bottom-left | bottom-right*

Specifies the alignment to use when placing the cell or group with respect to its parent group.

If a relative placement group has the **-compress** option set, and you add an element in that group with the **-alignment bottom-right** option, then the alignment type of that element is ignored.

-num_rows *integer*

Specifies the number of rows to which you add the leaf cell. You can specify multiple rows, ranging from 1 to 255. The default is 1 if you do not specify this option.

-num_columns *integer*

Specifies the number of columns to which you add the leaf cell. You can specify multiple columns, ranging from 1 to 255. The default is 1 if you do not specify this option. You cannot use the bottom-right and bottom-pin alignment settings for a leaf cell that occupies multiple columns.

-free_placement

Specifies that the cells being provided using **-leaf** option must be placed randomly, that is, similar to the cells of a bound. These cells can be added in multiple locations using the **-num_rows** and **-num_columns** options. The width and height of the placement area is automatically calculated for free placement cells placed inside relative placement group. You might need to specify the **-width** option when free placement cells are being added to boundary columns and the **-height** option when cells are being added to boundary rows. The cell being added should not belong to any other bound.

-hierarchy *group_name*

Specifies the relative placement group to be added hierarchically to the relative placement groups in *rp_groups*.

-instance *instance_name*

Specifies the hierarchical cell in which to instantiate the relative placement group specified with the **-hierarchy** option. The cell must be an instance of the reference design that contains the relative placement group specified with **-hierarchy** and must be in the design containing the relative placement groups specified in *rp_groups*. This option can be used only when adding a relative placement group with the **-hierarchy** option.

-keepout *keepout_name*

Specifies the name of the keepout to be added to the relative placement groups in *rp_groups*. Although the keepout is not a design object, you name the keepout to refer to it after it is created.

-width *integer*

Specifies the width of the keepout being added when used with **-keepout**. Unit for keepout width is the width of the site row for a particular library. If you do not specify the width, the keepout defaults to the width of the column into which the keepout is being added.

It also specifies the width of the placement area for multiple cells being added with the **-free_placement** option. The unit is the width of one site of site row.

-height *integer*

Specifies the height of the keepout being added when used with the **-keepout** option. Unit for keepout height is the height of the site row for a particular library. If you do not specify the height, the default value is height of the row of relative placement group to which the keepout is added.

It also specifies the height of the placement area for multiple cells being added with the **-free_placement** option. The unit is the height of the site row.

-type **hard | **soft** | **space****

Specifies whether a keepout is **hard**, **soft**, or **space**.

- A **hard** keepout keeps everything out of a location during legalization. This is the default.
- A **soft** keepout allows non-relative-placement cells to come into its location during the legalization stage.
- A **space** keepout allows non-relative-placement cells to come into its location during placement.

DESCRIPTION

This command adds an item to the specified relative placement groups. The relative placement groups must have been previously defined by using the **create_rp_group** command. The item can be either a leaf cell, a relative placement group, or a keepout. The item is placed in a particular lattice position of the group as specified by a row and column.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **add_to_rp_group** to add a cell to an existing relative placement group and then adds that group hierarchically to another existing group:

```
prompt> get_rp_groups ripple::grp_ripple
{ripple::grp_ripple}

prompt> add_to_rp_group ripple::grp_ripple -leaf carry_in_1
{ripple::grp_ripple}

prompt> add_to_rp_group example3::top_group -hier grp_ripple -instance U2
{example3::top_group}

prompt> add_to_rp_group example3::top_group -leaf { U1 U2 U3 U4 U5 } \
    -row 0 -column 1 -num_rows 2 -num_columns 3 -free_placement
{example3::top_group}
```

SEE ALSO

[remove_rp_groups\(2\)](#)
[write_rp_groups\(2\)](#)

alias

Creates a pseudo-command that expands to one or more words, or lists current alias definitions.

SYNTAX

```
string alias
  [name]
  [def]
```

Data Types

```
name   string
def    string
```

ARGUMENTS

name

Specifies a name of the alias to define or display. The name must begin with a letter, and can contain letters, underscores, and numbers.

def

Expands the alias. That is, the replacement text for the alias name.

DESCRIPTION

The **alias** command defines or displays command aliases. With no arguments, the **alias** command displays all currently defined aliases and their expansions. With a single argument, the **alias** command displays the expansion for the given alias name. With more than one argument, an alias is created that is named by the first argument and expanding to the remaining arguments.

You cannot create an alias using the name of any existing command or procedure. Thus, you cannot use **alias** to redefine existing commands.

Aliases can refer to other aliases.

Aliases are only expanded when they are the first word in a command.

EXAMPLES

Although commands can be abbreviated, sometimes there is a conflict with another command. The following example shows how to use **alias** to get around the conflict:

```
prompt> alias q quit
```

The following example shows how to use **alias** to create a shortcut for commonly-used command invocations:

```
prompt> alias include {source -echo -verbose}
```

```
prompt> alias rt100 {report_timing -max_paths 100}
```

After the previous commands, the command **include script.tcl** is replaced with **source -echo -verbose script.tcl** before the command is interpreted.

The following examples show how to display aliases using **alias**. Note that when displaying all aliases, they are in alphabetical order.

```
prompt> alias rt100  
rt100 report_timing -max_paths 100
```

```
prompt> alias  
include source -echo -verbose  
q quit  
rt100 report_timing -max_paths 100
```

SEE ALSO

[unalias\(2\)](#)

alib_analyze_libs

Reads in the target library files, analyzes each of them separately, and creates the corresponding alib files.

SYNTAX

```
integer alib_analyze_libs
```

DESCRIPTION

This command parses the *target_library* string. For each of the specified target libraries, the command attempts to find a valid alib. If no valid alib is found for target library X, library analysis occurs for X and the result is stored as X.alib in the **alib_library_analysis_path** variable directory. Note that the analysis is not affected by *dont_use* settings in the script where the command is issued.

EXAMPLES

Use the following command to analyze the x.db and y.db libraries:

```
set target_library "x.db y.db"  
set alib_library_analysis_path "./out"  
alib_analyze_libs
```

Two files, x.db.alib and y.db.alib are generated in a versioned directory under "./out". The directory is named "./out/alib-N", where N is the alib version number. To load these alibs, set the *alib_library_analysis_path* variable to ./out in your compile script. You do not need to specify the directory name, since this detail is managed entirely by the tool.

OPT-1310(n)
OPT-1311(n)

all_active_scenarios

Lists the active scenarios available in memory.

SYNTAX

string **all_active_scenarios**

ARGUMENTS

This command has no arguments.

DESCRIPTION

This command displays all active scenarios currently in memory. This list excludes scenarios that are inactive.

Creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example uses the **all_active_scenarios** command to list the active scenarios.

```
prompt> create_scenario MODE1
prompt> create_scenario MODE2
prompt> create_scenario MODE3
prompt> set_active_scenarios {MODE1 MODE3}
prompt> all_active_scenarios
MODE1 MODE3
```

SEE ALSO

[all_scenarios\(2\)](#)
[create_scenario\(2\)](#)

```
current_scenario(2)
remove_scenario(2)
set_active_scenarios(2)
```

all_clock_gates

Returns a collection of clock-gating cells or pins in the current design.

SYNTAX

```
collection all_clock_gates
  [-no_hierarchy]
  [-clock clock_name]
  [-cells]
  [-enable_pins]
  [-clock_pins]
  [-output_pins]
  [-test_pins]
  [-observation_pins]
  [-origin origin]
```

Data Types

clock_name string

ARGUMENTS

-no_hierarchy

Limits the search to only the current level of hierarchy. Subdesigns are not searched. By default, the search spans the full hierarchy down from the current level.

-clock *clock_name*

In the search, considers only clock-gating cells for registers originally clocked by *clock_name*. By default, the search considers registers clocked by all clocks.

-cells

Returns cells. This is the default behavior.

-enable_pins

Returns enable pins instead of cells.

-clock_pins

Returns clock input pins instead of cells.

-output_pins

Returns the output pins of the clock-gating cells that generate the gated clocks instead of the cells.

-test_pins

Returns test_mode or scan_enable input pins instead of cells.

-observation_pins

Returns the output pins of the observation logic, instead of cells.

DESCRIPTION

This command returns a collection of clock-gating cells or pins in the current instance, filtered by the specified options. By default, the command lists all clock-gating cells in the design. If you specify *clock_name*, the command lists only the clock-gating cells in the transitive fanout of the specified clock. The **-cells** option, which is the default, can be combined with one or more of the pins options.

Self-gating cells inserted by Power Compiler are excluded from the search. Use the **all_self_gates** command to get information about self-gating cells.

EXAMPLES

The following example tags all clock gates for registers originally clocked by CLK for removal:

```
prompt> remove_clock_gating -gating_cells [all_clock_gates -clock CLK]
```

The following example returns a list of test pins for all clock gates for registers originally clocked by CLK:

```
prompt> all_clock_gates -test_pins -clock CLK
```

SEE ALSO

`current_design(2)`
`current_instance(2)`
`report_clock_gating(2)`

all_clocks

Returns a collection of all clocks in the current design.

SYNTAX

collection **all_clocks**

ARGUMENTS

This command has no arguments.

DESCRIPTION

Returns a collection containing all clocks in the current design. The clocks must be defined in the design before running this command.

To create clocks, use the **create_clock** command. To remove clocks, use the **remove_clock** command. To list detailed information about all clocks in the design, use the **report_clock** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example applies the **set_dont_touch_network** command to all clocks in the current design:

```
prompt> set_dont_touch_network [all_clocks]
```

SEE ALSO

`create_clock(2)`
`remove_clock(2)`
`report_clock(2)`
`set_dont_touch_network(2)`

all_connected

Returns the objects connected to a net, port, pin, net instance, or pin instance.

SYNTAX

```
collection all_connected
  [-leaf]
  object
```

Data Types

object string

ARGUMENTS

-leaf

Specifies that only leaf pins are returned for a hierarchical net. For nonhierarchical nets, there is no difference in output.

object

Specifies the object whose connections are returned. The object must be a net, port, pin, net instance, or pin instance.

DESCRIPTION

The **all_connected** command returns a collection of objects connected to the specified net, port, pin, net instance, or pin instance. A net instance is a net in the hierarchy of the design. A pin instance is a pin on a cell in the hierarchy of a design.

If the **-leaf** option is used, a list of leaf pins of the net is returned.

To connect nets to ports or pins, use the **connect_net** command. To break connections, use the **disconnect_net** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **all_connected** to return the objects connected to MY_NET:

```
prompt> all_connected MY_NET
```

```
prompt> connect_net MY_NET OUT3  
Connecting net 'MY_NET' to port 'OUT3'.
```

```
prompt> connect_net MY_NET U65/Z  
Connecting net 'MY_NET' to pin 'U65/Z'.
```

```
prompt> all_connected MY_NET  
{OUT3 U65/Z}
```

```
prompt> all_connected OUT3  
{MY_NET}
```

```
prompt> all_connected U65/Z  
{MY_NET}
```

This example uses **all_connected** to associate net load capacitance with the net n47, which is connected to the pin instance C/Z:

```
prompt> set_load 0.147 [all_connected [get_pins U0/U1/C/Z]]  
Set "load" attribute to 0.147 for net "U0/U1/n47"
```

all_critical_cells

Returns a collection of critical leaf cells in the top hierarchy of the current design.

SYNTAX

```
collection all_critical_cells  
  [-slack_range range_value]
```

Data Types

range_value float

ARGUMENTS

-slack_range *range_value*

Specifies a margin of slack for searching top-hierarchy leaf cells in paths whose slacks are in the specified *range_value* relative to the worst slack of the current design. A top-hierarchy leaf cell is a cell in the top hierarchy and with no hierarchy underneath.

The *range_value* must be expressed in the same units as the technology library used during optimization. In addition, the *range_value* must be positive or 0.0. If no *range_value* is specified, the default is 0.0. A *range_value* of 0.0 means that top-hierarchy leaf cells in the most critical paths (those with the worst violations) are returned. If a positive *range_value* is specified, all top-hierarchy leaf cells are returned if they are in near-critical paths with slacks in the *range_value* relative to the worst slack of the current design.

DESCRIPTION

The **all_critical_cells** command returns a collection of leaf cells that are in the top hierarchy and in some path with a slack in the *range_value* relative to the worst slack of the current design. This command returns only those cells with no hierarchy underneath.

If all timing paths passing through a cell are unconstrained, the cell is assumed to be non-critical, and is not returned. You can use this command, along with the **group** command, to group together into a new subhierarchy those cells in the most critical paths. Then you can try various optimization techniques on the new subhierarchy.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists all top-hierarchy leaf cells in the worst critical paths of the current design:

```
prompt> all_critical_cells
```

The following example lists all top-hierarchy leaf cells in those paths within range 5.0 relative to the worst slack of the current design:

```
prompt> all_critical_cells -slack_range 5.0
```

The following example groups all top-hierarchy leaf cells in the worst critical paths into a new hierarchy, called CRIT, under the top hierarchy of the current design:

```
prompt> group [all_critical_cells] -design_name CRIT
```

The following example reports cell connections of all top-hierarchy leaf cells in the worst critical paths of the current design.

```
prompt> report_cell -connections [all_critical_cells]
```

SEE ALSO

`all_critical_pins(2)`
`current_design(2)`
`group(2)`
`report_cell(2)`

all_critical_pins

Returns a collection of critical endpoints or startpoints in the current design.

SYNTAX

```
collection all_critical_pins
  [-type endpoint | startpoint]
  [-slack_range range_value]
```

Data Types

range_value float

ARGUMENTS

-type endpoint | startpoint

Specifies that the pins or ports to be searched are either timing endpoints or timing startpoints. The default is **endpoint**.

-slack_range *range_value*

Specifies a margin of slack for searching timing endpoints (or startpoints) in paths whose slacks are in the specified *range_value* relative to the worst slack of the current design. The *range_value* must be expressed in the same units as the technology library used during optimization. In addition, the *range_value* must be positive or 0.0. If no *range_value* is specified, the default is 0.0. A *range_value* of 0.0 means that endpoints (or startpoints) in the most critical paths (those with the worst violations) will be returned. If a positive *range_value* is specified, endpoints (or startpoints) in near-critical paths with slacks in the *range_value* relative to the worst slack of the current design will be returned.

DESCRIPTION

The **all_critical_pins** command returns a collection of endpoints (or startpoints) that are in some timing path with a slack in the *range_value* relative to the worst slack of the current design. For a pin, if all timing paths passing through it are unconstrained, it is assumed to be non-critical, and it will not be returned.

This command may be used together with the **all_fanin** or **all_fanout** command to report useful information; for example, cells in the transitive timing fanin cone of the most critical endpoints.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists all endpoints in the worst critical paths of the current design:

```
prompt> all_critical_pins
```

The following example lists all startpoints in those paths within range 5.0 relative to the worst slack of the current design:

```
prompt> all_critical_pins -type startpoint -slack_range 5.0
```

The following example reports cells in the 3-level transitive fanin timing cone of endpoints in the worst critical paths:

```
prompt> report_cell [all_fanin -to [all_critical_pins] \  
-only_cells -levels 3 -flat]
```

The following example reports the logic in the transitive fanin of endpoints in the worst critical paths of the current design:

```
prompt> report_transitive_fanin -to [all_critical_pins]
```

SEE ALSO

`all_fanin(2)`
`current_design(2)`
`group(2)`
`report_cell(2)`
`report_transitive_fanin(2)`
`report_transitive_fanout(2)`

all_designs

Returns a collection containing all designs in the current design.

SYNTAX

collection **all_designs**

ARGUMENTS

There are no arguments to this command.

DESCRIPTION

The **all_designs** command returns a collection containing the designs in the current design hierarchy in bottom-up order. You must set the current design using the **current_design** command before using **all_designs**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[current_design\(2\)](#)

all_dont_touch

Returns a collection of **dont_touch** cells or nets from the current design or from the specified input collection.

SYNTAX

```
collection all_dont_touch
  -cells | -nets
  [input_coll]
```

Data Types

input_coll string

ARGUMENTS

-cells

Specifies that all cells with the **dont_touch** attribute are to be returned. The **-cells** and **-nets** options are mutually exclusive.

-nets

Specifies that all nets with the **dont_touch** attribute are to be returned. The **-cells** and **-nets** options are mutually exclusive.

input_coll

Searches the specified input collection and returns the collection of cells or nets having the **dont_touch** attribute. Objects are to be searched only from the content of *input_coll* rather than from the entire design. By default, this option is off.

DESCRIPTION

This command returns the collection of cells or nets that have the **dont_touch** attribute from the design or from a list that you specify. You can use wildcard characters, such as an asterisk (*) or question mark (?), when specifying the input cell list.

The command returns a standard Tcl collection. You can perform all of the generic collection-manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, on this collection handle.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the collection of all cells with the **dont_touch** attribute in the design:

```
prompt> all_dont_touch -cells  
{U20 U21 U23 SBLK/U1 SBLK/U2}
```

The following example shows the collection of all nets with the **dont_touch** attribute from an existing collection where *COLL* is its handle:

```
prompt> all_dont_touch -nets $COLL  
{n2 n5 SBLK/n2}
```

SEE ALSO

```
foreach_in_collection(2)  
get_attribute(2)  
get_cells(2)  
get_nets(2)  
report_attribute(2)  
set_attribute(2)  
set_dont_touch(2)  
set_dont_touch_network(2)  
sizeof_collection(2)
```

all_drc_violated_nets

Returns a collection of DRC-violated nets from the current design or from the specified input collection.

SYNTAX

```
collection all_drc_violated_nets
  -max_capacitance | -max_transition | -max_fanout
  [input_coll]
  [-bound upper]
  [-threshold threshold]
```

Data Types

<i>input_coll</i>	collection
<i>upper</i>	float
<i>threshold</i>	float

ARGUMENTS

-max_capacitance

Returns the collection of maximum capacity nets that violate design rule checking (DRC), as designated by **drc_violated_nets**.

-max_transition

Returns the collection of maximum transition nets that violate DRC, as designated by **drc_violated_nets**.

-max_fanout

Returns the collection of maximum fanout nets that violate DRC, as designated by **drc_violated_nets**.

input_coll

Searches the specified input collection and returns the requested collection of nets that violate DRC constraints. Objects are searched only from the contents of the specified input collection, rather than from the design.

-bound *upper*

Captures all DRC-violated nets that have values less than or equal to the bound specified by *upper*. By default, this option is off.

-threshold *threshold*

Captures all DRC-violated nets that have values greater than or equal to the threshold specified by *threshold*. By default, this option is off.

DESCRIPTION

The **all_drc_violated_nets** command returns a collection of DRC-violated nets from the current design or from the specified input collection. The tool can search the entire design hierarchy. It returns DRC-violated nets from the entire design, not just from the top level.

This command returns the 3 most common types of DRC violations: max_capacitance, max_transition, and max_fanout. You can specify each of the violations separately in this command. If you do not specify an option, a collection of all three types of DRC-violated nets is returned.

The command returns a standard Tcl collection. You can perform all of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, on this collection handle.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the collection of all maximum capacity DRC-violated nets from the design:

```
prompt> all_drc_violated_nets -max_cap
{n1 n2 n3 abc/n14}
```

The following example shows the collection of all **-max_fanout** DRC-violated nets from an existing collection stored in \$COLL:

```
prompt> all_drc_violated_nets -max_fanout $COLL
{n1 n3 abc/n14}
```

SEE ALSO

```
foreach_in_collection(2)
sizeof_collection(2)
```

all_fanin

Reports pins, ports, or cells in the fanin of specified sinks.

SYNTAX

```
collection all_fanin
  -to sink_list
  [-startpoints_only]
  [-exclude_bboxes]
  [-break_on_bboxes]
  [-only_cells]
  [-flat]
  [-levels count]
  [-trace_arcs arc_type]
```

Data Types

<i>sink_list</i>	list
<i>count</i>	int

ARGUMENTS

-to *sink_list*

Reports a list of sink pins, ports, or nets in the design and a timing fanin of each sink in the *sink_list*. If you specify a net, the effect is the same as listing all driver pins on the net.

-startpoints_only

Returns only the timing startpoints.

-exclude_bboxes

Excludes black boxes from the final result.

-break_on_bboxes

Stops timing fanin traversal on black boxes.

-only_cells

Results in a set of all cells in the timing fanin of the *sink_list*.

-flat

Specifies to function in the flat mode of operation. The two major modes in which **all_fanin** functions are hierarchical (the default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current sink are returned. Thus, pins within a level of hierarchy lower than that of the sink are used for traversal but are not reported.

-levels *count*

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are equidistant from the sink.

-trace_arcs arc_type

Specifies the type of combinational arcs to trace during the traversal. Allowed values are **timing**, which permits the tracing only of valid timing arcs (arcs that are neither disabled nor invalid due to case analysis), and **all**, which permits tracing of all combinational arcs regardless of either case analysis or arc disabling. The default in Design Compiler (both in topographical mode and non-topographical mode) is **timing**. The default in DC Explorer is **all**. You can change the default by setting the **fanin_fanout_trace_arcs** variable to the desired value.

DESCRIPTION

The **all_fanin** command reports the timing fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the timing fanin of a sink if there is a timing path through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells).

Multicorner-Multimode Support

Depending on the options used, this command either uses the current scenario or has no dependency on scenario-specific information.

EXAMPLES

The following examples show the timing fanin of a port in the design. The design comprises three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_fanin -to tout
{ii2/hin iv3/in iv3/out tin ii2/hout tout}

prompt> all_fanin -to tout -flat
{ii2/iv1/U1/a ii2/iv2/U1/z tin iv3/U1/a ii2/iv1/U1/z
 ii2/iv2/U1/a iv3/U1/z tout}
```

SEE ALSO

[all_fanout\(2\)](#)
[report_transitive_fanin\(2\)](#)

all_fanout

Returns a set of pins, ports, or cells in the fanout of the specified sources.

SYNTAX

```
collection all_fanout
  -clock_tree
  -from source_list
  [-endpoints_only]
  [-exclude_bboxes]
  [-break_on_bboxes]
  [-only_cells]
  [-flat]
  [-levels count]
  [-trace_arcs arc_type]
```

Data Types

<i>source_list</i>	list
<i>count</i>	int

ARGUMENTS

-clock_tree

Uses all clock source pins and/or ports in the design as the list of sources. Clock sources are specified by using the **create_clock** command. If there are no clocks, or if the clocks have no sources, the report is empty. Use the **report_clock** command to list the sources for all clocks in the design. The **-clock_tree** option generates a report that displays the clock trees or networks in the design. The **-clock_tree** and **-from** options are mutually exclusive.

-from *source_list*

Specifies a list of source pins, ports, or nets in the design. The timing fanout of each source in the *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net. The **-clock_tree** and **-from** options are mutually exclusive.

-endpoints_only

Returns only timing endpoints as a result.

-exclude_bboxes

Excludes black boxes from the final result.

-break_on_bboxes

Stops timing fanout traversal on black boxes.

-only_cells

Results in a set of all cells in the timing fanout of the *source_list*, rather than a set of pins or ports.

-flat

Specifies to function in the flat mode of operation. The two major modes in which **all_fanout** functions are hierarchical (the default) and flat. When in hierarchical mode, only objects from the same hierarchy level as the current source are returned. Thus, pins within a level of hierarchy lower than that of the source are used for traversal but are not reported.

-levels count

Stops traversal when reaching the perimeter of the search of *count* hops, where counting is performed over the layers of cells that are equidistant from the source.

-trace_arcs arc_type

Specifies the type of combinational arcs to trace during the traversal. Allowed values are **timing**, which permits the tracing only of valid timing arcs (arcs that are neither disabled nor invalid due to case analysis), and **all**, which permits tracing of all combinational arcs regardless of either case analysis or arc disabling. The default in IC Compiler and Design Compiler (both in topographical mode and non-topographical mode) is **timing**. The default in DC Explorer is **all**. The default can be changed by setting the **fanin_fanout_trace_arcs** variable to the desired value.

DESCRIPTION

The **all_fanout** command reports the timing fanout of specified source pins, ports, or nets in the design. A pin is considered to be in the timing fanout of a sink if there is a timing path through combinational logic from that source to the pin. The fanout report stops at the inputs to registers (sequential cells). The source pins or ports are specified by using the **-clock_tree** or **-from source_list** option.

Multicorner-Multimode Support

Depending on the options used, this command either uses the current scenario or has no dependency on scenario-specific information.

EXAMPLES

The following example shows the timing fanout of a port in the design. The design comprises the following three inverters in a chain named *iv1*, *iv2*, and *iv3*. The *iv1* and *iv2* inverters are hierarchically combined in a larger cell named *ii2*.

```
prompt> all_fanout -from tin
{iv3/out tout iv3/in ii2/hin ii2/hout tin}

prompt> all_fanout -from tin -flat
{tout ii2/iv2/U1/z ii2/iv1/U1/a iv3/U1/z iv3/U1/a
 ii2/iv2/U1/a ii2/iv1/U1/z tin}

prompt> all_fanout -from tin -levels 1 -only_cells
{iv3 ii2}
```

SEE ALSO

[all_fanin\(2\)](#)
[create_clock\(2\)](#)
[report_clock\(2\)](#)
[report_transitive_fanout\(2\)](#)

all_high_fanout

Returns a collection of high-fanout nets from the current design or from the specified input collection.

SYNTAX

```
collection all_high_fanout
  -nets
  [-threshold value]
  [input_coll]
  [-through_buf_inv]
```

Data Types

<i>value</i>	float
<i>input_coll</i>	collection

ARGUMENTS

-nets

Returns the collection of high-fanout nets.

-threshold *value*

Specifies a threshold value used to determine if a net is a high-fanout net. The *value* is a user-specified value. By default, the **high_fanout_net_threshold** variable value is used to determine if a net is a high-fanout net.

input_coll

Searches the specified input collection for high-fanout nets. Objects are to be searched only from the contents of the specified input collection, rather than from the design.

-through_buf_inv

Indicates to treat a buffer tree as transparent. The leaf loads of the buffer tree are treated as the fanouts of the net.

DESCRIPTION

The **all_high_fanout** command returns a collection of all high-fanout nets in the design. The tool searches the entire design hierarchy. It returns nets from the entire design, not just from the top level.

To determine if a net is a high-fanout net, use the **high_fanout_net_threshold** variable value as the threshold value. The command returns all nets with a fanout count higher than this threshold as high-fanout nets. You can also specify the threshold by using the **-threshold** option.

If you specify a value for *input_coll*, the command searches for high-fanout objects only from the specified collection, rather than from

the entire design.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection handle.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the collection of all high-fanout nets from the design:

```
prompt> all_high_fanout -nets
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from an existing collection stored in \$COLL:

```
prompt> all_high_fanout -nets $COLL
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example shows the collection of all high-fanout nets from the design having a fanout count of more than 100:

```
prompt> all_high_fanout -nets -threshold 100
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

SEE ALSO

[all_fanin\(2\)](#)
[all_fanout\(2\)](#)

all_ideal_nets

Returns a collection of ideal nets from the current design or from the specified input collection.

SYNTAX

```
collection all_ideal_nets  
  [input_coll]
```

Data Types

input_coll collection

ARGUMENTS

input_coll

Specifies the input collection to search for ideal nets.

If you do not specify this argument, the command searches for ideal nets in the current design.

DESCRIPTION

The **all_ideal_nets** command returns a collection of ideal nets.

If you specify a value for *input_coll*, the command searches for ideal nets only in the specified collection.

If you do not specify a collection, the command searches for ideal nets in the current design. The tool searches the entire design hierarchy. The command returns ideal nets from the entire design, not just from the top level.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection handle.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns a collection of all ideal nets from the design:

```
prompt> all_ideal_nets
```

```
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example returns a collection of all ideal nets from an existing collection stored in \$COLL:

```
prompt> all_ideal_nets $COLL
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

SEE ALSO

[all_fanout\(2\)](#)
[foreach_in_collection\(2\)](#)
[sizeof_collection\(2\)](#)

all_inputs

Returns a collection of input or inout ports in the current design.

SYNTAX

```
collection all_inputs
  [-clock clock_name]
  [-edge_triggered | -level_sensitive]
```

Data Types

clock_name string

ARGUMENTS

-clock *clock_name*

Limits the search to ports that have input delay relative to *clock_name*.

-edge_triggered

Limits the search to ports that have edge-triggered input delay as specified by the **set_input_delay** command with the **-clock** option.

-level_sensitive

Limits the search to ports that have level-sensitive input delay as specified by the **set_input_delay** command with the **-level_sensitive** option.

DESCRIPTION

The **all_inputs** command returns a collection of all input or inout ports in the current design, unless one of the options limits the search. The **all_inputs** command is usually used with a command that places attributes on input ports. To get detailed information on ports in the current design, use the **report_port** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example lists all input ports in the current design:

```
prompt> all_inputs
{A1 A2 BIDIR1}
```

The following example sets the drive value of all the input ports on the current design to 10:

```
prompt> set_drive 10.0 [all_inputs]
```

The following example marks with a multicycle value of 0 all paths from inputs having level-sensitive input delay relative to PHI1 to level-sensitive registers clocked by PHI1:

```
prompt> set_multicycle_path 0 \
-from [all_inputs -clock PHI1 -level_sensitive] \
-to [all_registers -data_pins -clock PHI1]
```

SEE ALSO

[all_outputs\(2\)](#)

all_isolation_cells

Returns a collection of isolation cells available in the design.

SYNTAX

```
collection all_isolation_cells
```

ARGUMENTS

The **all_isolation_cells** command has no arguments.

DESCRIPTION

The **all_isolation_cells** command returns a collection of the existing isolation cells in the design. The enabled level shifters also work as isolation cells, but that type of cell is not returned by this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[all_level_shifters\(2\)](#)
[check_mv_design\(2\)](#)

all_level_shifters

Returns a collection of level-shifter cells available in the design.

SYNTAX

```
collection all_level_shifters  
  [-type els | simple]
```

ARGUMENTS

-type els | simple

Specifies the type of level-shifter cells to include in the collection. If you specify **-type els**, the command returns only the enabled level-shifter cells. If you specify **-type simple**, the command returns only regular level-shifter cells. If you do not specify this option, the command returns all level-shifter cells.

DESCRIPTION

The **all_level_shifters** command returns a collection of existing level-shifter cells in the design. You can restrict the types of level-shifter cells returned in the collection by using the **-type** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

all_macro_cells

Returns a collection of all macro cells in the design or from a list of objects in the input collection.

SYNTAX

```
collection all_macro_cells  
  [input_coll]
```

Data Types

input_coll collection

ARGUMENTS

input_coll

Specifies the input collection to search and return the collection of macro cells. Objects are to be searched only from the content of the specified input collection rather than from the design.

DESCRIPTION

This command can return the collection of all macro cells from the design. The tool searches the entire design hierarchy. It returns cells from the entire design, not just from the top level. This command uses the same definition as used in the legalizing process to determine if a cell is a macro cell.

If you specify a value for *input_coll*, the command searches for macro cells only from the specified collection, rather than from the entire design.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection.

A library cell can be set as macro cell by using **set_cell_type** command. If user requires any cell to be set as macro cell, **cell_type** needs to be made BLOCK, COVER or RING. These **cell_type** attributes are the lef attributes and coming from LEF on all the existing macro cells. To remove these macro cell attributes from any macro library cell, **cell_type** can be set as PAD or CORE type.

In case of non-topographical mode, the all macro cells count will be same as the "Macro Count" results of the report_qor.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the collection of all macro cells from the design.

```
prompt> all_macro_cells
{macro1 top/macro2 top/macro4 macro10}
```

The following example shows the collection of all macro_cells from an existing collection stored in \$COLL.

```
prompt> all_macro_cells $COLL
{macro1 macro2}
```

SEE ALSO

```
foreach_in_collection(2)
sizeof_collection(2)
```

all_outputs

Returns a collection of output or inout ports in the current design.

SYNTAX

```
collection all_outputs
  [-clock clock_name]
  [-edge_triggered | -level_sensitive]
```

Data Types

clock_name string

ARGUMENTS

-clock *clock_name*

Limits the search to ports that have output delay relative to *clock_name*.

-edge_triggered

Limits the search to ports that have edge-triggered output delay as specified by the **set_output_delay** command with the **-clock** option.

-level_sensitive

Limits the search to ports that have level-sensitive output delay as specified by the **set_output_delay** command with the **-level_sensitive** option.

DESCRIPTION

The **all_outputs** command returns a collection of all output or inout ports in the current design, unless one of the options limits the search. This command is usually used with a command that places attributes on output ports. To get detailed information on ports in the current design, use the **report_port** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example lists all output ports:

```
prompt> all_outputs
{OUT1 OUT2 BIDIR1}
```

The following example sets a capacitive load of 3.5 on each output port:

```
prompt> set_load 3.5 [all_outputs]
```

The following example sets paths leading to output ports clocked by TSTCLK to be false.

```
prompt> set_false_path -to [all_outputs -clock TSTCLK]
```

all_physical_only_cells

Returns a collection of all the physical-only cells from a design or from a list of objects in an input collection.

SYNTAX

```
collection all_physical_only_cells
  [-lib_cells lib_list] [-cell_name list]
  [-coordinates {llx lly urx ury}]
  [input_coll_handle]
```

Data Types

<i>lib_list</i>	list
<i>list</i>	list
<i>llx</i>	float
<i>lly</i>	float
<i>urx</i>	float
<i>ury</i>	float
<i>input_coll_handle</i>	collection

ARGUMENTS

-lib_cells *lib_list*

Specifies a list of library cells. The tool searches for physical-only cells in the specified library cell list. The default behavior returns all physical-only cells from the entire design.

-cell_name *list*

Specifies the base instance name of the filler cells to be searched for in the design. The default behavior returns all physical-only cells from the entire design.

-coordinates {*llx lly urx ury*}

Specifies the coordinates of the area to search for physical-only cells. Returns a collection of the physical-only cells contained within the specified area. The default behavior returns all physical-only cells from the entire design.

input_coll_handle

Specifies the name of a collection from which to search for physical-only cells. Returns a collection of physical-only cells that are contained within the specified input collection. The default behavior returns all physical-only cells from the entire design.

DESCRIPTION

This command returns a collection of all the physical-only cells in the design. The tool searches the entire design hierarchy. It returns physical-only cells from the entire design, not just from the top level.

You can use wild cards, such as an asterisk (*) or question mark (?), when specifying cell instance names.

A standard Tcl collection is returned. All of the collection-manipulating commands, such as the **foreach_in_collection** and **sizeof_collection** commands, can be performed on the collection of physical-only cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example collects all the physical-only cells from the design.

```
prompt> all_physical_only_cells
{fill1 fill2 fill3 abc/fill4}
```

The following example collects all the physical-only cells from the design that have a library cell of type *OKOAFILLER*.

```
prompt> all_physical_only_cells -lib_cell OKOAFILLER
{hin in out tin hout tout}
```

The following example collects all the physical-only cells from an existing collection stored in \$COLL.

```
prompt> all_physical_only_cells $COLL
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

The following example collects all the physical-only cells from the design that have an instance name starting with *fill*.

```
prompt> all_physical_only_cells -cell_name fill*
{fill1 fill2 fill3}
```

SEE ALSO

`foreach_in_collection(2)`
`sizeof_collection(2)`

all_registers

Returns a collection of sequential cells or pins in the current design.

SYNTAX

```
collection all_registers
  [-no_hierarchy]
  [-clock clock_name]
  [-rise_clock rise_clock_name]
  [-fall_clock fall_clock_name]
  [-cells]
  [-data_pins]
  [-clock_pins]
  [-slave_clock_pins]
  [-output_pins]
  [-level_sensitive | -edge_triggered]
  [-master_slave]
  [-include_icg]
  [-include_operator_register]
```

Data Types

```
clock_name      string
rise_clock_name string
fall_clock_name string
```

ARGUMENTS

-no_hierarchy

Limits the search to only the current level of hierarchy. Subdesigns are not searched.

By default, the entire hierarchy is searched.

-clock *clock_name*

Considers only sequential cells clocked by the specified clock.

By default, all sequential cells in the current design are considered.

-rise_clock *rise_clock_name*

Considers only sequential cells triggered by the rising edge of the specified clock.

By default, all sequential cells in the current design are considered.

-fall_clock *fall_clock_name*

Considers only sequential cells triggered by the falling edge of the specified clock.

By default, all sequential cells in the current design are considered.

-cells

Returns a collection of sequential cells that meet the search criteria.

If you do not specify any of the object type options, the command returns a collection of sequential cells.

-data_pins

Returns a collection of data pins of the sequential cells that meet the search criteria.

-clock_pins

Returns a collection of clock pins of the sequential cells that meet the search criteria.

-slave_clock_pins

Returns a collection of slave clock pins of master-slave registers that meet the search criteria. Slave clock pins are specified as `clocked_on_also` in the library.

-output_pins

Returns a collection of output pins of the sequential cells that meet the search criteria.

-level_sensitive

Limits the search to level-sensitive cells.

-edge_triggered

Limits the search to edge-triggered cells.

-master_slave

Limits search to master_slave cells.

-include_icg

Returns a collection containing integrated clock-gating cells.

-include_operator_register

Performs synthetic netlisting even if no valid clock is specified.

DESCRIPTION

The **all_registers** command returns a collection of sequential cells or pins in the current design, filtered as specified by the options. By default, the command returns a collection of all sequential cells in the design. If you specify `clock_name`, it considers only the sequential cells in the transitive fanout of the sources of the clock.

You can use one or more of the **-cells**, **-data_pins**, **-clock_pins**, **-slave_clock_pins**, and **-output_pins** options to return a collection containing the respective types of objects. For example, if you use **-data_pins**, the command returns a collection containing the only the data pins of the sequential cells that meet the search criteria. If you use both **-cells** and **-data_pins**, the command returns a collection containing both the sequential cells and their data pins.

When the variable **all_registers_include_icg** is set to TRUE, the command returns a collection containing integrated clock-gating cells.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets max_delay targets for timing paths leading to data pins of all registers clocked by *PHI2*:

```
prompt> set_max_delay 10.0 -to [all_registers -clock PHI2 -data_pins]
```

The following example returns a list of data pins for all master-slave registers clocked by *clockB*:

```
prompt> all_registers -master_slave -data_pins -clock clockB
```

The following example returns a list of all level-sensitive cells and their clock (enable) pins:

```
prompt> all_registers -level_sensitive -cells -clock_pins
```

The following example shows how to push into an instance named *U1* and find level-sensitive cells without searching subdesigns of that instance:

```
prompt> current_instance U1
```

```
prompt> all_registers -no_hierarchy
```

SEE ALSO

create_clock(2)

set_max_delay(2)
all_registers_include_icg(3)

all_rp_groups

Returns a collection of specified relative placement groups and all groups in their hierarchy.

SYNTAX

```
collection all_rp_groups  
  [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups for which to search.

If you do not specify this argument, the command returns a collection that contains all relative placement groups currently loaded in memory.

DESCRIPTION

The **all_rp_groups** command returns a collection of the specified groups and all subgroups in their hierarchy.

If you do not specify the *rp_groups* argument, the command returns all relative placement groups currently loaded in memory.

If no relative placement groups are found, the command returns an empty string.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **all_rp_groups** command:

```
prompt> get_rp_groups
```

```
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> all_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> all_rp_groups ripple::grp_ripple
{ripple::grp_ripple mul::grp_mul}

prompt> remove_rp_groups -all -quiet
1

prompt> all_rp_groups
```

SEE ALSO

all_rp_hierarchicals

Returns a collection of hierarchical relative placement groups that contain the specified groups in their hierarchy. The specified groups can be either included or instantiated in their parent group.

SYNTAX

```
collection all_rp_hierarchicals  
  [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups whose ancestor groups are to be in the collection returned by this command. The specified groups can be either included or instantiated in their parent group.

If you do not specify this argument, this command returns a collection that contains all hierarchical relative placement groups currently loaded in memory.

DESCRIPTION

The **all_rp_hierarchicals** command returns a collection of hierarchical groups that are ancestors of the relative placement groups specified in the *rp_groups* argument.

If you do not specify the *rp_groups* argument, the command returns a collection that contains all hierarchical relative placement groups currently loaded in memory.

If no relative placement groups are found, the command returns an empty string.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **all_rp_hierarchicals** command:

```
prompt> get_rp_groups
{b::top a0::a0_group b::u_top/a1_group
 b::u_top/a1_group_include b::u_nxt/a1_group
 b::a1_group_include a1::a1_group}

prompt> all_rp_hierarchicals
{b::a1_group_include b::u_nxt/a1_group
 b::u_top/a1_group_include b::u_top/a1_group b::top}

prompt> all_rp_hierarchicals b::u_top/a1_group_include
{b::u_top/a1_group}

prompt> remove_rp_groups -all -quiet
1

prompt> all_rp_hierarchicals
```

[create_rp_group\(2\)](#)
[remove_rp_groups\(2\)](#)

all_rp_inclusions

Returns a collection that contains the hierarchical relative placement groups that include the specified groups.

SYNTAX

```
collection all_rp_inclusions  
    [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the included relative placement groups whose parent groups are to be included in the collection returned by this command.

If you do not specify this argument, this command returns a collection that contains all hierarchical relative placement groups in the design that contain included groups.

DESCRIPTION

The **all_rp_inclusions** command returns a collection that contains the hierarchical groups that include the relative placement groups specified in the *rp_groups* argument.

If you do not specify the *rp_groups* argument, the command returns a collection that contains all hierarchical relative placement groups currently in memory that include other relative placement groups.

If no relative placement groups are found, the command returns an empty string.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **all_rp_inclusions** command:

```
prompt> get_rp_groups
{mul::grp_mul mul::big_grp ripple::grp_ripple
example3::g2 example3::top_group}

prompt> all_rp_inclusions
{mul::big_grp example3::g2}

prompt> all_rp_inclusions mul::grp_mul
{mul::big_grp}

prompt> remove_rp_groups -all -quiet
1

prompt> all_rp_inclusions
```

all_rp_instantiations

Returns a collection of hierarchical relative placement groups that instantiate the specified groups.

SYNTAX

```
collection all_rp_instantiations  
  [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the instantiated relative placement groups whose parent groups are to be included in the collection returned by this command.

If you do not specify this argument, this command returns a collection that contains all hierarchical relative placement groups in the design that contain instantiated groups.

DESCRIPTION

The **all_rp_instantiations** command returns a collection of hierarchical relative placement groups that instantiate the groups specified in the *rp_groups* argument.

If you do not specify the *rp_groups* argument, the command returns a collection that contains all hierarchical relative placement groups currently in memory that instantiate other relative placement groups.

If no relative placement groups are found, the command returns an empty string.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **all_rp_instantiations** command:

```
prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> all_rp_instantiations
{ripple::grp_ripple example3::top_group}

prompt> all_rp_instantiations ripple::grp_ripple
{example3::top_group}

prompt> remove_rp_groups -all -quiet
1

prompt> all_rp_instantiations
```

[remove_rp_groups\(2\)](#)

all_rp_references

Returns a collection of relative placement groups that directly contain the specified cells, which are either leaf cells or hierarchical cells that contain instantiated relative placement groups.

SYNTAX

```
collection all_rp_references
  [cell_list]
  [-design design_name]
```

Data Types

<i>cell_list</i>	list
<i>design_name</i>	string

ARGUMENTS

cell_list

Specifies the cells (either leaf cells or hierarchical cells that contain instantiated relative placement groups) whose parent groups are to be included in the collection returned by this command.

If you do not specify this argument, the command returns a collection that contains all relative placement groups that directly contain any leaf cells in the specified design.

-design *design_name*

Specifies the design in which to locate the specified cells.

If you do not specify this option, the tool looks for the cells in the current design.

DESCRIPTION

The **all_rp_references** command returns a collection of relative placement groups that directly contain the cells (either leaf cells or hierarchical cells that contain instantiated relative placement groups) specified in the *cell_list* argument.

If you do not specify the *cell_list* argument, the command returns a collection that contains all relative placement groups that directly contain any leaf cells in the specified design.

A group directly contains a leaf cell if the cell was added to the group by using the **-leaf** option of the **add_to_rp_group** command.

A group directly contains a hierarchical cell if the cell was used to hierarchically instantiate another group by using the **-instance** option of the **add_to_rp_group** command.

This command is supported only for designs that do not contain multiply-instantiated designs.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **all_rp_references** command:

```
prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::ripple
example3::top_group}

prompt> all_rp_references
{mul::grp_mul ripple::grp_ripple example3::ripple}

prompt> all_rp_references U1 -design mul
{mul::grp_mul}

prompt> remove_rp_groups -all -quiet
1

prompt> all_rp_references
```

all_scenarios

Lists all defined scenarios available in memory.

SYNTAX

string **all_scenarios**

ARGUMENTS

The **all_scenarios** command has no arguments.

DESCRIPTION

The **all_scenarios** command displays the scenarios currently defined in memory. This list includes both active and inactive scenarios.

Creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example uses **all_scenarios** to list the available scenarios:

```
prompt> create_scenario MODE1
```

```
prompt> create_scenario MODE2
```

```
prompt> all_scenarios  
MODE1 MODE2
```

SEE ALSO

[all_active_scenarios\(2\)](#)
[create_scenario\(2\)](#)

```
current_scenario(2)
remove_scenario(2)
set_active_scenarios(2)
```

all_self_gates

Returns a collection of self-gating cells or pins in the current design. This command is supported only in topographical mode.

SYNTAX

```
collection all_self_gates
  [-no_hierarchy]
  [-clock clock_name]
  [-cells]
  [-enable_pins]
  [-clock_pins]
  [-output_pins]
  [-test_pins]
```

Data Types

clock_name string

ARGUMENTS

-no_hierarchy

Limits the search to only the current level of hierarchy. Subdesigns are not searched. By default, this option is off.

-clock *clock_name*

Considers only self-gating cells for registers originally clocked by *clock_name* in the search. The *clock_name* can be either a string or collection of one object. By default, this option is off.

-cells

Returns cells. This is the default.

-enable_pins

Returns enable pins instead of cells. By default, this option is off.

-clock_pins

Returns clock-input pins instead of cells. By default, this option is off.

-output_pins

Returns gated-clock output pins instead of cells. By default, this option is off.

-test_pins

Returns test_mode or scan_enable input pins instead of cells. By default, this option is off.

DESCRIPTION

This command returns a collection of self-gating cells or pins in the current design, filtered as specified by the options. By default, the command lists self-gating cells in the design. If you specify *clock_name*, it considers self-gating cells in the transitive fanout of the specified clock in the search. Normally, it considers all self-gating cells in the search. The **-cells** option, which is the default, can be combined with one or more of the pins options.

Traditional clock-gating cells inserted by the Power Compiler are excluded from the search. Use the **all_clock_gates** command to get information about them.

EXAMPLES

The following example returns all self-gating cells for registers originally clocked by CLK:

```
prompt> all_self_gates -clock CLK
```

The following example returns a list of test pins for all self-gating cells for registers originally clocked by CLK:

```
prompt> all_self_gates -test_pins -clock CLK
```

SEE ALSO

[compile_ultra\(2\)](#)
[report_self_gating\(2\)](#)
[all_clock_gates\(2\)](#)

all_test_modes

Displays all of the test modes that are defined for the current design.

SYNTAX

```
list all_test_modes
```

ARGUMENTS

The **all_test_modes** command has no arguments.

DESCRIPTION

The **all_test_modes** returns a list of all the modes defined for the current design. The **define_test_mode** command is used to define a test mode of operation for a design.

EXAMPLES

The following is an example of the test modes report:

```
set mode_list [all_test_modes]
foreach m $mode_list {
    current_test_mode $m
    dft_drc
}
```

SEE ALSO

[list_test_modes\(2\)](#)
[current_design\(2\)](#)
[current_test_mode\(2\)](#)
[define_test_mode\(2\)](#)
[insert_dft\(2\)](#)

all_threestate

Returns a collection of three-state cells or nets.

SYNTAX

```
collection all_threestate
  -nets
  [input_coll]
```

Data Types

input_coll collection

ARGUMENTS

-nets

Specifies that the collection of three-state nets is to be returned.

input_coll

Searches the specified input collection and returns a collection of three-state nets. Objects are to be searched only from the content of the specified input collection, rather than from the design.

DESCRIPTION

The **all_threestate** command returns a collection of all three-state nets from the design. The tool searches the entire design hierarchy. It returns three-state nets from the entire design, not just from the top level.

If you specify a value for *input_coll*, the command searches for three-state nets only from the specified collection, rather than from the entire design.

Only the nets that are driven by a pin that is tristate or bidirectional are returned as three-state nets.

If you do not specify the **-nets** option, the **all_threestate** command returns an error.

A standard Tcl collection is returned. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection handle.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns a collection of all three-state nets from the design:

```
prompt> all_threestate -nets
{ii2/hin iv3/in iv3/out tin ii2/hout tout}
```

SEE ALSO

[all_fanout\(2\)](#)
[foreach_in_collection\(2\)](#)
[sizeof_collection\(2\)](#)

all_tieoff_cells

Returns a collection of all tie-off cells in the current design or in the input collection.

SYNTAX

```
collection all_tieoff_cells  
  [input_coll]
```

Data Types

input_coll collection

ARGUMENTS

input_coll

Searches the specified input collection and returns a collection of tie-off cells. Objects are to be searched only from the content of the specified input collection, rather than from the design.

DESCRIPTION

The **all_tieoff_cells** command returns a collection of all tie-off cells from the current design. The tool searches the entire design hierarchy. It returns tie-off cells from the entire design, not just from the top level.

Tie-off cells are the constant cells that the tool introduced in the design. To find the value of a tie-off cell, the tool examines the corresponding lib_cell of each cell to determine if it is logic-0 or logic-1.

If you specify a value for *input_coll*, the command searches for tie-off cells or nets only from the specified collection, rather than from the entire design.

This command returns a standard Tcl collection. All of the generic collection manipulating commands, such as **foreach_in_collection**, **sizeof_collection**, and so on, can be performed on this collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns a collection of all tie-off cells from the design:

```
prompt> all_tieoff_cells
{logic1 logic0}
```

The following example returns a collection of all tie-off cells from an existing collection stored in \$COLL:

```
prompt> all_tieoff_cells $COLL
{logic1}
```

SEE ALSO

`foreach_in_collection(2)`
`sizeof_collection(2)`

all_upf_repeater_cells

Returns a collection of repeater cells available in the design by virtue of the UPF repeater-supply port attribute.

SYNTAX

collection **all_upf_repeater_cells**

ARGUMENTS

None

DESCRIPTION

The **all_upf_repeater_cells** command returns a collection of the repeater cells in the design, that were inserted or matched at the domain boundary pin to honor the specification of the repeater-supply UPF attribute on the port. Repeater cells are buffers and inverters using supplies specified by the **set_port_attributes** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[set_port_attributes\(2\)](#)

analyze

Analyzes the specified HDL source files and stores the resulting templates into the specified library in a format ready to specialize and elaborate to form linkable cells of a full design.

SYNTAX

```
status analyze
[-format verilog | sverilog | vhdl]
[-define define_list]
[-library library_name | -work library_name]
[-uses design_libs_list]
[-vcs vcs_opts]
[-create_update]
[-update]
[-recursive]
[-autoread]
[-rebuild]
[-output_script output_string]
[-exclude exclude_list]
[-verbose]
[-top top_design_name]
file_list
```

Data Types

define_list	string
library_name	string
design_libs_list	string
vcs_opts	string
output_string	string
exclude_list	list
top_design_name	string
file_list	list

ARGUMENTS

-format verilog | sverilog | vhdl

Specifies the format of the files to be analyzed. The supported formats are Verilog, SystemVerilog, and VHDL.

Specifies that the **-autoread** option should look for files in the specified language whose extensions match the extensions in the list identified by the **hdlin_autoread_verilog_extensions**, **hdlin_autoread_sverilog_extensions**, or **hdlin_autoread_vhdl_extensions** variable. The **-autoread** option supports Verilog, SystemVerilog, and VHDL formats. By default, **-autoread** reads in all the files it finds that have Verilog, SystemVerilog, and VHDL extensions. You can use the **-autoread** option to specify file names in the *file_list* that do not have one of the language-specific extensions.

-define define_list

Specifies a list of constant macros to be defined for the session of the **analyze** command. This is useful for the inclusion of Verilog or SystemVerilog code enclosed by `ifdef/^endif constructs. For details, see the *HDL Compiler for Verilog User Guide*.

-library *library_name*

Specifies *library_name* as the current work library (whose **-path** receives all analyzed output files). The *library_name* should be previously established by the **define_design_lib** command. Design libraries (directories containing template intermediate files) should not be confused with .db or .ddc linkage libraries (files containing design cells).

By default, the **analyze** command stores all output in the work design library. To store design elements in libraries other than work library, use the **-library** option. A writable directory must exist at the path defined for the current work library.

-work *library_name*

An alias for **-library**. This option is not available with the **-autoread** option.

-uses *design_libs_list*

This option is not available with the **-format vhdl** or **-autoread** option.

SystemVerilog and Verilog designs might contain unresolved references to unelaborated design templates without indication of where those template definitions are located.

The compiler and linker always search for these templates first in the home directory of the parent design. By default, they then continue each template search by visiting every design library defined by the **define_design_lib** command. The **-uses** option overrides this last step. It stores a design library search order (as a cell attribute named **link_design_libraries**) within each design being analyzed. Later, elaboration or linking will follow this prescribed order rather than visiting every known library. An empty list argument limits the search to just the home library of the parent design. You do not need to repeat the **-library_name** setting, and you cannot override a search of the work directory.

-vcs *vcs_opts*

Specifies all VCS-specific command-line options. The options must be specified as a single string, such as enclosed within braces ({}) or double quotation marks (""). Options specified by the **-vcs** option follow the VCS command-line syntax:

[**-sverilog** | **-verilog**] Specifies the format of the files to be analyzed.

[**-y *directory_path***] Specifies the directories that contain the library files to be searched for unresolved module instantiations in the design.

[**+libext+.*extension1+...***] Specifies the extension to consider during a file search in the -y library directories. The default is no extension.

[**-v *library_file***] Holds several module definitions to be used during the search for unresolved modules.

[**-f *command_file***] Specifies a command file.

[**+define+*macro_name+...***] Defines a macro.

[**+incdir+*dir1+...***] Includes directories in the search list.

src_file1 Specifies the files that are to be analyzed.

This option is not available with the **-autoread** option.

-create_update

Facilitates the packaging of HDL files for distribution performed by developers of DesignWare parts. For details, see the *DesignWare Developer's Guide*. This option is not available with the **-autoread** option.

-update

Facilitates the installation of DesignWare parts in DesignWare installation scripts. For details, see the *DesignWare Developer's Guide*. This option is not available with the **-autoread** option.

-recursive

Specifies that the **analyze -autoread** command must recursively scan the directory trees below those specified in the *file_list* list. By default, the **-autoread** option looks only in the specified directories.

This option can be used only with the **-autoread** option.

-autoread

Specifies to use the **-autoread** mode for script-free analysis of whole HDL source directories or directory trees. All HDL source files located in those directories are prescanned, grouped, and then ordered into distinct source code streams based on their mutual inclusion and package-reference dependences. Some or all source streams are finally analyzed using the basic command.

By default, the **-autoread** option creates or replaces only a subset of analyzed result files; it works in an incremental-update mode that resembles the Unix make command. If an HDL source file does not exist or is newer than the intermediate files it should produce, only that file and the source streams that require it are reanalyzed.

For more information, see the description for the **-rebuild** option.

-rebuild

Replaces any result files regardless of their timestamp. It analyzes all the indicated HDL source streams as if the result library was empty.

This option can be used only with the **-autoread** option.

-output_script output_string

Creates a Tcl script that is compatible with Design Compiler and Formality.

The file reading order for third-party tools and a DOT language file dependency graph are embedded in the script as comments.

This option is available only with the **-autoread** option.

-exclude exclude_list

Specifies a list of files and directories that are not to be analyzed. An **analyze -autoread [...] file_list** command checks each HDL source path against all elements of the *exclude_list*; it ignores a file if it or any of its directory paths matches any excluded path.

This option can be used only with the **-autoread** option.

-verbose

Prints out more messages for the **-autoread** option.

This option can be used only with the **-autoread** option.

-top top_design_name

Identifies the top-level component of a hierarchical design specified within the **-autoread** HDL source directories.

The **analyze -autoread -top design_name** command selects a subset of the indicated HDL source streams to analyze. Its goal is to analyze into intermediate form precisely those source files required for a later elaboration and linking of *design_name*. Files in the indicated directories that are not required to elaborate the design hierarchy descending from *design_name* are prescanned but the design templates they would produce are not created or replaced.

If the **-top** option is not provided, all HDL source streams indicated by the **file_list** argument are analyzed.

This option can be used only with the **-autoread** option.

file_list

Specifies the files to be analyzed.

To analyze multiple files, list them by using curly braces, {}. Note: Source files in a list are effectively concatenated into a single source stream in the listed order.

In **-autoread** mode only, the **file_list** argument can also specify directory names. All HDL source files located in those directories are prescanned. For more information about prescanning, see the descriptions for the **-autoread** and **-recursive** options.

DESCRIPTION

This command translates the specified HDL files and stores the intermediate format in the specified library.

The following paragraphs describe the support for the **-autoread** option:

The **-autoread** option reads in the files from *file_list*, determines the dependencies between them, and analyzes them in the right order to prevent errors due to missed or misplaced files.

The dependencies are calculated only from the files or directories present in *file_list*. If *file_list* changes between consecutive calls with the **-autoread** option, the dependency inference is performed over the latest set of files provided. Based on this, all required sources must be present in *file_list* option or be available if the **-recursive** option is used on each call with the **-autoread** option.

If the top design name is provided by the **-top** option, only the source files required for elaborating that top design are analyzed. This filtering is based on file dependencies previously inferred. If the **-top** option is not provided, all sources are ordered, grouped, and analyzed per the dependency inferred between them.

To locate the source files, the command expands each item in the *file_list* list with the **search_path** variable. Then, it determines whether the result is excluded by the **-exclude** option or the **hdlin_autoread_exclude_extensions** variable. If it is not excluded and a file ends with one of the extensions in the **hdlin_autoread_vhdl_extensions** variable list, it is considered a VHDL source file. If the file ends with one of the extensions in the **hdlin_autoread_verilog_extensions** variable list, it is considered a Verilog source file. If the file ends with one of the extensions in the **hdlin_autoread_sverilog_extensions** variable list, it is considered a SystemVerilog source file.

When expanding a directory, the command collects the files from the directory, and from its subdirectories and theirs recursively if the **-recursive** option is set. The command then performs all extension checks on these files. If the **-format** option is set, only files with Verilog, SystemVerilog, or VHDL extensions are collected based on the value of the option.

After the **-autoread** option collects all of the source files, it performs the following dependency checks:

- Detects analyze dependencies: List RTL files in the right order for analyzing. For example, analyze the file that contains a VHDL entity before analyzing files that defines architectures of that entity, or analyze the file that contains a SystemVerilog package declaration before the files that import that package.
- Detects Verilog and SystemVerilog compilation unit dependencies: Determine if a file needs to be analyzed in the same compilation unit with other files. For example, if a file defines macros, SystemVerilog local parameter, and SystemVerilog enumerated values, and the file is not explicitly included by the file that requires those definitions, the **-autoread** option groups them in the same compilation unit in the correct order. This might not always be possible, such as when a macro is defined several times in different files and the **-autoread** option cannot determine which of those alternatives is the right choice.
- Detects link dependencies: Schedule the analyze stage for files required for elaboration of the design hierarchy. For example, if a Verilog or SystemVerilog design that is instantiated in one source file is declared on a different source file provided in the *file_list*, the second file also requires to be analyzed for a complete top-down design elaboration.
- Detects include dependencies: If a Verilog or SystemVerilog file is included in another source and the file changes between two consecutive calls of the **-autoread** option (in the same synthesis session), the **analyze** command includes this file and all files that include them to update the design.
- Infers the target library for VHDL files. However, if the **-library** option is specified, this step is skipped and VHDL files provided in the *file_list* are analyzed into the specified design library.

After the dependency check, all the required HDL files specified by the *file_list* option (regarding its dependencies and the **-top** design option if defined) are analyzed.

When the **-autoread** option is used again (with the same *file_list* setting) after a file is changed, only the updated source files are analyzed.

The **-autoread** option executes the dependency analysis based only on the current *file_list* information. All HDL source files that might have relevant dependency relationships should be passed together in one **analyze -autoread** command.

EXAMPLES

The following example analyzes the packages.vhd file and stores the results in the MY_LIB design library:

```
prompt> analyze -work MY_LIB -format vhdl packages.vhd
```

The following example analyzes two SystemVerilog clients of two libraries:

```
prompt> define_design_lib BUSDEFN -path /remote/IP/metra/big_bus
prompt> define_design_lib NClib -path ../../NCD/libNC
prompt> analyze -format sverilog -uses { BUSDEFN NClib } { senderAlice.sv receiverBob.sv }
```

The following example assumes that the current directory is the source directory. It specifies the source file list early in the command line and gives options, including the name of the top-level entity later.

```
prompt> analyze {.} -autoread -recursive -top E1
```

The next example specifies extensions for Verilog files that are different from the default (".v"), sets the source list and the exclude list, and calls the command with the name of the top-level module name, forcing it to only collect files with Verilog extensions:

```
prompt> set hdlin_autoread_verilog_extensions {.ve .VE}
prompt> set my_sources {mod1/src mod2/src}
prompt> set my_excludes {mod1/src/incl mod2/src/incl}
prompt> analyze $my_sources -exclude $my_excludes -autoread \
    -format verilog
```

Note that excluding include directories explicitly is only necessary if include files have the same extensions as source files and not all include files are included in the source.

analyze_datapath

Provides a datapath analysis report that lists the resources and datapath blocks used in the current design.

SYNTAX

```
analyze_datapath  
[-file file_name]
```

Data Types

file_name string

ARGUMENTS

-file *file_name*

Specifies the file name of a log file that contains the **report_resources -hierarchy** and **report_area -designware** reports from a previously compiled design. This option enables you start the tool and use the **analyze_datapath** command to generate a datapath analysis report for a design without having to read in and compile the design a second time.

DESCRIPTION

The **analyze_datapath** command provides a datapath analysis report that lists a summary of the resources and datapath blocks used in the current design. The report includes information reported by the **report_resources -hierarchy** command and the **report_area -designware** command.

The report displays the area of singleton DesignWare designs and extracted datapath designs. The report summarizes the number of singleton DesignWare components, summarizes the number of datapath designs, and lists the designs output width ranges.

EXAMPLES

The following example displays resource information for the current design:

```
prompt> analyze_datapath
```

```
*****
```

```
Estimate of Datapath Content
```

```
Extracted Datapath: area = 45.9%, parts = 125  
Singleton Datapath: area = 22.4%, parts = 168
```

```
Total Datapath: area = 68.3%, parts = 293
*****
```

```
*****
```

Estimate of Datapath Types

Singlets:

component	out width	count	min	max	ave
DW01_add	23.5	69	7	32	
DW01_sub	11.5	38	9	16	
DW01_inc	16.4	19	9	20	
DW_cmp	14.8	6	12	16	
DW_mult_uns	19.1	35	8	32	
DW_mult_tc	21.0	1	21	21	

Datapaths:

operation	out width	count	min	max	ave
+ -	16.8	340	6	32	
*	22.6	50	15	31	
?	15.4	69	9	32	
== !=	12.0	5	12	12	

In the following example, the resource_area_rpt.txt file contains the **report_resources -hierarchy** and **report_area -designware** reports from a previously compiled design. The **-file** option is used to read the resource_area_rpt.txt file and generate a datapath analysis report based on the data in the file. You do not need to read in and compile the design a second time.

```
prompt> analyze_datapath -file resource_area_rpt.txt
```

```
*****
```

Estimate of Datapath Content

Extracted Datapath: area = 45.9%, parts = 125
Singleton Datapath: area = 22.4%, parts = 168

Total Datapath: area = 68.3%, parts = 293

```
*****
```

Estimate of Datapath Types

Singlets:

component	out width	count	min	max	ave
DW01_add	23.5	69	7	32	
DW01_sub	11.5	38	9	16	
DW01_inc	16.4	19	9	20	
DW_cmp	14.8	6	12	16	
DW_mult_uns	19.1	35	8	32	
DW_mult_tc	21.0	1	21	21	

Datapaths:

operation	out width	count	min	max	ave
-----------	-----------	-------	-----	-----	-----

+ -	340	6	32	16.8
*	50	15	31	22.6
?	69	9	32	15.4
== !=	5	12	12	12.0

analyze_datapath_extraction

Analyzes DesignWare datapath extraction.

SYNTAX

```
status analyze_datapath_extraction
      [-no_automroup]
      [-no_report]
      [-filter_msg none | low | medium]
      [-sort_msg]
      [-max_msgs max_num_msgs]
      [-html_file_name html_file]
      [design_list]
```

ARGUMENTS

-no_automroup

Specifies that automatic ungrouping is disabled. All hierarchies are preserved unless otherwise specified. The **-no_automroup** option in **analyze_datapath_extraction** behaves the same way as the **-no_automroup** option in **compile_ultra**. If you plan to specify the **-no_automroup** option in **compile_ultra**, you should also specify the **-no_automroup** option in **analyze_datapath_extraction**.

-no_report

Specifies not to report contained resources at the end of the analysis.

-filter_msg none | low | medium

Turns on message filtering. Messages with severity levels less than or equal to the specified level are filtered out.

-sort_msg

Sorts the leakage detection messages (HDL-120, HDL-132) in each design based on their potential impact from high to low.

-max_msgs max_num_msgs

Specifies the maximum number of leakage detection messages (HDL-120, HDL-132) to display in each design. The message sorting **-sort_msg** option is turned on automatically.

-html_file_name html_file

Writes all outputs to the specified HTML file.

design_list

Specifies list of designs to run datapath extraction analysis.

DESCRIPTION

This command analyzes the datapath extraction of the current design.

When a DesignWare operator is not extracted, it analyzes the reason why it is not extracted. If it is due to the RTL coding, the tool issues a message about the RTL coding style that interferes with datapath extraction.

After the analysis, a report shows the contained resources in the design. This report helps to find the resources in the design source code. Note that the datapath names in this report can differ from the datapath names in the report generated using the **report_resources** command after compilation. However, the names of the contained resources will be the same.

For more information about RTL coding styles that help improve datapath extraction, see to the coding guidelines documented in "Coding Guidelines for Datapath Synthesis" on SolvNet (<https://solvnet.synopsys.com/retrieve/015771.html>).

Here are examples of possible warning messages issued by the **analyze_datapath_extraction** command:

"HDL-120": Issued when a DesignWare operator is breaking the datapath due to leakage on its fanout or the fanout of its driver. This DesignWare operator can be the boundary node of an extracted datapath block.

Datapath leakage occurs when an internal operand is not wide enough to store the result of an operation but the full result is required later. Operands with leakage must be binary and must be at the boundary of a datapath block. Therefore, operands with leakage will break a potentially larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

Example 1: module test(a, b, c, d, e, f, o1, o2, o3); input [10:0] a, b; input [5:0] c, d, e, f; output [8:0] o1; output [9:0] o2; output [7:0] o3; assign o1 = a + b + c; (add_9, add_9_2) assign o2 = f + o1; (add_10) assign o3 = e + o1; (add_11) endmodule

In this design, the input 'o1' of 'add_10' is truncated. Therefore, the following message is issued:

Information: Operator associated with resources 'add_10' in design 'test' breaks the datapath extraction because there is leakage due to truncation on the fanout of its driver 'add_9 add_9_2'. (HDL-120)

On the other hand, the width of 'o3' is smaller than the width of 'o1.'Therefore, there is no leakage on the input of 'add_11'.

Example 2: module leakage_a (a, b, c, z); input signed [7:0] a, b; input [7:0] c; output [9:0] z; wire signed [8:0] t; assign t = a + b; //add_6 // leakage: signed result used in wider unsigned expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(signed) and fanout(unsigned) of add_6:

Information: Operator associated with resources 'add_6' in design 'leakage_a' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Example 3: module leakage_b (a, b, c, z); input [7:0] a, b; input signed [7:0] c; output signed [10:0] z; wire signed [8:0] t; assign t = a + b; // add_7 // leakage: unsigned result used in wider signed expression assign z = t + c; endmodule

There is leakage due to sign mismatch at the fanin(unsigned) and fanout(signed) of add_7:

Information: Operator associated with resources 'add_7' in design 'leakage_b' breaks the datapath extraction because there is leakage due to driver/load sign mismatch. (HDL-120)

Subtraction can give negative results that cannot be represented with an unsigned operand of limited width. It is recommended to declare the operands as signed. Note that constants used in signed operations need to be marked signed as well.

Example 4: It is recommended to change the following RTL code: input [13:0] a ; input [13:0] b ; wire [15:0] o = a - 14'd4 - b ;
to

input signed [13:0] a ; input signed [13:0] b ; wire signed [15:0] o = a - 14'sd4 - b;

The "HDL-120" message is associated with coding guideline 19. (<https://solvnet.synopsys.com/retrieve/015771.html#leakage>).

"HDL-121": There is a sequential cell that breaks the datapath extraction.

Example: module test (clk, en, a, b, c, z); input clk, en; input [7:0] a, b; input [15:0] c; output [15:0] z; reg [15:0] prod;
always @ (posedge clk) begin if (en) begin prod <= a * b; end end assign z = prod + c; endmodule

There is a register between the multiplier and the adder. The following message will be issued:

Information: There is sequential cell in between operator associated with 'mult_11' and 'add_15' in design 'test'. (HDL-121)

The extracted datapath block cannot contain sequential cells (for example, registers). The register in between operators will break a potential larger datapath block into smaller datapath blocks, resulting in suboptimal QoR.

The "HDL-121" message is associated with coding guideline 12. (<https://solvnet.synopsys.com/retrieve/015771.html#pipelining>).

"HDL-125": Design contains instantiated DW. If the instantiated DW is replaced with an inferred DW OP, it could be extracted.

Example: module test(a,b,c,z); parameter wl = 5; input [wl-1:0] a,b,c; output [2*wl-1:0] z;

```
wire [wl-1:0] sum; assign sum = (b+a); DW02_mult #(wl, wl)U_mult(sum, c, 1'b0, z); endmodule
```

The instantiated DW02_mult can be replaced by an inferred multiplier. The following message will be issued:

Information: Cell 'U_mult' in design 'test' can not be extracted because it instantiates 'DW02_mult', which could be inferred with operator '*' instead. (HDL-125)

The instantiated DesignWare component cannot be extracted into datapath blocks. If the RTL design uses inferred the DesignWare operation instead of instantiated DesignWare components, the inferred DesignWare operator might be extracted into a datapath block.

The "HDL-125" message is associated with coding guideline 11.
(https://solvnet.synopsys.com/retrieve/015771.html#component_instantiation).

EXAMPLES

The following example shows the analysis report about leakage that breaks the datapath extraction.

prompt > analyze_datapath_extraction

Information: Checking out the license 'DesignWare'. (SEC-104)

Running analyze_dp_extraction ...

Information: Operator associated with resources 'add_8 add_8_2' in design 'test' breaks the datapath extraction because there is leakage due to truncation on its fanout. (HDL-120)

`report_resources(2)`

analyze_dw_power

Reports the DesignWare delay and power contribution.

SYNTAX

```
int analyze_dw_power
  [-nosplit]
  [-hierarchy]
  [-sort slack | dyn_pwr | lkg_pwr]
  [-sortAscending]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-hierarchy

Reports the DesignWare information in the hierarchy of the current design or the current instance. By default, resources used only in the top level of the current design or the current instance are reported.

-sort slack | dyn_pwr | lkg_pwr

Sort the report by the sorting criteria, from largest to smallest.

-sortAscending

Sort the report in ascending order. This option only works when the **-sort** option is also specified.

DESCRIPTION

This command lists the slack and power contribution of synthetic cells in the current design.

For the generated DesignWare netlist, the command reports the best case slack that the generator can achieve during optimization. For the DesignWare netlist with static implementation, the slack reported is the worst case for the design. If the design is ungrouped, the slack of the ungrouped design is reported. Otherwise, the slack of the design is reported.

For the static DesignWare netlist, only the negative slacks are reported.

This report also shows the power contribution of all the synthetic modules in the current design.

If a synthetic module is ungrouped before propagating the timing and power context, the command does not report the delay and power contribution. For these cells, the **path group** column of the report is empty. The **DW slack** column is **na**. For these DesignWare designs, because they are ungrouped after they are optimized for area or power, setting the **power_effort** to medium or high might

not improve power.

The report does not include DesignWare with small bitwidth that are ungrouped. The power of such DesignWare cells are not accounted for the total DesignWare power contribution. Therefore, the total number of DesignWare reported in this report might be different from the total number of DesignWare reported by the **report_area** or the **report_resources** command.

The power contribution of each DesignWare cell is shown in **dyn power %** and **Ikg power %** columns. If the power contribution of a DesignWare cell is very small, this column might show a value of **0.00**. The power of these DesignWare cells is included in the total DesignWare power.

The power consumption of all synthetic cells are summarized in the power summary of this report. The slack information is not reported for DesignWare netlists with static implementation. So, the number of cells listed in the dw_power_analysis table might not match the number in the power summary report.

For hierarchical DesignWare netlists, only the slack and power contribution of the top-level design are reported. The subcomponents of the DesignWare are not reported.

To enable reporting of the ungrouped DesignWare components, set the **synlib_enable_analyze_dw_power** variable to 1 before compiling the design.

EXAMPLES

The following example generates the **analyze_dw_power** report:

```
prompt> analyze_dw_power
```

```

analyze_minpwr_library

Displays function, drive strength, area and power characteristics of cells from a target library used in datapath generation.

SYNTAX

```
status analyze_minpwr_library  
  [-legend]  
  [library_list]
```

Data Types

library_list list

ARGUMENTS

-legend

Provides a more detailed description of cell types

library_list

Specifies a list of one or more target libraries to be analyzed. If a list is not specified, libraries from the **target_library** variable are used.

DESCRIPTION

This command displays function, drive strength, area and power characteristics of cells of the library that are used in datapath generation. It also checks for cells or combinations of cells that can improve power QoR during datapath generation.

EXAMPLES

The following examples use the demo class.db library. The **analyze_minpwr_library** command prints some general attributes of the library.

Libraries Used:

```
class (File: ~/class.db)
```

```
Library doesn't specify units for: leakage_power
```

```
Library units: time=1ns voltage=1V capacitance=0.100000f dynamic_power=100nW
```

Note: library doesn't contain any cells fully characterized for power.

This description is followed by three tables.

The first table lists significant cells used in datapath generation.

For cells selected for datapath generation...					
Cell Type	Largest Drive	Best Small Area Drive	Best Dynamic Power	Best Leakage Power	
Not	B4IP	IVI	B4IP	B4IP	
And2	AN2I	AN2I	AN2I	AN2P	
Xor2	EOI	EOI	EOI	EOP	
Xor3	EO3P	EO3P	EO3P	EO3P	
Nand2	ND2P	ND2I	ND2P	ND2P	
Xnor2	ENI	ENI	ENI	ENP	
Xnor3	EN3P	EN3P	EN3P	EN3P	
AOI21	AO6P	AO6	AO6P	AO6P	
Maj23	*NA*	*NA*	*NA*	*NA*	
Maj23N	AO5P	AO5	AO5P	AO5P	
AddAB	*NA*	*NA*	*NA*	*NA*	
AddABC	*NA*	*NA*	*NA*	*NA*	
AddABCD	*NA*	*NA*	*NA*	*NA*	
AddNABC	*NA*	*NA*	*NA*	*NA*	
Benc	*NA*	*NA*	*NA*	*NA*	
Bmux	*NA*	*NA*	*NA*	*NA*	
Mux2	MUX21HP	MUX21H	MUX21HP	MUX21HP	
Mux4	*NA*	*NA*	*NA*	*NA*	

NA - the library does not contain a cell that implements this function

The second table shows specific attributes of the cells listed in the first table.

Library Cell	Cell Area	Cell Drive	Dynamic Power	Leakage Power	
AN2I	2.00000	0.12539	2.50000	*INV*	
AO2	2.00000	0.73931	5.00000	*INV*	
AO2P	4.00000	0.37418	10.00000	*INV*	
AO4	2.00000	0.73931	5.00000	*INV*	
AO4P	4.00000	0.37418	10.00000	*INV*	
AO6	2.00000	0.73931	3.75000	*INV*	
AO6P	3.00000	0.37418	7.50000	*INV*	
AO7	2.00000	0.73931	3.75000	*INV*	
AO7P	3.00000	0.37418	7.50000	*INV*	

INV This power value isn't characterized in the library.

The third table lists characteristics for the lowest area and power versions of the library cells. The area, power, and drive-strength characteristics are checked for potential problems. Informational warning messages are generated first, followed by the cell characterization table.

The cell characterization table contains the following information for each cell type:

Smallest Cell : The smallest cell that is found in the library

Total # Drives : Number of different drive strengths for this cell

Min Area # Drives : Number of different drive strengths for the minimum area version of this cell

Estim Size : Estimated size of the cell based on the estimated grid size

Actual Size : Cell size from the library data

Dynamic Power : Dynamic power from the library data

Min # Trans : Estimated minimum number of transistors required to implement the cell

Estim # Grids : Estimated number of grids required to implement the cell

Actual # Grids : Calculated number of grids for the cell based on the area of the smallest inverter in the library

When a potential problem in the cell is detected, an asterisk (*) is added to the value in the characterization table.

The following example flags the potential problems in some library cells.

Information: Xnor3 Cell too large (too many grids). (UISN-89)

Information: Maj23 Cell does not exist. (UISN-86)

Information: Maj23N Not enough total drives (should have at least 4). (UISN-87)

Information: Maj23N No low power cell (should have at least 2 drives for minimum footprint). (UISN-88)

Cell Characterization for Lowest Area / Power

Estimated grid size = 0.500000

`target_library(3)`

analyze_mv_design

Analyzes multivoltage design connections.

SYNTAX

```
status analyze_mv_design
[-level_shifter | -always_on | -lib_cells]
[-from_pin from_pin_list]
[-to_pin to_pin_list]
[-net target_net]
[-isolation]
[-enable_level_shifter]
[-retention]
[-verbose]
[-voltage_type all | nominal]
```

Data Types

<i>from_pin_list</i>	list
<i>to_pin_list</i>	list
<i>target_net</i>	list

ARGUMENTS

-level_shifter

Enables level-shifter analysis, which is based on load-to-driver pin arguments.

-always_on

Enables always-on analysis, which is based on the target net argument.

-lib_cells

Reports the unmapped isolation, enable level shifter and retention cells for the current design, which is based on **-isolation**, **-enable_level_shifter** and **-retention** arguments.

-from_pin *from_pin_list*

Specifies the driver (leaf cell pin or top-level port) for level-shifter analysis.

-to_pin *to_pin_list*

Specifies the loads (leaf cell pins or top-level ports) for level-shifter analysis.

-net *target_net*

Specifies the net for always-on analysis.

-isolation

Enables unmapped isolation cell reporting with **-lib_cells**. This option is assumed by default with **-lib_cells**.

-enable_level_shifter

Enables unmapped enable level shifter cell reporting with **-lib_cells**. This option is assumed by default with **-lib_cells**.

-retention

Enables unmapped retention cell reporting with **-lib_cells**. This option is assumed by default with **-lib_cells**.

-verbose

Generates detailed information in the report.

DESCRIPTION

The **analyze_mv_design** command performs multivoltage analysis and reports design details that can help you understand multivoltage-related issues. You can perform one of level-shifter analysis or always-on analysis or unmapped power management cell reporting by using the **-level_shifter** or **-always_on** or **-lib_cells** option.

The level-shifter analysis lists variable settings, power state table information, signal connections, and library availability information. The input for the level-shifter analysis is a pin-to-pin connection, which can be derived easily from the output of the **check_mv_design** command.

The following variable settings are reported in the level-shifter analysis output:

- Level Shifters on clock nets:

This setting is controlled by the **auto_insert_level_shifters_on_clocks** variable. It specifies the list of clock nets considered for automatic level shifter insertion. If the value is "all", every clock net is considered. The default is an empty string.

- Level shifter on top nets:

This setting is controlled by the **compile_no_new_cells_at_top_level** variable. It controls the capability of the tool to insert level-shifter cells at top level. When the variable value is set to **true**, no new level-shifter cells are accepted. The default is **false**.

- Level shifters allowed on leaf pin boundary:

This setting is controlled by **mv_allow_ls_on_leaf_pin_boundary** variable. When the setting is **true**, the tool is allowed to insert level shifters at any driver or load pins of a net, even if the pins are not on a power domain boundary. The default is **false**.

The always-on analysis reports details about always-on constraints, related supply nets, relevant power state table settings, and library cell availability for the target net.

With **-lib_cells** option, this command reports unmapped isolation, enable level shifter and retention cells for the current design. The report will list out every element that is not mapped along with the reason on why it cannot be mapped.

If the user does not specify any other option with **-lib_cells**, tool will assume **-isolation**, **-enable_level_shifter** and **-retention** options.

User can limit the reporting of isolation or enable level shifter or retention cells by specifying one of **-isolation** or **-enable_level_shifter** or **-retention** option respectively.

EXAMPLES

The following command analyzes a specified level-shifter connection:

```
prompt> analyze_mv_design -level_shifter \
    -from_pin gprs_nrestore -to_pin GPRs/A_reg_reg[0]/NRESTORE
```

Pin: =domain boundary= GPRs/gprs_ret1;
Type: Hierarchical Port; Domain Boundary;
Constraint: not defined

Net: GPRs/gprs_ret1;
Domain: GPRS;
Local Fanout: 608;
Primary Supply Nets: VDDGS, VSS,
Available Supply Nets: VSS, VDDG, VDDGS,
- Neither driver pin related supply nets (VDD, VSS) nor load pin related
supply nets (VDDG, VSS) are primary supplies in the domain 'GPRS'

Pin: GPRs/A_reg_reg[31]/NRESTORE;
Type: Cell Input Pin; Lib Cell: RSDFCSRHD2BWP;

Level Shifter Analysis - Target Libraries

Required pin-to-pin level shifter type: H2L

All level shifters cells found in the target libraries: 12
 Usable level shifter cells: 12
 Usable level shifter cells of type H2L: 4
 Lib Cell 'mylib_wc09072/LVHL' works in the required voltage range:
 Input voltage range [0.700 - 1.300]
 Output voltage range [0.700 - 1.300]
 Lib Cell 'mylib_wc0909/LVHL' works in the required voltage range:
 Input voltage range [0.700 - 1.300]
 Output voltage range [0.700 - 1.300]
 Lib Cell 'mylib_bc11088/LVHL' works in the required voltage range:
 Input voltage range [0.700 - 1.300]
 Output voltage range [0.700 - 1.300]
 Lib Cell 'mylib_bc1111/LVHL' works in the required voltage range:
 Input voltage range [0.700 - 1.300]
 Output voltage range [0.700 - 1.300]

1

The following command reports the unmapped isolation and enable level shifter in current design:

```
prompt> analyze_mv_design -lib_cells
```

.....

Isolation mapping failures:

Element(s)	Cell name(s)	Strategy	Domain	Clamp	Sense	Reasons
mid_inst/out	snps_PDC_iso0_snps_out1_UPF_ISO					
	iso0	PDC	0	low	TLS mismatch(2);	
					Cannot infer regular iso	

Enable level shifter mapping failures:

Element(s)	Cell name(s)	Strategy	Domain	Clamp	Sense	Reasons
------------	--------------	----------	--------	-------	-------	---------

Enable level shifter mapping should succeed.

TLS mismatch: Library cell(s) cannot be used as they violate
 target_library_subset constraint

Cannot infer regular iso: Inferring a regular isolation library cell will
 lead to more corruption compared to RTL.
 NOR-style isolation is needed

Retention mapping failures:

Cell name	Strategy	Domain	Reasons
mid/bot/q1_reg	PD1_RET1	PD1	Scan register type mismatch(1)
mid/bot/q2_reg	PD1_RET1	PD1	Scan register type mismatch(1)

Scan register type mismatch: Some retention library cell(s) do not meet either set_register_type -exact or \
 set_scan_register_type restriction

analyze_mv_feasibility

Analyzes multivoltage feasibility of current design.

SYNTAX

```
status analyze_mv_feasibility
  [-lib_cells]
  [-resolved_strategy]
  [-isolation]
  [-enable_level_shifter]
  [-level_shifter]
  [-repeater]
  [-retention]
  [-format output_format]
  [-domain domain_name]
  [-strategy strategy_name]
  [-elements objects]
  [-disable_clubbing]
```

Data Types

<i>output_format</i>	string
<i>domain_name</i>	string
<i>strategy_name</i>	string
<i>objects</i>	list

ARGUMENTS

-lib_cells

Analyzes the possibility of the tool to map isolation and enable level shifter cells for the current design with the technology libraries provided. This option is assumed by default.

-resolved_strategy

Generates text based report of the highest precedence isolation, level-shifter, repeater and retention strategy resolved on domain boundary pins or sequential cells. This option is assumed if the command is issued standalone.

-isolation

Enables isolation analysis. This option is assumed by default.

-enable_level_shifter

Enables enable level shifter analysis. This option is assumed by default with option -lib_cells.

-level_shifter

Enables reporting of resolved level shifter strategies. This option is assumed by default with option -resolved_strategy.

-repeater

Enables reporting of resolved repeater strategies. This option is assumed by default with option `-resolved_strategy`.

-retention

Enables reporting of resolved retention strategies. This option is assumed by default with option `-resolved_strategy`.

-format *output_format*

This option takes a string value and the allowed value is **html**. This option is a means to specify the output format of the report. By default, only text based report will be generated on the standard output.

-domain *domain_name*

This option takes a string value. Full hierarchical name of power domain should be specified. This option restricts isolation/repeater/level-shifter resolved strategy report to have boundary (upper or lower) pins of the given domain. Similarly, it restricts retention resolved strategy report to have sequential cells of the given domain. This option is only allowed with `-resolved_strategy`.

-strategy *strategy_name*

This option takes a string value. This option restricts isolation/repeater/level-shifter resolved strategy report to have domain boundary(upper or lower)pins with the given strategy. Similarly, it restricts retention resolved strategy report to have sequential cells with the given strategy. When specifying a power management strategy, a power domain should also be specified with `-domain` option. If the specified strategy is not a part of the specified power domain, the command fails. This option is only allowed with `-resolved_strategy`.

-elements *objects*

Behaviour with `-resolved_strategy`: This option takes list of pin names or cell names. Full hierarchical names should be specified. This option is used to restrict resolved strategy report to only have boundary(upper or lower) pins and cells which are part of the specified element list. If a pin name is specified in the element list, resolved level-shifter/isolation/repeater report will be generated only if it is a domain boundary pin. If a leaf cell is specified, resolved retention strategy report will be only if it is a sequential element with a resolved retention strategy. If hierarchical cell name is specified in the element list, then resolved level-shifter/repeater/isolation strategy report will be generated for all the domain boundary pins under the scope of this hierarchical cell, resolved retention strategy report will be generated for all the sequential elements under the scope of this hierarchical cell.

Behaviour with `-lib_cells`: This option takes list of pin names, net names or cell names. Full hierarchical names should be specified. This option is used to restrict `lib_cells` report to only have those unmapped isolation and enable level shifter cells that are inserted at the specified pins, nets (pins of nets) or cells (pins of cells).

-disable_clubbing

This option disables clubbing of rows in resolved strategy report. This option does not take any value.

DESCRIPTION

With `-lib_cells` option, this command analyzes the possibility of the tool to map isolation and enable level shifter cells for the current design with the technology libraries provided.

In the event any isolation or enable level shifter cells cannot be mapped this command will generate a text based report by default on the standard output. The report will list out every element that would not be mapped along with reason on why it cannot be mapped.

With `-format html` option, tool will also generate a detailed HTML report. The HTML report will list all the technology library cells that will be attempted for mapping but discarded, along with the reason for discarding it.

If the user does not specify any option with this command, tool will assume all of `-lib_cells`, `-isolation` and `-enable_level_shifter` options and will analyze the possibility of the tool to map both isolation and enable level shifter cells for the current design with the technology libraries provided.

User can limit the analysis to isolation or enable level shifter cells by specifying one of `-isolation` or `-enable_level_shifter` option respectively.

When mapping analysis is requested, this command will return a status of 1 when isolation and enable level shifter cells can be

mapped along with an information message. It will return a status of 0 when any of them cannot be mapped along with an error message.

With **-resolved_strategy** option, user can generate a text report of all domain boundary pins with a resolved isolation/level-shifter/repeater strategies and all sequential cells with resolved retention strategy. The reported strategy will be the highest precedence strategy on the domain boundary or sequential cell. This option assumes **-isolation**, **-level_shifter**, **-repeater**, **-retention** by default.

User can restrict report to specific domain, strategy or objects with **-domain**, **-strategy**, **-elements** options respectively.

By default, rows of resolved strategy and mapping analysis text reports are clubbed. If **-disable_clubbing** is used, resolved strategy report will not club pins or sequential cells belonging to the same hierarchical cells or bus to a single row. Each domain boundary pin or sequential cell will be reported in a separate row.

When resolved strategy report is requested, this command will return a status of one when there are no errors reported and a status of 0 otherwise.

EXAMPLES

The following command analyzes current design with the technology libraries provided:

```
prompt> analyze_mv_feasibility -lib_cells
```

```
.....
```

Isolation mapping failures:

Element(s)	Strategy	Domain	Clamp	Sense	Reasons
mid_inst/out	iso0	PDC	0	low	TLS mismatch(2); Cannot infer regular iso

Enable level shifter mapping failures:

Element(s)	Strategy	Domain	Clamp	Sense	Reasons
------------	----------	--------	-------	-------	---------

Enable level shifter mapping should succeed.

TLS mismatch: Library cell(s) cannot be used as they violate
target_library_subset constraint

Cannot infer regular iso: Inferring a regular isolation library cell will
lead to more corruption compared to RTL.

NOR-style isolation is needed

Error: Not all the isolation and enable level shifter cells can be mapped . (UPF-909)
0

```
prompt> analyze_mv_feasibility -resolved_strategy
```

analyze_rtl_congestion

Reports pre-synthesis congestion analysis.

SYNTAX

```
status analyze_rtl_congestion  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing application to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **analyze_rtl_congestion** command reports pre-synthesis congestion analysis for the current design. The command evaluates the RTL for potential congestion issues and reports the issues so you can resolve them early in the design flow.

The report includes the line numbers in the RTL where the issues occur to help you identify where RTL changes are needed.

The following types of structures are known to cause congestion:

- Large MUXes
- Large data switches
- Large selectors
- Large ROMS
- Parallel high-fanout nets

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **analyze_rtl_congestion** command:

```
prompt> analyze_rtl_congestion
```

```
*****
```

Report : RTL congestion

append_to_collection

Adds objects to a collection and modifies a variable.

SYNTAX

```
collection append_to_collection
  [-dict dict_var]
  [-unique]
  var_name
  object_spec
```

Data Types

<i>dict_var</i>	variable referencing a dict
<i>var_name</i>	variable referencing a collection
<i>object_spec</i>	list

ARGUMENTS

-dict *dict_var*

Specifies a variable name referencing a dict object. When this is specified the *var_name* argument specifies the key in the dict to update.

-unique

Indicates that duplicate objects are to be removed from the resulting collection. By default, duplicate objects are not removed.

var_name

Specifies a variable name. The objects matching *object_spec* are added into the collection referenced by this variable.

object_spec

Specifies a list of named objects or collections to add.

DESCRIPTION

The **append_to_collection** command allows you to add elements to a collection. This command treats the variable name given by the *var_name* option as a collection, and it appends all of the elements in *object_spec* to that collection. If the variable does not exist, it is created as a collection with elements from the *object_spec* as its value. If the variable does exist and it does not contain a collection, it is an error.

Alternatively this command may also update a value in a dict. When *-dict* is specified the *dict_var* is treated as a dict and the key specified by *var_name* is updated. If the dict variable is unset the dict is created. If the value referenced by the variable is not a dict it is an error.

The result of the command is the collection that was initially referenced by the `var_name` option (or dict key value), or the collection created if the variable did not exist.

The **append_to_collection** command provides the same semantics as the common use of the **add_to_collection** command; however, this command shows significant improvements in performance.

An example of replacing the **add_to_collection** command with the **append_to_collection** command is provided below. For example,

```
set var_name [add_to_collection $var_name $objs]
```

Using the **append_to_collection** command, the command becomes:

```
append_to_collection var_name $objs
```

Updating a key in a dictionary:

```
append_to_collection -dict drivers $pinName $newDrivers
```

The **append_to_collection** command can be much more efficient than the **add_to_collection** command if you are building up a collection in a loop. The arguments of the command have the same restrictions as the **add_to_collection** command. For more information about these restrictions, see the **add_to_collection** man page.

EXAMPLES

The following example from PrimeTime shows how a collection can be built up using the **append_to_collection** command:

```
prompt> set xports
Error: can't read "xports": no such variable
      Use error_info for more info. (CMD-013)
prompt> append_to_collection xports [get_ports in*]
{in0 in1 in2}
prompt> append_to_collection xports CLOCK
{in0 in1 in2 CLOCK}
```

SEE ALSO

sizeof_collection(2)
dict(2)
```

apply_clock_gate_latency

Annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the **set_clock_gate_latency** command.

SYNTAX

```
status apply_clock_gate_latency
```

ARGUMENTS

The **apply_clock_gate_latency** command has no arguments.

DESCRIPTION

The **apply_clock_gate_latency** command annotates the clock latencies on the existing clock-gating cells based on the settings previously specified using the **set_clock_gate_latency** command.

Use this command to do the following:

- Manually annotate clock-latency values specified by the **set_clock_gate_latency** command to existing clock-gating cells
- Modify clock-latency values applied to clock-gating cells after gate-level clock gating is finished.

If an inconsistent clock-latency setting is detected during annotation, the tool tries to resolve it to produce a situation where clock latencies are monotonically increasing values in the path going from the clock source to the gated registers. The following actions can be performed to achieve this:

- Assume that clock-gating cell A is directly driving one or more registers, and some clock-latency settings have been provided for the timing of these gated registers by using value 0 for the **stage** option of **set_clock_gate_latency** command or by propagation of latency specified for the clock object. In this situation, the latency annotated on cell A is higher than the latency provided for gated registers, then the latency on clock-gating cell A is overwritten with the latency provided for gated registers. If this fix is done, it is informed by warning message PWR-746.
- If clock-gating cell A is driving another clock-gating cell B, and the clock latency set on A is higher than the one set on B, the tool resolves it by overwriting the clock latency on A with the value set on B. If this fix is done, it is also informed by warning message PWR-746.

To remove the settings specified using **set_clock_gate_latency**, use the **reset_clock_gate_latency** command.

If the variable **power_cg_physically_aware_cg** is enabled, then the annotation of latency values from **set_clock_gate_latency** is disabled.

Multicorner-Multimode Support

The actual clock latency annotation performed during the execution of **compile_ultra** or **apply_clock_gate_latency** commands is

done for all the scenarios for which a clock latency value is available.

SEE ALSO

`reset_clock_gate_latency(2)`
`set_clock_gate_latency(2)`
`set_clock_latency(2)`

apply_power_model

Apply a power model which describes the power intent of a reference library cell to instances.

SYNTAX

```
status apply_power_model
  power_model_name
  [-elements instance_names]
  [-supply_map supply_map_list]
  [-port_map port_map_list]
  [-parameters param_map_list]
  [-all_hard_macros]
```

Data Types

<i>power_model_name</i>	string
<i>instance_names</i>	list of instances
<i>supply_map_list</i>	list of power_model_supply_set current_scope_supply_set
<i>port_map_list</i>	list of power_model_supply/logic_port current_scope_supply/logic_net
<i>param_map_list</i>	list of power_model_parameter parameter_value

ARGUMENTS

power_model_name

Specifies the name of the power model to be applied. The name should be a simple (non-hierarchical) name.

The applied power model is searched in this descending order of preference:

1. Power models defined in the current scope.
2. Power models defined in any direct ancestor scope: the closest the better.
3. Power models defined in user power model library. Please see variables upf_power_model_search_path and upf_power_model_library.
4. Power models defined in any scope.

-elements instance_names

Specifies a collection of cells that this power model should be applied to.

If this option is not specified, the power model will be applied to all cells in and under the current scope whose reference library cells match those specified in the power model (i.e. library cells listed in -for option of the define_power_model command).

-supply_map supply_map_list

Specifies the mapping of supply sets in the power model to supply sets in the current scope. For example: -supply_map {{model_vdd top_vdd} {model_vss top_vss}}

-port_map port_map_list

Specifies the mapping of supply/logic ports in the power model to supply/logic nets in the current scope. For example: -port_map {{model_supply_port top_supply_net} {model_logic_port top_logic_net}}

-parameters *param_map_list*

Specifies the mapping of parameters in the power model to actual parameter values. For example: -parameters {{model_param1 "value_1"} {model_param2 "value_2"}}

-all_hard_macros

Apply power models to all hard macro cells under the current scope with matching power model, i.e., the macro lib cell is included in the -for option of the define_power_model command, or the power model name is the lib cell name.

power_model_name must not be provided and no other options can be specified.

DESCRIPTION

The apply_power_model command binds the power_model_name to the cell instances specified by the -elements option. The associated parameter binding specified via the -parameters option allows objects within the environment to be bound to parameters defined within the power model. Not all parameters within the power model need to be bound to objects in the environment and parameters that are not bound shall retain their default values during run time.

The apply_power_model command sets the scope to each of the specified set of instances, referred to as the instance scope, and then executes the set of UPF commands in the power model power_model_name. Upon return, the current scope is restored to the scope in which the command was invoked. Similarly, the command also sets the design top instance to specified instance, and restores it to previous state after executing UPF commands for that instance.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example applies a power model to two macro cells:

```
prompt> define_power_model MODEL -for {macro_lib_cell} {
  create_supply_set SS_macro
  create_supply_set SS_macro_ao
  create_supply_port VDD_macro
  create_supply_port VSS_macro
}
prompt> create_supply_set SS_top
prompt> create_supply_set SS_top_ao
prompt> create_supply_net VDD_top
prompt> create_supply_net VSS_top
prompt> apply_power_model MODEL -elements {u1/macro u2/macro}
  -supply_map {{SS_macro SS_top} {SS_macro_ao SS_top_ao}}
  -port_map {{VDD_macro VDD_top} {VSS_macro VSS_top}}
```

The following example applies a power model to all instanced cells of lib_cell in or under the current scope. Power domain PD_macro will be created in each of the macro cells:

```
prompt> define_power_model MODEL -for {lib_cell} {
  add_parameter DOMAIN -default domain -description "top power domain in model"
  create_supply_net VDD
  create_supply_net VSS
  create_supply_set SS -function {power VDD} -function {ground VSS}
```

```
create_power_domain PD_$DOMAIN -supply {primary SS} -include_scope  
}  
prompt> apply_power_model MODEL -parameters {{DOMAIN macro}}
```

The following example applies power model MODEL_A to all instantiated cells of lib_cell_A and applies power model lib_cell_B to all instantiated cells of lib_cell_B in or under the current scope:

```
prompt> sh cat ./power_model.upf  
define_power_model MODEL_A -for {lib_cell_A} { create_power_domain PD_A }  
prompt> sh cat ./lib_cell_B.upf  
define_power_model lib_cell_B { create_power_domain PD_B }  
prompt> set upf_power_model_search_path ".."  
prompt> set upf_power_model_library "power_model.upf lib_cell_B.upf"  
prompt> apply_power_model -all_hard_macros
```

apropos

Searches the command database for a pattern.

SYNTAX

```
string apropos
      [-symbols_only]
      pattern
```

Data Types

pattern string

ARGUMENTS

-symbols_only

Searches only command and option names.

pattern

Searches for the specified *pattern*.

DESCRIPTION

The **apropos** command searches the command and option database for all commands that contain the specified *pattern*. The *pattern* argument can include the wildcard characters asterisk (*) and question mark (?). The search is case-sensitive. For each command that matches the search criteria, the command help is printed as though **help -verbose** was used with the command.

Whereas **help** looks only at command names, **apropos** looks at command names, the command one-line description, option names, and option value-help strings. The search can be restricted to only command and option names with the **-symbols_only** option.

When searching for dash options, do not include the leading dash. Search only for the name.

EXAMPLES

In the following example, assume that the **get_cells** and **get_designs** commands have the **-exact** option. Note that without the **-symbols_only** option, the first search picks up commands which have the string "exact" in the one-line description.

```
prompt> apropos exact
get_cells      # Create a collection of cells
[-exact]       (Wildcards are considered as plain characters)
```

```
patterns      (Match cell names against patterns)

get_designs   # Create a collection of designs
[-exact]       (Wildcards are considered as plain characters)
patterns      (Match design names against patterns)

real_time     # Return the exact time of day

prompt> apropos exact -symbols_only
get_cells     # Create a collection of cells
[-exact]       (Wildcards are considered as plain characters)
patterns      (Match cell names against patterns)

get_designs   # Create a collection of designs
[-exact]       (Wildcards are considered as plain characters)
patterns      (Match design names against patterns)
```

SEE ALSO

`help(2)`

as_collection

Find a collection by name

SYNTAX

```
string as_collection
      [-check]
      collection1
```

Data Types

collection1 string

ARGUMENTS

-check

Return 1 if collection1 is a collection

collection1

The collection to convert

DESCRIPTION

This command looks up a string value and returns it as a collection if the collection is still live. All other values are passed through this command unmodified.

This command also provides a simple way to check if the input is a collection.

EXAMPLES

Check if a value is a collection:

```
prompt> as_collection -check [get_cells]
1
prompt> as_collection -check hello
0
```

SEE ALSO

`collections(2)`
`foreach_in_collection(2)`

associate_supply_set

Associates a supply set handle to another supply set handle or supply set reference, or associates a list of supply sets.

SYNTAX

```
status associate_supply_set  
  supply_set_names  
  -handle supply_set_handle
```

Data Types

<i>supply_set_names</i>	list
<i>supply_set_handle</i>	string

ARGUMENTS

-handle *supply_set_handle*

Specifies the supply set handle on which the action is performed.

This is an optional argument.

DESCRIPTION

The **associate_supply_set** command associates the supply set handle specified with the **-handle** option to the specified supply set. Also **associate_supply_set** command associates a list of supply sets. After the association, the tool treats corresponding functions in each supply set to be virtually connected. So, the supply sets inherit common switching behavior and must eventually be resolved to the same physical supply net.

A supply set supports the following functions:

Power
Ground

Multicorner-Multimode Support

This command has no dependency on scenario specific information.

EXAMPLES

The following example associates primary supply handle of domain PD1 to a supply set SS1

```
prompt> associate_supply_set SS1 \
           -handle PD1.primary
1

prompt> associate_supply_set {SS1 PD1.primary}
1
```

SEE ALSO

[create_supply_set\(2\)](#)

balance_buffer

Builds a balanced buffer tree on user-specified nets and drivers.

SYNTAX

```
status balance_buffer
  [-from start_point_list]
  [-to end_point_list]
  [-net net_list]
  [-force]
  [-library library_name]
  [-prefer buffer | inverter | lib_cell_name]
```

Data Types

<i>start_point_list</i>	string
<i>end_point_list</i>	string
<i>net_list</i>	string

ARGUMENTS

-from *start_point_list*

Specifies a list of driver pins from which buffer trees are to be created.

-to *end_point_list*

Specifies a list of loads to buffer.

-net *net_list*

Specifies a list of nets to buffer.

-force

Forces **balance_buffer** implementation regardless of cost effect.

-library *library_name*

Specifies the library where the *lib_cell_name* is contained. You must specify this option when specifying *lib_cell_name*. If you do not specify *lib_cell_name*, this option is ignored.

-prefer buffer | inverter | lib_cell_name

Specifies the preferred cell type for the buffer tree.

- When *buffer* is specified, the tool creates a buffer tree using buffer-type library cells.
- When *inverter* is specified, the tool creates a buffer tree using inverter-type library cells.
- When *lib_cell_name* is specified, that library cell is the only cell used to form the buffer tree. You must specify *library_name*.

when specifying *lib_cell_name*. The library cell must be a buffer or an inverter library cell.

DESCRIPTION

The **balance_buffer** command creates DRC-free balanced buffer trees on user-specified nets and drivers. It removes existing buffer trees on the specified nets or drivers if any are present and builds a new DRC-free buffer tree. The buffer trees created in one hierarchy considers loads and drivers across hierarchies and creates buffer trees at the fanout nets into these hierarchies.

The **balance_buffer** command generates a layered buffer tree, where each stage uses the same buffer or inverter and each gate of a given stage roughly drives the same load capacitance. The type of cells used are a combination of buffer and inverter cells available from the target library, unless the **-prefer** option is specified.

Any input port driving a net that is to be buffered by **balance_buffer** must have its drive value set. Otherwise, the default value specifies that the input port has infinite drive, and no buffer tree is created. The **balance_buffer** command uses the NLDM information specified in the target library for calculations on a buffer tree.

Note that **balance_buffer** does not take clock skew into account and, therefore, is not recommended for clock trees.

EXAMPLES

In the following example, a buffer tree is first built from port i0. Then, two additional buffer trees are built to drive load1 and load2.

```
prompt> read -f edif test.edif
prompt> set_driving_cell -cell IV i0
prompt> balance_buffer -from i0
prompt> balance_buffer -to {load1, load2}
```

compile(2)

balance_registers

Moves the registers of the current design to achieve a minimum cycle time.

SYNTAX

status **balance_registers**

DESCRIPTION

The **balance_registers** command moves the registers of a design to obtain a minimum cycle time. You do not have to set the **balance_registers** attribute to invoke **balance_registers** outside of the **compile** command. Using **balance_registers** outside of **compile** usually gives better control and better quality of results because the gate-level netlist used as a starting point is defined exactly by the initial compile.

The **balance_registers** command has the following requirements:

- All registers must be edge-triggered flip-flops clocked by the same phase of the same clock; or, all registers must be master-slave elements with the same signals for the master and slave pins.
- Flip-flops and master-slave elements cannot be present in the same design.
- Master and slave clock waveforms cannot overlap.
- The clock pins of all flip-flops in the design must be connected to the same clock port. The interconnection from the clock port to the clock pins can contain buffer and inverter cells having one input and one output pin. All paths from the clock port to the clock pins of the registers can contain either an even number (including zero) of inverters or an odd number of inverters. These paths cannot be comprised of both even and odd numbers of inverters in a single design.

The outputs of the clock network can be connected to only sequential cells. The clock network of the retimed design will not contain any cells.

- Flip-flops that have asynchronous set or clear pins are not moved.
- Designs cannot contain a combinational loop.
- Set the timing constraints for the design in the following way:
 - The external clock port of the design must have a clock constraint created by the **create_clock** command. This will be called the base clock.
 - All primary inputs of the design must have a non-negative input delay relative to the base clock.
 - All primary outputs of the design must have a non-negative output delay relative to the base clock.
 - Negative input and output delays are tolerated, but the quality of the final retiming result may be worse.
 - Input and output delays relative to virtual clocks or clocks other than the base clock are ignored.
 - Point-to-point timing exceptions as created by the **set_false_path**, **set_multicycle_path**, **set_max_delay**, and **set_min_delay** commands are tolerated but ignored.

- Case analysis constraints are ignored.
- Designs cannot contain tristate cells or unmapped synthetic library components.

By default, **balance_registers** ungroups all instances in a design before moving registers. Avoid ungrouping by setting the **dont_touch** attribute on instances that are not to be ungrouped. The **balance_registers** command does not ungroup an instance that has the **dont_touch** attribute, and does not place any registers inside an instance that has the **dont_touch** attribute.

The **balance_registers** command includes a delay modeling capability. For predictability, the algorithm selects a flip-flop from the target library with small setup time, good drive at the outputs, and low input loading as compared with other registers in the library. This register is designated as the preferred flip-flop. Sequential mapping is invoked in the final step to improve the circuit by remapping the registers. The preferred flip-flop helps provide tighter bounds on the performance variation after the **balance_registers** sequence. To disable delay modeling, set the shell variable **balance_reg_delay** to 0.

As part of the delay modeling capability, **balance_registers** provides some statistics on the delays in the circuit. If the preferred flip-flop appears as a driver for a net, **balance_registers** analyzes the circuit to compute the clock-pin-to-next-state-pin delay for that net. The maximum of all these clock-pin-to-next-state pin delays is used as a reference for checking the input delays of the design. They should be larger than the average clock-pin-to-next-state pin delay.

The clock-pin-to-next-pin-delay, the setup time of the preferred flip-flop and the clock uncertainty sum up to the clock correction. The sum of the clock correction and the maximum critical path length reported when balance registers has finished the register moving phase give an estimate for the clock period after retiming. However, the value of the clock correction does not influence the minimum clock period achieved. An example detailing the output of the delay modeling capability is shown in the EXAMPLES section. More information on the **balance_registers** command can be found in the Design Compiler documentation.

EXAMPLES

The following example reads in the design pipe_mult_32.db, and moves the registers to achieve a minimum cycle time:

```
prompt> read pipe_mult_32.db
```

```
prompt> balance_registers
```

The output provided by the delay modeling capability shows that the sequential cell F611 from the target library is selected as the preferred flip-flop F611. The relevant delay information of the design is summarized in the two tables titled "Design Analysis" and "Clock-to-Q delay distribution."

```
prompt> balance_registers pipe_test
```

```

break

Immediately exits a loop structure.

SYNTAX

int **break**

ARGUMENTS

None

DESCRIPTION

The **break** command immediately exits the innermost loop structure. Use the **break** command to terminate a **while** loop, rather than waiting until the loop evaluates to zero.

The **break** command returns the integer 1, indicating successful operation. A syntax error is reported if **break** is used outside a loop structure.

EXAMPLES

In the following example, a list of file names is scanned until the first file name that is a directory is encountered. The **break** command is used to terminate the foreach loop when the first directory name is encountered.

```
foreach f [which {VDD.ave GND.tech p4mvn2mb.idm}] {
    echo -n "File $f is "
    if { [file isdirectory $f] == 0 } {
        echo "NOT a directory"
    } else {
        echo "a directory"
        break
    }
}
```

SEE ALSO

```
continue(2)
while(2)
```

capture_detailed_script_runtime

Enable detailed capture of runtime script report to a file.

SYNTAX

```
status capture_detailed_script_runtime
      [-start]
      [-stop]
      [-output output]
```

ARGUMENTS

-start

Start detailed capture of report script runtime to a file

-stop

Stop detailed capture of report script runtime to a file

-output *output*

Specify a file name for the output

DESCRIPTION

The **report_script_runtime** command reports the wall clock or CPU time used by commands issued on the current session. It also reports on the number of times the command was executed. The **capture_detailed_script_runtime** command enables detailed capture of runtime script report to a file.

SEE ALSO

[report_script_runtime\(2\)](#)

cd

Changes the current directory.

SYNTAX

status **cd**
[*directory*]

Data Types

directory string

ARGUMENTS

directory

Specifies an existing directory name.

DESCRIPTION

The **cd** command changes the current directory to the specified *directory*. If you do not specify *directory*, your login or home directory becomes the new current directory. By default, the current directory is the directory where the shell is invoked.

A file specification of dot (.) is shorthand for the current directory. Dot is commonly included in the **search_path** variable. Changing the current directory changes the interpretation of "." in the **search_path** variable.

Note that the **sh** command cannot be used to change directories.

EXAMPLES

The following are examples of using the **cd** command:

```
prompt> cd /usr/designer  
prompt> pwd  
/usr/designer
```

```
prompt> cd joe  
prompt> pwd  
/usr/designer/joe
```

```
prompt> cd ..bob
```

```
prompt> pwd
/usr/designer/bob

prompt> cd ~
prompt> pwd
/usr/designer/joe

prompt> cd ~doug
prompt> pwd
/usr/designer/doug

prompt> cd
prompt> pwd
/usr/designer/joe

prompt> cd /usr/designer
prompt> ls
bob    designs    doug
joe    one.ddc    two.ddc

prompt> cd designs
prompt> ls
one.ddc    other.ddc

prompt> set_app_var search_path ". ~"

prompt> read_ddc {one.ddc two.ddc}
Loading ddc file '/usr/designer/designs/one.ddc'
Loading ddc file '/usr/designer/joe/two.ddc'

prompt> cd /tmp

prompt> read_ddc one.ddc
Loading ddc file '/usr/designer/joe/one.ddc'
```

SEE ALSO

ls(2)
pwd(2)

cell_of

Returns the cell objects for the specified pins in the current design.

SYNTAX

```
list cell_of
    [object_list]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of pins in the current design whose cells are returned by the **cell_of** command.

DESCRIPTION

The **cell_of** command returns a list of cell objects that own the pins specified in the *object_list*. If no cells are found, the return value is an empty list ({}). Double quotation marks (" ") are needed for pin names that are ambiguous to the command parser.

EXAMPLES

The following example returns the cell of the specified pin in the current design:

```
prompt> cell_of U1/P
{U1}
```

The following example returns the cell of pin "reg(8)/Q" in the current design:

```
prompt> cell_of "reg(8)/Q"
{reg(8)}
```

The following example returns the list of cells for the given list of pins. The first cell is the owner cell of the first pin and the second cell is the owner cell of the second pin.

```
prompt> cell_of {U3/B U9/A}
{U3 U9}
```

The following example returns the cell of the given pin. The cell name is a hierarchical name at the current level, which can be found

after ungrouping.

```
prompt> cell_of {U3/U1/B}  
{U3/U1}
```

The following example returns a warning message when the pin does not exist in the current design:

```
prompt> cell_of U999/Z  
Warning: Can't find pin 'U999/Z' in design 'TOP'. (UID-95)  
{}
```

The following example returns the cell of a hierarchical pin:

```
prompt> cell_of U1/U2/U3/A  
{U1/U2/U3}
```

SEE ALSO

[all_connected\(2\)](#)

change_link

Changes the design to which a cell is linked.

SYNTAX

```
status change_link
  object_list
  design_name
  [-all_instances]
  [-force]
  [-pin_map pin_map_list]
```

Data Types

```
object_list    list
design_name    string
pin_map_list   list
```

ARGUMENTS

object_list

Specifies the cells or references in the current design for which to change the link.

design_name

Specifies the name of the design to which to link the cells or references in the object list.

-all_instances

Enables the command to accept instance cells in the object list.

-force

Enables the command to allow mismatched pin counts, as long as any mismatched cells in the object list have fewer pins than the specified design.

-pin_map pin_map_list

Specifies the pin mapping used to map old pin names to new pin names. The pin name must be the reference cell pin name.

To specify the pin mapping, use the following syntax:

```
 {{old_pin1 new_pin1} ... {old_pin_n new_pin_n}}
```

New pins maintain the same net connections as the corresponding old pins.

DESCRIPTION

The **change_link** command specifies a design for which to change the link for a cell or reference.

If you specify a cell in the object list, the command changes it to one occurrence of the specified design. If you specify a reference in the object list, the command changes all cells of the specified reference type to occurrences of the design.

You can change the cell or reference link only to a compatible design. For example, the design must have the same number of ports with the same name and direction as the cell or reference.

Although the *design_name* argument accepts names in the format *library/library_cell*, it does not imply that the actual library cell used for the new cell will be from the specified library. The actual library cell used is determined by the current link library settings.

During **change_link** activity, all Synopsys database format link information is copied from the old design to the new design. If the old design is a synthetic module, all attributes of the old synthetic module are moved to the new link. After running the **change_link** command, link the design with the **link** command.

Use the **-all_instances** option when any cell in the *object_list* argument is an instance in the lower hierarchy and its parent cell is not unique. All similar instance cells under the same parent design are automatically linked to the new reference design. You do not have to change the current design to change the link for the instance cells in the lower design hierarchy. You do not need to use the **-all_instances** option if none of the cells in the *object_list* argument is an instance in the lower hierarchy or its parent cell is unique.

A common use of the **change_link** command for hierarchical cells is to rename designs and to change the cell links to the designs of the new names. In these cases, use the **rename_design** command with the **-update_links** option instead of the **copy_design**, **rename_design**, **change_link** and **remove_design** command set. The **rename_design** command provides faster runtime. For more information, see the **rename_design** command man page.

EXAMPLES

The following example shows a common use of the **change_link** command. The *ADDER* design is copied to a new design named *MY_ADDER*. The *U1* and *U2* cells are then linked from the current design to *MY_ADDER*.

```
prompt> copy_design ADDER MY_ADDER
Copying design 'ADDER' to 'MY_ADDER'
```

```
prompt> change_link {U1 U2} MY_ADDER
```

The following example shows an improper use of the **change_link** command. The specified cell does not have the same number of ports as the design to which it is being linked.

```
prompt> change_link U3 HALF_ADDER
Error: Number of pins on cell 'U3' don't equal design 'HALF_ADDER'
```

The following example uses the **-all_instances** option:

```
prompt> current_design
Current design is 'top'.
{top}

prompt> get_cells -hierarchical -filter "ref_name == bot"
{mid1/bot1 mid1/bot2}
1

prompt> get_cells -hierarchical -filter "ref_name == IVA"
{mid1/bot1/inv1 mid1/bot2/inv1 mid1/bot1/inv2 mid1/bot2/inv2 mid1/inv3}
1
```

```
prompt> change_link mid1/bot1/inv1 lsi_10k/IVAP -all_instances
Information: Changed link for all instances of cell 'inv1' in subdesign 'bot'. (UID-193)
1

prompt> get_cells -hierarchical -filter "ref_name == IVAP"
{mid1/bot1/inv1 mid1/bot2/inv1}
1

prompt> get_cells -hierarchical -filter "ref_name == IVA"
{mid1/bot1/inv2 mid1/bot2/inv2 mid1/inv3}
1
```

In the previous example, the bot design has cells named inv1 and inv2 that were linked to lsi_10k/IVA. The mid1/bot1 and mid1/bot2 cells instantiate the bot design. The mid1/inv3 cell is also linked to lsi_10k/IVA. After running the **change_link** command in the example, the mid1/bot1/inv1 and mid1/bot2/inv1 cells are relinked to lsi_10k/IVAP, because they are the instances of the same inv1 cell in the bot design. The mid1/bot1/inv2 and mid1/bot2/inv2 cells are not relinked because they are not the instances of the inv1 cell in the bot design. The mid1/inv3 cell is not relinked because it is not in an instance that instantiates the bot design.

The following example uses the **change_link** command to change the reference of cell using the **-pin_map** option:

```
prompt> change_link U3 lsi_10k/IVDA -pin_map { {A B} {Z X}}
```

SEE ALSO

rename_design(2)
```

change_names

Changes the names of ports, cells, and nets in a design.

SYNTAX

```
status change_names
  [-rules name_rules]
  [-hierarchy]
  [-verbose]
  [-names_file names_file]
  [-log_changes log_file]
  [-restore]
  [-dont_touch object_list]
  [-instance instance]
  [-new_name new_name]
  [-skip_inactive_constraints]
  [-dont_touch_collection object_list]
```

Data Types

<i>name_rules</i>	string
<i>names_file</i>	string
<i>log_file</i>	string
<i>object_list</i>	list
<i>instance</i>	string or instance object
<i>new_name</i>	string

ARGUMENTS

-rules *name_rules*

Specifies a name rule set that details the rules to which the object names must conform. The *name_rules* file is defined by using the **define_name_rules** command.

By default, this value is the *name_rules* file specified by the **default_name_rules** variable.

The tool ignores the **-rules** option if you specify the **-names_file** option.

-hierarchy

Modifies all names in the design hierarchy.

By default, the tool changes only objects in the current design.

-verbose

Reports every name change.

By default, the tool provides only a summary of the number of name changes in the design.

-names_file *names_file*

Specifies a file of manual name changes. These name changes are not subject to any name rules, but an error is reported if any name changes are not unique.

By default, the command automatically makes name changes based on the naming rules.

If you specify this option, the tool ignores the **-rules** option.

-log_changes log_file

Specifies the log file in which to record all name changes.

If you run multiple **change_names** commands, the *log_file* must be empty before running the first**change_names** command.

-restore

Reverses the changes recorded in the *names_file* during the current session and restores the contents of the file to the state it was in when opened.

-dont_touch object_list

Specifies the designs on which the **change_names** command is not to be applied. You can specify any design under the hierarchy of the current design in the object list to ensure that the **change_names** command does not apply any changes to them. The dot (.) character represents the current design.

By default, there are no designs in the list.

-instance instance

Specifies the instance on which to apply the **change_names** command.

This option must be used with the **-new_name** option to specify a new instance name.

This option is mutually exclusive with all other options except **-new_name** and **-verbose**.

-new_name new_name

Specifies the new instance name when the **-instance** option is used. The new name must consist of only alphanumeric characters and the underscore (_) and must start with an alphabetical character. Specify only the instance name, not a hierarchical name. The new name cannot be a reserved word used by Verilog, SystemVerilog, or VHDL. The new name must not conflict with an existing instance, port, and net name within the same design. The leading backslash will be removed from the new name.

-skip_inactive_constraints

When you specify this option, the inactive constraints (that are part of the non-current design or part of inactive scenarios) are not preserved when you use the **-instance** option with **change_names**. This option has no impact when you do not specify the **-instance** option.

-dont_touch_collection object_list

Specifies the collection on which the **change_names** command is not to be applied. The collection can include designs, cells, ports, nets. You can specify a collection in the object list to ensure that the **change_names** command does not apply any changes to them.

DESCRIPTION

The **change_names** command changes the names of ports, cells (including physical-only cells), and nets in a design to conform to specified name rules.

This command cannot be used to change the name of library cells or bus ports.

To change the name of bus ports, you must first use the **remove_bus** command to remove the bus property from the port.

If an object name does not conform to the specified rules, the tool changes the name and ensures that the new name is unique within

the design.

By default, the tool changes the names of bus members to force them to use the same base name as their owning bus. If you do not want the names of bus members, set the **change_names_dont_change_bus_members** variable to **true** before running the **change_names** command.

To show the effects of running this command without actually making the changes, use the **report_names** command.

There are two primary reasons for using the **change_names** command:

- It enables you to modify design object names in the tool so that the names match those that are ultimately created for a saved design. The names the tool displays in reports and in other information match those used in your target system.
- It enables you to define naming rules specific to your target system. For example, you might be using VHDL as a design transfer mechanism, but the naming rules of your system might be more restrictive than those supported by the true VHDL format.

To obtain a list of available name rules, use the **report_name_rules** command. For information about naming rules that can be affected during the execution of the **change_names** file, see the **define_name_rules** man page.

When you run the **change_names** command with no options, it operates on the ports, cells, and nets in the current design. When you specify the **-hierarchy** option, changes are expanded to include all design objects within the current design hierarchy.

For runtime reasons, it's best to use the **-instance** option only when you have a small list of instances to be renamed. If you have a big list of instances to be renamed, you must use the **-rule** option with **change_names** or use the **-skip_inactive_constraints** option and apply the constraints after running **change_names -instance**.

Names File Format

To specify a name change, you must specify the following four fields:

```
design_name object_type object_name new_name
```

The *design_name* field is a design currently read into the tool. The *object_type* field is **port**, **cell**, or **net**. The *object_name* field is the name of an object within the specified design. The *new_name* field is the name that replaces the existing name.

If the file contains a report bar formed by a dashed line (-----), the tool ignores all information above the report bar. The tool parses all lines after the report bar (or all lines, if the file does not contain a report bar).

By default, the tool parses each line into four fields, which are separated by whitespace characters, such as blanks, tabs, or new lines.

This format matches the format of the **report_names** command output, which allows you to redirect the output of the **report_names** command to a file, edit it, and then use it as input to the **change_names** command.

The tool also supports the use of a semicolon (;) as a delimiter to separate the name change specifications in the file. If you use a delimiter, you must add the following line above the report bar formed by the dashed line (-----):

```
use delimiter:true
```

The following example shows a names file without a delimiter:

```
*****
Report : names
      -rules MY_RULES
Design : TOP
Version: v3.0
Date   : Tue Aug 13 14:24:23 2007
*****
```

Design	Type	Object	New Name
TOP	cell	U\$1	U_1
TOP	net	NET_NAME_IS_WAY_TOO_LONG	NET_NAME_IS_WAY_TOO
TOP	net	12345	N12345

The following example shows a names file with a delimiter:

```
use delimiter:true

Design      Type   Object        New Name
-----
TOP         cell   U$1           U_1 ;
TOP         net    NET_NAME_IS_WAY_TOO_LONG
                      NET_NAME_IS_WAY_TOO ;
TOP         net    12345          N12345 ;
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to change the names in the current design to conform to the rules defined by the **default_name_rules** variable:

```
prompt> list default_name_rules
default_name_rules = "EXAMPLE"

prompt> change_names
Information: Using name rules 'EXAMPLE'.
Information: 4 names changed in design 'TOP'.
```

The following example shows how to use the **-verbose** option to show each name changed by the **change_names** command.

```
prompt> change_names -verbose
Information: Using name rules 'EXAMPLE'.
```

Design	Type	Object	New Name
TOP	port	A1	a_
TOP	port	A2	a_a
TOP	port	A3	a_b
TOP	port	A4	a_c

The following example shows how to use the **-hierarchy** option to change names throughout the design hierarchy. Typically, you want to change the names of all designs in the hierarchy to conform to your name rules.

```
prompt> change_names -hierarchy
Information: Using name rules 'EXAMPLE'.
Information: 12 names changed in design 'HALF_ADDER'.
Information: 35 names changed in design 'SUBTRACTOR'.
Information: No names changed in design 'TOP'.
```

The following example shows how to use the **define_name_rules** command to create a set of simple name rules. In this example, the name rules require that all names use uppercase characters or numerals.

```
prompt> define_name_rules CAPS_ONLY -allow "A-Z 0-9"

prompt> change_names -rules CAPS_ONLY -verbose
Information: Using name rules 'CAPS_ONLY'.
```

Design	Type	Object	New Name
MY_BUFFER	port	a1	A1
MY_BUFFER	port	a2	A2
MY_BUFFER	port	b1	B1
MY_BUFFER	port	b2	B2

```
MY_BUFFER    cell  u1          U1
MY_BUFFER    cell  u2          U2
```

The following example shows how to make manual name changes to design objects by using the **report_names** and **change_names** commands. First, redirect a report of all the original design objects to a file and edit the file to make manual changes. Use the edited names file to direct the name changes made by the **change_names** command. In this case, the tool ignores the name rules and makes only the specified changes.

```
prompt> report_names -original > TOP.names
/* Edit the TOP.names names file */
prompt> change_names -names_file TOP.names
Information: 15 names changed using names file 'TOP.names'
```

The following example shows how to use the **-instance** option to change one instance name:

```
prompt> change_names -instance a1 -new_name a2
```

The following example shows how to rename a bus port by first removing the bus property and then using the **change_names** command to change the name.

```
prompt> remove_bus -type port -name my_bus
prompt> change_names -names_file name.change -verbose
```

The following example shows how to specify a **dont_touch_collection** to avoid name changes on the objects in the collection.

```
prompt> change_names -rules verilog -hierarchy -verbose -dont_touch_collection [list [get_designs top]]
prompt> change_names -rules verilog -hierarchy -verbose -dont_touch_collection [list [get_nets n*]]
prompt> change_names -rules verilog -hierarchy -verbose -dont_touch_collection [list [get_ports a[0]] [get_nets a[0]]]
prompt> change_names -rules verilog -hierarchy -verbose -dont_touch_collection [list [get_cells a_reg*] [get_ports a[0]] [get_nets a[0]]]
```

```

change_selection

Changes the selection in the GUI, taking a collection of objects and changing the selection according to the type of change specified.

SYNTAX

```
status change_selection
  [-name slct_bus]
  [-replace]
  [-add]
  [-remove]
  [-toggle]
  [-type object_type]
collection
```

Data Types

<i>slct_bus</i>	string
<i>object_type</i>	list
<i>collection</i>	list

ARGUMENTS

-name *slct_bus*

Specifies to change the selection bus by using the value of *slct_bus*. By default, the command changes the selection bus by using the name *global*.

-replace

Replaces the current selection with the objects in the collection. This is the default behavior when no options are specified.

-add

Adds the objects in the collection to the current selection. By default, this option is off.

-remove

Removes the objects that are specified in the collection from the current selection. By default, this option is off.

-toggle

Adds each item that is specified in the collection to the selection bus if it is not currently contained in the selection bus. If it is currently contained in the selection bus, it is removed. By default, this option is off.

-type *object_type*

Specifies the type to change. Only those items from the collection that are of the type specified by *object_type* are used to change the selection. The valid values are **design**, **port**, **net**, **cell**, **pin**, and **path** (timing path). By default, the command uses the entire collection.

collection

Specifies the collection of objects to use to change the selection. The type of change that is applied to the current selection with the *collection* is specified by the options listed above. By default, this option is off.

DESCRIPTION

The **change_selection** command changes the selection in the GUI. When selections are changed, the GUI updates all relevant windows to reflect it.

A collection of objects and the type of change are given as input to the command. The collection of objects might be returned as the result of another command, such as the **get_designs** command. If the collection is empty and you use the **-replace** option (or let the command default by specifying no option), the current selection is cleared.

If you use the **-type** option, only the type of objects specified are used to change the current selection. For example, if you use **-type design**, the command uses only the design objects in the collection to change the current selection. If you do not use the **-type** option, all objects in the collection are used to change the current selection. For example, if you use the **-add** option without using the **-type** option, all objects, regardless of their type, are added to the current selection.

For information about collections, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example replaces the current selection with the collection of design objects, regardless of type:

```
prompt> change_selection [get_designs]
```

The following example adds a cell named U5 to the selection made in the example above:

```
prompt> change_selection -add [get_cells U5]
```

The following example removes all pin objects from the current selection:

```
prompt> change_selection -remove -type pin [get_selection]
```

The following example clears the selection:

```
prompt> change_selection ""
```

The following example creates a new selection bus and adds a net named n1 to the selection:

```
prompt> set slct [create_selection_bus]
```

```
prompt> change_selection -name $slct [get_nets 1]
```

query_objects(2)

characterize

Captures information about the environment of specific cell instances and assigns the information as attributes on the design to which the cells are linked.

SYNTAX

```
status characterize
  cell_list
  [-no_timing]
  [-constraints]
  [-connections]
  [-power]
  [-verbose]
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies the cells in the current design whose designs are to be characterized.

-no_timing

Indicates not to characterize the timing characteristics of the design. Attributes representing the timing environment or requirements are not placed on the subdesigns.

-constraints

Places area, power, connection class, and design rule constraint information on the subdesigns.

-connections

Characterizes the connection attributes of the design.

-power

Uses the switching activity information of the specified cells to annotate the corresponding subdesigns.

-verbose

Echoes the equivalent commands that are applied to the subdesign being characterized.

DESCRIPTION

The **characterize** command places on a design the information and attributes that characterize its environment in the context of a specified instantiation in another design.

The primary purpose of the **characterize** command is to capture the timing environment of the subdesign. This occurs if the **characterize** command is run without the **-no_timing** option.

The command derives and asserts the following on the design to which the instance is linked:

- Unless the **-no_timing** option is used, the **characterize** command places on the subdesigns any timing characteristics previously set by the following commands:

```
create_clock
group_path
read_sdf
read_clusters
set_annotated_check
set_annotated_delay
set_auto_ideal_net
set_disable_timing
set_drive
set_driving_cell
set_false_path
set_ideal_latency
set_ideal_net
set_ideal_transition
set_input_delay
set_load
set_max_delay
set_min_delay
set_multicycle_path
set_operating_conditions
set_output_delay
set_resistance
set_timing_ranges
set_wire_load_model
set_wire_load_mode
set_wire_load_selection_group
set_wire_load_min_block_size
```

- If the **-constraint** option is used, the **characterize** command places on the subdesigns any area, power, connection class, and design rule constraints previously set by the following commands:

```
set_cell_degradation
set_connection_class
set_dont_touch_network
set_fanout_load
set_fix_multiple_port_nets
set_ideal_network
set_ideal_net
set_max_area
set_max_capacitance
set_max_fanout
set_max_power
set_max_transition
set_min_capacitance
set_min_porosity
```

- If the **-connections** option is used, the **characterize** command places on the subdesigns any connection attributes previously set by the following commands:

```
set_equal
set_logic_one
set_logic_zero
set_logic_dc
set_opposite
```

set_unconnected

Note that connection class information is applied only if the **-constraint** option is used.

- If the **-power** option is used, the **characterize** command places on the subdesigns any switching activity information, toggle rates, and static probability previously set, calculated, or saved by the following commands:

report_power
set_switching_activity

In most cases, characterizing a design removes the effects of any previous characterization and replaces all relevant information. However, in the case of back-annotation (the **set_load**, **set_resistance**, **read_sdf**, **set_annotated_delay**, an **set_annotated_check** commands), the annotations are moved during the characterize step, and cannot overwrite existing annotations made on the subdesign. In this case, annotations must be explicitly removed from the subdesign by using the **reset_design** command before running the **characterize** command the next time.

The **characterize** command can be used with **set_dont_touch** to maintain the hierarchy during optimization. This method of optimization is known as bottom-up optimization. It can be applied using a golden instance or a uniquify approach. An alternative to bottom-up optimization is top-down optimization, otherwise known as hierarchical compile. In top-down optimization, the tool performs characterization and optimization of subdesigns automatically.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the golden instance approach to bottom-up optimization. This is useful when the same design is used in several places, with a similar environment. The **characterize** and **set_dont_touch** commands are used to optimize the subdesign once and reference that optimized design in several places. The characterization is done using a golden instance (U1 in this case) and reflects the environment of that instance. Assume that U1 and U2 both reference the design named ADDER and have similar environments.

Characterize the ADDER design with respect to instance "U1" and compile it:

```
prompt> current_design TOP
prompt> characterize U1
prompt> current_design ADDER
prompt> compile
```

Compile the top level while preserving "U1" and "U2":

```
prompt> current_design TOP
prompt> set_dont_touch {U1 U2}
prompt> compile
```

The following example shows the uniquify approach to bottom-up optimization. If a design is used in more than one place with different environments, use the **uniquify** command to create a design for each instance. You can now characterize the new designs and optimize each separately.

Uniquify the hierarchy so that all hierarchical cells reference different designs. This creates new design names such as ADDER_1 and ADDER_2:

```
prompt> current_design TOP
prompt> uniquify
```

Characterize the unique designs with respect to their environments, and compile each design:

```
prompt> characterize {U1 U2}
prompt> current_design ADDER_1
prompt> compile
prompt> current_design ADDER_2
```

```
prompt> compile
```

Compile the top-level design while preserving U1 and U2:

```
prompt> current_design TOP
prompt> set_dont_touch {U1 U2}
prompt> compile
```

The following example shows top-down optimization. In top-down optimization, the tool implicitly performs characterization for each subdesign.

```
prompt> current_design TOP
prompt> uniquify
prompt> compile
```

check_bindings

Checks the bindings in a synthetic library module definition.

SYNTAX

```
status check_bindings
  [-bindings binding_list]
  [-pin_widths pin_width_list]
  module_name
```

Data Types

<i>binding_list</i>	list
<i>pin_width_list</i>	list
<i>module_name</i>	string

ARGUMENTS

-bindings *binding_list*

Lists the bindings of the module to check. The default is to check all bindings.

-pin_widths *pin_width_list*

Lists the pin width that is checked for the *bound_operator*. The default is specified by the operator's **check_pin_widths** attribute. The **-pin_widths** option can be used only if all specified bindings bind to the same operator.

module_name

Specifies the name of the synthetic library module whose bindings you want to check. This parameter is required.

DESCRIPTION

The **check_bindings** command ensures that bindings from a synthetic library module to synthetic library operators are correct.

By default, **check_bindings** checks every binding of the specified module. The **check_bindings** command verifies that a binding implements a particular operator correctly. The binding under test is correct if it generates a design that is functionally the same as the "golden" binding. All Synopsys operators are associated with thoroughly-tested golden bindings.

To check a binding for a particular operator, that operator must be annotated with a module and binding known to be correct. Do this using the **check_module** and **check_binding** attributes. For example:

```
operator (ADD_UNS_OP) {
  check_module : "add";
  check_binding : "b1";
  check_pin_widths : "A=1,B=1,Z=1; A=3,B=4,Z=5";
```

```
/* other declaration go here */  
}
```

By default, each binding to an operator is verified for a number of different operator pin widths. The default pin widths are specified by a **check_pin_widths** attribute on the operator. The **check_pin_widths** attribute is a list of pin-width specifications, separated by semicolons (;). Each pin-width specification is a comma (,) separated list of pin sizes. Pin sizes are specified by a pin name, followed by an equal sign (=), followed by a pin width.

The preceding example runs one verification for operators with all pins of width 1 and a second verification with the pin A pin of width 3, pin B of width 4, and pin Z of width 5.

LIMITATIONS

Because **check_bindings** is based on **check_design**, it inherits the same limitations. The **check_bindings** command does not verify noncombinational parts unless the flip-flop names are identical. The **check_bindings** command also does not check very large multipliers because the verification is too expensive.

EXAMPLES

The following example checks the bindings to the SYNTH_ADD module:

```
prompt> check_bindings SYNTH_ADD
```

The next example checks binds b1 and b2 for specific pin widths. Note that **-pin_widths** lists are specified in the list format of dc_shell, not as a single string (as used in the previous **check_pin_widths** attribute).

```
prompt> check_bindings  
-binding { b1 b2 }  
-pin_widths { "A=2,B=2,Z=2" "A=31,B=31,Z=32" }  
SYNTH_ADD
```

[synthetic_library\(3\)](#)

check_block_abstraction

Checks the readiness of a block abstraction for usage in a top-level design at various stages of the flow.

SYNTAX

status **check_block_abstraction**

ARGUMENTS

The **check_block_abstraction** command has no arguments.

DESCRIPTION

The **check_block_abstraction** command checks the blocks linked to the top-level design to ensure they are ready for the top-level compile flow. The following general checks are performed:

- Scenario consistency in multicornor-multimode blocks.
- The existence of **dont_touch** attribute settings on blocks and cells.

If any error messages are reported by this command, you should resolve them before proceeding further. If any warning messages are reported by this command, you should review them before proceeding further.

Multicorner-Multimode Support

This command uses information from active scenarios only.

EXAMPLES

The following example checks the blocks in the current design and reports the errors to be resolved:

```
prompt> check_block_abstraction
Error: No scenario data loaded from block reference 'blk1'. (ILM-151)
Error: dont_touch attribute incorrectly set to false on block design 'blk2'. (ILM-121)
0
```

SEE ALSO

`create_block_abstraction(2)`
`set_top_implementation_options(2)`
`report_block_abstraction(2)`

check_bsd

Checks whether a design's boundary-scan implementation is compliant with IEEE Std 1149.1.

SYNTAX

```
status check_bsd
[-verbose true | false]
[-infer_instructions true | false]
[-effort low | medium | high]
```

ARGUMENTS

-verbose true | false

Generates multiple warning or error messages for a set of similar violations during a single step when set to **true**. By default, a warning or error message is generated for only the first violating cell or port.

-infer_instructions true | false

Specifies whether **check_bsd** should analyze the logic to identify the implemented instructions.

When set to **false**, the tool uses only instruction information that was previously specified with the **set_bsd_instruction** command. In the insertion flow, this is provided by **set_bsd_instruction -view spec** commands for specified instructions and by the tool for automatically implemented mandatory instructions. In the existing-logic flow, this is provided with the **set_bsd_instruction -view existing_dft** command. The **check_bsd** command reports this as follows:

...Using the implemented instructions information.

When set to **true**, the tool uses logic analysis to identify the implemented instructions, with an analysis effort optionally specified by the **-effort** option. The **check_bsd** command reports this as follows:

...Inferring the implemented INTEST instruction.
...Inferring the implemented CLAMP instruction.
...Inferring the implemented HIGHZ instruction.
...Inferring the implemented IDCODE & USERCODE instruction.
...Inferring the implemented RUNBIST instruction.

If any instructions have been specified with the **set_bsd_instruction** command, the default is **false**. If no instructions have been specified, the default is **true**.

When this option is set to **true**, note the following:

- Any instruction information specified with the **set_bsd_instruction** command is ignored. If you write out a BSDL file, nonstandard (user-defined) instructions will have USER<n> names and all user-defined test data registers will have UTDR<n> names.
- All unused encodings are assigned to the BYPASS instruction in the BSDL file.

-effort low | medium | high

Controls the effort used to search for implemented instructions when the **-infer_instructions** option is set to **true** and the instruction

register width is 16 or greater. The effort levels are:

- **low** - uses only heuristics
- **medium** - uses heuristics first, then random opcode generation for limited sequential search
- **high** - uses a full sequential search

If the **-infer_instructions** option is set to **true** and the instruction register width is less than 16, this option is ignored and a full sequential search (the **high** effort level) is used.

Instruction register masking can be used to reduce search runtime. See the DESCRIPTION section for more information.

DESCRIPTION

The **check_bsd** checks whether the current design's boundary-scan implementation is compliant with IEEE Std 1149.1. You must specify the Test Access Ports (TMS, TCK, TRST, TDI, and TDO) using the **set_dft_signal -view existing** command. If violations to any of the IEEE Std 1149.1 rules are found, the appropriate messages are generated. Check the design for any unresolved references before using this command. Set system clocks using the **set_dft_clock** command in order to see correct functionality. Specify any compliance enable ports using the **set_bsd_compliance** command.

Fatal error messages indicate that your design violates an IEEE Std 1149.1 rule and the violation is serious enough that the compliance checker can no longer continue analysis. You cannot use subsequent tools (for example, the BSDL generator) until you correct the violation.

Error messages indicate that your design violates an IEEE Std 1149.1 rule, but it is still possible to analyze further and gather more information about the design. However, you cannot use subsequent tools (for example, the BSDL generator) until you correct the violation.

Warning messages indicate that your design violates an IEEE Std 1149.1 rule, but the violation does not prevent the BSDL generator from generating BSDL.

When the tool must infer the implemented instructions, you can shorten the sequential search space by masking bits within the IR instruction opcodes using the following two application variables:

- The **test_cc_ir_masked_bits** variable specifies the IR bits to be masked. The compliance checker masks the IR bits that contain "1" in the binary equivalent to the decimal integer value assigned to this variable. For details, see the man page for the **test_cc_ir_masked_bits** variable.
- The **test_cc_ir_value_of_masked_bits** variable specifies a predefined value to be forced onto the masked IR bits. The decimal integer value assigned to this variable is converted to binary for the bit width of the IR, and the masked bits are forced with the corresponding values during the search operation. For details, see the man page for the **test_cc_ir_value_of_masked_bits** variable.

The least significant bit of the IR is considered to be the bit closest to the TDO port.

By default, compliance check is done in accordance with the IEEE1149.1-2001 standard version. You can switch back to the IEEE1149.1-1993 standard version, by setting the **-ieee1149.1_1993** option of the **set_bsd_configuration** command.

For more details about the IEEE Std 1149.1 rules, refer to the *IEEE Std Test Access Port and Boundary-Scan Architecture*.

EXAMPLES

The following command performs compliance checking for the current design, and illustrates the types of messages that are output:

```
prompt> current_design my_boundary_scan  
prompt> set_dft_signal -view existing -port my_tdi -type TDI
```

```
prompt> set_dft_signal -view existing -port my_tdo -type TDO
prompt> set_dft_signal -view existing -port my_tms -type TMS
prompt> set_dft_signal -view existing -port my_trst -type TRST -active_state 0
prompt> set_dft_signal -view existing -port my_tck -type TCK -timing {45 55}

IEEE 1149.1 Summary

4 state elements found in the TAP controller
5 cells found in the Instruction Register
5 standard instructions found.
11 user defined instructions found.
1 cells in BYPASS register
32 cells in DEVICE ID register
5 cells in boundary-scan register

IEEE 1149.1 Violation Summary

6 Violations found in extraction of TAP Controller
Violates Rules: 3.3.1b 3.6.1b
Violates Rules: 3.3.1b 3.6.1b
Violates Rules: 3.3.1b 3.6.1b
1 Violations found in extraction of BYPASS register
Violates Rules: 9.1.1b

SEE ALSO

`set_bsd_compliance(2)`
`set_dft_signal(2)`

check_budget

Checks that user-specified budgets and fixed delays are consistent with path constraints.

SYNTAX

```
status check_budget
  [-verbose]
  [-tolerance tolerance]
  [-from object_list]
  [-to object_list]
  [-no_interblock_logic]
  [cell_list]
```

Data Types

<i>tolerance</i>	float
<i>object_list</i>	list
<i>cell_list</i>	list

ARGUMENTS

-verbose

Shows the path segments that cause violation of timing constraints. By default, only the number of paths that violate timing constraints are shown.

-tolerance *tolerance*

Specifies that only paths with a slack greater than *tolerance* in absolute value are checked and reported. By default, all paths are checked and reported.

-from *object_list*

Shows only the paths from the named pins, ports, or endpoints clocked by named clocks. By default, all paths that violate timing constraints are shown.

-to *object_list*

Shows only the paths to the named pins, ports, or endpoints clocked by named clocks. By default, all paths that violate timing constraints are shown.

-no_interblock_logic

Specifies that interblock logic is not to be budgeted. By default, the tool considers interblock logic not fixed.

cell_list

Specifies a list of cells to budget. This option must be set only when the **check_budget** command is used before the **allocate_budget** command.

DESCRIPTION

The **check_budget** command checks that the user-specified budgets and fixed delays are consistent with path constraints. Inconsistencies exist when the sum of user-specified budgets and fixed delays along a path exceed the value of the path constraint. By default, the report shows only the number of paths that violate the timing constraints. The **-verbose** option shows details about the violations. The **cell_list** option allows you to check user budgets on the specified cells before budget allocation. This option must not be used after budget allocation.

EXAMPLES

The following example shows a report using only the default values:

```
prompt> check_budget
```

```
*****
Check budget
*****
```

```
Design has 2 violations.
1
```

The following example shows a report with the verbose option.

```
prompt> check_budget -verbose
```

```
*****
Check budget
*****
```

```

SEE ALSO

`report_path_budget(2)`
`set_user_budget(2)`

check_design

Checks the current design for consistency.

SYNTAX

```
status check_design
  [-summary]
  [-no_warnings]
  [-one_level]
  [-multiple_designs]
  [-no_connection_class]
  [-nosplit]
  [-unmapped]
  [-cells]
  [-ports]
  [-designs]
  [-nets]
  [-tristates]
  [error-ids]
  [-html_file_name html_file]
```

ARGUMENTS

-summary

Displays a summary of the warning messages instead of one message per warning. This does not affect the way error messages are issued.

-no_warnings

Suppresses warning messages, so only error messages are printed.

-one_level

Performs checks at only the current level of hierarchy. By default, **check_design** checks the current level and all designs below the current level.

-multiple_designs

Reports warning messages related to multiply-instantiated designs. With this option, the tool lists all multiply-instantiated designs along with instance names and associated attributes, such as **dont_touch**, **black_box**, and **ungroup**. By default, these messages are suppressed.

-no_connection_class

Suppresses connection class warning messages. This switch is useful while working on GTECH designs and netlists on which connection class violations are expected. By default, these messages are reported.

-nosplit

Prevents lines from being split when column fields overflow. Most of the design information is listed in fixed-width columns. If the

information for a given field exceeds the column width, the next field begins on a new line in the correct column.

-unmapped

Reports warning messages for unmapped cells when the cells are being checked. By default, these messages are suppressed.

-cells

Reports the following warning messages for cells: LINT-0, LINT-1, LINT-10, LINT-32, LINT-33, LINT-58, LINT-59, LINT-60, and LINT-61 (if the **-unmapped** option is used).

-ports

Reports the following warning messages for ports: LINT-5, LINT-6, LINT-8, LINT-28, LINT-29, LINT-31, and LINT-52.

-designs

Reports the following warning messages for designs: LINT-25, LINT-46, and LINT-55.

-nets

Reports the following warning messages for nets: LINT-2, LINT-3, LINT-4, LINT-35, LINT-38, LINT-47, and LINT-54.

-tristates

Reports the following warning messages for tristates: LINT-34 and LINT-63.

error-ids

Reports warning messages for specified error IDs, such as LINT-2.

-html_file_name *html_file*

Generates a report for the **check_design** command in HTML format. By default, the **check_design** command writes reports in standard output. The **-html_file_name** option redirects the output to a specified HTML file.

DESCRIPTION

The **check_design** command checks the internal representation of the current design for consistency, and issues error and warning messages as appropriate.

Error messages indicate design problems of such severity that the **compile** command does not accept the design; for example, recursive hierarchy in a design (when a design references itself) is an error. Warning messages are informational and do not necessarily indicate design problems. However, these messages should be investigated.

The **check_design** command flags multiple instances of a design within a system. If a design is instantiated in two different designs, a warning message is issued. For information on how to respond to error messages dealing with multiple instances, see the **uniquify** command man page.

The **check_design -summary** command automatically runs on every design that is compiled. However, you can use the **check_design** command explicitly to see warning messages.

Potential problems detected by this command include unloaded input ports or undriven output ports, nets without loads or drivers or with multiple drivers, cells or designs without inputs or outputs, mismatched pin counts between an instance and its reference, tristate buses with non-tristate drivers, wire loops (timing loops with no cells in them) across hierarchies, and so forth.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command checks the current design for problems and issues error and warning messages:

```
prompt> check_design
```

The following command checks only the current level of the design:

```
prompt> check_design -one_level
```

SEE ALSO

`check_timing(2)`
`compile(2)`
`current_design(2)`
`set_boundary_optimization(2)`
`set_dont_touch(2)`
`uniquify(2)`
`check_design_allow_non_tri_drivers_on_tri_bus(3)`
`check_design_check_for_wire_loop(3)`

check_error

Reports extended information on message IDs from the last command.

SYNTAX

```
status check_error
      [-verbose]
      [-reset]
```

ARGUMENTS

-verbose

Displays the list of message IDs found during previous commands.

By default, the command only returns the error status.

-reset

Resets the list of previously found message IDs. After resetting the error list, the **check_error -verbose** command returns an empty list.

By default, the command does not modify the message list.

DESCRIPTION

The **check_error** command is used to compare error, warning, or informational messages issued by previous commands to the list of message IDs specified by the **check_error_list** variable. While it is most commonly used for error messages, the variable may contain error, warning, or informational message IDs.

If the **check_error** command finds message IDs that are specified in the **check_error_list** variable, the command returns 1. If the **check_error** command does not find any messages that are specified by the **check_error_list** variable, the command returns 0.

Messages that are suppressed by the **suppress_message** command are reported by **check_error**. If you want suppressed messages to be ignored by **check_error** then you must remove their message IDs from the **check_error_list** variable.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to use the **check_error** command to check if execution errors are specified by the **check_error_list** variable:

```
prompt> printvar check_error_list
check_error_list = "UID-3 UID-4 EQN-18 EQN-19"

prompt> check_error
0

prompt> link
Error: Current design is not defined. (UID-4)
0

prompt> check_error
1

prompt> check_error -verbose
{UID-4}
1
```

The following command resets the error list:

```
prompt> check_error -reset -verbose
{UID-4}
1

prompt> check_error -verbose
0
```

To use the **check_error** command in a script to see if specified errors occurred in the previous commands, use the following command:

```
prompt> if { [check_error] } {
    echo failure_message
    exit
} else {
    echo success_message
}
```

SEE ALSO

[check_error_list\(3\)](#)
[suppress_message\(2\)](#)

check_implementations

Checks the implementations in a synthetic library module definition.

SYNTAX

```
status check_implementations
  [-implementations implementation_list]
  [-parameters parameter_list]
  module_name
```

Data Types

<i>implementation_list</i>	list
<i>parameter_list</i>	list
<i>module_name</i>	string

ARGUMENTS

-implementations *implementation_list*

Lists the implementations of the module to check. The default is all implementations.

-parameters *parameter_list*

Lists the module parameters to use when checking. The default is to use the parameters specified by the **check_params** attribute of the module.

module_name

Specifies the name of the synthetic library module whose implementations you want to check. This argument is required.

DESCRIPTION

The **check_implementations** command ensures that when you add a new implementation to an existing module, the new implementation works in the same manner as the old implementation.

Check implementations are provided by Synopsys for all Synopsys modules. They are never used to implement hardware, only for verification.

```
module (mod1) {
  /* Other declarations go here */
  check_implementation(check_add) {
  }
  /* other implementations go here */
}
```

By default, every implementation of a module is compared to the verify implementation. For parameterized modules, a verification is performed for each of the **check_params** that is specified for the module.

The **check_params** attribute is a list of parameter specifications, separated by semicolons (;), which specifies a test to be run. Each parameter specification is a comma (,) separated list of parameter names, followed by an equal sign (=), followed by a value. For example, the specification below runs one verification with n=2 and m=3, and a second verification with n=5 and m=8 for each implementation:

```
<examplelast>
check_params : "n=2,m=3; n=5,m=8" ;
<body>

check_implementations -impl {rpl cla}add
```

LIMITATIONS

Because **check_implementations** is based on **check_design**, it inherits the same limitations. The **check_implementations** command does not verify noncombinational parts unless the flip-flop names are identical. The **check_implementations** command also does not check very large multipliers because the verification is too expensive.

EXAMPLES

The following example checks all implementations of the SYNTH_ADD module:

```
prompt> check_implementations SYNTH_ADD
```

This example checks the ripple and carry-lookahead implementations for parameter values of 33 and 63:

```
prompt> check_implementations -impl { rpl_add cla_add } \
-param { "n=33" "n=63" } SYNTH_ADD
```

SEE ALSO

[check_bindings\(2\)](#)
[synthetic_library\(3\)](#)

check_library

Performs consistency checks between logic and physical libraries, across logic libraries, and within physical libraries.

SYNTAX

```
status check_library
[-logic_library_name logic_library_name_list]
[-mw_library_name phys_library_name_list]
[-physical_library_name phys_library_name_list]
[-cells cell_list]
```

Data Types

<i>logic_library_name_list</i>	list
<i>phys_library_name_list</i>	list
<i>cell_list</i>	list

ARGUMENTS

-logic_library_name *logic_library_name_list*

Specifies the logic libraries (.db) to be checked. Other types of libraries such as .ILM are not supported.

For logic versus logic library checking, specify two or more libraries, such as the minimum and maximum libraries. If you have set the **-compare** or **-validate** options of the **set_check_library_options** command, specify only two libraries.

If you do not specify this option, the command determines the logic libraries in the following order:

- The minimum and maximum libraries that were set with the **set_min_library** command.
- If you have set the **-scaling** option of the **set_check_library_options** command, the scaling libraries that were set with the **define_scaling_lib_group** command.
- The link libraries that were set with the **link_library** and **search_path** variables.
For logic versus logic library checking, the command first groups the link libraries by cell set, and within each group or family the command checks consistencies across all libraries in the same group. The grouping is by majority (> 50%) of same name cells. For example, if lib1 has 9 cells and lib2 has 6, and 5 of them are the same, then they are grouped together.

This option is ignored for physical library checking.

-mw_library_name *phys_library_name_list*

Specifies Milkyway reference libraries to be checked.

If you do not specify this option, the command uses the reference libraries from the open Milkyway design library. If there is no open Milkyway design library, the command uses the reference libraries specified in the **mw_reference_library** variable.

-physical_library_name *phys_library_name_list*

Specifies NDM based physical libraries (.frame) to be checked. You can specify multiple physical libraries. For cross checking, specify both logic and physical libraries. If libraries are not specified explicitly in **check_library**, the ones loaded/opened at runtime

will be used. The libraries to be checked are in the following priority:

- 1) explicitly specified in check_library command
- 2) logic libraries associated with the specified physical library
- 3) loaded or opened logic and physical libraries at runtime -mw_library_name and -physical_library_name cannot be specified together.

-cells cell_list

Specifies a list of cell names to be checked. If not specified, all cells in the libraries are checked.

DESCRIPTION

The **check_library** command checks and reports the items described below, based on the settings of the **set_check_library_options** command.

If you do not run the **set_check_library_options** command and do not specify any options with the **check_library** command, the **check_library** command checks logic versus physical library consistency for the libraries that are set up for the current design. If there are no libraries set up for the current design, the command does not perform any checks.

During logic library checking, to report the delay, power, and noise characterization values in the libraries, the Liberty-format description of the libraries must have the **library_features** attribute set to the respective values: **report_delay_calculation**, **report_power_calculation**, and **report_noise_calculation**.

Use the **check_library** command to verify the libraries before reading in a design.

This command checks library qualities in three main areas:

- Physical library quality
- Logic versus physical library consistency
- Logic versus logic library consistency

All of the checking functions are available in Design Compiler and the functions of logic versus logic library checking are also available in Library Compiler.

Physical Library Quality Checking

Physical library qualities are checked as follows:

- Technology data consistency between the specified main library and each linked reference library
- CEL view versus FRAM view in the library for missing views and mismatched views
- Cells with identical names in different reference libraries and the specified main library
- Signal electromigration rules
- Antenna rules and missing antenna properties
- Rectilinear cells
- Physical-only cells
- Physical properties for place and route including unit tiles for the libraries
- Pin routability
- Technology data quality

- DRC for each cell in the library

Logic Versus Physical Library Consistency Checking

The command performs the following consistency checks between logic and physical libraries:

- Missing cells in the logic or physical library
If you specify multiple logic libraries and no cells are found in any of the libraries that match the physical library, the cells are counted as missing in the logic library unless they are physical-only cells. Otherwise, if the cells are found in any of the logic libraries, such as the first library, they are counted as consistent in cell names.
- Missing or mismatched pins (pin names, directions, and types) in the logic and physical library.
Note that the **input** pin direction keyword in a logic cell versus the **Input** keyword in a physical cell is not a mismatch.
- Area values of each standard cell between the logic (.lib or .db) model and FRAM view (PRBoundary and CellBoundary)
- Cell footprint (**cell_footprint** attribute)
- Bus character naming style in logic and physical libraries.

By default, missing cells and pins and mismatched pins are checked.

For logic versus physical library checking, at the end of checking the command reports a cross-check summary that includes the following information:

- Number of cells missing in the logic library (excluding physical-only cells)
- Number of cells missing in the physical library
- Number of cells with missing or mismatched pins in libraries, if any
- The logic versus physical library quality checking PASSED or the logic library is INCONSISTENT with the physical library

Logic Versus Logic Library Consistency Checking

Logic versus logic library consistency checks include:

- General checking at library, cell, pin, and timing group levels for missing cells, missing and mismatched pins or pg_pins, and timing arcs.
- Special checking for timing, noise, and power scaling
- Special checking for the UPF or multivoltage flow, such as pg_pins, power management cells, and power data
- Special checking for the multicorner-multimode flow, such as operating conditions and power-down functions
- Library characterization and validation

For logic versus logic library checking, at the end of checking the command reports a summary for each specified option. For example, for the **-mcmm** option, it reports:

Logic library consistency check FAILED for MCMM.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the lib1.db and lib2.db logic libraries are checked against the phys_lib physical libraries for missing cells and pins, mismatched pins, the cell footprint, and the bus delimiter:

```
prompt> set_check_library_options -cell_footprint -bus_delimiter
1
```

```
prompt> check_library -mw_library_name {phys_lib} \
-logic_library_name {lib1.db lib2.db}
```

```
#BEGIN_XCHECK_LIBRARY
```

check_license

Checks the availability of a license for a feature.

SYNTAX

```
status check_license
      feature_list
```

Data Types

feature_list list

ARGUMENTS

feature_list

Specifies the list of features to be checked. If more than one feature is specified, they must be enclosed in curly braces ({}). By looking at your key file, you can determine all of the features licensed at your site.

DESCRIPTION

The **check_license** command checks on a license for the named features. It does not check out the license.

The **list_licenses** command provides a list of the features that you are currently using.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example checks on the license for the multivoltage feature:

```
prompt> check_license {Galaxy-MV}
```

SEE ALSO

```
get_license(2)
license_users(2)
list_licenses(2)
remove_license(2)
```

check_mv_design

Checks for violations in a multivoltage design.

SYNTAX

```
status check_mv_design
  [-verbose]
  [-isolation]
  [-target_library_subset]
  [-opcond_mismatches]
  [-connection_rules]
  [-level_shifters]
  [-power_nets]
  [-clock_gating_style]
  [-objects object_name_list]
  [-models]
  [-max_messages message_count]
  [-output output_file_name]
```

Data Types

<i>message_count</i>	unsigned integer
<i>output_file_name</i>	string

ARGUMENTS

-verbose

Reports the violations in detail. When this option is not used, only a summary of the violations is reported in the log file.

-isolation

Reports electrical isolation issues:

- Nets that require isolation, but the isolation cell is missing
- Nets that do not require isolation, but an isolation cell is present
- Isolation cells that do not cross a power domain boundary

-target_library_subset

Checks for inconsistent settings between the target library, target library subset, and operating conditions. This option reports the following conditions:

- Conflicts between the target library subset and the global **target_library** variable setting. The target library subset must be a subset of the library set specified by the **target_library** variable.
- Conflicts between the operating condition and target library subset. There must be at least one library from the target library subset that has the same process, voltage, and temperature as the operating condition being used on a block.

- Conflicts between a cell and the target library subset specification on the parent design of the cell. This check ensures that the cells from the specified target library subset are used.

-opcond_mismatches

Reports the technology cells instantiated in the design with incompatible operating conditions. The option checks for conflicts between a cell and the operating condition specified on the parent design of the cell. This check ensures that the operating condition at which the cell is characterized matches the operating condition specified on the design.

-connection_rules

Reports violations in the always-on synthesis and pass-gate connections:

- Always-on net driven by a normal cell
- Always-on net or a net from an always-on domain driving a pass gate
- Always-on cell driving a normal net
- Two pass gates connected to each other

-level_shifters

Reports level shifter violations:

- Net requiring level-shifting with no level-shifter cell
- Net on which a level-shifter cell cannot be added because either the net is marked as **dont_touch** or the net is driven by a pin operating at a different voltage
- Level-shifter cell shifting an incorrect voltage difference
- Input pin of a level-shifter cell driven by a pin operating at a different voltage
- Output pin of a level-shifter cell driving pins operating at a different voltage
- Level-shifter cell that violates level-shifter strategy settings

-power_nets

Reports power and ground pin connections, including the following information:

- PG pin mismatch between the logical library and FRAM library
- Power and ground connection summary
- Power and ground pins whose connections cannot be derived and the reason that the derivation fails
- Power and ground pins whose existing connections do not match with the derived connection from the power domains.

A mismatch between an existing PG connection and the connection derived from the power domains can occur for any of the following reasons:

- "Unknown power pin type" indicates either the power pin does not have a type or the pin has a type without connection semantics. Automatic power connection supports the following power pin types: primary_power_pin, primary_ground_pin, backup_power_pin, backup_ground_pin, internal_power_pin, and internal_ground_pin.
- "Invalid pin type for the cell or the cell's power domain" indicates that the cell's power domain does not have a power net connection with the matching type for the power pin type. For example, this situation occurs when a regular cell has a backup ground pin, but the cell's power domain does not have a backup ground net connection.
- "No signal pin that uses this PG pin as the related_power_pin/related_ground_pin." This issue occurs only on level-shifter and isolation cells. The power connection of a power pin on a level-shifter or isolation cell is obtained through tracing cells connected to related signal pins of the power pin. The power connection fails if a power pin has no related signal pin, for example, when no signal pin uses the power pin as the related_power_pin or related_ground_pin in the logical library cell definition.
- "Cells connected to the related signal pins of the level shifter or isolation cell requiring different PG nets." This issue occurs

only on level-shifter and isolation cells. The tool cannot derive a proper power net for a specific pin because different nets are needed for the same pin, based on cells connected to the related signal pins.

- "Back-to-back connection of level-shifter and isolation cell" occurs when a level-shifter or isolation cell is directly connected to another level-shifter or isolation cell. The automatic connection of a power pin on such level-shifter or isolation cells might fail if the tracing of related signal connections reaches only other level-shifter or isolation cells.

This option also reports bias pin connections, when a supply net and its connected supply nets through supply ports or power switches are used as the power/nwell/deepnwell net, and also as the ground/pwell/deeppwell net.

-clock_gating_style

Reports hierarchical blocks for which there is no library cell that meets its operating condition and specified clock-gating style. Clock-gate insertion cannot be performed.

-objects object_name_list

This option takes a list of pins, or ports as input. It checks level shifting and isolation violations on the paths through the given pins. The option must be specified with one of -level_shifter and -isolation, or both, and it is an error to specify-objects with the options other than -level_shifter, -isolation, or -verbose. The same violation will not be reported more than once.

-models

Reports any modeling errors found in the available library models.

-max_messages message_count

Sets a maximum limit on the number of messages written into the log file and output file.

-output output_file_name

Writes the output of the **check_mv_design** command to a file specified by the file name argument. If a file of the specified name already exists, it is over-written.

This file can be opened in the **MV Advisor** browser in the **Design Vision** GUI. Alternatively, the same file can be opened in an HTML browser by using the absolute path of the file.

The output file contains the details of all violations reported, even when the **-verbose** option is not used.

DESCRIPTION

The **check_mv_design** command checks the design, multivoltage constraints, electrical isolation requirements, and connection rules. It issues error and warning messages as appropriate.

The checker options can be combined to adjust the level of detail in the final report. If the command is used without any checker options, it reports only a summary of all violations found.

If the **-verbose** option is used, the command reports details of all violations in the log file. The **-max_messages** option limits the number of violations reported. When other checker options are specified, the message count specified by the **-max_messages** option applies to each type of check performed. If no specific checker is specified, the message count applies to the total number of messages generated by all types of checks performed. If **-max_messages** is not specified, the command writes out all messages without limit.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command reports all multivoltage violations in the design:

```
prompt> check_mv_design -verbose
```

```
-----  
Target Library Subset Checks  
-----
```

No Errors/Warnings Found.

```
-----  
Power Domain Checks  
-----
```

Warning: Isolation cell is required on net A_INST/OUTPUT connecting A_INST and B_INST. (MV-042)

Warning: Isolation cell is required on net B_INST/OUTPUT connecting B_INST and top. (MV-042)

Warning: Isolation cell A_INST/iso1 is used to isolate a net that is not crossing power domain boundary. (MV-044)

```
-----  
Power Domain Checks Summary  
-----
```

Warning: Found 2 net(s) without isolation. (MV-046)

Warning: Found 1 isolation cell(s) on net(s) not crossing power domain boundaries. (MV-048)

```
-----  
Cell Operating Condition Checks  
-----
```

No Errors/Warnings Found.

```
-----  
Power Domain and Operating Condition Consistency Checks  
-----
```

No Errors/Warnings Found.

The following command generates a summary of all violations in the design:

```
prompt> check_mv_design
```

```
-----  
Target Library Subset Checks  
-----
```

No Errors/Warnings Found.

```
-----  
Power Domain Checks  
-----
```

Warning: Found 2 net(s) without isolation. (MV-046)

Warning: Found 1 isolation cell(s) on net(s) not crossing power domain boundaries. (MV-048)

```
-----  
Cell Operating Condition Checks  
-----
```

No Errors/Warnings Found.

Power Domain and Operating Condition Consistency Checks

No Errors/Warnings Found.

The following example reports violations related to electrical isolation:

```
prompt> check_mv_design -verbose -isolation
```

Power Domain Checks

Warning: Isolation cell is required on net A_INST/OUTPUT connecting A_INST and B_INST. (MV-042)

Warning: Isolation cell is required on net B_INST/OUTPUT connecting B_INST and top. (MV-042)

Warning: Isolation cell A_INST/iso1 is used to isolate a net that is not crossing power domain boundary. (MV-044)

Power Domain Checks Summary

Warning: Found 2 net(s) without isolation. (MV-046)

Warning: Found 1 isolation cell(s) on net(s) not crossing power domain boundaries. (MV-048)

The following example reports violations related to power nets:

```
prompt> check_mv_design -verbose -power_nets
```

Power/Ground Pin Connection Checks

Error: Supply net sn1 and its connected supply net(s) are used as both power/nwell/deepnwell net and ground/pwell/deepnwell net. (MV-601)

Error: Supply net sn2 and its connected supply net(s) are used as both power/nwell/deepnwell net and ground/pwell/deepnwell net. (MV-601)

Error: Power net hookup for power domains is not specified properly (MV-503)

The following example shows how to use the *-output* option of the **check_mv_design** command.

```
prompt> check_mv_design -verbose -output my_file.cmvd
```

SEE ALSO

```
remove_target_library_subset(2)
set_operating_conditions(2)
set_target_library_subset(2)
```

check_rp_groups

Checks the relative placement constraints and reports any failures.

SYNTAX

```
collection check_rp_groups
  {rp_groups | -all}
  [-output filename]
  [-verbose]
  [-critical]
```

Data Types

<i>rp_groups</i>	list or collection
<i>filename</i>	string

ARGUMENTS

rp_groups

Specifies the relative placement groups that will be checked for failures. This option and the **-all** option are mutually exclusive.

-all

Specifies that all relative placement groups will be checked. This option and the *rp_groups* argument are mutually exclusive.

-output *filename*

Specifies the name of the output file for the report.

If you do not specify this option, the report is written to the standard output.

-verbose

Reports relative placement cell orientation failures that are not reported otherwise. It also returns more detailed alignment and utilization failure messages that include the exact location details of the failures.

DESCRIPTION

The **check_rp_groups** command checks any violations of relative placement constraints for the specified relative placement groups. The violations include failing to place the specified relative placement groups and the placed relative placement groups not meeting relative placement constraints.

The command returns a collection containing the relative placement groups that are checked. If no groups are checked, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples use **check_rp_groups** to check for relative placement failures:

```
prompt> get_rp_groups
{compare::g1 compare::g2 compare::g4 compare::g7}

prompt> check_rp_groups -all -out failures
{compare::g7 compare::g4 compare::g2 compare::g1}

prompt> check_rp_groups compare::g4 -out g4_failures
{compare::g4}

prompt> check_rp_groups compare::g4
```

```
*****
Report: The relative placement groups not meeting all constraints but placed.
Version: B-2008.09
Date: Mon Sep 11 04:44:34 2008
Number of relative placement groups: 1
*****
```

```
relative placement GROUP: compare::g4
-----
```

```
Warning: Possible placement failure of relative placement group 'compare::g4'
(RPGP-027)
{compare::g4}
```

```
prompt> check_rp_groups compare::g1
*****
```

```
Report: The relative placement groups that could not be placed.
Version: B-2008.09
Date: Mon Sep 11 04:47:25 2008
Number of relative placement groups: 1
*****
```

```
relative placement GROUP: compare::g1
-----
```

```
Warning: Possible placement failure of relative placement group 'compare::g1'
(RPGP-027)
{compare::g14}
```

[remove_rp_groups\(2\)](#)

check_scan_def

Performs scan chain structural consistency checking based either on the scan chain information stored as an attribute in the current .ddc file, or an ASCII SCANDEF file.

SYNTAX

```
status check_scan_def  
[-file file_name]
```

Data Types

file_name string

ARGUMENTS

-file *file_name*

Specifies an optional SCANDEF file containing scan chain information to be used for checking.

If this option is not specified, the command looks for the SCANDEF information stored in the current design database.

DESCRIPTION

The **check_scan_def** command performs a scan chain structural checking based on the scan chain information stored in the current .ddc input file. If the scan chain passes all structural checks, the scan chain status will be "VALIDATED" (V). If the scan chain fails a structural check, the scan chain status will be "FAILED" (F).

If the **-file** option is not used, the **write_scan_def** command must first be issued to annotate the SCANDEF information to the current design database; otherwise this command issues an error message. See the **write_scan_def** man page for more information.

This command is used in the Design Compiler environment. In the IC Compiler environment, use the **check_scan_chain** command instead.

This command does not support scan chain validation against SCANDEF files written with the **write_scan_def -expand** command. When the **-expand** option is used, scan chain elements inside black-box CTL models are included in the SCANDEF file. This is needed when moving to IC Compiler, where the CTL models are replaced by the actual subdesigns. If the **check_scan_def** command used with such an expanded SCANDEF file, the report shows FAILED for all scan chains that have elements in black box subdesigns.

EXAMPLES

The following is an example of the output of the **check_scan_def** command when no file is specified:

```

prompt> check_scan_def
Checking SCANDEF...
  Checking scan cell correspondence between SCANDEF and netlist...
  Checking scan chain checking...
All checks completed.
*****
```

Report : Scan DEF check
 Design : design name
 Version: software version
 Date : current date

```
*****
```

Information from SCANDEF file:
 Number of SCANCHAINS: 2

Checking between SCANDEF file and design:
 Total SCANCHAINS checked: 2
 VALIDATED : 2
 FAILED : 0

Chain name	Status	#cells	Scan IN	Scan OUT
1	V	62	U10/C	alu1/U381/A
2	V	61	U11/C	U9/B

1

The following example shows the result when a file is specified with the **check_scan_def** command:

```

prompt> check_scan_def -file temp.def
Reading DEF file temp.def
Checking SCANDEF...
  Checking scan cell correspondence between SCANDEF and netlist...
  Checking scan chain checking...
All checks completed.
*****
```

`write_scan_def(2)`

check_scenarios

Performs consistency checks between the scenarios, for scenario specific information such as TLUplus files, operating conditions on the libraries, clocks and so on.

SYNTAX

```
status check_scenarios
  [-output]
  [-display]
```

ARGUMENTS

-output

Specifies the directory to store the output. By default output is stored in HTML format in the directory, design_dir/check_scenarios_mmddyyyy_pid

-display

Opens a HTML browser to display the data. The browser to be used is defined by the Tcl variable, gui_online_browser.

DESCRIPTION

The **check_scenarios** command checks and reports issues with the scenarios. The command performs the following checks: TLUplus, clock related information such as clock periods, default versus nominal PVT on libraries, PVT from blocks versus parent, and PVT of library cells.

Multicorner-Multimode Support

This command uses information from all active scenarios. This command also supports designs that are not multicorner-multimode designs.

EXAMPLES

The following is an example of the **check_scenarios** command:

```
prompt> check_scenarios
check_scenarios
Warning: The complexity of the scenario (s1) might cause long runtime and high
memory usage. (MCMM-212)
Warning: Scenario (s1) has instances which referenced library cells that are
```

marked as "dont_use". (MCMM-225)

Warning: Scenario (s2) has a library setup issue with regard to the PVT values
and the operating condition. (MCMM-213)

Information: HTML report can be found at

/WORKING_DIRECTORY/run/check_scenarios_7132009_21451/check_scenarios_0.html

SEE ALSO

[gui_online_browser\(3\)](#)

check_synlib

Performs semantic checks on synthetic libraries.

SYNTAX

status **check_synlib**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **check_synlib** command performs checking on synthetic libraries found in the synthetic library search path (**synthetic_library**) and listed by the **link_library** variable. Synthetic libraries can contain errors that cannot be detected using the **read_lib** command. Note that **check_synlib** also implicitly checks against standard.sldb.

The **check_synlib** command returns one of the following two values:

- 0 : Errors were reported.
- 1 : No critical errors were found.

Run **check_synlib** after you set the **synthetic_library** variable and the .sldb files exist, but before commands such as **compile** or **replace_synthetic** use any of these libraries.

EXAMPLES

The following example checks the synthetic libraries named in the **synthetic_library** variable for compatibility. The two libraries are my_synlib_0.sldb and my_synlib_1.sldb.

```
prompt> synthetic_library = {"my_synlib_0.sldb", "my_synlib_1.sldb"}  
prompt> check_synlib
```

SEE ALSO

```
compile(2)
read_lib(2)
replace_synthetic(2)
report_synlib(2)
synthetic_library(3)
```

check_target_library_subset

Checks and prints out the inconsistent settings among target library, target library subset, and operating conditions.

SYNTAX

```
status check_target_library_subset
  [-verbose]
  [-max_messages int]
```

ARGUMENTS

The **check_target_library_subset** command has no arguments.

DESCRIPTION

This command checks and prints out the inconsistent settings among target library, target library subset, and operating conditions. The command checks for the following:

- Conflicts between the target library subset and the global **target_library** variable. The target library subset should be a subset of the library set being specified by the **target_library** variable.
- Conflicts between operating condition and target library subset. There should be at least one library from the target library subset that has the same process, nom_voltage, and temperature as the operating condition being used on that block.
- Conflicts between the library cell of the mapped cell and target library subset. A warning is issued if the library cell of a mapped cell is not from any of the libraries of the target library subset. Note that this is not an error, because the subset applies only to new cells being created during optimization, not to existing cells in the block.

Multicorner-Multimode Support

Depending on the options used, this command either uses the current scenario or has no dependency on scenario-specific information.

target_library(3)

check_timing

Checks for possible timing problems in the current design.

SYNTAX

```
status check_timing
  [-overlap_tolerance minimum_distance]
  [-override_defaults check_list]
  [-multiple_clock]
  [-sdc_runtime]
  [-retain]
  [-include check_list]
  [-exclude check_list]
```

Data Types

<i>minimum_distance</i>	float
<i>check_list</i>	list

ARGUMENTS

-overlap_tolerance *minimum_distance*

Specifies the minimum distance allowed between the master-close edge and the slave-open edge. If the distance is less than the **-overlap_tolerance** value, the tool issues a warning message. Use this option to check for the master-slave clock overlap. By default, this option is off.

-override_defaults *check_list*

Overrides the checks defined by the **timing_check_defaults** variable by using the *check_list* argument. If you use the **-override_defaults** option with a *check_list*, you need to perform the final list of checks with the *check_list* argument of the **-override_defaults** option.

-multiple_clock

Issues a warning when multiple clocks reach a register clock pin. If more than one clock signal reaches a register clock pin, and the **timing_enable_multiple_clocks_per_reg** variable is set to **false**, the clock to use for analysis is undefined, and the tool issues a warning message. In this case, use either the **set_case_analysis** or **set_disable_timing** command so that only one clock can propagate from the sources to the register clock pin. By default, this option is off.

-sdc_runtime

Issues a report on the dirty constraints set on the design, which can contribute to high runtime. The default file name is **sdc_runtime.log**. Use the **sdc_runtime_analysis_log_file** variable to generate report with a different log file name. You can also generate this report by setting the **sdc_runtime_analysis_enable** variable to **true** and compile the design. When you use the **-sdc_runtime** option, the tool ignores all other options of the **check timing** command and generates only the SDC dirty constraint report. These checks are not influenced by the **timing_check_defaults** variable. By default, this option is off.

-retain

Issues a warning if any of the RETAIN values are larger than its corresponding delay value. The RETAIN values should be less

than their corresponding delay values so that they can be considered for hold violations. Otherwise, the RETAIN values might be considered for setup violations. By default, this option is off.

-include *check_list*

Adds the checks listed in *check_list* to the checks defined by the **timing_check_defaults** variable.

-exclude *check_list*

Subtracts the checks listed in *check_list* from the checks defined by the **timing_check_defaults** variable.

DESCRIPTION

This command checks the timing attributes placed on the current design and issues warning messages as needed. The warning messages provide information that identifies and corrects potential errors. The warning messages do not necessarily indicate design problems.

This command without any options performs the checks defined by the **timing_check_defaults** variable. Redefine this variable to change the value. If the **-override_defaults** option is not used, the final list of checks to be performed is the list of checks specified by the **timing_check_defaults** variable, plus the list of checks specified by the **-include** option, minus the list of checks specified by the **-exclude** option. If you use the **-override_defaults** option with a *check_list*, you need to perform the final list of checks with the *check_list* argument of the **-override_defaults** option.

The alphabetically ordered list below shows the meaning of each check:

clock_crossing

Checks clock interactions when there are multiple clock domains. If a clock launches one or more paths that are captured by other clocks, it will have an entry in the clock crossing report. If all paths between two clocks are false paths or they are exclusive or asynchronous clocks, the path is marked with an asterisk (*). If only some of the paths are set as false paths, the path is marked by a number sign (#).

clock_no_period

Warns if clocks with no period are specified.

data_check_multiple_clock

Warns if multiple clocked signals reach a data check register reference pin. The analysis is done separately for each of the clocked domains. If the **timing_enable_multiple_clock_per_reg** variable is set to **false**, only one of the clocked signals is analyzed.

data_check_no_clock

Warns if no clocked signal reaches a data check register reference pin. In this case, no setup or hold checks are performed on the constrained pin.

gated_clock

Warns about the gated clocks. Disables the gating timing arcs only if the **propagated_clock** attribute is set on that clock.

generated_clock

Checks the generated clock network. The following types of issues are reported:

- The source pin (master point) is not the clock source.
- The definition point of the generated clock has no path to the sourcepoint.
- The generated clocks form a loop.

generic

Warns about generic (unmapped) cells in the design. The timing of paths through generic cells is inaccurate, because the generic

cells have zero delay.

ideal_clocks

Warns about any clock networks that are ideal. Generally, all clocks should be propagated so that the clock network timing is accurately calculated. Especially in the presence of crosstalk, the delay changes induced by other nets on the clock network are not reflected in the calculated slacks in the design.

ideal_timing

Warns when the user-defined ideal transition or latency is set on a normal pin (not ideal).

loops

Warns about combinational feedback loops. If the feedback loop is not broken by the **set_disable_timing** command, it is automatically broken by disabling one or more timing arcs.

multiple_clock

This item should be specified with the **-multiple_clock** option.

net_no_driving_info

Warns about any net that does not have driving pins or that there are no timing arcs on the driver pins. The warning is issued only when the net has coupled parasitic.

no_driving_cell

Warns about any port that does not have a driving cell. The warning is issued only when the net connected to the port has parasitic. When no driving cell is specified, the net is assigned to a strong driver for modeling aggressor effects, which can be pessimistic. Also, a port with no driving cell could act as a strong victim, which could underestimate the crosstalk effect.

no_input_delay

Warns if no clock-related delay is specified on an input port, where it propagates to a clocked latch or output port. If the **timing_input_port_default_clock** variable is set to **true**, a default clock is assumed for the input port. Otherwise, it will not be clocked, and the paths are unconstrained. In this case, if there is no input delay specified, the **check_timing** command does not generate warnings.

partial_input_delay

Warns about any ports have partially defined input delay; only the minimum or only the maximum delay defined with the **set_input_delay** command. As a result, some paths starting from the port with partially defined input delay might become unconstrained and some potential violations could be missed.

pulse_clock_cell_type

Warns if an instance cell has a mismatched pulse type defined from its library cell.

retain

This check item should also be specified by the **-retain** option.

unconstrained_endpoints

Warns about unconstrained timing endpoints. This warning identifies timing endpoints that are not constrained for maximum delay (setup) checks. If the paths to the endpoint are all false paths, endpoints are not reported as unconstrained endpoints.

The warning messages that can occur when you use this command are described below.

- The following warning message is issued when the waveforms applied to a master-slave register are overlapping or have different periods. Use the **create_clock** command to modify one of the waveforms.

The overlap check first determines the intended master-slave waveform relationships based on the ideal clock waveforms. Then, the clock network delay and uncertainty is applied to the waveforms and if the distance between the related edges is less than the overlap tolerance, the tool issues a warning message.

WARNING: The following master-slave registers have overlapping clock violations. The waveforms or periods might be

invalid.

- The following warning message identifies timing endpoints (output ports and register data pins) that are not constrained. If the endpoint is a register data pin, use the **create_clock** command for the appropriate clock source to constrain the pin. Use the **set_output_delay** or **set_max_delay** command to constrain output ports. The **set_output_delay** command constrains only the path when the delay is relative to a clock.

WARNING: The following endpoints are not constrained for maximum delay.

- The following warning message identifies gated clocks. Disable the gating timing arcs only if the **propagated_clock** attribute is set on that clock.

WARNING: The clock network starting at "clk" is gated by the following input pins. The gating timing arcs might need to be disabled for clocks with the "propagated_clock" attribute.

- The following warning message is issued when the design contains unmapped cells (generic logic), which causes the timing of the paths through the generic cells to be inaccurate because generic cells have zero delay.

WARNING: Design "*design_name*" contains unmapped cells.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example checks the timing of the current design and issues warning messages as needed:

```
prompt> check_timing
Information: Checking 'unexpandable_clocks'...
Information: Checking 'generic'...
Information: Checking 'latch_fanout'...
Information: Checking 'loops'...
Information: Checking 'generated_clocks'...
```

check_tlu_plus_files

Checks the files used for TLUPlus extraction.

SYNTAX

status **check_tlu_plus_files**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **check_tlu_plus_files** command performs consistency checks on the TLUPlus files used for virtual route and postroute extraction, which are specified by using the **set_tlu_plus_files** command. If the TLUPlus files are from a Milkyway design library attachment, this command does not do any checking because the attachment was already checked when it was attached.

The following items are checked for consistency:

- Layer names
The consistency check ensures that the conductor and via layer names are consistent across the Milkyway, ITF, and mapping files. The tool also checks that the number of layers are consistent between the ITF files and the Milkyway technology files. The tool issues error messages if there are inconsistencies.
- Etch values
The tool checks that the etch values in the ITF files are consistent with the delta width values in the Milkyway technology files under minimum, nominal, and maximum conditions. The signs used to indicate expand and shrink are opposite in the ITF files and the Milkyway technology files. The tool issues warning messages if there are inconsistencies.
- Minimum width and minimum spacing
The tool checks that the minimum width and minimum spacing are consistent between the ITF files and the Milkyway technology files, and among different minimum, nominal, and maximum ITF files. The tool issues warning messages if there are inconsistencies.
- Conductor thickness
The tool checks that the conductor thicknesses are consistent between the ITF files and the Milkyway technology files. The tool issues warning messages if there are inconsistencies.

Multicorner-Multimode Support

This command uses information from all scenarios.

EXAMPLES

The following example runs the consistency checks:

```
prompt> check_tlu_plus_files
```

SEE ALSO

[check_library\(2\)](#)
[set_tlu_plus_files\(2\)](#)

check_upf

Checks the UPF loaded on a hierarchical design for validity of references across the abstract boundary between the top level and the block level.

SYNTAX

status **check_upf**

ARGUMENTS

This command has no arguments.

DESCRIPTION

In hierarchical flow designs, the **save_upf** command saves only the UPF constraints that apply to the top-level design. This command tests the UPF loaded into the current design for any reference that crosses the boundary between the top level and the block level, and generates a warning for each UPF command or argument that will be dropped when the **save_upf** command is used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

```
prompt> check_upf
Warning: The following elements have been dropped from a UPF statement: mid/block (UPF-701)
Warning: UPF statement 'set_isolation' will be dropped because its scope belongs to an
abstract hierarchy. (UPF-702)
0
```

SEE ALSO

[load_upf\(2\)](#)
[save_upf\(2\)](#)

clean_buffer_tree

Removes the buffer tree at the specified driver pin, load pin, or driver net on a mapped design.

SYNTAX

```
status clean_buffer_tree
  [-from start_point_list]
  [-to object_list]
  [-net net_list]
  [-source_of object_list]
  [-hierarchy]
  [-global]
  [-threshold integer_in_1]
```

Data Types

<i>start_point_list</i>	list
<i>object_list</i>	list
<i>net_list</i>	list
<i>integer_in_1</i>	integer

ARGUMENTS

-from *start_point_list*

Specifies the starting point of the buffer tree to be removed. The *start_point_list* must contain only pins or ports. This option can be used in conjunction with the **-to** and **-net** options.

-to *object_list*

The buffer tree removal starts at the immediate buffer source of the specified pins or ports. The *object_list* must contain only pins or ports. This option can be used in conjunction with the **-from** and **-net** options.

-net *net_list*

Specifies the driver net that is the starting point for the buffer tree to be removed. The *net_list* must contain only nets. This option can be used in conjunction with the **-from** and **-to** options.

-source_of *object_list*

The complete buffer tree in the fanin to the object up to the object itself is removed. The *object_list* must contain only output ports or input pins. This option cannot be used in conjunction with the **-from**, **-to** or **-net** options.

-hierarchy

Removes the buffer tree across the hierarchy. By default, the buffer tree removal stops when it reaches the hierarchy boundary.

-global

Searches for high-fanout buffer tree root pins in the *net_list*. This option is not valid with the **-from**, **-to**, and **-net** options.

-threshold *integer_in_1*

Specifies the fanout threshold range that determines which buffer trees are cleaned up. If the number of sink pins driven from the primary root pin of the buffer tree is larger than the threshold, the buffer tree circuitry is cleaned up. This option is only valid with the **-global** option.

Valid **-threshold** values are from 1 to 1,000,000.

DESCRIPTION

The **clean_buffer_tree** command removes a buffer tree at a specified driver pin, load pin, or driver net on a mapped design. When given a driver pin or driver net, the buffer tree is removed with this driver as the root. When given a load pin, the buffer tree is removed with the immediate driver of the load pin as the root. By default, this command does not remove the buffer tree across the hierarchy. To enable buffer tree removal across boundaries, specify the **-hierarchy** option when running the command.

The buffer tree removal process starts at the source and removes all buffer and inverter cells in its transitive fanout cone until it finds nonbuffer cells or hierarchy boundaries. This does not apply if the **-hierarchy** option is specified.

Buffer and inverter cells that have the **dont_touch** attribute or that are connected to a net that has the **dont_touch** attribute are not removed. Similarly, any cells that follow these cells in the transitive fanout are not removed.

The **clean_buffer_tree** command adds an inverter driving all of the original buffer tree's inverted loads after it has removed all buffers and inverters in the tree.

This command accepts the final implementation of buffer tree removal, even if it negatively impacts the timing or DRC violations in the design.

EXAMPLES

The following example removes a buffer tree without crossing hierarchical boundaries:

```
prompt> clean_buffer_tree -from cell1/O
```

The following example removes a buffer tree that crosses hierarchical boundaries:

```
prompt> clean_buffer_tree -hierarchy -from cell1/O
```

close_lib

Decrements the open count of a library. A library is removed from memory when its open count is zero.

SYNTAX

```
status close_lib
  [-save_designs]
  [-force]
  [-purge]
  [-all]
  [-compress]
  [library]
```

Data Types

library collection

ARGUMENTS

-save_designs

Saves any designs in the design library that are open and modified but not yet saved. If the design library contains a technology section that has been modified, it is also saved.

When you use this option, the modified designs and technology section are saved regardless of whether the design library is removed from memory.

This option is not supported in the library manager.

-force

Removes the library from memory, even if its technology section or some of its designs have been modified but not saved (and you did not use the **-save_designs** option).

-purge

Removes the library from memory, regardless of its open count.

-all

Removes all libraries from memory, regardless of their open counts.

-compress

To be used with "-save_designs" to save libraries in compressed format. This option is applicable to design library only. It is error to use this option without -save_designs.

library

Specifies the library to close. This can either be a name or a collection of a single library.

By default, the command closes the current library.

DESCRIPTION

This command decrements the open count of the specified library. The command closes the library and removes it from memory when at least one of the following conditions is satisfied:

- The open count is zero.
- The **-purge** option is used.
- The **-force** option is used.

If you try to remove a library from memory that is on the reference library list of another open design library, the tool issues an error message and does not remove the library from memory.

In the library manager, you can use this command to remove a library from an aggregate library workspace.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example removes the current design library from memory after saving any open and modified-but-not-saved designs.

```
prompt> close_lib -purge -save_designs  
1
```

The following example saves the open and modified-but-not-saved designs in all open design libraries and then removes the design libraries from memory.

```
prompt> close_lib -all -save_designs  
1
```

close_mw_lib

Closes the current Milkyway library.

SYNTAX

status **close_mw_lib**

ARGUMENTS

The **close_mw_lib** command has no arguments.

DESCRIPTION

This command closes the current Milkyway library. It returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example closes the current Milkyway library:

```
prompt> close_mw_lib  
1
```

collections

Describes the methodology for creating collections of objects and querying objects in the database.

DESCRIPTION

Synopsys applications build an internal database of objects and attributes applied to them. These databases consist of several classes of objects, including designs, libraries, ports, cells, nets, pins, clocks, and so on. Most commands operate on these objects.

By definition:

A collection is a group of objects exported to the Tcl user interface.

Collections have an internal representation (the objects) and, sometimes, a string representation. The string representation is generally used only for error messages.

Collections represent an ordered sequence of database objects. These collections provide constant time random access to the objects contained in the sequence.

A set of commands to create and manipulate collections is provided as an integral part of the user interface. The collection commands encompass two categories: those that create collections of objects for use by another command, and one that queries objects for viewing. The result of a command that creates a collection is a Tcl object that can be passed along to another command. For a query command, although the visible output looks like a list of objects (a list of object names is displayed), the result is an empty string.

An empty string "" is equivalent to the empty collection, that is, a collection with zero elements.

To illustrate the usage of the common collection commands, the man pages have examples. Most of the examples use PrimeTime as the application. In all cases, the application from which the example is derived is indicated.

Homogeneous and Heterogeneous Collections

A homogeneous collection contains only one type of object. A heterogeneous collection can contain more than one type of object. Commands that accept collections as arguments can accept either type of collection.

Lifetime of a Collection

Collections are active only as long as they are referenced. Typically, a collection is referenced when a variable is set to the result of a command that creates it or when it is passed as an argument to a command or a procedure. For example, in PrimeTime, you can save a collection of design ports by setting a variable to the result of the **get_ports** command:

```
pt_shell> set ports [get_ports *]
```

Next, either of the following two commands deletes the collection referenced by the *ports* variable:

```
pt_shell> unset ports
pt_shell> set ports "value"
```

Collections can be implicitly deleted when they go out of scope. Collections go out of scope for various reasons. An example would be when the parent (or other antecedent) of the objects within the collection is deleted. For example, if our collection of ports is owned by a design, it is implicitly deleted when the design that owns the ports is deleted. When a collection is implicitly deleted, the variable that referenced the collection still holds a string representation of the collection. However, this value is useless because the collection is gone, as illustrated in the following PrimeTime example:

```
pt_shell> current_design
{"TOP"}
```

```
pt_shell> set ports [get_ports in*]
{"in0", "in1"}

pt_shell> remove_design TOP
Removing design 'TOP'...

pt_shell> query_objects $ports
Error: No such collection '_sel26' (SEL-001)
```

Iteration

To iterate over the objects in a collection, use the **foreach_in_collection** command. You cannot use the Tcl-supplied **foreach** iterator to iterate over the objects in a collection, because the **foreach** command requires a list, and a collection is not a list. In fact, if you use the **foreach** command on a collection, it destroys the collection.

The arguments of the **foreach_in_collection** command are similar to those of **foreach**: an iterator variable, the collection over which to iterate, and the script to apply at each iteration. Note that unlike the **foreach** command, the **foreach_in_collection** command does not accept a list of iterator variables.

The following example is an iterative way to perform a query in PrimeTime. For more information, see the **foreach_in_collection** man page.

```
pt_shell> \
foreach_in_collection s1 $collection {
    echo [get_object_name $s1]
}
```

Manipulating Collections

A variety of commands are provided to manipulate collections. In some cases, a particular command might not operate on a collection of a specific type. This is application-specific. Consult the man pages from your application.

- **add_to_collection** - This command creates a new collection by adding a list of element names or collections to a base collection. The base collection can be the empty collection. The result is a new collection. In addition, the **add_to_collection** command allows you to remove duplicate objects from the collection by using the *-unique* option.
- **append_to_collection** - This command appends a set of objects (specified by name or collection) to an existing collection. The base collection is passed in through a variable name, and the base collection is modified directly. It is similar in function to the **add_to_collection** command, except that it modifies the collection in place; therefore, it is much faster than the **add_to_collection** command when appending.
- **remove_from_collection** - This command removes a list of element names or collections from an existing collection. The second argument is the specification of the objects to remove and the first argument is the collection to have them removed from. The result of the command is a new collection. For example, in PrimeTime:

```
pt_shell> set dports \
[remove_from_collection [all_inputs] CLK]
{"in1", "in2", "in3"}
```

- **compare_collections** - This command verifies that two collections contain the same objects (optionally, in the same order). The result is "0" on success.
- **copy_collection** - This command creates a new collection containing the same objects in the same order as a given collection. Not all collections can be copied.
- **index_collection** - This command extracts a single object from a collection and creates a new collection containing that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index. Not all collections can be indexed.
- **sizeof_collection** - This command returns the number of objects in a collection.

Filtering

In some applications, you can filter any collection by using the **filter_collection** command. This command takes a base collection and creates a new collection that includes only those objects that match an expression.

Some applications provide a *-filter* option for their commands that create collections. This allows objects to be filtered out before they are ever included in the collection. Frequently this is more efficient than filtering after the they are included in the collection. The following examples from PrimeTime filters out all leaf cells:

```
pt_shell> filter_collection \
[get_cells *] "is_hierarchical == true"
{"i1", "i2"}
pt_shell> get_cells * -filter "is_hierarchical == true"
{"i1", "i2"}
```

The basic form of a filter expression is a series of relations joined together with AND and OR operators. Parentheses are also supported. The basic relation contrasts an attribute name with a value through a relational operator. In the previous example, *is_hierarchical* is the attribute, *==* is the relational operator, and *true* is the value.

The relational operators are

<i>==</i>	Equal
<i>!=</i>	Not equal
<i>></i>	Greater than
<i><</i>	Less than
<i>>=</i>	Greater than or equal to
<i><=</i>	Less than or equal to
<i>=~</i>	Matches pattern
<i>!~</i>	Does not match pattern

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with *==* and *!=*. The value can be only true or false.

Additionally, existence relations determine if an attribute is defined or not defined, for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

defined
undefined

These operators apply to any attribute as long as it is valid for the object class. See the appropriate man pages for complete details.

Sorting Collections

In some applications, you can sort a collection by using the **sort_collection** command. It takes a base collection and a list of attributes as sort keys. The result is a copy of the base collection sorted by the given keys. Sorting is ascending, by default, or descending when you specify the *-descending* option. In the following example from PrimeTime, the command sorts the ports by direction and then by full name.

```
pt_shell> sort_collection [get_ports *] \
{direction full_name}
{"in1", "in2", "out1", "out2"}
```

Implicit Query of Collections

In many applications, commands that create collections implicitly query the collection when the command is used at the command line. Consider the following examples from PrimeTime:

```
pt_shell> set_input_delay 3.0 [get_ports in*]
1
pt_shell> get_ports in*
{"in0", "in1", "in2"}
pt_shell> query_objects -verbose [get_ports in*]
{"port:in0", "port:in1", "port:in2"}
```

```
pt_shell> set iports [get_ports in*]
{"in0", "in1", "in2"}
```

In the first example, the **get_ports** command creates a collection of ports that is passed to the **set_input_delay** command. This collection is not the result of the primary command (**set_input_delay**), and as soon as the primary command completes, the collection is destroyed. The second example shows how a command that creates a collection automatically queries the collection when that command is used as a primary command. The third example shows the verbose feature of the **query_objects** command, which is not available with an implicit query. Finally, the fourth example sets the variable *iports* to the result of the **get_ports** command. Only in the final example does the collection persist to future commands until *iports* is overwritten, unset, or goes out of scope.

```

compare_collections

Compares the contents of two collections. If the same objects are in both collections, the result is "0" (like string compare). If they are different, the result is nonzero. The order of the objects can optionally be considered.

SYNTAX

```
int compare_collections
  [-order_dependent]
  collection1
  collection2
```

Data Types

collection1 collection
collection2 collection

ARGUMENTS

-order_dependent

Indicates that the order of the objects is to be considered; that is, the collections are considered to be different if the objects are ordered differently.

collection1

Specifies the base collection for the comparison. The empty string (the empty collection) is a legal value for the *collection1* argument.

collection2

Specifies the collection with which to compare to *collection1*. The empty string (the empty collection) is a legal value for the *collection2* argument.

DESCRIPTION

The **compare_collections** command is used to compare the contents of two collections. By default, the order of the objects does not matter, so that a collection of cells u1 and u2 is the same as a collection of the cells u2 and u1. By using the **-order_dependent** option, the order of the objects is considered.

Either or both of the collections can be the empty string (the empty collection). If two empty collections are compared, the comparison succeeds (that is, **compare_collections** considers them identical), and the result is "0".

EXAMPLES

The following example from PrimeTime shows a variety of comparisons. Note that a result of "0" from **compare_collections** indicates success. Any other result indicates failure.

```
prompt> compare_collections [get_cells *] [get_cells *]
0
prompt> set c1 [get_cells {u1 u2}]
{u1 u2}
prompt> set c2 [get_cells {u2 u1}]
{u2 u1}
prompt> set c3 [get_cells {u2 u4 u6}]
{u2 u4 u6}
prompt> compare_collections $c1 $c2
0
prompt> compare_collections $c1 $c2 -order_dependent
-1
prompt> compare_collections $c1 $c3
-1
```

The following example builds on the previous example by showing how empty collections are compared.

```
prompt> set c4 ""
prompt> compare_collections $c1 $c4
-1
prompt> compare_collections $c4 $c4
0
```

SEE ALSO

[collections\(2\)](#)

compare_delay_calculation

Compares the Arnoldi-based delays with the Elmore delays in the current design.

SYNTAX

```
status compare_delay_calculation
  [-verbose]
  [-ccs]
```

ARGUMENTS

-verbose

Creates histogram-style reports showing the distribution of the delay differences when using the Arnoldi-based and Elmore delay models.

-ccs

Creates histogram-style reports showing the delay differences when using Composite Current Source (CCS) models and nonlinear delay models (NLDM).

DESCRIPTION

The **compare_delay_calculation** command calculates and compares the timing results of the current design using the Arnoldi-based and Elmore delay models. This command reports pin-to-pin delays, max transition, several DRC violations and the worst slack within each path group for both delay models. In the verbose mode this command creates histogram-style reports showing the distribution of the Arnoldi-based and Elmore delay differences on the paths with negative slacks. The distribution of the differences is represented by the two histograms showing the delay differences in the library units and in the percentage.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an Arnoldi-based and Elmore delay calculation report:

```
prompt> compare_delay_calculation -verbose
```

Percent of Arnoldi-based delays = 66.67%

	Elmore	Arnoldi		
Max Transition	0.195	0.521		
DRC Violations	1	1		
Group	WNS	TNS	WNS	TNS
CLK1	1.71	3.96	1.46	2.64
default	0.00	0.00	0.00	0.00

Histograms for Delays with Negative Slack

Difference (%)	Count	%
0 - 1	2	8.33
1 - 5	5	20.83
5 - 10	3	12.50
10 - 50	10	41.67
50 - 100	4	16.67
100+	0	0.00
Difference(lib_units)	Count	%
0.0 - 0.001	0	0.00
0.001- 0.01	3	12.50
0.01 - 0.05	7	29.17
0.05 - 0.1	0	0.00
0.1 - 1.0	14	58.33
1.0+	0	0.00

Histograms for Slews with Negative Slack

Difference (%)	Count	%
0 - 1	0	0.00
1 - 5	8	33.33
5 - 10	9	37.50
10 - 50	3	12.50
50 - 100	4	16.67
100+	0	0.00
Difference(lib_units)	Count	%
0.0 - 0.001	0	0.00
0.001- 0.01	12	50.00
0.01 - 0.05	0	0.00
0.05 - 0.1	0	0.00
0.1 - 1.0	12	50.00
1.0+	0	0.00

compare_lib

Performs a cross-reference check between a technology library and a symbol library or between a technology library and a physical library.

SYNTAX

```
status compare_lib  
    library1  
    library2
```

Data Types

```
library1  string  
library2  string
```

ARGUMENTS

library1

Specifies the name of a technology library.

library2

Specifies the name of a symbol library or physical library to be compared with the technology library.

DESCRIPTION

The **compare_lib** command compares the specified libraries consistency. The first library is a technology library and the second library is a symbol or physical library. For this command to run successfully, the libraries to be compared must be in the Synopsys internal database format and must also exist in memory. To compile a library, use the **read_lib** command. To load a compiled library, use the **read_file** command.

The **compare_lib** command performs the following checks:

- First, it ensures that each component in the technology library has a corresponding definition in the symbol or physical library.
- Second, it crosschecks the pin names of each component in the technology library against the pin names defined for its corresponding symbol or physical representation.
- Third, it ensures that each component in the symbol or physical library has a corresponding definition in the technology library.
- Fourth, it crosschecks the pin names of each component in the symbol or physical library against the pin names defined for its corresponding technology cell.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example compares a technology library and a symbol library:

```
prompt> compare_lib tech.lib.db sym.lib.sdb
```

SEE ALSO

`read_file(2)`
`read_lib(2)`
`report_lib(2)`
`write_lib(2)`

compare_supplies

compares voltage levels or relative ON-ness between two given supplies.

SYNTAX

```
status compare_supplies
  supply_list
  [-on_status]
  [-voltage_level]
```

Data Types

supply_list list

ARGUMENTS

supply_list

Specifies a list of 2 supplies. The first supply specified is treated as the 'reference' supply to which the second supply ('specified' supply) will be compared to. Supplies can either be supply net names or supply set handles.

-on_status

If specified, this option will return one of 4 values: "equal" if the reference supply is equal to the specified supply. "more_on" if the specified supply is more ON as compared to the reference supply. "less_on" if the specified supply is less ON as compared to the reference supply. "independent" if the specified supply may be more or less ON as compared to the reference supply depending on the PST State.

-voltage_level

If specified, this option will return one of 4 values: "equal", if both reference and specified supplies are at the same voltage and no level-shifting is needed. "higher", if reference supply is lower voltage as compared to the specified supply. "lower", if the reference supply is higher voltage as compared to the specified supply. "independent", if the reference supply is higher/lower voltage as compared to the specified supply depending on the PST State. If the two supplies specified belong to the same correlated supply group, they will be compared based on the rules for supplies in the same correlated supply group.

DESCRIPTION

This command is used to compare voltage levels or relative always-ON levels of two given supplies. Options -on_status and -voltage_level can be used separately or in combination. Supplies list must consist of exactly 2 supplies.

SEE ALSO

report_pst(2)

compile

Performs logic-level and gate-level synthesis and optimization on the current design.

SYNTAX

```
status compile
[-no_map]
[-map_effort medium | high]
[-area_effort none | low | medium | high]
[-incremental_mapping]
[-exact_map]
[-ungroup_all]
[-boundary_optimization]
[-auto_ungroup area | delay]
[-no_design_rule
 | -only_design_rule
 | -only_hold_time]
[-scan]
[-top]
[-power_effort none | low | medium | high]
[-gate_clock]
```

ARGUMENTS

-no_map

Specifies not to map the current design into the target technology library. With this option, generic Boolean equations and generic flip-flops represent the resulting design.

-map_effort medium | high

Specifies the relative amount of CPU time spent during the mapping phase of **compile**. Valid values are **medium** and **high**. You can select one value. The default is **medium**.

-area_effort none | low | medium | high

Specifies the relative amount of CPU time spent during the area recovery phase of **compile**. Valid values are **none**, **low**, **medium**, and **high**. You can select one value. The default is the specified *map_effort*.

-incremental_mapping

Specifies to attempt only incremental improvements to the gate structure of a design. Portions of a design that are already mapped are exempt from logic-level optimization, and the resulting design should be the same (if no improvements can be made) or better in terms of its design constraints. Implementations for DesignWare operators are reselected in an incremental compile run if the swap can improve the optimization cost based on the optimization constraints on the design.

-exact_map

Specifies that the sequential elements in the final design must exactly match the descriptions specified in the HDL description. SEQGEN is a technology-independent representation of a sequential element that is inferred by HDL Compiler from HDL descriptions of sequential circuits. When you specify this option, the tool attempts to find sequential elements in the target

technology library that match the behavior of only the SEQGEN element (that is, no surrounding logic is considered). In the event that an exact match for a SEQGEN is not available, a different sequential element is used. Use of the **-exact_map** option would disable sequential output inversion. For more information, see **compile_seqmap_enable_output_inversion**. For improved sequential inference, use this option in conjunction with the HDL directives **sync_set_reset**, **sync_set_reset_local**, and **sync_set_reset_all**. The new attributes or directives tell HDL Compiler how to connect nets to the SEQGEN component. Use of the attributes and directives with the **-exact_map** option ensures that the results of **compile** are predictable. Use of the **-exact_map** option does not mean the QN pin won't be used in the mapped sequential element.

-ungroup_all

Collapses all levels of hierarchy in a design, except those that have the **dont_touch** attribute set.

-boundary_optimization

Optimizes across all hierarchical boundaries in the design. This can change the function of the design so that it can operate only in its current environment. If input or output ports are complemented as a result of using this option, port names are changed according to the **port_complement_naming_style** variable.

-auto_ungroup area | delay

Specifies to automatically ungroup hierarchies in the design. A hierarchy is considered for automatic ungrouping only if it satisfies all of the following criteria:

- It does not have the **dont_touch** or **ungroup** attribute set on it.
- There are no timing constraints or exceptions set on its pins.
- Its wire load model is the same as that of its parent, or the **compile_auto_ungroup_override_wlm** variable is set to **true**.
- It has fewer child cells than the value of the **compile_auto_ungroup_area_num_cells** variable if you select **area**.

If you select **area**, all hierarchies that meet the above criteria are ungrouped. The **-auto_ungroup area** option is generally used to ungroup small hierarchies in the design to improve area recovery. It does not have a significant impact on the timing of the design.

The **-auto_ungroup delay** option employs an intelligent ungrouping strategy that attempts to improve the overall timing of the design. It chooses hierarchies that are most likely to benefit from the extra boundary optimizations that ungrouping exposes. The algorithm emphasizes hierarchies containing paths that are either critical, or likely to become critical, after subsequent optimization steps.

Delay-driven auto-ungrouping offers a less CPU-intensive alternative to using the **-ungroup_all** option for improving design timing.

-no_design_rule

Determines, along with the **-only_design_rule** and **-only_hold_time** options, whether the command fixes design-rule violations before exiting. The **-no_design_rule** option specifies for the command to exit before fixing design-rule violations, thus allowing you to check the results in a constraint report before fixing the violations. The **-no_design_rule**, **-only_design_rule**, and **-only_hold_time** options are mutually exclusive. You can use only one of the options. The default is to perform both design-rule fixing and mapping optimizations before exiting.

-only_design_rule

Determines, along with the **-no_design_rule** and **-only_hold_time** options, whether the command fixes design-rule violations before exiting. The **-only_design_rule** option specifies for the command to perform only design-rule fixing; that is, mapping optimizations are not performed. The **-no_design_rule**, **-only_design_rule**, and **-only_hold_time** options are mutually exclusive. You can use only one option. The default is to perform both design-rule fixing and mapping optimizations before exiting.

-only_hold_time

Determines, along with the **-no_design_rule** and **-only_design_rule** options, whether the command fixes design-rule violations before exiting. The **-only_hold_time** option specifies for the command to perform only hold-time fixing, ignoring other design rules. The **set_fix_hold** command must be specified for hold-time fixing to be performed. The **-no_design_rule**, **-only_design_rule**, and **-only_hold_time** options are mutually exclusive. You can select only one option. The default is to perform both design-rule fixing and mapping optimizations before exiting.

-scan

Specifies that the command is to consider the impact of scan insertion on mission-mode constraints during optimization. This option

causes the command to replace all sequential elements during optimization. Some scan-replaced sequential cells might be converted to nonscan cells later in the test synthesis process because of test design-rule violations or explicit user specifications. By accounting for the impact of internal scan insertion from the start of the design process, test-ready compile eliminates the need for future reoptimization.

-top

Fixes design-rule and top-level timing violations for a design but does not perform any mapping on the design. By default, this option fixes all design-rule violations, but it only fixes the timing violations whose paths cross top-level hierarchical boundaries. If you want this option to fix timing violations for all paths, set the **compile_top_all_paths** variable to **true**.

-power_effort none | low | medium | high

Specifies the relative amount of CPU time spent during the power optimization phase of **compile**. Valid values are **none**, **low**, **medium**, and **high**. You can select one value. The default is the specified *map_effort*. Since power optimization in **compile** is enabled by power constraints, this option is ignored if there is no power constraint on the design.

-gate_clock

Enables clock gating optimization: clock gates are automatically inserted or removed. The **-gate_clock** option cannot be used in combination with the **-only_design_rule** option. When used in combination with the **-exact_map** option, it may not be possible to honor the **-exact_map** option for those registers that are involved with clock-gating optimization.

A clock-gating cell is not modified or removed if it or its parent hierarchical cell is marked **dont_touch** with the **set_dont_touch** command.

DESCRIPTION

The **compile** command performs logic-level and gate-level synthesis and optimization on the current design. Optimization is controlled by user-specified constraints on the design. These constraints describe goals for the optimization process, such as making the smallest circuit possible or trying to make specified outputs arrive by a specified time. The optimization process trades off timing and area constraints to provide the smallest possible circuit that meets specified timing requirements. Values for the area and speed of components used in synthesizing and optimizing the design are obtained from user-specified libraries.

Constraints fall into one of two categories: design rule constraints and optimization constraints. Design rule constraints reflect technology-specific restrictions that must be met for a design to function correctly. Optimization constraints reflect less critical design goals and restrictions that are desirable but not crucial for the operation of a design.

The design rule constraints are **max_transition**, **max_fanout**, **max_capacitance**, and **min_capacitance**. All other constraints are optimization constraints. Examples include maximum delay and maximum area.

During optimization, both types of constraints are considered; however, precedence is given to meeting design rule constraints. The **min_delay** and **fix_hold** constraints are treated similarly to design rule constraints, except that they have lower priority than the maximum delay constraints. The priority given to various constraints can be modified by using the **set_cost_priority** command.

Often when a design read from an HDL description is optimized, new designs modeled from the synthetic library are generated. These designs are named according to the style specified in the **synthetic_design_naming_style** variable.

When the current design is hierarchical, and there are multiple design instances of a subdesign, it is not necessary to run the **uniquify** command before running the **compile** command. The **uniquify** command can still be used on multiple design instances so they can be individually optimized. For all designs marked with the **uniquify** attribute, **compile** copies and renames them according to the **uniquify_naming_style** variable.

The **compile** command does not optimize across hierarchical boundaries unless the **boundary_optimization** attribute is set to **true**. All synthetically generated designs are created with this attribute set to **true**. If boundary optimization causes ports to be complemented, port names are changed according to the **port_complement_naming_style** variable.

To customize the way the **compile** command optimizes subdesigns, use compile directives. Commands for placing these directives include **set_flatten** and **set_structure**. Command-line options pass global directives that affect how the entire design is optimized to the **compile** command.

If the current design or any of its subdesigns is represented as a state table, the **compile** command automatically performs finite state

machine optimizations on these designs. Finite state machine synthesis is also controlled with compile directives placed directly on these designs by using commands such as **set_fsm_encoding** and **set_fsm_minimize**.

If the current design or any of its subdesigns contains arithmetic operations (additions, subtractions, multiplications, and comparisons), the **compile** command automatically transforms them into datapath blocks to be implemented by a datapath generator. Datapath optimization can be controlled by using the **hlo_disable_datapath_optimization** variable.

The **compile** command reports progress in real time by displaying a report. During optimization, the report shows incremental results each time a transformation is applied to the design. The default fields of the report are ELAPSED TIME, AREA, WORST NEG SLACK, TOTAL NEG SLACK, DESIGN RULE COST, and ENDPOINT.

ELAPSED TIME

Tracks the elapsed time since the beginning of the current **compile** or **reoptimize_design**.

AREA

Shows the area of the design during the optimization.

WORST NEG SLACK

Shows the worst negative slack (max_path violation) in all path groups.

TOTAL NEG

Shows the sum of the negative slack across all endpoints in the design.

DESIGN RULE COST

Measures the distance between the actual results and the user-specified design rule constraints.

ENDPOINT

Shows the endpoint currently being worked on. When a delay violation is being fixed, the object for the ENDPOINT is a pin or a port. When a design rule violation is being fixed, the object for the ENDPOINT is a net.

You can specify other fields in addition to or instead of any of the default fields. For a list of available fields and other details about specifying the compile log format, see the **compile_log_format** variable man page.

To display the same log format as the 1998.02 version, set **compile_log_format = ""**. The fields for the 1998.02 version are TRIALS, AREA, DELTA DELAY, TOTAL NEGATIVE SLACK, and DESIGN RULE COST. The new default does not have the TRIALS and DELTA DELAY fields.

TRIALS

Tracks the number of transformations that the optimizer tries before making the current selection.

DELTA DELAY

Shows the current maximum delay cost of the design, which is the sum of the worst negative slack (max_path violation) in each path group.

The log written by **compile** shows the different phases of optimization. In addition to the Resource Allocation and Mapping phases, there are four more phases. The first of these is the Delay Optimization phase, which fixes max_path violations. In the Phase 1 Design Rule Fixing phase, design-rule violations are fixed without creating any new max_path delay violations. In the Phase 2 Design Rule Fixing phase, max_path delay constraints might be impacted while fixing design-rule violations. Finally, there is an Area Recovery phase that attempts to reduce the area of the design while keeping other constraints intact. The Area Recovery phase always does some minimal cleanup, but it performs more CPU-intensive area recovery only if max_area constraints have been set on the design. If the **-only_design_rule** option is used, the Delay Optimization phase and Area Recovery phase are skipped. If the **-no_design_rule** option is used, both Phase 1 Design Rule Fixing and Phase 2 Design Rule Fixing are skipped. If the **set_cost_priority** command with the **-delay** option has been used before using the **compile** command, Phase 2 Design Rule Fixing is skipped.

The **set_local_link_library** command sets the **local_link_library** attribute on a design. The **local_link_library** attribute contains a list of design and library files that are searched before the files are specified with the **link_library** variable whenever a link operation is performed. The **target_library** variable specifies a technology library or a list of technology libraries containing the components (usually from a specific ASIC supplier) to use during optimization. The **compile** command sets the **local_link_library** attribute of

the top-level design to the value of the **target_library** variable.

If **compile** is interrupted by an interrupt signal during an interactive process, it displays the following menu:

Please type in one of the following options:
1 to Write out the current state of the design
2 to Abort optimization
3 to Kill the process
4 to Continue optimization
Please enter a number:

If you select option 1, the design is written out and the menu reappears.

If the process is running in the background, you cannot use the menu. The number of interrupt signals determines what action is performed. The sequence is as follows:

^AC Information: Preparing to interrupt optimization... (INT-5)
^AC Information: Aborting Optimization... (INT-6)
^AC Information: Process terminated by interrupt. (INT-4)

The interrupt signal can be different from one machine to another.

EXAMPLES

The following examples apply to all modes.

The following command specifies that the current design be optimized without mapping the logic:

```
prompt> compile -no_map
```

The following command optimizes the design TEST twice; once for speed and once for area:

```
prompt> current_design TEST
prompt> set_max_delay 2.0 -to [all_outputs]
prompt> compile
prompt> set_max_area 250
prompt> compile
```

The following example specifies that the command perform restricted optimizations across hierarchical boundaries:

```
prompt> compile -boundary_optimization
```

The following example demonstrates a simple optimization strategy. The commands in the example first define the current design. Design attributes and constraints are set. Optimization phases for **compile** are defined. The **compile** command is executed with the specified options.

```
prompt> current_design TRIAL
prompt> set_wire_load_model "10x10"
prompt> set_operating_conditions "WCCOM"
prompt> create_clock -period 12 \
    -waveform {0 6} CLK
prompt> set_input_delay 2 [all_inputs]
prompt> set_output_delay 3 [all_outputs]
prompt> set_max_area 580
prompt> set_structure -boolean false
prompt> set_flatten -phase true -effort medium
prompt> compile -incremental_mapping \
    -no_design_rule
```

prompt> **report_constraint**

compile_exploration

Performs a fast mapping of gates with limited timing and area optimization.

SYNTAX

```
status compile_exploration
[-check_only]
[-exact_map]
[-gate_clock]
[-no_autoungroup]
[-no_boundary_optimization]
[-no_seq_output_inversion]
[-scan]
```

ARGUMENTS

-check_only

Checks whether the design and libraries have all the data that the **compile_exploration** command requires to run.

-exact_map

Specifies that sequential cells are mapped exactly as indicated in the HDL code. Specifying this option does not mean that QN pins are not to be used in the mapped sequential element. Specifying the **-exact_map** option disables sequential output inversion. For more information, see the **compile_seqmap_enable_output_inversion** variable.

-gate_clock

Enables clock-gating optimization, which automatically removes or inserts clock gates. When this option is used with the **-exact_map** option, the command might not honor the **-exact_map** option for those registers that are involved with clock-gating optimization.

A clock-gating cell is not modified or removed if the cell or its parent hierarchical cell is marked with the **dont_touch** attribute by the **set_dont_touch** command.

-no_autoungroup

Specifies to disable automatic ungrouping completely. All hierarchies are preserved unless otherwise specified.

-no_boundary_optimization

Specifies not to perform any hierarchical boundary optimization. By default, boundary optimization is turned on during the **compile_exploration** step.

-no_seq_output_inversion

Disables sequential output inversion. The sequential phase of all sequential elements is the same as in the RTL. When this option is not specified, the **compile_exploration** command can invert sequential elements during mapping and optimization.

-scan

Enables the examination of the impact of scan insertion on mission-mode constraints during optimization as in a normal compile.

Use this option to replace all sequential elements during optimization. Some scan-replaced sequential cells might be converted to nonscan cells later in the test synthesis process because of test design rule violations or explicit specifications.

DESCRIPTION

The **compile_exploration** command performs a fast mapping of gates with limited timing and area optimization. It typically runs much faster than the **compile** or **compile_ultra** command. Like the **compile** command, the optimization is controlled by constraints that you specify for the design. The **compile_exploration** command is targeted for high-performance designs with very tight timing constraints. It provides you with a simple approach to achieve critical delay optimization.

When used with the **set_host_options** command, the **compile_exploration** command uses up to the specified number of CPU cores on the same computer for parallel execution. For more details, see the description of the **-max_cores** option of the **set_host_options** man page.

This command can be used in the same manner as the **compile** command.

By default, the **compile_exploration** command incorporates two ungrouping phases for design hierarchies. The first phase occurs before the mapping step of first pass and attempts to ungroup small design hierarchies. The second ungrouping phase occurs during the mapping optimization step and applies a delay-based ungrouping strategy for design hierarchies. If you need to preserve all design hierarchies, specify the **-no_auoutgroup** option.

By default, if dw_foundation.sldb is not specified in the list of the **synthetic_library** variable and the DesignWare license is checked out successfully, dw_foundation.sldb is automatically added to the synthetic library to improve the QoR by using the licensed DesignWare architectures. This behavior occurs in the current command only, and it does not affect the user-specified synthetic library and link library lists.

By default, the **compile_exploration** command performs hierarchical boundary optimization, which can change the function of the design. Therefore, hierarchical boundary optimization can only operate in its current environment. If input or output ports are complemented as a result of this optimization, port names are changed according to the setting of the **port_complement_naming_style** variable. To disable hierarchical boundary optimization, specify the **-no_boundary_optimization** option.

[compile_ultra\(2\)](#)

compile_prefer_runtime

Overrides runtime-intensive user settings with settings designed to improve runtime. The **compile_prefer_runtime** command settings take effect when you run the **compile_ultra**, **compile_ultra -incremental**, or the **optimize_netlist -area** command.

SYNTAX

```
status compile_prefer_runtime
```

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **compile_prefer_runtime** command overrides runtime-intensive user settings with settings designed to improve runtime. The user-specified settings are reverted back to their original settings at the end of the optimization flow. The command also sets some internal variables to reduce runtime. The command overrides the user settings before optimization starts during **compile_ultra** and **optimize_netlist** and before **report_congestion**. The command is supported only in topographical mode.

Use the **compile_prefer_runtime** command only if runtime is a concern. The command disables runtime-intense optimizations, and therefore it might impact QOR. The effect of the setting changes depends on the design. You might not see runtime improvements on all designs.

For detailed information about the values that are changed when you use the **compile_prefer_runtime** command, see the "Using Topographical Technology" chapter in the *Design Compiler User Guide*.

EXAMPLES

The following example enables runtime mode settings during compile:

```
prompt> compile_prefer_runtime
prompt> compile_ultra
```

SEE ALSO

```
compile_ultra(2)
optimize_netlist(2)
report_congestion(2)
```

compile_ultra

Performs a high-effort compile on the current design for better quality of results (QoR).

SYNTAX

```
status compile_ultra
[-incremental]
[-scan]
[-exact_map]
[-no_auoutgroup]
[-no_seq_output_inversion]
[-no_boundary_optimization]
[-no_design_rule | -only_design_rule]
[-timing_high_effort_script
 | -area_high_effort_script]
[-top]
[-retimed]
[-gate_clock]
[-self_gating]
[-check_only]
[-congestion]
[-spg]
[-no_auto_layer_optimization]
```

ARGUMENTS

-incremental

Runs **compile_ultra** in incremental mode. In the incremental mode, the tool does not run the mapping or implementation selection stages.

-scan

Enables the examination of the impact of scan insertion on mission-mode constraints during optimization, as in a normal compile. Use this option to replace all sequential elements during optimization. Some scan-replaced sequential cells can be converted to nonscan cells later in the test synthesis process because of test design rule violations or explicit specifications.

-exact_map

Specifies that sequential cells are mapped exactly as indicated in the HDL code. Use of the **-exact_map** option does not mean the QN pin won't be used in the mapped sequential element. Use of the **-exact_map** option would disable sequential output inversion. For more information, see **compile_seqmap_enable_output_inversion**.

-no_auoutgroup

Specifies that automatic ungrouping is completely disabled. All hierarchies are preserved unless otherwise specified.

-no_seq_output_inversion

Disables sequential output inversion. The phase sequential of all sequential elements is the same as in the RTL. Without this option, **compile_ultra** is free to invert sequential elements during mapping and optimization. For more information, see the man

page for the **compile_seqmap_enable_output_inversion** variable.

-no_boundary_optimization

Specifies that no hierarchical boundary optimization is to be performed. By default, boundary optimization is turned on during **compile_ultra** activity.

Specifies that no hierarchical boundary optimization is to be performed. By default, the **-no_boundary_optimization** option does not disable constant propagation across design hierarchies. To disable constant propagation with the **-no_boundary_optimization** option, set the **compile_enable_constant_propagation_with_no_boundary_opt** variable to **false**.

This option sets the **compile_preserve_subdesign_interfaces** variable to **true**.

-no_design_rule

Determines whether the command fixes design rule violations before exiting. The **-no_design_rule** option specifies for the command to exit before fixing design rule violations, thus allowing you to check the results in a constraint report before fixing the violations. The default is to perform both design rule fixing and mapping optimizations before exiting.

The **-no_design_rule** and **-only_design_rule** options are mutually exclusive. Use only one option.

-only_design_rule

Determines whether the command fixes design rule violations before exiting. The **-only_design_rule** option specifies for the command to perform only design rule fixing; that is, mapping optimizations are not performed. The default is to perform both design rule fixing and mapping optimizations before exiting.

The **-no_design_rule** and **-only_design_rule** options are mutually exclusive. Use only one option. The **-only_design_rule** option can be used only with the **-incremental** option.

-timing_high_effort_script

This option is available in the tool to support backward compatibility with existing scripts and is ignored for optimization purposes.

-area_high_effort_script

This option is available in the tool to support backward compatibility with existing scripts and is ignored for optimization purposes.

-top

Fixes design rule and top-level timing violations in a design. By default, this option fixes all design rule violations, but only those timing violations whose paths cross top-level hierarchical boundaries. If you want this option to fix timing violations for all paths, set the **compile_top_all_paths** variable to **true**.

-retime

Uses the adaptive retiming algorithm during optimization to improve delay. This option is ignored if the **-only_design_rule** option or the **-top** option is chosen at the same time.

-gate_clock

Enables clock gating optimization: clock gates are automatically inserted or removed. The **-gate_clock** option cannot be used in combination with the **-only_design_rule** option. When used with the **-exact_map** option, it might not be possible to honor the **-exact_map** option for those registers that are involved with clock gating optimization.

A clock gating cell is not modified or removed if it or its parent hierarchical cell is marked **dont_touch** with the **set_dont_touch** command.

-self_gating

Enables the execution of self-gating insertion.

Self-gating is a clock gating technique that optimizes dynamic power by gating the clock signal in those cycles in which the data saved in a register remains unchanged. An enable condition is computed by comparing the stored data with the new data arriving at the data pin, and that signal is used to drive the inserted self-gating cell.

A self-gating cell can be shared across several registers by creating a combined enable condition so that the area and power overhead due to the inserted cells is minimized.

The selection of registers to be gated and the grouping of them to form the self-gating banks are driven by the switching activity at the registers' data pins, the timing slack available, and the physical proximity between the registers to be grouped.

This option is only supported in Design Compiler topographical mode.

The **-self_gating** option cannot be used in combination with the **-only_design_rule** option.

-check_only

Checks whether the design and libraries have all the data that **compile_ultra** requires to run successfully. This option is available only in Design Compiler topographical mode.

-congestion

This option will be obsolete in a future release. See the **-spg** option for information about congestion optimization.

-spg

This option is available only in Design Compiler topographical mode. Enables physical guidance, congestion optimization, and automatic layer optimization. Congestion optimization reduces routing-related congestion. Physical guidance enables Design Compiler Graphical to save coarse placement information and pass this coarse placement information to IC Compiler. With this coarse placement, IC Compiler can begin the implementation flow with the **place_opt** command.

IC Compiler no longer needs to re-create the coarse placement by running commands such as **create_placement**, **remove_buffer_tree**, or **psynopt**. By using the Design Compiler coarse placement as a starting point for placement, runtime and area correlation with IC Compiler are improved.

Design Compiler Graphical automatically performs layer-aware optimization when you use the **-spg** option, modeling parasitic variation across metal layers in a way that benefits optimization. This optimization helps remove excess pessimism, leading to better area and power.

In addition to the default layer-aware optimization, you can also specify net constraints for layer optimization by setting specific constraints using the **set_net_routing_layer_constraints** command or by creating a net-search pattern.

In the net-search pattern approach, you define a net-search pattern by using the **create_net_search_pattern** command and then define associated minimum and maximum routing layer constraints for the search pattern by using the **set_net_search_pattern_delay_estimation_options** command. Design Compiler invokes net-pattern identification after the high-fanout synthesis step in **compile_ultra** and assigns the minimum and maximum constraints to the matching nets. The subsequent optimizations consider the effects of the constraints (for example, the unit resistance and capacitance values of matching nets will change) during buffering and buffer removal. You can define as many net-search patterns and associated layer constraints as needed. In general, however, it is recommended to start with very long nets (for example, 500 um) with top routing layers (for example, M7 and M8). You should consider this approach when your design shows significant unit resistance variation (see RCEX-011 resistance values) across all available routing layers.

Note that the user-constraints and net-pattern layer optimization methods might affect runtime.

-no_auto_layer_optimization

The **-no_auto_layer_optimization** option is obsolete. Running the option has no effect on layer optimization.

DESCRIPTION

The **compile_ultra** command performs a high-effort compile on the current design for better quality of results (QoR). As with the **compile** command, optimization is controlled by constraints that you specify on the design. This command is targeted toward high-performance designs with very tight timing constraints. It provides you with a simple approach to achieve critical delay optimization. The **compile_ultra** command packages all the DC Ultra features and enables them by default. It requires a DC Ultra license plus a DesignWare Foundation license. This command provides the best strategy for optimum overall QoR and performance.

When used in conjunction with the **set_host_options** command, **compile_ultra** uses up to the user-specified number of CPU cores on the same computer for parallel execution. See the description of the **-max_cores** option in the **set_host_options** man page for more information.

This command can be used in the same manner as the **compile** command.

By default, **compile_ultra** incorporates two ungrouping phases for design hierarchies. The first phase is performed before "Pass1 Mapping" and attempts to ungroup small design hierarchies. This first ungrouping phase can be turned off using the following command:

```
set compile_ultra_ungroup_small_hierarchies false
```

The second ungrouping phase is performed during "Mapping Optimization" and applies a delay-based ungrouping strategy for design hierarchies. If you need to preserve all design hierarchies, use the **-no_aoutounroup** option. If you want to preserve the hierarchies for a specific block, use the **set_ungroup** command.

By default, if dw_foundation.sldb is not in the synthetic_library list, and the DesignWare license is successfully checked out, dw_foundation.sldb is automatically added to the synthetic_library to use the QoR benefit provided by the licensed DesignWare architectures. This behavior occurs in the current command only, and it does not affect the user-specified **synthetic_library** and **link_library** list.

By default, all DesignWare hierarchies are unconditionally ungrouped in the second pass of compile. You can set the **compile_ultra_ungroup_dw** variable to control the ungrouping process of DesignWare components.

By default, hierarchical boundary optimization is performed on the design. This can change the function of the design so that it can operate only in its current environment. If input or output ports are complemented as a result of this optimization, port names are changed according to the **port_complement_naming_style** variable. Use the **-no_boundary_optimization** option to turn off the boundary optimization feature.

By default, the tool applies a compile strategy intended to improve the resulting area of the design, possibly at the cost of additional runtime. The strategy can make changes to variables or constraints that modify **compile_ultra** behavior and perform additional passes to achieve better area.

EXAMPLES

The following example turns off boundary optimization for cell U1:

```
prompt> set_boundary_optimization [get_cells U1] false
prompt> compile_ultra
```

SEE ALSO

[create_net_search_pattern\(2\)](#)
[set_net_search_pattern_delay_estimation_options\(2\)](#)

compute_polygons

Returns a list or collection of polygons that exactly cover the region computed by performing a Boolean operation on the input polygons.

SYNTAX

```
list compute_polygons
  -boolean and | or | not | xor
  poly_list1
  poly_list2
```

Data Types

poly_list1 list or collection
poly_list2 list or collection

ARGUMENTS

-boolean and | or | not | xor

Specifies the Boolean operation to perform on the two input polygon lists or collections to produce the output polygon list or collection.

"**and**" finds the area occupied by both the first and second input polygon list or collection.

"**or**" finds the area occupied by either the first or second input polygon list or collection, or occupied by both.

"**not**" finds the area occupied by the first input polygon list or collection and not occupied by the second polygon list or collection.

"**xor**" finds the area occupied by either the first or second input polygon list or collection, but not both.

poly_list1

Specifies the first list or collection of input polygons. You can specify a single polygon or multiple polygons, representing the first argument for the geometric Boolean operation.

To specify a polygon as a list, enter a sequence of X-Y coordinate pairs that represent the successive vertices of the polygon, using the following format:

$\{\{x_1\ y_1\}\ \{x_2\ y_2\}\ \dots\ \{x_N\ y_N\}\ \{x_1\ y_1\}\}$

The coordinate unit size is specified in the technology file; typically it is microns.

Polygons must be rectilinear, so the X coordinate of each data point must match the X coordinate of a neighboring data point, and the Y coordinate must match the Y coordinate of the other neighboring data point. The last point in the list must be the same as the first.

Instead of specifying lists of coordinates, you can specify a polygon collection. In that case, the output of the command is also a collection.

poly_list2

Specifies the second list or collection of input polygons. The command performs a Boolean operation between the first and the second list or collection of polygons.

DESCRIPTION

This command performs a Boolean operation (OR, AND, NOT, or XOR) between two polygons or between two sets of polygons, specified as lists of vertices or as polygon collections. It returns the result in the same form as the input polygons, either a list or a polygon collection. The result can be a single polygon or a set of multiple, disjoint polygons.

Before using this command, the Milkyway design library containing the input polygons must be open. The input polygons must be rectilinear, consisting of only vertical and horizontal line segments that meet at right angles.

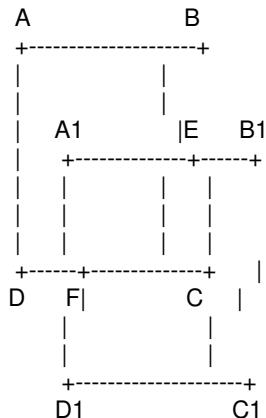

You can directly pass the output of this command as a parameter directly to another **compute_polygons** command, but not to the other polygon commands, **convert_from_polygon**, **resize_polygon**, or **get_polygon_area**. This is because the other polygon commands can only take a single polygon as input. Instead, you must use a Tcl list command such as the **foreach** or **lindex** command to extract each polygon from the returned list, and then pass each polygon to the other polygon command.

To view the coordinates of a polygon collection stored in a variable, use the following command:

```
prompt> get_attribute $variable_name coordinate
```

EXAMPLES

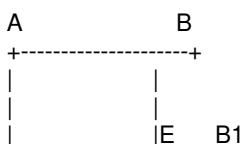

Assume that you have two polygons, A-B-C-D-A and A1-B1-C1-D1-A1, as shown in the following figure:

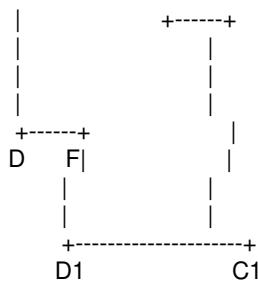

The following example performs the Boolean OR operation on these input polygons. The result is the B-E-B1-C1-D1-F-D-A-B polygon.

```
prompt> compute_polygons -boolean or \
{{0 30} {30 30} {30 10} {0 10} {0 30}} \
{{10 20} {40 20} {40 0} {10 0} {10 20}}
{{30.000 30.000} {30.000 20.000} {40.000 20.000} {40.000 0.000} {10.000 0.000}
{10.000 10.000} {0.000 10.000} {0.000 30.000} {30.000 30.000}}
```

The following figure shows the resulting polygon.

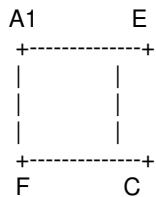

The following example performs the Boolean AND operation on the same input polygons. The result is the A1-E-C-F-A1 polygon.

```
prompt> compute_polygons -boolean and \
{{0 30} {30 30} {30 10} {0 10} {0 30}} \
{{10 20} {40 20} {40 0} {10 0} {10 20}}
{{10.000 20.000} {30.000 20.000} {30.000 10.000}
{10.000 10.000} {10.000 20.000}}
```

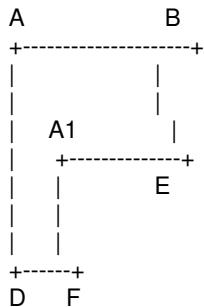

The following figure shows the resulting polygon.

The following example performs the Boolean NOT operation on these input polygons. The result is the B-E-A1-F-D-A-B polygon, which is the region covered by the first polygon, A-B-C-D-A, but not covered by the second polygon, A1-B1-C1-D1-A1.

```
prompt> compute_polygons -boolean not \
{{0 30} {30 30} {30 10} {0 10} {0 30}} \
{{10 20} {40 20} {40 0} {10 0} {10 20}}
{{30.000 30.000} {30.000 20.000} {10.000 20.000} {10.000 10.000}
{0.000 10.000} {0.000 30.000} {30.000 30.000}}
```

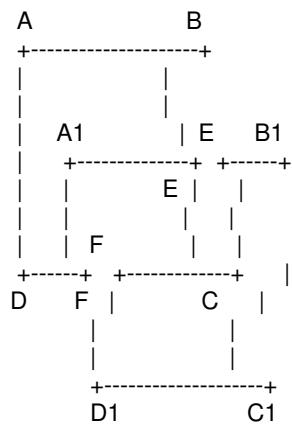

The following figure shows the resulting polygon.

The following example performs the Boolean XOR operation on these input polygons. The result is two polygons, B-E-A1-F-D-A-B and B1-C1-D1-F-C-E-B1, which are the areas covered by either input polygon, but not both.

```
prompt> compute_polygons -boolean xor \
{{0 30} {30 30} {30 10} {0 10} {0 30}} \
{{10 20} {40 20} {40 0} {10 0} {10 20}}
{{30.000 30.000} {30.000 20.000} {10.000 20.000} {10.000 10.000} {0.000 10.000}
{0.000 30.000} {30.000 30.000} {{40.000 20.000} {40.000 0.000} {10.000 0.000}
{10.000 10.000} {30.000 10.000} {30.000 20.000} {40.000 20.000}}
```

The following figure shows the resulting polygons, moved apart slightly to clearly show the disjoint regions.

The following example shows how **compute_polygons** can accept list of polygons as input.

```
prompt> compute_polygons -boolean or {{0 0} {10 0} {10 10} \
{0 10} {0 0} {{20 0} {30 0} {30 10} {20 10} {20 0}}} \
{{10 0} {20 0} {20 10} {10 10} {10 0}} \
{{0.000 10.000} {30.000 10.000} {30.000 0.000} {0.000 0.000} {0.000 10.000}}
```

connect_logic_net

Connects a logic net to logic ports in a UPF description.

SYNTAX

```
status connect_logic_net
  net_name
  -ports port_list
  [-reconnect]
```

Data Types

```
net_name    string
port_list   list
```

ARGUMENTS

net_name

Specifies the net name. You must use a simple name.

-ports *port_list*

Specifies the ports connected to the net. The ports must be on the interface of the active UPF scope or on the design elements that are located in the active scope and its descendants.

-reconnect *reconnect*

Allows a port that is already connected to a net to be disconnected from the existing net and connected to the newly specified net.

DESCRIPTION

This command connects a logic net to the specified ports. The net is propagated through implicitly created ports and nets throughout the logic hierarchy in the descendant tree of the active UPF scope. The connection from the specified net in the active UPF scope to any element in the port list cannot cross any power-domain boundaries. The -reconnect option disconnects any existing net from the specified port and connects the newly specified net to all the ports present in the port_list.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`create_logic_port(2)`
`create_logic_net(2)`

connect_net

Connects the specified net to the specified pins or ports.

SYNTAX

```
status connect_net
    net
    object_list
```

Data Types

<i>net</i>	string
<i>object_list</i>	list

ARGUMENTS

net

Specifies the net to connect. The net must be a scalar (single bit) net, and must exist in the current design.

object_list

Specifies a list of pins and ports to which the net is to be connected. Pins and ports must be at the same hierarchical level as the specified net, and must exist in the current design. If a specified pin or port is already connected, the tool issues an error message.

DESCRIPTION

This command connects a net to the specified pins or ports at the same hierarchical level. The net can be at any level of hierarchy but the pins or ports must be at the same level. A net can be connected to many pins or ports; however, you cannot connect a pin or port to more than one net.

To disconnect objects on a net, use the **disconnect_net** command.

To display pins and ports on a net, use either the **all_connected** or **get_nets -of \$net** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **connect_net** to connect net NET0 to ports A1 and A2 and pin U1/A. The **all_connected** command returns the objects connected to net NET0.

```
prompt> connect_net NET0 [get_ports {A1 A2}]  
prompt> connect_net NET0 [get_pins U1/A]  
prompt> all_connected NET0  
{A1 A2 U1/A}
```

The following example shows the error message generated when you attempt to connect a pin or port to more than one net:

```
prompt> connect_net MY_NET_1 PORT1  
Connecting net 'MY_NET_1' to port 'PORT1'.  
prompt> connect_net MY_NET_2 PORT1  
Error: Object 'PORT1' is already connected to net 'MY_NET_1'.
```

The following example shows how **connect_net** is used to connect the U1/MY_NET net to the U1/MY_PORT port:

```
prompt> connect_net U1/MY_NET U1/MY_PORT
```

connect_pin

Connects pins or ports at any level of hierarchy.

SYNTAX

```
status connect_pin
  -from from_object
  -to to_list
  [-port_name port_name]
  [-verbose]
```

Data Types

```
from_object    collection
to_list        collection
port_name     string
```

ARGUMENTS

-from *from_object*

Specifies the pin or port from which to make the connection. The direction of the pin or port cannot be inout.

-to *to_list*

Specifies the pins and ports to which to make the connection. The pins and ports can be at any level of the hierarchy. The direction of the pins or ports cannot be inout.

-port_name *port_name*

Specifies the base name to use as the names of ports that are created on subdesigns to make the connection.

-verbose

Specifies that the tool displays individual netlist operations while making the global connections.

DESCRIPTION

This command performs global connections between the source object specified in the **-from** option and the objects specified in the **-to** option. The specified pins and ports can be at any level of hierarchy. The parent design of the pins and ports must be unique.

While making the global connections, ports and nets are created in the subdesigns, if needed. Ports in the subdesigns are reused regardless of their names, when the from pin is already connected to a net. Also, a port in a subdesign is reused if it is unconnected and the name is as specified by the **-port_name** option.

Wherever applicable, the name of the net that is created is the name of the connecting port, as long as there is no net with the same

name in that design. If there is an existing net with the name, the name of the net is generated.

The **connect_pin** command ensures that multiply-driven nets are not created. The command does not allow a connection from an output pin to an output pin.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **connect_pin** command to connect the U1/Z output pin to the mid1/bot1/U3/A input pin.

Use the **report_net -connections** or **report_cell -connections** command to view the connections.

```
prompt> connect_pin -from [get_pins U1/Z] \
    -to [get_pins mid1/bot1/U3/A]
prompt> report_net -connections [get_net -of [get_pins U1/Z]]
```

SEE ALSO

[all_connected\(2\)](#)
[connect_net\(2\)](#)
[create_port\(2\)](#)
[report_cell\(2\)](#)
[report_net\(2\)](#)

connect_supply_net

Connects the supply net to specified supply ports and pins.

SYNTAX

```
status connect_supply_net
  supply_net_name
  -ports list
  [-vct vct_name]
```

Data Types

<i>supply_net_name</i>	string
<i>list</i>	list
<i>vct_name</i>	string

ARGUMENTS

supply_net_name

Specifies the name of the supply net to be connected, which must be an existing simple (nonhierarchical) supply net name.

-ports list

Specifies the supply ports or pins that are to be connected with the supply net. Each item in the list is the hierarchical name of a supply port or pin.

-vct vct_name

Specifies the value conversion table (VCT) to be used in this connection.

The tool supports only the following 14 predefined VCT names: UPF2VHDL_SL ; UPF_GNDZERO2VHDL_SL ; UPF2SV_LOGIC ; UPF_GNDZERO2SV_LOGIC ; VHDL_TIED_HI ; SV_TIED_HI ; VHDL_TIED_LO ; SV_TIED_LO ; VHDL_SL2UPF ; VHDL_SL2UPF_GNDZERO ; SV_LOGIC2UPF ; SV_LOGIC2UPF_GNDZERO ; SV_LOGIC2UPF_MD ; SV_LOGIC2UPF_GNDZERO_MD.

DESCRIPTION

The **connect_supply_net** command makes an explicit connection of a supply net to specified supply ports or pins. It overrides (has higher precedence than) the automatic connection semantics that might otherwise apply.

If a design element is not connected explicitly to any supply net using the **connect_supply_net** command, it shares the primary power or ground supply net with the power domain to which it belongs.

Before they can be connected, the supply net must be created in the same power domain as the supply port. The instance that contains the pin must also be in the extent of the same power domain.

The command can be used to connect a supply net to bias pins. Bias pins that meet following conditions are supported:

- The bias pin is from a macro cell
- The bias pin direction is "input" or "inout"
- The bias pin physical_connection is "routing_pin"

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example connects a supply net named VSS with the supply port VSS:

```
prompt> create_power_domain PD1 -elements INST_1  
PD1  
prompt> create_supply_net VSS -domain PD1  
VSS  
prompt> create_supply_port VSS -domain PD1  
VSS  
prompt> connect_supply_net VSS -ports VSS  
1
```

The following example shows how to connect a supply set with a supply port:

```
prompt> connect_supply_net sset.power -ports VDD  
1  
prompt> connect_supply_net sset.ground -ports VSS  
1
```

SEE ALSO

`create_supply_net(2)`
`report_supply_net(2)`

continue

Begins the next loop iteration.

SYNTAX

int **continue**

ARGUMENTS

None

DESCRIPTION

This command begins the next iteration of the innermost loop. To immediately reevaluate the condition of a while loop, use the **continue** command, rather than executing the remaining statements to the end.

The **continue** command always returns the integer 1, indicating successful operation. A syntax error is reported if the **continue** command is used outside a loop structure.

EXAMPLES

The following example plots the first 10 sheets of the current design, except for sheet 5:

```
set p 0
while {$p <= 10} {
    if {$p % 2} {
        incr p
        continue
    }
    echo "$p squared is: [expr $p * $p]"; incr p
```

SEE ALSO

[break\(2\)](#)
[while\(2\)](#)

convert_from_polygon

Converts each polygon into a list or collection of mutually exclusive rectangles.

SYNTAX

```
list convert_from_polygon
  polygons
  [-format polygon | rectangle]
```

Data Types

polygons polygon list or collection

ARGUMENTS

polygons

Specifies the list or collection of input polygons to be decomposed into rectangles. You can specify a single polygon or multiple polygons.

To specify a polygon as a list, enter a sequence of X-Y coordinate pairs that represent the successive vertices of the polygon, using the following format:

$\{\{x_1\ y_1\}\ \{x_2\ y_2\}\ \dots\ \{x_N\ y_N\}\ \{x_1\ y_1\}\}$

The coordinate unit size is specified in the technology file; typically it is microns.

Polygons must be rectilinear, so the X coordinate of each data point must match the X coordinate of a neighboring data point, and the Y coordinate must match the Y coordinate of the other neighboring data point. The last point in the list must be the same as the first.

Instead of specifying lists of coordinates, you can specify a polygon collection. In that case, the output of the command is also a collection.

-format *polygon* | *rectangle*

Specifies the output format of the resulting rectangles.

By default, each resulting rectangle is represented as two data points at opposite corners of the rectangle:

$\{x_1\ y_1\}\ \{x_2\ y_2\}$

If you specify **-format polygon**, each resulting rectangle is represented in polygon format, using five data points for the round trip around the perimeter of the rectangle:

$\{\{x_1\ y_1\}\ \{x_2\ y_1\}\ \{x_2\ y_2\}\ \{x_1\ y_2\}\ \{x_1\ y_1\}\}$

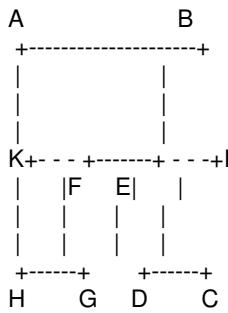

DESCRIPTION

This command converts a polygon into a list of mutually exclusive rectangles. The returned rectangles are represented as a list of coordinates or a collection. Before using this command, the Milkyway design library must be open.

Note that this command might return a list of disjoint polygons. Because the polygon commands take a single polygon as input, you cannot directly pass the result as a parameter to another polygon command. Instead, you must use a Tcl list command, such as the **foreach** or **lindex** command, to extract each polygon from the returned list, and then pass each polygon to the polygon command.

EXAMPLES

The following example converts the A-B-C-D-E-F-G-H-A polygon to three rectangles, K-F-G-H, E-I-C-D, and A-B-I-K.

```
prompt> convert_from_polygon {{0 20} {30 20} {30 0} \
{20 0} {20 10} {10 10} {10 0} {0 0} {0 20}}
{{0.000 0.000} {10.000 10.000}} {{20.000 0.000}
{30.000 10.000}} {{0.000 10.000} {30.000 20.000}}
```

SEE ALSO

[convert_to_polygon\(2\)](#)
[compute_polygons\(2\)](#)
[resize_polygon\(2\)](#)

convert_pg

Converts RTL PG information extracted from RTL into UPF. This command is supported only in UPF mode.

SYNTAX

```
status convert_pg  
    [-net_creation_style style]
```

Data Types

style string

ARGUMENTS

-net_creation_style *style*

Optional argument which tells **convert_pg** the style of supply net to be created in case a matching supply net is not found in the UPF. Valid values for *style* are *domain_dependent* and *domain_independent*.

DESCRIPTION

The **convert_pg** command converts the PG network information extracted from RTL during the **link** command into UPF constraints. For the **link** command to extract the PG network from RTL, the **dc_allow_rtl_pg** Tcl Boolean variable must be set before reading in the RTL.

The PG network is converted into a set of domain-dependent UPF constraints or domain-independent UPF constraints depending on the *style* specified to the **-net_creation_style** option.

The **convert_pg** command requires some basic UPF constraints to have been loaded and at least a top level power domain defined already. It then tries to match each RTL PG net with an existing supply net, if any. If there is no match, then either a domain-dependent supply net or a domain-independent supply net is created for the RTL PG net, based on the value specified to the **-net_creation_style** option. In addition, supply ports are also created as required. If a supply net cannot be created because of the lack of knowledge of a target power domain, then errors are reported.

The RTL net connections to PG pins are converted to **connect_supply_net** commands. If your UPF connects a different supply net to the same PG pins, then an error is reported.

If **convert_pg** command can successfully convert all of the PG network to UPF, then it returns a status of 1. Otherwise, a status of 0 is returned.

After the **convert_pg** command converts the PG network to UPF successfully, subsequent calls to the **convert_pg** command yield nothing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show different usages of the **convert_pg** command and its outcome.

The following shows the behavior when the **convert_pg** command is called without any RTL PG information.

```
prompt> convert_pg  
Information: The design does not contain any RTL-derived PG nets. (UPF-439)
```

The following shows the behavior when the **convert_pg** command is called without loading any UPF constraints.

```
prompt> convert_pg  
Error: No top level power domain found.
```

The following shows the behavior when the **convert_pg** command is called again after a successful call.

```
prompt> convert_pg  
Information: The design does not contain any RTL-derived PG nets. (UPF-439)
```

The following shows the behavior when the **convert_pg** command successfully converts the PG network into domain-dependent UPF.

```
prompt> convert_pg -net_creation_style domain_dependent  
Generating UPF for PG netlist derived from RTL:
```

```
create_supply_net {vdd} -domain {TOP}  
create_supply_port {vdd} -direction {in}  
connect_supply_net {vdd} -port {vdd}  
connect_supply_net {vdd} -port {mid1/U1/VDD mid1/bot1/U1/VDD}  
1
```

SEE ALSO

[dc_allow_rtl_pg\(3\)](#)

convert_to_polygon

Returns a polygon list for the specified objects.

SYNTAX

```
list convert_to_polygon
  [-quiet]
  [-collection]
  object_spec
```

Data Types

object_spec object collection

ARGUMENTS

-quiet

Suppresses the reporting of error and warning messages.

-collection

This option is not supported in Design Compiler.

object_spec

Specifies the input object collection. The object class must be fixed cells, fixed physical-only cells, a placement blockage, or a move bound.

DESCRIPTION

This command returns polygons calculated from the input objects. The returned polygon is represented as a list of polygon vertex coordinates.

EXAMPLES

The following example returns a polygon list from the MB#123 move bound.

```
prompt> convert_to_polygon [get_bounds MB#123]
{{99.490 111.340} {117.590 111.340} {117.590 112.620} {99.490 112.62}
{99.490 111.340}}
```

SEE ALSO

`convert_from_polygon(2)`
`compute_polygons(2)`
`resize_polygon(2)`

copy_collection

Duplicates the contents of a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

collection **copy_collection**
 collection1

Data Types

collection1 collection

ARGUMENTS

collection1

Specifies the collection to be copied. If an empty string is used for the *collection1* argument, the command returns the empty string (a copy of the empty collection is an empty collection).

DESCRIPTION

This command is no longer needed and is provided only to make old scripts work without modification.

EXAMPLES

The following example from PrimeTime shows the result of copying a collection. Functionally, it is not much different than having multiple references to the same collection, except it is slower.

```
prompt> set c1 [get_cells "U1*"]
{U1 U10 U11 U12}
prompt> set c2 [copy_collection $c1]
{U1 U10 U11 U12}
prompt> unset c1
prompt> query_objects $c2
{U1 U10 U11 U12}
```

SEE ALSO

collections(2)

copy_design

Copies a design to a new design, or copies a list of designs to a new file in dc_shell memory.

SYNTAX

```
string copy_design
      design_list
      target_name
```

Data Types

```
design_list  string
target_name   string
```

ARGUMENTS

design_list

Specifies a lists of designs to copy. If a design is specified, the *target_name* must be a file name. All of the listed designs are copied to the the specified file with their base design names.

target_name

Specifies the name of the new design to create or the name of the file to which multiple designs are copied.

DESCRIPTION

The **copy_design** command copies a list of designs either to a target file or to a newly created design.

In the first form, the **copy_design** command copies the contents of *design_name* to *target_name*. The attributes and constraints of *design_name* are copied with the design. A design cannot be copied over another design that already exists in dc_shell.

In the second form, **copy_design** copies the designs listed in *design_name* to the file specified by *target_name*.

To write these files to disk, use the **write** command.

EXAMPLES

This example copies the design named *TEST* to the design named *BILL*:

```
prompt> copy_design TEST BILL
Information: Copying design /usr/example/TEST.DB:TEST to /usr/example/TEST.db:BILL.
```

(UIMG-45)

```
prompt> list_designs
BILL    TEST.db (*)
```

This example copies design *TEST* to the new file *my_test.db*:

```
prompt> copy_design TEST /usr/example/my_test.db:TEST
Information: Copying design /usr/example/TEST.db:TEST to /usr/example/my_test.db:TEST.
(UIMG-45)
```

```
prompt> list_designs -show_file
/usr/example/TEST.db
TEST (*)
```

```
/usr/example/my_test.db
TEST
```

In this example, the **get_designs** command is used with **copy_design** to copy all of the designs currently read into dc_shell to a single file:

```
prompt> list_designs -show_file
/usr/example/TEST.db
TEST (*)
```

```
/usr/example/ADDER.db
ADDER
```

```
prompt> copy_design [get_designs *] /usr/dc/project/all.db
Information: Copying design /usr/example/TEST.db:TEST to /usr/dc/project/all.db:TEST.
(UIMG-45)
Information: Copying design ADDER.db:ADDER to /usr/dc/project/all.db:ADDER.
(UIMG-45)
```

```
prompt> list_designs -show_file
/usr/example/TEST.db
TEST (*)
```

```
/usr/example/ADDER.db
ADDER
```

```
/usr/dc/project/all.db
ADDER  TEST
```

If you attempt to copy multiple designs without specifying a target file name as the second argument of the **copy_design** command, an error is generated, as shown below:

```
prompt> copy_design {A, B, C} all.db:TEST3
Error: Cannot copy multiple designs to a single design
(UIMG-4)
```

SEE ALSO

```
current_design(2)
get_designs(2)
remove_design(2)
rename_design(2)
write(2)
```

copy_lib

Copies one or more design libraries from one location to another.

SYNTAX

```
status copy_lib
[-force]
[-merge | -no_designs]
[-from_lib source_name]
-to_lib destination_name
```

Data Types

<i>source_name</i>	string
<i>destination_name</i>	string

ARGUMENTS

-force

Overwrites the destination library when the library is modified but not yet saved. If this option is not specified, the command stops and issues an error message if the library is modified but not yet saved.

-merge

Merges the source library into the destination library. This option is used for incremental update. Normally, the destination library is (re)initialized before the copy begins. This option can be used only if both the source and destination libraries are design libraries. Note that lib-cell libraries cannot be merged, and library attributes, technology, and parasitic_tech data are not merged. If the destination library does not already contain technology or parasitic_tech data, the command copies the technology or tech_parasitic data from the source library to the destination library. Only libraries with compatible technology can be merged, and the command performs a technology compatibility test if both the source and destination libraries contain technology sections. The **-merge** option fails if the source and destination technologies are incompatible.

-no_designs

Copies the source library to the destination library, without copying the designs in the source library. This option is mutually exclusive with the **-merge** option. The command copies the library attributes, ref_lib list, view_switch list, technology, and parasitic_tech from the source library without copying any of the designs. This option is useful when splitting a source library that contains subblocks into a separate destination libraries that each contain a subblock.

-from_lib *source_name*

Specifies the name of source NDM library. If you specify a list of NDM library names, the designs in each library are copied to the destination library. If there are duplicate designs in the source libraries, the design from the first library in the list that contains the duplicate is copied to the destination library. If the **-no_designs** option is used, the **-from_lib** option must contain a single library. If this option is not specified, the command uses the current library. Use the **current_lib** command to determine the current library.

-to_lib *destination_name*

Specifies the destination library name. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after the last '/' becomes the name of the library. It will be an error if the a library, file, or directory of the same

name already exists on disk.

DESCRIPTION

This command copies one or more source libraries into a destination library. If technology data and a ref_lib list exists, they are copied as well. Note that the command fails if there are conflicts in technology data among the source libraries or between the source and destination libraries when the **-merge** option is used. When there are conflicts in design data, the data from the first library in the source list is used (or from the destination library if the **-merge** option is used and a conflict exists). Note that conflicts are resolved on the design level, not down to the view level. For example, if a source library has topLib1:Mid.timing and another source library has topLib2:Mid.design, only the first design is copied. The destination target is reinitialized (deleted) before the copy unless the **-merge** option is used. When the source and destination libraries contain a reference library list, the source reference list is appended to the target library and the duplicate entries are removed.

The command returns 1 if successful, or 0 otherwise. If an illegal name is given, a Tcl error is raised.

Note that when overriding an existing library (without the **-merge** option), there is no automatic rebinding to the new design or technology data in the library. All original designs in the library are removed, and designs from other libraries that used to bind to those removed designs become unbound. Any other libraries or designs that used to bind to the technology data of the overridden library are also be unbound and are saved without a technology section.

It is also an error to copy (or merge) from (or into) lib-cell library. It is also an error to copy over a library that is opened for read-only, or to copy over a library that has unsaved and modified data without using the **-force** option.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example copies library lib1 into the library design_lib.

```
prompt> copy_lib -from_lib "lib1" -to_lib design_lib  
1
```

The following example copies the designs from lib1 and lib2 into the library top_lib.

```
prompt> copy_lib -from_lib "lib1 lib2" -to_lib top_lib  
1
```

The following example merges the designs from lib1 and lib2 into the library mid_lib, without reinitializing mid_lib

```
prompt> copy_lib -merge -from_lib "lib1 lib2" -to_lib mid_lib  
1
```

The following example copies the technology and ref_lib list from lib1 to lib2 without copying the designs.

```
prompt> copy_lib -no_designs -from_lib "lib1" -to_lib lib2  
1
```

copy_mw_lib

Copies a Milkyway library to another location.

SYNTAX

```
status copy_mw_lib
  [-from mw_lib]
  -to lib_name
```

Data Types

<i>mw_lib</i>	string
<i>lib_name</i>	string

ARGUMENTS

-from *mw_lib*

Specifies the name of the source Milkyway library to be copied. The *mw_lib* value can be a library name or a collection of libraries. By default, the command uses the current Milkyway library.

-to *lib_name*

Specifies the destination Milkyway library name.

DESCRIPTION

The **copy_mw_lib** command copies a Milkyway library to another location. It returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example copies a Milkyway library design to another location:

```
prompt> copy_mw_lib -from design -to design.bak
1
```

SEE ALSO

[rename_mw_lib\(2\)](#)

cputime

Reports the CPU time in seconds.

SYNTAX

```
status cputime
      [-all]
      [-verbose]
```

ARGUMENTS

-all

Reports the total CPU time of the main process and its child processes. This is the default; this option is kept for backward compatibility.

-verbose

Reports in detail the CPU time and elapsed (wall-clock) time of the main process and each child process, including placement, extraction, and routing.

DESCRIPTION

The **cputime** command reports the CPU time in seconds. If you specify **-verbose**, it reports the CPU time and elapsed (wall-clock) time for the main process and each child process. The runtime numbers are collected from the operating system.

When you use the **set_host_options** command, the tool runs multiple threads. Currently the operating system measures the CPU time by adding the usage for all threads. It does not take into account parallelization of the threads. This means that the report might show a larger CPU time than elapsed time when you use **set_host_options**. The elapsed time (wall-clock time) is more appropriate for measuring multicore runtime.

The elapsed time depends on many external factors and can vary for every session. It depends on factors such as the I/O traffic, the network traffic, RAM and swap usage, and the other processes running on the same machine. When the elapsed time is much longer than the CPU time, it might point out an inefficiency of the computing environment, such as insufficient memory, too many processes running on the same machine, or a slow network. The only way to make the elapsed time close to the CPU time is to run only one session on a machine with enough RAM and using the local disk.

EXAMPLES

The following example shows the default command output:

```
prompt> cputime
```

1202

The following example shows the output when using the **-verbose** option:

```
prompt> cputime -verbose
Main process CPU: 1202 s (0.33 hr) Elapse: 1800 s (0.50 hr)
Child "placement" called 3 times, total CPU: 200 s (0.06 hr)
  Elapse: 250 s (0.07 hr)
Child "extraction" called 2 times, total CPU: 100 s (0.03 hr)
  Elapse: 150 s (0.04 hr)
Total CPU: 1502 s ( 0.42 hr) Elapse: 1800 s ( 0.50 hr)
```

1523

create_auto_path_groups

Creates path groups for the current design.

SYNTAX

```
string create_auto_path_groups
    -mode rtl | mapped
    [-exclude IO | macro | ICG]
    [-slack slack]
    [-max max]
    [-min_regs_per_hierarchy min_regs]
    [-prefix prefix]
    [-file file_name]
    [-verbose]
    [-user_path_groups_file user_file_name]
    [-skip]
```

Data Types

<i>slack</i>	double
<i>max</i>	int
<i>min_regs</i>	int
<i>prefix</i>	string
<i>file_name</i>	string
<i>user_file_name</i>	string

ARGUMENTS

-mode rtl | mapped

Specifies if paths groups should be created for all hierarchies before optimization (**-mode rtl**) or only for hierarchies that fail timing after optimization (**-mode mapped**).

-exclude IO | macro | ICG

Prevents the generation of specific path groups. Supported values are **macro**, **IO**, and **ICG**. You can specify any combination of values. By default, the command creates path groups for I/Os, macros, and integrated clock-gating cells.

-slack *slack*

Specifies the slack value used to create group paths in mapped mode. The default is 0.0.

-max *max*

Specifies the maximum number of path groups in mapped mode. The default is 0, which means unlimited.

-min_regs_per_hierarchy *min_regs*

Specifies the minimum number of registers per hierarchy to be considered for path groups in **rtl** mode. The default is 10.

-prefix *prefix*

Specifies the prefix of the path groups names. The default is synopsys_pg_.

-file *file_name*

Writes **group_path** commands to the specified file.

-verbose

Activates the verbose mode.

-user_path_groups_file *user_file_name*

Specifies the file to which user path groups are saved. The default is auto_path_groups.user_path_groups.tcl.

DESCRIPTION

Creates path groups automatically for the current design. You can create path groups either after elaboration or after the initial compile.

To create path groups after the design has been elaborated, run the **create_auto_path_groups** command with the **-mode rtl** option. This creates one path group per hierarchy within the design. If there are multiple levels of hierarchy, the tool creates path groups for each level. The advantage of creating path groups at this stage is that the tool can perform all optimizations during the initial compile. However, the number of hierarchical levels within the design can be large, leading to a large number of path groups and causing excessive runtime. Modules that have the **optimize_registers** attribute set on them are excluded to avoid the possibility of **optimize_registers** not working on the modules that have a path group set on them.

To create path groups after the design has successfully completed the initial compile, run the **create_auto_path_groups** command with the **-mode mapped** option. This creates one path group per hierarchy only for those hierarchies within the design that are not meeting timing. If there are multiple levels of hierarchy that are not meeting timing, the tool creates path groups for each of those levels. Fewer path groups are created when you use the **-mode mapped** option compared to the **-mode rtl** option because, in most cases, not all hierarchical blocks violate timing. Only those that fail to meet timing are assigned a separate path group, and therefore the runtime impact is reduced. In most cases, use this flow.

When you use the **-mode mapped** option, you can provide a slack value by specifying the **-slack** option or provide the maximum number of paths by specifying the **-max** option. The default slack value is zero, which means that the command creates path groups for all violating paths. The default maximum number of paths value is zero, which means that the number of path groups is unlimited. When you set the **-max** option to a value other than zero, path groups are created only for hierarchies with the maximum worst violations.

You can control path groups names by using the **-prefix** option. By default, the prefix is synopsys_pg_. For example, path group names by default would be synopsys_pg_0, synopsys_pg_1, and so on.

The generated **group_path** commands are listed in the output file specified by the **-file** option. You can edit the output file and add weight or **critical_range** options on particular path groups.

You can remove path groups generated by the **create_auto_path_groups** command by using the **remove_auto_path_groups** command.

Notes

If the design has inserted clock gates at the GTECH stage, you should run the **create_auto_path_groups** command only after the initial compile (with the **-mode mapped** option). This would lead to the creation of fewer path groups than running the **create_auto_path_groups** command before optimization (with the **-mode rtl** option), resulting in better runtime.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

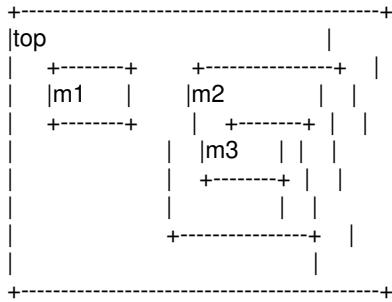

The following example creates path groups after design elaboration and removes them after compile. First, read the RTL, perform analyze and elaborate, and read the SDC constraints.

```
prompt> create_auto_path_groups -mode rtl # creates path groups at pre-compile stage
prompt> compile_ultra
prompt> report_qor                      # reports both user and script-created path groups
prompt> remove_auto_path_groups      # removes only the script-created path groups
prompt> report_qor                      # reports only the user-created path groups
```

The following example creates path groups after compile and removes them after incremental compile. First, read the RTL, perform analyze and elaborate, and read the SDC constraints.

```
prompt> compile_ultra
prompt> create_auto_path_groups -mode mapped # creates path groups at post-compile stage
prompt> compile_ultra -incremental
prompt> report_qor                      # reports both user and script-created path groups
prompt> remove_auto_path_groups      # removes only the script-created path groups
prompt> report_qor                      # reports only the user-created path groups
```

Consider an example with the following design hierarchy:

If paths groups are created after elaboration:

```
prompt> create_auto_path_groups -mode rtl -exclude {IO macro ICG}
INFO: Collecting hierarchies without optimize_registers...
INFO: Creating path groups for hierarchies without optimize_registers...
INFO: group_path -name synopsys_pg_0 -to [get_cells m1/*
-filter "is_hierarchical==false && is_sequential==true"] -priority 1
INFO: group_path -name synopsys_pg_1 -to [get_cells m2/*
-filter "is_hierarchical==false && is_sequential==true"] -priority 1
INFO: group_path -name synopsys_pg_2 -to [get_cells m2/m3/*
-filter "is_hierarchical==false && is_sequential==true"] -priority 1
```

If paths groups are removed after compile:

```
prompt> remove_auto_path_groups
INFO: remove_path_group synopsys_pg_2
INFO: remove_path_group synopsys_pg_1
INFO: remove_path_group synopsys_pg_0
```

If **set_optimize_registers** is set on m2 and paths groups are created after elaboration:

```
prompt> set_optimize_registers [get_designs [get_attribute [get_cells m2] ref_name]] true
prompt> create_auto_path_groups -mode rtl -exclude {IO macro ICG}
INFO: Collecting hierarchies without optimize_registers...
INFO: Creating path groups for hierarchies without optimize_registers...
INFO: group_path -name synopsys_pg_0 -to [get_cells m1/* -filter "is_hierarchical==false &&
is_sequential==true"] -priority 1
```

If paths groups are removed after compile:

```
prompt> remove_auto_path_groups
INFO: remove_path_group synopsys_pg_0
```

SEE ALSO

[remove_auto_path_groups\(2\)](#)

create_block_abstraction

Generates a block abstraction for the current design. The command identifies the interface logic of the current design and annotates the design in memory with the interface logic.

SYNTAX

```
status create_block_abstraction
      [-include objects]
```

Data Types

objects collection

ARGUMENTS

-include *objects*

Specifies the additional leaf cells and nets that are to be included in the block abstraction.

Logical hierarchical cells and pins are ignored.

If either one of the following conditions exist, the entire block is included in the block abstraction:

- The number of leaf cells included exceeds 95 percent of the total leaf cells in the block.
- The number of nets included exceeds 95 percent of the total nets in the block.

DESCRIPTION

This command creates a block abstraction of the current design and annotates the design in memory with the interface logic.

To save the block abstraction, you must use the **write_file** command immediately after creating the block abstraction. The **write_file** command writes the complete design, including the block abstraction information, into a single .ddc file.

Creating a block abstraction by using the **create_block_abstraction** command allows you to perform transparent interface optimization on the block in the top-level flow.

You can create block abstractions in either Design Compiler or Design Compiler in topographical mode. However, you must use topographical mode to optimize block abstractions with transparent interface optimization, and only block abstractions created in topographical mode are optimized.

At the top level, use the **set_top_implementation_options** command to specify which blocks should be integrated with the top-level design as block abstractions.

The **create_block_abstraction** command first determines the interface logic.

The following netlist objects are part of the interface logic:

- All cells, pins, and nets in timing paths from input ports to registers or output ports.
- All cells, pins, and nets in timing paths to output ports from registers or input ports.
- The following clock-gating circuitry:
 - Any logic in the connection from the master clock to the generated clocks.
 - The clock trees that drive interface registers, including any logic in the clock tree.
 - The longest and shortest clock paths from the clock ports.
- The side-load cells of all nonideal and non-DRC disabled nets.

By default, the **create_block_abstraction** command ignores an input or inout port during interface logic identification, if the percentage of the total registers in the transitive fanout of the port is greater than or equal to the threshold percentage specified in the **abstraction_ignore_percentage** variable. (The default is 25.) The ports that are ignored are then connected to already-identified interface logic. Also, minimum and maximum critical timing paths are retained for these ignored ports.

This default helps to identify the test enable and reset ports of your design. Examine the current value of the **abstraction_ignore_percentage** variable and change it, if needed. The default might potentially ignore ports you do not want to ignore or fail to ignore ports that you do want to ignore. Carefully read the messages that the **create_block_abstraction** command issues when you use the default to see which ports have been ignored and to what percentage of registers they fanned out.

The **create_block_abstraction** command implicitly performs an **update_timing** on the design, if required.

The **create_block_abstraction** command ignores case analysis settings, if any, during interface logic identification. You must specify the appropriate case analysis settings at the top level. This is done to make the block abstraction more context independent.

The **create_block_abstraction** command assumes all latches found in the interface logic are potential borrowers; thus, all logic from I/O ports to flip-flops or output ports are identified as belonging to the interface logic.

Multicorner-Multimode Support

This command uses information from all scenarios.

For a multicorner-multimode design,

- The **create_block_abstraction** command automatically detects the presence of multiple scenarios (multiple modes or corners) and determines the interface logic for each scenario. The interface logic identified for each scenario is retained as the interface logic of the block abstraction. If an interface timing path is disabled in one scenario but enabled in another, the path is included in the interface logic.
- Net capacitance, resistance, and annotated delays are stored as part of abstraction information for each specified TLUPlus file and temperature.
- Power consumption of the design is calculated for each scenario. The calculated power data is stored in attributes in the design and can be used by the **report_power** command during the final assembly step of the entire chip.

EXAMPLES

The following example shows how to create and save a block abstraction:

```
prompt> read_ddc MY_DES.compiled.ddc
prompt> create_block_abstraction
prompt> write_file -hierarchy -format ddc -output MY_DES.abstract.ddc
```

SEE ALSO

check_block_abstraction(2)
report_block_abstraction(2)
set_top_implementation_options(2)
```

create_bounds

Creates a fixed move bound or floating group bound in the design.

SYNTAX

```
status create_bounds
[-name bound_name]
[-coordinate {llx1 lly1 urx1 ury1 ...}]
[-dimension bound_dimension]
[-diamond central_object]
[-effort low | medium | high | ultra]
[-type soft | hard]
[-exclusive]
[-color color]
[-cycle_color]
[-repelling diamond | rect]
[-groups list]
object_list
```

Data Types

<i>bound_name</i>	string
<i>llx1</i>	float
<i>lly1</i>	float
<i>urx1</i>	float
<i>ury1</i>	float
<i>bound_dimension</i>	list
<i>central_object</i>	object
<i>color</i>	integer or string
<i>list</i>	object_list
<i>object_list</i>	list

ARGUMENTS

-name *bound_name*

Specifies the name of the bound.

-coordinate {*llx1 lly1 urx1 ury1* ...}

Specifies rectangular move bounds by specifying the coordinates of the lower-left and upper-right corners for each rectangle. The coordinates are in microns relative to the chip origin.

Each combination of $\{llx\ lly\ urx\ ury\}$ defines a target placement area for the objects. The coarse placement engine can place cells in any of the rectangles. These placeable areas can overlap or be disjoint.

You can specify rectilinear move bounds by dividing the rectilinear region into individual rectangular bounds and specifying the rectangles in the coordinate list.

-dimension *bound_dimension*

Specifies the dimension of a group bound or diamond bound in microns. The dimension of a group bound is specified as *{width height}*, while the dimension of a diamond bound is specified as *extent*.

-diamond central_object

Creates a diamond bound centered on the specified object, which can be a port, cell, or pin.

The objects in the bound are constrained to lie within the distance specified by the **-dimension** option (measured as a Manhattan distance) of the specified object. A diamond bound is always a soft bound.

If you specify this option, you must also specify the **-dimension** option.

-effort low | medium | high | ultra

Specifies the effort to bring cells closer inside a group bound.

The default is **medium**.

This option is mutually exclusive with the **-coordinate** and **-dimension** options.

-type soft | hard

Specifies the type of the bound to be either **hard** or **soft**.

To use this option, you must also specify either the **-coordinate** or **-dimension** option. The bound type cannot be set for automatically generated group bounds or diamond bounds.

The default is **soft**.

-exclusive

Creates an exclusive move bound.

Exclusive move bounds require all of their cells to be placed inside them and prohibit the placement of other cells in the same area. Exclusive move bounds are respected by both coarse placement and legalization.

-color color

Specifies the move bound color. You can specify the color either by specifying an integer value between 0 and 63 or by specifying one of the following keywords: **black**, **blue**, **green**, **cyan**, **brown**, **purple**, **red**, **magenta**, **salmon**, **orange**, **yellow**, or **white**.

The default is **no_color**, meaning that no color is specified.

-cycle_color

Allows the tool to automatically assign a move bound color.

By default, this option is **off**.

-repelling diamond | rect

Specifies a bound to be repelling rather than attractive. A repelling bound specifies a floating area between a pair of objects to keep them apart in the bound. You can specify either a diamond-shaped bound (diamond) or a rectangle-shaped bound (rect) for specifying the shape of the repelling bound.

-groups list

Specifies a list of groups containing modules and leaf cells which will obey the repelling bound distance constraint in dual core lock step (DCLS) designs. No ports are allowed in the groups, and an object may not appear in two different groups.

object_list

Specifies a list of cells, ports, and pins to be included in the bound.

- If a cell is a hierarchical cell, the bound applies to all cells in the subdesign.

- If a port is a hierarchical port, the corresponding port is attached to the bound instead.
- If a pin is a leaf pin, the lower-left point of the first geometry of the pin is marked on the cell of the pin, and the cell is added to the bound.
- If a pin is a hierarchical pin, it is ignored.

A cell can be assigned to only one move bound; an error occurs if a specified cell already belongs to another move bound.

This argument is optional; you can create an empty move bound and later associate cells with it by using the **update_bounds** command.

DESCRIPTION

The **create_bounds** command allows you to define region-based placement constraints for coarse placement.

There are three types of bounds: move bounds, group bounds, and diamond bounds.

- Move bounds restrict the placement of cells to a specific region of the core area.

To create a move bound, use the **-coordinate** option.

- Group bounds are floating region constraints. Cells in the same group bound are placed within a specified bound, but the absolute coordinates are not fixed. Instead, they are optimized by the placer.

To create a group bound, use the **-dimension** option.

- Diamond bounds are region constraints centered on a specific object, which can be fixed or floating. Other objects in the same diamond bound are placed within the specified Manhattan distance from the central object but their absolute coordinates are not fixed. Instead, they are optimized by the placer.

To create a diamond bound, use the **-diamond** option together with the **-dimension** option.

If you do not use any of these options, the tool creates a group bound with a bounding box computed internally by the tool. In this case, you can use the **-effort** option to specify the effort level used to bring the cells closer. All automatically generated bounds are soft bounds; you cannot use the **-type** option to change the bound type for these group bounds.

Generally, there is no guarantee that cells are placed completely within the bounds. For instance, coarse placement can violate the bounds if the quality of its primary placement objectives would otherwise be destroyed.

In these situations, you should revisit the bounds and floorplan to ensure that the design is not overconstrained. Alternatively, you can use the **-type hard** option to specify the bound type to be **hard**. The default is **soft**. The coarse placer tries to honor the hard bound as hard constraints while sacrificing other objectives, such as timing and routability. You should not use many hard bounds because this can lead to inferior placement solutions.

The bounds created by the **create_bounds** command are persistent and do not need to be re-created when the design is reloaded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example constrains the placement of the INST_1 instance to lie within the rectangle with its lower-left corner at (100, 100) and its upper-right corner at (200, 200):

```
prompt> create_bounds -name "temp" -coordinate {100 100 200 200} INST_1
```

The following example creates a hard rectilinear move bound on a hierarchical instance named INST2. The rectilinear move bound is created as a set of two rectangles: one with its lower-left corner at (10, 10) and its upper-right corner at (30, 20), and one with its lower-left corner at (20, 20) and its upper-right corner at (30, 30).

```
prompt> create_bounds -name "temp2" \
-coordinate {10 10 30 20 20 20 30 30} \
-type hard INST_2
```

The following example creates a diamond bound centered on the pin MOD/U1/A. The cells MOD/INST1 and MOD/INST2 are constrained to lie at most 64 microns of Manhattan distance away from MOD/U1/A.

```
prompt> create_bounds -name "temp3" \
-dimension 64 \
-diamond MOD/U1/A \
{MOD/INST1 MOD/INST2}
```

SEE ALSO

`remove_bounds(2)`
`report_bounds(2)`
`set_cell_location(2)`
`update_bounds(2)`

create_bsd_patterns

Generates a set of functional patterns for a boundary-scan design.

SYNTAX

```
status create_bsd_patterns
  -output test_program_name
  [-effort low | medium | high]
  [-type pattern_type]
  [-setup_instructions instruction_list]
  [-bsd_test_setup enable | disable]
  [-jtag_reset enable | disable]
```

Data Types

```
test_program_name    string
pattern_type        string
instruction_list    list
```

ARGUMENTS

-output *test_program_name*

Specifies the name of the output test program. On completion, **create_bsd_patterns** writes out the Synopsys pattern database (*test_program_name.vdb*) file that contains the generated patterns and the fault status information. By default, the *test_program_name* is *design_name* and the file is named *design_name.vdb*. This file is placed in the current working directory.

-effort low | medium | high

Controls the effort used to search for implemented instructions if the boundary-scan database has not been previously built by the **check_bsd**, **insert_dft**, or **read_bsdl** command and the tool must infer the implemented instructions. For more information, see the man page for the **check_bsd** command.

-type *pattern_type*

Generates vectors to test the various aspects of the boundary scan of the design.

This option allows you to generate vectors to test bsr, tap, tdr, and reset mechanisms of the boundary scan of the design separately. This option allows generation of leakage vectors and all functional vectors (bsr, tap, tdr, and reset vectors). The option also allows generation of vectors to test AC receivers and transmitters.

You must specify one of the following values:

all generates everything (the default).

functional generates {tap_controller, reset, bsr, tdr, ac_input_pulse, ac_input_train, ac_output_pulse, ac_output_train}.

dc_parametric generates vectors to {bsr, leakage}. Can also be used to measure voltage and current levels for I/O.

tap_controller generates vectors to test the tap finite state machine function.

reset generates vectors to test the asynchronous and synchronous reset mechanism.

tdr generates vectors to test that each instruction implemented selects the corresponding test data register.

bsr generates vectors to test the function of the boundary scan register.

leakage generates vectors to test I/O leakage.

ac_input_pulse generates vectors for AC input tests with EXTEST_PULSE instruction. These vectors test the preset/transition/single ended/dc behaviors of AC receivers and the DC behavior of the AC instruction.

ac_input_train generates vectors for AC input tests with EXTEST_TRAIN instruction. These vectors test the preset/transition/single ended/dc behaviors of AC receivers and the DC behavior of the AC instruction.

ac_output_pulse generates vectors for AC output tests with EXTEST_PULSE instruction. These vectors test the transition behavior of AC drivers with the AC instruction. The vectors also test AC/DC selection cells.

ac_output_train generates vectors for AC output tests with EXTEST_TRAIN instruction. These vectors test the transition behavior of AC drivers with the AC instruction. The vectors also test AC/DC selection cells.

The default behavior is to generate both functional and DC parametric vectors. This is the same as running the command with the **-type all** option.

-setup_instructions *instruction_list*

Specifies one or more user-defined instructions whose associated test data registers are to be initialized at the beginning of the test program.

This method creates a test_setup procedure for the test program that initializes the user-defined test data registers (UTDRs) associated with the specified instructions. The initialization data is be specified with the **-bsd_init_data** option of the **set_bsd_instruction** command.

By default, no test_setup procedure is created. This option is mutually exclusive with the **-bsd_test_setup** option.

-bsd_test_setup enable | disable

Specifies that a custom test_setup procedure to be used for the test patterns.

This method inserts the test_setup section from the provided STIL protocol file into the created patterns. The setup protocol must be read using the **read_test_protocol -section test_setup** command prior to pattern creation.

By default, no test_setup procedure is created. This option is mutually exclusive with the **-setup_instructions** option.

-jtag_reset enable | disable

Specifies whether to enable JTAG reset operations during the test program.

If you are using the **-setup_instructions** or **-bsd_test_setup** option to initialize configuration registers at the beginning of the test program, and the configuration registers are affected by the JTAG reset signal, you can use the **-jtag_reset disable** option to suppress JTAG resets during the test program.

When the **-setup_instructions** option is used, BSD Compiler creates a test_setup procedure that asserts the JTAG reset signal before loading the specified configuration registers, but it suppresses all subsequent JTAG reset signals in the test program.

When the **-bsd_test_setup** option is used, you supply a custom test_setup procedure that is responsible for asserting JTAG reset and initializing the configuration registers. BSD Compiler suppresses all subsequent JTAG reset signals in the test program.

If the **tap_controller** or **reset** type is specified with the **-type** option, the **-jtag_reset disable** option is ignored because the JTAG reset signal must be asserted during these tests. If the **all** type is specified, the **tap_controller** and **reset** tests are omitted from the test program.

This option can only be specified together with the **-setup_instructions** or **-bsd_test_setup** option.

By default, JTAG resets are enabled.

DESCRIPTION

The **create_bsd_patterns** command generates functional test patterns for a boundary-scan design. If the boundary-scan database was not previously built by the **check_bsd**, **insert_dft**, or **read_bSDL** command, the command performs an implicit compliance check before proceeding. If a boundary-scan design is non-compliant, the **create_bsd_patterns** command does not generate any functional vectors. If a boundary-scan design is compliant, the **create_bsd_patterns** command generates functional test patterns to test the synchronous and asynchronous TAP reset, the TAP controller finite state machine, the implemented boundary-scan instructions and associated test data registers, and the boundary-scan register.

If the design contains IEEE 1149.6 logic, the generated functional vectors also include tests for AC receivers and transmitters. Note that these vectors are not generated if compliance checker is run prior to pattern generation.

The test patterns are stored in the Core Test Language (CTL) model for the design, which can be converted to different formats using the **write_test** command.

EXAMPLES

The following example performs functional testbench generation on the current design and writes out the bscan.vdb Synopsys pattern database:

```
prompt> create_bsd_patterns -out bscan
Loading db file '/u/root_dir/libraries/my_class.db'
Loading design 'M1'
...Starting IEEE 1149.1 Compliance Checking.
...Inferring the boundary scan protocol for the design 'M1'.
...Generating the BSD test patterns for the design 'M1'.
....Generating vectors to test the asynchronous test logic reset.
....Generating vectors to test the synchronizing sequence of 5 1's on tms.
....Generating vectors to test the TAP FSM.
....Generating vectors to test boundary scan instructions.
.....Generating vectors to test the 'BYPASS' instruction.
.....Generating vectors to test the 'EXTEST' instruction.
.....Generating vectors to test the 'SAMPLE' instruction.
.....Generating vectors to test the 'CLAMP' instruction.
.....Generating vectors to test the 'HIGHZ' instruction.
.....Generating vectors to test the 'IDCODE' instruction.
.....Generating vectors to test the boundary scan register.
...Writing test program bscan to file /tmp/bsdvec/bscan.vdb.
```

BSD test patterns are generated successfully.

create_buffer_tree

Creates a buffer tree for the specified driver pins and nets.

SYNTAX

```
status create_buffer_tree
  [-from pin_net_list]
  [-incremental]
  [-no_legalize]
  [-on_route [-skip_detail_route]]
  [-align_hierarchy_for_long_nets]
```

Data Types

pin_net_list collection

ARGUMENTS

-from *pin_net_list*

Specifies the driver pins and nets for which the tool creates buffer trees. When the **-from** option is not specified, the **create_buffer_tree** command works on all drivers with a transitive fanout of 5 or more.

-incremental

Sets the scope of creating the buffer tree for the specified nets rather than the entire buffer tree driven by the specified nets. When this option is specified, the **create_buffer_tree** command constructs a buffer tree, if needed, on each net specified by the **-from** option to reduce the high fanout of each net, but it does not remove any existing buffers or inverters. So, the scope of creating buffer trees is a single specified net.

-no_legalize

Disables placement legalization at the end of buffering. By default Design Compiler does not do placement legalization so the option doesn't have any effect.

-on_route

Perform the postroute optimization flow, where it fixes DRC violations by using the route_opt command and then the focal_opt command. It focuses mainly on fixing maximum net length, so you need to specify the max_net_length constraint by using the set_max_net_length command, before using this option. The final database is a detail routed database.

It is recommended to use the **-align_hierarchy_for_long_nets** option with the **-on_route** option to ensure that optimization occurs for long nets crossing logical hierarchies.

You can use the **-from** option with this option to fix DRC violations for the concentrated nets. However, if you use the **-from** option, the design must be detail routed and you cannot use the **-skip_detail_route** or **-align_hierarchy_for_long_nets** options.

This option is not supported in Design Compiler topographical mode and will be ignored.

-skip_detail_route

Skips detail routing when used with the **-on_route** option. By default the **-on_route** option triggers full detail routing after topology-based DRC optimization. This option can reduce runtime of the **on_route** option by skipping the final detail route.

This option can only be used with the **-on_route** option. This option cannot be combined with the **-from** option.

This option is not supported in Design Compiler topographical mode and will be ignored.

-align_hierarchy_for_long_nets

Enables additional optimizations and port punching for long nets that crosses multiple hierarchies. Long nets are those nets that violate the maximum net length constraint for the design. You can specify `max_net_length` constraint via command `set_max_net_length` before using this option. If you use this option and the design does not have a maximum net length constraint, the command fails with an error message.

When you use this option, the tool first performs high-fanout net fixing and also fixing DRC violations, such as maximum transition and capacitance, for low fanout nets. It then performs preroute topology-based buffering and port punching for the nets that violate the maximum net length constraint and crosses multiple hierarchies. If both of these conditions are not met, this additional optimization is not performed.

This option does not fix all maximum net length constraint. You have to rely on the **-on_route** option to fix the remaining violations.

This option can be used alone or with the **-on_route** option, but it cannot be used with the **-from** options.

This option is not supported in Design Compiler topographical mode and will be ignored.

DESCRIPTION

The **create_buffer_tree** command creates a buffer tree for each specified driver pin and for the driver pin of each specified net.

The **create_buffer_tree** command generates a hierarchical buffer tree, and buffers are inserted across hierarchical boundaries. The command is location-based. Therefore, the specified driver pin should not be a hierarchical pin because a hierarchical pin does not have a location.

Use this command on a placed design only. The command requires the following libraries and information:

- The physical libraries that correspond to the specified logic libraries.
- The capacitance and resistance per unit length derived from the physical library or user-specified.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example creates a buffer tree that is implemented at driver a/O:

```
prompt> create_buffer_tree -from [get_pins a/O]
```

The following example creates buffer trees for driver a/O and net n1:

```
prompt> create_buffer_tree -from {[get_pins a/O] [get_nets n1]}
```

`remove_buffer_tree(2)`
`report_buffer_tree(2)`
`report_ahfs_options(2)`
`report_net_fanout(2)`
`set_ahfs_options(2)`

create_bus

Creates a port bus or a net bus.

SYNTAX

```
status create_bus
  object_list
  bus_name
  [-type type_name]
  [-sort]
  [-no_sort]
  [-start start_bit]
  [-end end_bit]
```

Data Types

```
object_list    list
bus_name      string
type_name     string
start_bit     integer
end_bit       integer
```

ARGUMENTS

object_list

Specifies a list of ports or nets to be put into a bus. If both ports and nets have the same names, the ports are put into the bus.

This option is required.

bus_name

Specifies the name of the bus. This name cannot be the same as any other bus or object of the same type. Port bus names must be different from the names of ports, and net bus names must be different from the names of nets.

This option is required.

-type *type_name*

Assigns the specified *type_name* to the bused port. Valid types are port or net. This name appears in port declarations when a design with the bused ports is written to a file in the VHDL format. All buses that are assigned the same type name must be the same width (contain the same number of members).

-sort

Sorts the bits of the bus specified in *object_list* in alphanumeric order. By default, bits sort in reverse alphanumeric order.

-no_sort

Specifies that the order of the bits in the bus should be the same as specified on the command line. By default, bits sort in reverse alphanumeric order.

-start *start_bit*

Specifies the start bit for the bus.

-end *end_bit*

Specifies the end bit for the bus.

DESCRIPTION

The **create_bus** command creates a bus object of the type port or net. The number of objects in the list determines the bus width. Buses appear as multibit ports on a design or as multiwire nets in a design. This command groups any number of ports or any number of nets into a bus object. Unless the **-sort** or **-no_sort** option is selected, the specified objects are sorted by reverse alphanumeric order of names before the bus is created.

When using Design Vision to create a design schematic, bused nets are inferred from bused ports or pins in the design. Bused nets only appear as nets in a schematic if they are connected to a bused port.

If the start bit and end bit for the bus are specified with the **-start** and **-end** options, the bus is created with these start and end indices. If only the start bit is specified, an upward-going bus starting at that start bit is built. If only the end bit is specified, an upward-going bus ending at that end bit is built.

EXAMPLES

This example groups the A1, A2, and A3 ports into a bus named *A*. The ports must already exist. The order in which the ports appear in the bus is A3, A2, A1.

```
prompt> create_bus {A1 A2 A3} A
```

This example groups the B1, B2, and B3 nets into a bus named *B*. The nets must already exist and there must not be any ports with the same names. The order in which the nets appear in the bus is B3, B2, B1.

```
prompt> create_bus {B1 B2 B3} B
```

This example groups the C1, C2, and C3 nets into a bus named *C*. The nets must already exist and because the object *net* is defined in the **get_nets** command, it does not matter if there are ports with the same name. The order in which the nets appear in the bus is C3, C2, C1.

```
prompt> create_bus [get_nets C1 C2 C3] C
```

This example groups the existing D1, D2, and D3 ports into a bus named *D* and assigns the 3-bit type to the bus:

```
prompt> create_bus {D1 D2 D3} D -type "3-bit"
```

This example groups the existing D1, D2, and D3 ports into a bus named *D* and assigns it the index range 6-to-4. Port D1 is assigned index 6, port D2 to index 5, and port D3 to index 4.

```
prompt> create_bus {D1 D2 D3} D -start 6 -end 4
```

This example groups the E1, E2, and GH ports into a bus named *E*. The ports must already exist. Because the **-sort** option is used, the first bit is port E1, the second bit is port E2, and the third bit is port GH.

```
prompt> create_bus {E2 GH E1} E -sort
```

This example groups the R1, R2, and GH ports into a bus named *R*. The ports must already exist. Because the **-no_sort** option is used, the first bit is port R1, the second bit is port R2, and the third bit is port GH.

```
prompt> create_bus {R1 R2 GH} R -no_sort
```

This example groups the ports in the MID subdesign into a bus named *NEW*. U1 is a unique instantiation of MID.

```
prompt> create_bus {U1/R1 U1/R2 U1/GH} NEW -no_sort
```

This example groups the nets in the MID subdesign into a bus named *NET_BUS*. U1 is a unique instantiation of MID.

```
prompt> create_bus [get_nets U1/R1 U1/R2 U1/GH] NET_BUS -no_sort
```

SEE ALSO

`get_nets(2)`
`remove_bus(2)`
`report_bus(2)`

create_cell

Creates leaf or hierarchical cells in the current design or its subdesigns.

SYNTAX

```
status create_cell
      cell_list
      [reference_name]
      [-hierarchical]
      [-logic 0 | 1]
      [-only_physical]
```

Data Types

<i>cell_list</i>	list
<i>reference_name</i>	string

ARGUMENTS

cell_list

Specifies the names of cells created in the current design. Each cell name must be unique within the current design.

reference_name

Specifies the design or library cell that new cells reference. You must specify the *reference_name* unless you use the **-logic** option. Ports on the reference determine the name, number, and direction of pins on the new cell.

-hierarchical

Creates hierarchical cell instances and designs with the name given by *cell_list* if the *reference_name* is not specified.

If you specify the *reference_name*, the *cell_list* must have a single element. The command creates the hierarchical cell instance with the name given by the single *cell_list* and also creates the design with the name given by *reference_name*.

-logic 0 | 1

Specifies that the new cell generates a logic 0 or logic 1 value. The logic value must be either **0** or **1**. By using this option, the cell contains a single output pin. By default, this option is off.

-only_physical

Creates a new physical or physical-only cell using a reference from the physical library. The **-only_physical** option sets the *is_physical_only* attribute on the created physical-only cell. After you create a physical-only cell, you must assign a location to that cell. Unlike physical cells with logic functions, the tool does not assign a location to a physical-only cell during synthesis. To assign a location, use the **set_cell_location** command, Tcl commands, or a DEF file. By default, this option is off.

DESCRIPTION

This command creates new leaf or hierarchical cells in the current design or its subdesigns based on the *cell_list* argument. New leaf cells are the instantiation of an existing design or library cell. New hierarchical cells are the instantiation of a new design. New cells are the instantiation of an existing design, a library cell, a logic 0 generator, or a logic 1 generator.

The created cells are unplaced. To be viewed properly in the GUI, the cells must be placed either manually by using the **set_cell_location** command or automatically by using placement commands.

To remove cells from the current design, use the **remove_cell** command.

Although the *reference_name* argument accepts names in the format *library/library_cell*, the command might not instantiate the actual library cell from the specified library. The actual library cell to be used is determined by the current link library settings.

EXAMPLES

The following example creates a cell named *cell1* under the subdesign corresponding to the *mid1* cell:

```
prompt> create_cell {mid1/cell1} my_lib/AND2
Creating cell 'cell1' in design 'mid'.
```

The following example creates a cell named *cell2* in the design corresponding to the *m1/U1* and *m2/U1* instances. The cell names *cell2* is a logic 0 generator. The design corresponding to *m1/U1* and *m2/U1* must be unique.

```
prompt> create_cell {m1/U1/cell2 m2/U1/cell2} -logic 0
```

The following example creates cells using existing designs as references:

```
prompt> create_design ALPHA
prompt> current_design ALPHA
prompt> create_cell U1 ADDER
prompt> create_cell U2 SUBTRACTOR
```

The following example creates logic 1 and logic 0 cells:

```
prompt> create_cell LOGIC_ONE -logic 1
prompt> create_cell LOGIC_ZERO -logic 0
```

The following example creates leaf cells using library cells as references.

```
prompt> create_cell {U3 U4} my_lib/NAND2
prompt> create_cell "U5" my_lib/NOR2
```

The following example creates hierarchical cell *H1* with the new design name *DESIGN1*, and creates leaf cell *U2* under the new hierarchical cell using library cells as references:

```
prompt> create_cell -hierarchical H1 DESIGN1
prompt> create_cell H1/U2 my_lib/NAND2
```

The following example creates hierarchical cells *H2* and *H3* with the design name *H2* and *H3* separately. Also, it creates leaf cell *U3* under the new hierarchical cell *H2* using library cells as references.

```
prompt> create_cell -hierarchical {H2 H3}
```

```
prompt> create_cell H2/U3 my_lib/NAND2
```

The following example creates physical cells using physical library cells as references:

```
prompt> create_cell -only_physical {U3 U4} lib.pdb:my_lib/pad0
```

```
prompt> create_cell -only_physical phys_inst1 test_lib.pdb:mylib/PAD0
```

SEE ALSO

`remove_cell(2)`
`report_cell(2)`
`set_cell_location(2)`

create_clock

Creates a clock object and defines its waveform in the current design.

SYNTAX

```
status create_clock
  [-name clock_name]
  [-add]
  [source_objects]
  [-period period_value]
  [-waveform edge_list]
  [-comment comment_string]
```

Data Types

<i>clock_name</i>	string
<i>source_objects</i>	list
<i>period_value</i>	float
<i>edge_list</i>	list
<i>comment_string</i>	string

ARGUMENTS

-name *clock_name*

Specifies the name of the clock being created. If you do not use this option, the clock is given the same name as the first clock source specified in *source_objects*. If you do not use *source_objects*, you must use this option, which creates a virtual clock not associated with a port or pin. Use this option along with *source_objects* to give the clock a more descriptive name than that of the pin or port where it is applied.

If you specify the **-add** option, you must use the **-name** option and the clocks with the same source must have different names.

-add

Specifies whether to add this clock to the existing clock or to overwrite the existing clock. Use this option to capture the case where multiple clocks must be specified on the same source for simultaneous analysis with different clock waveforms. When you specify this option, you must also use the **-name** option. Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the synthesis timing engine must explore all possible combinations of launch and capture clocks. Use the **set_false_path** command to disable unwanted clock combinations. This option is ignored (the default), unless multiple clocks analysis is enabled by setting the **timing_enable_multiple_clocks_per_reg** variable to **true**.

source_objects

Specifies a list of pins or ports on which to apply this clock. If you do not use this option, you must use **-name** *clock_name*, which creates a virtual clock not associated with a port or pin. If you specify a clock on a pin that already has a clock, the new clock replaces the old clock unless you use the **-add** option.

-period *period_value*

Specifies the period of the clock waveform in library time units.

-waveform edge_list

Specifies the rise and fall edge times, in library time units, of the clock over an entire clock period. The first time in the list is a rising transition, typically the first rising transition after time zero. There must be an even number of increasing times, and they are assumed to be alternating rise and fall times. The numbers must represent one full clock period. If **-waveform edge_list** is not specified, but **-period period_value** is, a default waveform with a rise edge of 0.0 and a fall edge of *period_value*/2 is assumed.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

DESCRIPTION

The **create_clock** command creates a clock object in the current design. The command defines the specified *source_objects* as clock sources in the current design. A pin or port can be a source for a single clock. If *source_objects* is not specified, but a *clock_name* is given, a virtual clock is created. A virtual clock can be created to represent an off-chip clock for input or output delay specification. For more information about input and output delay, refer to the **set_input_delay** and **set_output_delay** command man pages.

Clock objects hold attributes that affect the clock network, such as **dont_touch_network**, **fix_hold**, and **propagated_clock**. Using **create_clock** on an existing clock object overwrites the attributes previously set on the clock object. The **create_clock** command also defines the waveform for the clock. The clock can have multiple pulses per period. Setup and hold path delays are automatically derived from the clock waveforms of the path startpoint and endpoint. The **fix_hold** attribute (set by the **set_fix_hold** command) directs **compile** to fix hold violations for a clock.

By default, a new path group is created for the clock. This groups together the endpoints related to this clock for cost function calculation. To remove the clock from its assigned group, use the **group_path** command to reassign the clock to another group or to the default path group. For more information, refer to the **group_path** command man page.

The new clock has ideal timing, so no propagation delay through the clock network is assumed. To enable propagation delay through the clock network, use the **set_propagated_clock** command. To add skew or uncertainty to the ideal waveform, use the **set_clock_latency** or **set_clock_uncertainty** command.

To show information about all clock sources in a design, use the **report_clock** command. To get a list of clock sources, use the **get_clocks** command. To return sequential cells related to a given clock, use the **all_registers** command. To undo **create_clock**, use the **remove_clock** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates a clock on port *PHI1* with a period of 10.0, rise at 5.0, and fall at 9.5:

```
prompt> create_clock "PHI1" -period 10 -waveform {5.0 9.5}
```

In the following example, the clock has a falling edge at 5 and a rising edge at 10, with a period of 10. Because the **-waveform** option expects the edges to be ordered first rise then fall, and to increase in value, the fall edge can be given as 15; that is, the next falling edge after the first rise edge at 10.

```
prompt> create_clock "PHI2" -period 10 -waveform {10 15}
```

The following example creates a clock named *CLK* on pin *u13/Z*, with a period of 25, fall at 0.0, rise at 5.0, fall at 10.0, rise at 15.0, and so forth:

```
prompt> create_clock "u13/Z" -name "CLK" -period 25 -waveform {5 10 15 25}
```

The following example creates a virtual clock named *Hl2* with a period of 10.0, rise at 0.0, and fall at 5.0:

```
prompt> create_clock -name "PHl2" -period 10 -waveform {0.0 5.0}
```

The following example creates a clock with multiple sources and a complex waveform:

```
prompt> create_clock -name "clk2" -period 10 -waveform {0.0 2.0 4.0 6.0} \
{clkgen1/Z clkgen2/Z clkgen3/Z}
```

create_command_group

Creates a new command group.

SYNTAX

```
string create_command_group
  [-info info_text]
  group_name
```

ARGUMENTS

-info *info_text*

Help string for the group

group_name

Specifies the name of the new group.

DESCRIPTION

The **create_command_group** command is used to create a new command group, which you can use to separate related user-defined procedures into functional units for the online help facility. When a procedure is created, it is placed in the "Procedures" command group. With the **define_proc_attributes** command, you can move the procedure into the group you created.

The *group_name* can contain any characters, including spaces, as long as it is appropriately quoted. If *group_name* already exists, **create_command_group** quietly ignores the command. The result of **create_command_group** is always an empty string.

EXAMPLES

The following example demonstrates the use of the **create_command_group** command:

```
prompt> create_command_group {My Procedures} -info "Useful utilities"
prompt> proc plus {a b} { return [expr $a + $b] }
prompt> define_proc_attributes plus -command_group "My Procedures"
prompt> help
My Procedures:
  plus
```

...

SEE ALSO

`define_proc_attributes(2)`

`proc(2)`

create_core_area

Defines the core area for the current design.

SYNTAX

```
status create_core_area
  -coordinate {{llx lly} {urx ury}}
  [-tile_name tile_name]
  [-direction horizontal | vertical]
  [-name core_name]
```

Data Types

<i>llx</i>	integer
<i>lly</i>	integer
<i>urx</i>	integer
<i>ury</i>	integer
<i>tile_name</i>	string
<i>core_name</i>	string

ARGUMENTS

-coordinate {{*llx lly*} {*urx ury*}}

Specifies a rectangular core area based on the specified lower-left and upper-right coordinates.

-tile_name *tile_name*

Specifies a unit tile for the core area.

-direction horizontal | vertical

Specifies the direction for the tiles. Tiles are added in rows to create the core area.

-name *core_name*

Specifies the core name. Design Compiler topographical mode does not support this option. The tool ignores any name specified by this option.

DESCRIPTION

The **create_core_area** command is deprecated. Use the **create_site_row** command to create a core area.

The **create_core_area** command defines the core area for the current design. The command cannot overwrite any previously-specified core area. The tool issues a warning for this condition.

EXAMPLES

The following example shows how to create a core area:

```
prompt> create_core_area -coordinate {{0 0} {200 200}}
```

SEE ALSO

`create_site_row(2)`
`remove_core_area(2)`

create_design

Creates a design in dc_shell memory.

SYNTAX

```
status create_design
      design_name
      [file_name]
```

Data Types

```
design_name   string
file_name     string
```

ARGUMENTS

design_name

Specifies the name of the design to be created. A *design_name* must be unique within the default file unless *file_name* is specified.

file_name

Specifies the name of the file in which the new design is placed. The *file_name* argument is optional. By default, the design is placed in *design_name.db* in the current directory. The file is not written by **create_design**. The design is placed in a default file in dc_shell.

DESCRIPTION

The *create_design* command creates a new design in dc_shell. The new design created is empty. A new design contains no sub-objects. Sub-objects can be created with the **create_bus**, **create_cell**, **create_net**, and **create_port** commands. To make the new design the working design in dc_shell, use the **current_design** command. To remove designs from dc_shell, use the **remove_design** command.

EXAMPLES

The following example uses **create_design** to create a design:

```
prompt> create_design ADDER
prompt> list_designs
```

```
prompt> current_design ADDER
```

The following example specifies the default file for the new design:

```
prompt> create_design SUBTRACTOR "/tmp/blat.db"
```

```
prompt> list_designs -show_file
```

In the following example, **create_design** specifies a nonunique design name:

```
prompt> create_design example
```

```
prompt> create_design example
```

`remove_port(2)`

create_dft_netlist

Creates a DFT netlist from the current design.

SYNTAX

```
status create_dft_netlist
      -type extest
```

ARGUMENTS

-type extest

Specifies the type of DFT netlist to create. There is only one valid type supported:

- **-type extest**

This DFT netlist type removes all logic in the design except that needed to operate in the outward-facing EXTEST mode. Only the following logic types are kept: wrapper chains and wrapper control logic, interface logic between wrapper chains and I/O ports, test mode decode logic, and 1500 controller and any other logic required for EXTEST operation.

This DFT netlist type is supported only for wrapped cores.

DESCRIPTION

The **create_dft_netlist** command creates a DFT netlist from the current design. Currently only one type, **extest**, is supported.

This command modifies the current design in memory. After running it, write out the DFT netlist file using the **write -format verilog** command. Because the **create_dft_netlist** command removes logic from the design in memory, these should be the last steps in your core creation script.

This command cannot be used in an ILM generation flow.

EXAMPLES

The following example creates and writes out an EXTEST-only netlist after writing the full-netlist design files:

```
# preview and insert DFT
preview_dft -test_wrappers all
insert_dft

# write block-level files
write -hierarchy -format ddc -output block_1.ddc
```

```
write_test_model -format ddc -output block_1.ctlddc  
# write an EXTEST-only netlist  
create_dft_netlist -type extest  
write -format verilog -hierarchy -output block_1_EXTEST.vg
```

SEE ALSO

[set_wrapper_configuration\(2\)](#)
[write\(2\)](#)

create_die_area

Creates the die area for the current design.

SYNTAX

```
status create_die_area
      -coordinate list
      -polygon list
```

ARGUMENTS

DESCRIPTION

The **create_die_area** command creates the die area for the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates the die area with an L-shape by defining a polygon:

```
prompt> create_die_area -polygon {{0 0} {0 400} {200 400} {200 200} \
      {400 200} {400 0} {0 0}}
```

SEE ALSO

[get_die_area\(2\)](#)
[remove_die_area\(2\)](#)

create_failsafe_fsm_group

Creates one failsafe_fsm_group

SYNTAX

```
status create_failsafe_fsm_group
    -rule failsafe_fsm_rule
    [-name group_name]
    [-registers registers]
    [-parity par_registers]
    [-synchronizer sync_register]
    [-error_signal signal]
```

Data Types

<i>failsafe_fsm_rule</i>	string
<i>group_name</i>	string
<i>registers</i>	collection
<i>par_registers</i>	collection
<i>sync_register</i>	collection
<i>signal</i>	object

ARGUMENTS

-rule *failsafe_fsm_rule*

Specifies the failsafe fsm rule based on which this group needs to be created.

-name *group_name*

Name of the new failsafe_fsm_group. If not specified, the name will be automatically generated by the tool.

-registers *registers*

Specifies the collection of state registers of the group.

-parity *par_registers*

Specifies the collection of parity register of the group.

-synchronizer *sync_register*

Specifies the synchronizer associated with the group only if there's one.

-error_signal *signal*

Specifies the error_signal provided by the user for that particular group.

DESCRIPTION

This command creates one failsafe_fsm_group based on the given parameters. It stores the reference to the original failsafe fsm rule which was honored to create it.

EXAMPLES

The following example creates a failsafe_fsm_group.

```
prompt> create_failsafe_fsm_group -rule rule1 \
      -registers {flop1 flop2 flop3} \
      -encoding_style hamming2
      -name group1
```

SEE ALSO

[create_failsafe_fsm_rule\(2\)](#)
[report_failsafe_fsm_rules\(2\)](#)

create_failsafe_fsm_rule

Creates one failsafe_fsm_rule

SYNTAX

```
status create_failsafe_fsm_rule
  [-name rule_name]
  [-encoding_style encoding_style]
  [-error_detection_synchronizer]
  [-distance values]
  [-register_mapping lib_cell_list]
  [-fit_rate_threshold fit_rate_threshold]
```

Data Types

<i>rule_name</i>	string
<i>encoding_style</i>	string
<i>values</i>	list
<i>lib_cell_list</i>	collection
<i>fit_rate_threshold</i>	float

ARGUMENTS

-name *rule_name*

Optionally specifies the name of the rule to be created. If not specified, a name will be automatically generated and assigned.

-encoding_style *encoding_style*

Specifies the encoding_style on the rule.

-error_detection_synchronizer

Optionally specifies that synchronizer register is needed. By default, there's no synchronizer register.

-distance *values*

Specifies the distance values for repelling bound constraint for redundancy group. It could be either in the form of an {x y} pair or a single number denoting radial distance. The values are in user units. The values cannot be negative. The distances are measured edge-to-edge, or in other words, from the boundary of one register to the closest boundary of another. For -type dual_mode or triple_mode, this option must be specified. For -type fault_tolerant, this option is unnecessary and will be ignored.

Specifying the {x y} distance pair means that either "x" or "y" separation must be honored. In other words, each pair of registers in the group should be either "x" distance apart measured on X-axis, or "y" distance apart measured on Y-axis. This will effectively create a rectangular keep-out region around each register, in which it is forbidden to place another register of the same group. It is allowed to specify a distance of zero for "x" or "y", but not for both simultaneously.

Specifying the single "r" value means that the Manhattan distance between each pair of registers in the group should be at least "r". The Manhattan distance between two redundancy registers is defined as the sum of the vertical distance and horizontal distance between their closest edges. Specifying a radial distance thus creates an octagonal keep-out region around each register, wherein another register of the same group must not be placed. For cells in the same column, the horizontal distance is 0. For cells in the

same row, the vertical distance is 0. This "r" value cannot be zero.

-register_mapping *lib_cell_list*

Optionally specifies the list of lib_cells for mapping.

DESCRIPTION

This command creates a new failsafe_fsm_rule based on the options specified. This rule can be then applied to safety-critical registers. The rule can specify replacement of the register either to another fault-tolerant register, or by a group of redundant registers. In latter case, the minimum separations between the redundant registers can be specified which can be considered by the placement engine. If the pins of the redundant registers should be split to different branches of trees, the types to be considered can also be specified.

EXAMPLES

The following example creates a failsafe_fsm_rule.

```
prompt> create_failsafe_fsm_rule -name FSM_RULE1 \
    -distance 10 \
    -encoding_style hamming2 \
    -error_detection_synchronizer
```

create_generated_clock

Creates a generated clock object.

SYNTAX

```
string create_generated_clock
  [-name clock_name]
  [-add]
  source_objects
  -source master_pin
  [-master_clock clock]
  [-divide_by divide_factor
    | -multiply_by multiply_factor]
  [-duty_cycle percent]
  [-invert]
  [-preinvert]
  [-edges edge_list]
  [-edge_shift edge_shift_list]
  [-combinational]
  [-comment comment_string]
```

Data Types

<i>clock_name</i>	string
<i>source_objects</i>	list
<i>master_pin</i>	list
<i>clock</i>	string
<i>divide_factor</i>	integer
<i>multiply_factor</i>	integer
<i>percent</i>	float
<i>edge_list</i>	list
<i>edge_shift_list</i>	list
<i>comment_string</i>	string

ARGUMENTS

-name *clock_name*

Specifies the name of the generated clock. If you do not use this option, the clock receives the same name as the first clock source specified in the **-source** option. If you specify the **-add** option, you must use the **-name** option and the clocks with the same source must have different names.

-add

Specifies whether to add this clock to the existing clock or to overwrite. Use this option to capture the case where multiple generated clocks must be specified on the same source, because multiple clocks fan into the master pin. Ideally, one generated clock must be specified for each clock that fans into the master pin. If you specify this option, you must also use the **-name** option.

Defining multiple clocks on the same source pin or port causes longer runtime and higher memory usage than a single clock, because the synthesis timing engine explores all possible combinations of launch and capture clocks. Use the **set_false_path**

command to disable unwanted clock combinations. This option is ignored by default, unless multiple clocks analysis is enabled by setting the **timing_enable_multiple_clocks_per_reg** variable to **true**.

source_objects

Specifies a list of ports or pins defined as generated clock source objects.

-source master_pin

Specifies the master clock pin, which is either a master clock source pin or a pin in the fanout of the master clock and driving the generated clock definition pin. The clock waveform at the master pin is used for deriving the generated clock waveform.

-master_clock clock

Specifies the master clock to be used for this generated clock if multiple clocks fan into the master pin.

-divide_by divide_factor

Specifies the frequency division factor. If the *divide_factor* is 2, the generated clock period is twice as long as the master clock period.

-multiply_by multiply_factor

Specifies the frequency multiplication factor. If the *multiply_factor* is 3, the period is one third as long as the master clock period.

-duty_cycle percent

Specifies the duty cycle (in percent), if frequency multiplication is used. This is a number between 0 and 100. The duty cycle is the high pulse width.

-invert

Inverts the generated clock signal regardless of whether the sense of the source clock on the master pin is unate or non-unate (in case of frequency multiplication and division).

-preinvert

Creates a generated clock based on the inverted clock signal only when the source clock on the master pin has a non-unate sense, or the generated clock will not be inverted just as this option has not been specified. The difference between the **-invert** option and the **-preinvert** option is that the **-invert** option first creates the generated clock, then inverts the signal, and the **-preinvert** option first inverts the signal, and then creates the generated clock signal.

-edges edge_list

Specifies a list of positive integers that represents the edges from the source clock that are to form the edges of the generated clock. The edges are interpreted as alternating rising and falling edges and each edge must be not less than its previous edge. The number of edges must be an odd number and not less than 3 to make one full clock cycle of the generated clock waveform. The first edge must be greater than or equal to 1. For example, 1 represents the first source edge, 2 represents the second source edge, and so on.

-edge_shift edge_shift_list

Specifies a list of floating-point numbers that represents the amount of shift, in library time units, that the specified edges are to undergo to yield the final generated clock waveform. The number of edge shifts specified must be equal to the number of edges specified. The values can be positive or negative, with positive indicating a shift later in time, and negative a shift earlier in time. For example, 1 indicates that the corresponding edge is to be shifted by 1 library time unit.

-combinational

Specifies that the source latency paths for this type of generated clock only includes the logic where the master clock propagates along combinational paths. The source latency paths will not flow through sequential element clock pins, transparent latch data pins, or the source pins of other generated clocks.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

DESCRIPTION

The **create_generated_clock** command creates a generated clock object in the current design. This command defines a list of objects as generated clock sources in the current design. You can specify a pin or a port as a generated clock object. The command also specifies the clock source from which it is generated. The advantage of using this command is that whenever the master clock changes, the generated clock changes automatically.

The generated clock can be created as a frequency-divided clock with the **-divide_by** option, a frequency-multiplied clock with **-multiply_by**, or an edge-derived clock with **-edges**. In addition, the frequency-divided or frequency-multiplied clock can be inverted with the **-invert** option. The shifting of edges of the edge-derived clock is specified with the **-edge_shift** option. The **-edge_shift** option is used for intentional edge shifts and not for clock latency. If a generated clock is specified with a *divide_factor* that is a power of 2 (1, 2, 4, ...), the rising edges of the master clock are used to determine the edges of the generated clock. If the *divide_factor* is not a power of 2, the edges are scaled from the master clock edges.

Using **create_generated_clock** on an existing **generated_clock** object overwrites the attributes of the **generated_clock** object.

The **generated_clock** objects are expanded to real clocks at the time of analysis.

The following commands can reference the generated_clock:

```
set_clock_latency
set_clock_uncertainty
set_propagated_clock
set_clock_transition
```

To display information about generated clocks, use the **report_clock** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates a frequency **-divide_by** 2 generated clock:

```
prompt> create_generated_clock -divide_by 2 \
      -source CLK [get_pins test]
```

The following example creates a frequency **-divide_by** 3 generated clock. If the master clock period is 30, and the master waveform is {24 36}, the generated clock period is 90 with waveform {72 108}.

```
prompt> create_generated_clock -divide_by 3 \
      -source CLK [get_pins div3/Q]
```

The following example creates a frequency **-multiply_by** 2 generated clock with a duty cycle of 60%:

```
prompt> create_generated_clock -multiply_by 2 \
      -duty_cycle 60 -source CLK [get_pins test1]
```

The following example creates a frequency **-multiply_by** 3 generated clock with a duty cycle equal to the master clock duty cycle. If the master clock period is 30, and the master waveform is {24 36}, the generated clock period is 10 with waveform {8 12}.

```
prompt> create_generated_clock -multiply_by 3 \
      -source CLK [get_pins div3/Q]
```

The following example creates a generated clock whose edges are edges 1, 3, and 5 of the master clock source. If the master clock period is 30, and the master waveform is {24 36}, the generated clock period is 60 with waveform {24, 54}.

```
prompt> create_generated_clock -edges {1 3 5} \
-source CLK [get_pins test2]
```

The following example shows the generated clock in the previous example with each derived edge shifted by 1 time unit. If the master clock period is 30, and the master waveform is {24 36}, the generated clock period is 60 with waveform {25, 55}.

```
prompt> create_generated_clock -edges {1 3 5} \
-edge_shift {1 1 1} -source CLK [get_pins test2]
```

The following example creates an inverted clock:

```
prompt> create_generated_clock -divide_by 2 -invert
```

create_lib

Creates a design library.

SYNTAX

```
status create_lib
  [-technology tech_path
   | -use_technology_lib tech_lib_name]
  [-scale_factor scale_factor]
  [-ref_libs ref_libs]
  [-convert_sites site_name_pairs_list]
  [-base_library_path base_library_path]
  library_name
```

Data Types

<i>tech_path</i>	string
<i>tech_lib_name</i>	string
<i>scale_factor</i>	int
<i>ref_libs</i>	list
<i>site_name_pairs_list</i>	list
<i>base_library_path</i>	string
<i>library_name</i>	string

ARGUMENTS

-technology *tech_path*

Specifies the technology file for this library.

-use_technology_lib *tech_lib_name*

Specifies the reference library to use as a dedicated technology library.

The library must contain a technology section and must be one of the libraries specified with the **-ref_libs** option.

This option is mutually exclusive with the **-technology** option, and it must be used with the **-ref_libs** option.

-scale_factor *scale_factor*

Specifies the length precision for this library. The length precision for the library must be the multiple of the length precision of all of its reference libraries. The value is specified in terms of units per micron. By default, a length precision of 10000 is used, which implies one internal unit is equal to one Angstrom or 0.1 nm

Choose a *scale_factor* value that will result in a whole number of database units per minimum grid spacing. For example, if your minimum grid spacing is 1 nm, the default scale_factor of 10000 dbu per micron could be used. But if your minimum grid spacing is 0.25 nm, a scale factor of, for example, 4000, must not be used because rounding errors might result.

-ref_libs *ref_libs*

Specifies the reference libraries for this library.

In addition to pre-built cell libraries, this option accepts physical source data such as physical libraries (which contain frame views of the cells), LEF files, and Milkyway libraries.

You can specify the reference libraries and physical source data using absolute or relative paths. If you specify the libraries with a relative path or with no path, the tool uses the search path defined with the **search_path** variable to locate the libraries.

If fusion library is the only source of cell libraries, this option is not required.

-convert_sites site_name_pairs_list

Specifies the mapping for the site names in the technology file in the following format:

```
{tech_file_site_name new_site_name}
```

This option must be used with the **-technology** option.

-base_lib base_library_path

Creates a sparse library based on the specified library. The base library must be a design lib and cannot be a lib-cell library. No other options can be specified when the **-base_lib** option is used. For example, the sparse library must use the same technology file and ref_libs as the base library.

library_name

Specifies the name of the new library. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after the last '/' becomes the name of the library. It is an error if a library, file, or directory with the same name already exists on disk.

The name can be a simple path, a path relative to the current working directory, or an absolute path. The name cannot contain spaces or the colon (":") character, which is used to delimit the library and design name.

The *library_name* is optional when **-base_lib** option is used. If unspecified, the name of the created local sparse library matches the name of the base library specified using the **-base_lib**.

DESCRIPTION

The **create_lib** command creates a new design library which is a container from where the physical information of the cell can be obtained. The library can contain technology information specified with the **-technology** option. It enables **NDM mode** for current Design Compiler NXT session. If there are sites defined in the technology file (and one is being used), you can use the **-convert_sites** option to map the sites from one name to another. This same option is used with the **read_def** command to ensure that the site names match among all the input data.

You can directly specify the library's reference library path list with the **-ref_libs** option. Alternatively, if you specify physical source data with the **-ref_libs** option, the tool creates the cell libraries and sets them as reference libraries. The supported physical source data includes physical libraries, which contain the frame views of the cells, LEF files, and Milkyway libraries. The logic libraries are determined from the **link_library** variable.

When the **-base_lib** option is used the **create_lib** command creates a new sparse library based upon an existing design library on disk. The sparse library uses the same technology file and ref_libs as the base library. Initially, a sparse library does not have any locally stored blocks. It copies the base library's catalog and ref_lib list into memory as its own and also remembers the full path of the base library for reference.

The library is then opened and made the current library.

If the command is successful, it returns the status integer 1. If there is an error, it returns a **TCL_ERROR**.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
Saving library 'r4000.nlib'
Information: Using the 'create_lib' command has enabled NDM mode for the current Design Compiler NXT session. (DCT-294)
1
prompt> current_lib
r4000.nlib
```

The following example creates a library named r4000 in the current directory that uses the tcbn90g.tf technology file and has a scale factor of 4000.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf r4000 -scale_factor 4000
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
Saving library 'r4000.nlib'
Information: Using the 'create_lib' command has enabled NDM mode for the current Design Compiler NXT session. (DCT-294)
1
prompt> current_lib
r4000.nlib
```

The following example creates a library named top_lib in the ./lib_dir directory that uses the tcbn90g.tf technology file.

```
prompt> create_lib -technology LIBS/TECH/tcbn90g.tf lib_dir/top_lib
Information: Loading technology file '/usr/LIBS/TECH/tcbn90g.tf' (FILE-007)
Saving library 'top_lib'
1
```

The following example creates a library named design_lib in the /home/user directory that uses the my_tech.tf technology file.

```
prompt> create_lib -technology my_tech.tf /home/user/design_lib
Information: Loading technology file 'my_tech.tf' (FILE-007)
Saving library 'design_lib'
1
```

The following example creates a sparse library named r4000_sparse_lib based on the design library r4000 in the /home/user directory.

```
prompt> create_lib -base_lib r4000 /home/user/r4000_sparse_lib
Information: Incrementing open_count of library 'r4000' to 2. (LIB-017)
Information: Creating Sparse View library 'r4000_sparse_lib' with base library 'r4000'. (NDM-103)
Information: Updating library catalog of Sparse View library 'r4000_sparse_lib' from base library 'r4000'. (NDM-104)
Information: Updating library attachments of Sparse View library 'r4000_sparse_lib' from base library 'r4000'. (NDM-104)
Warning: Library configuration will not be performed: technology file not specified. (LIB-117)
Information: Decrementing open_count of library 'r4000' to 1. (LIB-018)
Saving library 'r4000_sparse_lib'
1
```

create_link_block_abstraction

Generates IC Compiler II abstract NDM references for the current design and all the DCNXT block abstractions in the current design via link feature.

SYNTAX

```
status create_link_block_abstraction
      [-top_block]
      [-output_ddc_file output_file_name]
      [-output_ndm_dir ndm_cache_dir]
      [-overwrite]
```

Data Types

<i>output_file_name</i>	string
<i>ndm_cache_dir</i>	string

ARGUMENTS

-top_block

Creates IC Compiler II abstract for current design.

The **-top_block** option is used along with **-output_ddc_file**.

-output_ddc_file *output_file_name*

Specifies a single file into which designs are written in ddc format.

The **-top_block** option is used along with **-output_ddc_file**.

-output_ndm_dir *ndm_cache_dir*

Specifies cache directory where the IC Compiler II abstract NDMs are saved.

-overwrite

Regenerates IC Compiler II abstracts and overwrites any existing ones in the cache directory.

DESCRIPTION

This command creates IC Compiler II abstracts for the current design and all the DCNXT block abstractions present in the design using IC Compiler II link feature. To support DCNXT block abstraction flow, the generated IC Compiler II abstracts can be used during link placer features and link reporting features.

At the top level, **set_top_implementation_options** command is used to specify the blocks that are integrated with the top-level

design as block abstractions. When **create_link_block_abstraction** command is run, it creates IC Compiler II abstracts for all the blocks integrated as block abstractions. In addition to the blocks specified via **set_top_implementation_options**, the command can also create IC Compiler II abstract for current design, if **-top_block** and **-output_ddc_file** options are specified together. To create IC Compiler II abstract corresponding to current design, it's required to run **create_block_abstraction** command first to determine the interface logic. The command errors out if interface logic is not marked in the current design or the design has any unmapped and/or unplaced cells. When the IC Compiler II abstract is created for current design, the command also writes out the complete design, including the block abstraction information, into a single .ddc file specified by **-output_ddc_file** option. The generated IC Compiler II abstract will be linked to the written out .ddc file via checksum mechanism. When the current design is used as a block abstraction, user needs to provide the command written .ddc file so that the appropriate IC Compiler II abstract can be picked by the tool.

The command provides a caching mechanism so that the earlier generated IC Compiler II abstracts can be re-used. The **create_link_block_abstraction** command creates the IC Compiler II abstracts for each DCNXT block abstraction and places them in the cache. The tool generates a unique checksum for the block level .ddc files and creates a one-to-one mapping between the block level .ddc files and IC Compiler II abstracts name. If the block level .ddc files are not changing, tool can generate the IC Compiler II abstract names and pick them up from the cache directory.

The user cache directory can be specified using option **-output_ndm_dir**. If specified, the abstract NDM references will be created in that directory. If the option is not specified, the command will create a default cache directory **hier_ndm** in the current working directory and generate the IC Compiler II abstracts corresponding to each DCNXT block abstractions in the default cache directory. If the cache directory doesn't have write permission, the command will fail. The directories in **search_path** is also included in cache directories. However, these directories are read-only.

The abstracts corresponding to each block abstraction are searched in the following order of preference:

- User-specified cache directory via option **-output_ndm_dir**
- Default cache directory **hier_ndm**
- Directory list in **search_path** variable setting

If the abstract is found in multiple directories, the one based on the above order will be picked up.

When the command is triggered, it first checks if the IC Compiler II abstracts are already present in the cache directory or not. If an abstract is found for a block, no abstract generation is triggered for the same and the cached abstracts are used during link features. This helps avoiding the abstract generation every-time the command is run and helps saving runtime.

The tool builds the cache internally when the command is run. Thus, it's required to run the command even if the IC Compiler II abstracts are already present in specified cache directory, default cache directory **hier_ndm** or/and **search_Path**. If the IC Compiler II abstracts are not found in the cache directories, compile flow and report_congestion command will error out.

During link features, the tool will pick all the required IC Compiler II abstracts from the cache directories.

The IC Compiler II abstracts can be force regenerated by using **-overwrite** option. The abstracts will be written out in the default cache directory **hier_ndm**, if option **-output_ndm_dir** is not specified.

The command does not support block abstractions with transparent interface optimization.

In Milkyway mode, the command fails if **set_icc2_options** command is not run before invoking it.

The command is available only in DCNXT topographical mode.

Multicorner-Multimode Support

This command uses information from all scenarios.

EXAMPLES

The following example shows how to create and save a block abstraction:

```
prompt> create_lib -technology tech.tf -ref_libs std_ref.nlib design_nlib
prompt> set_top_implementation_options -block_references "mid_bam"
prompt> read_ddc mid_bam.ddc
```

```
prompt> read_verilog top.v
prompt> link
prompt> set_icc2_options -ref $ref_ndm_files -tech $mw_tech_file
prompt> create_link_block_abstraction
```

SEE ALSO

create_logic_net

Defines a logic net.

SYNTAX

```
status create_logic_net  
      net_name
```

Data Types

net_name string

ARGUMENTS

net_name

Specifies the name of the net to create. You must use a simple name.

DESCRIPTION

The **create_logic_net** command creates a logic net in the active scope. It is an error if the specified net name already exists in the active scope.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[create_logic_port\(2\)](#)
[connect_logic_net\(2\)](#)

create_logic_port

Defines a logic port.

SYNTAX

```
string create_logic_port
      port_name
      [-direction in | out | inout]
```

Data Types

port_name string

ARGUMENTS

port_name

Specifies the name of the port to create. You must use a simple name.

-direction in | out | inout

Specifies the direction of the port.

The default is **in**.

DESCRIPTION

The **create_logic_port** command creates a logic port on the active scope. It returns the name of the created port.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

create_missing_constraints

Generates missing path constraints in the current design based on user-specified default settings.

SYNTAX

```
status create_missing_constraints
  [-period period_value]
  [-waveform edge_list]
  [-input_delay delay_value]
  [-output_delay delay_value]
  [-pin_load load_value]
  [-driving_lib_cell lib_cell_name]
  [-driving_lib_pin lib_pin_name]
  [-exclude object_list]
  [-clock_tracing_mode tracing_mode]
  [-output file]
  [-no_apply]
```

Data Types

period_value	float
edge_list	list
delay_value	float
load_value	float
lib_cell_name	string
lib_pin_name	string
object_list	string
tracing_mode	string
file	string

ARGUMENTS

-period period_value

Specifies the default period value for missing clocks.

-waveform edge_list

Specifies the rise and fall times for one default clock period.

The *period_value* and *edge_list* are passed to the **create_clock** command for generating missing clocks.

If both **-period period_value** and **-waveform edge_list** are not specified, the create missing clock feature is disabled.

-input_delay delay_value

Specifies default value for ports with missing input delay. If **-input_delay delay_value** is not specified, the create missing input delay for port feature is disabled.

The *delay_value* will be passed to the **set_input_delay** command for generating missing input delay constraints.

-output_delay *delay_value*

Specifies the default value for ports with missing output delay. If **-output_delay *delay_value*** is not specified, the create missing output delay for port feature is disabled.

The *delay_value* is passed to the **set_output_delay** command for generating missing output delay constraints.

-pin_load *load_value*

Specifies the default pin capacitance value for output ports. If **-pin_load *load_value*** is not specified, the create missing pin load for port feature is disabled.

The *load_value* value is passed to the **set_load** command for generating missing load constraints.

-driving_lib_cell *lib_cell_name*

Specifies the library cell name for ports with missing driving cells.

-driving_lib_pin *lib_pin_name*

Specifies library cell pin name for ports with missing driving cells.

The *lib_cell_name* and *lib_pin_name* names are passed to the **set_driving_cell** command for generating missing driving cell constraints.

-exclude *object_list*

Specifies the ports and clock exclusion list to skip SDC constraint generation.

-clock_tracing_mode *tracing_mode*

Specifies the tracing mode for tracing clocks from missing clock pins. The possible values are:

simple
advanced

When set to **simple** (the default value), the tool traces only ports as clocks; when set to **advanced**, the tool traces ports and register outputs as clocks.

-output *file*

Writes SDC constraints to the specified file.

-no_apply

Creates SDC constraints without applying them.

DESCRIPTION

This command generates missing path constraints in the current design based on the default settings specified with this command.

The commands *write_sdc*, *remove_sdc* and *reset_design* can be used to write out, remove, and reset SDC constraints generated by this command, respectively.

This command does nothing if no options are specified.

This command is for the DC Explorer flow only.

```

create_multibit

Creates a multibit component for the specified list of cells or cell instances in the current design.

SYNTAX

```
status create_multibit
  object_list
  [-name multibit_name]
  [-sort]
  [-no_sort]
```

Data Types

```
object_list    list
multibit_name  string
```

ARGUMENTS

object_list

Specifies a list of cells in the current design for which a multibit component is to be created.

-name *multibit_name*

Specifies the name to be given to the new multibit component. If this option is omitted, the name of the first cell in the component is used to generate a name for the multibit component. If a multibit component by the name *multibit_name* already exists in the current design, an error is issued and the command terminates.

-sort

Sorts the cells specified in *object_list* in alphanumeric order. By default, cells are sorted in reverse alphanumeric order of their names.

-no_sort

Specifies that the order of the cells in the multibit component should be the same as specified on the command line. By default, cells are sorted in reverse alphanumeric order of their names.

DESCRIPTION

The **create_multibit** command creates a new multibit component and each cell or instance in *object_list* is inserted into that multibit component. If a name is provided, the new multibit component gets that name; otherwise, a name is generated internally. If a cell instance is given, the parent of the cell instances should be the same and the parent must be unique.

If the cells in the list are MUX_OP cells, a separate multibit component is created for each cell.

The list of cells is sorted in a reverse alphanumeric order by default. Use the **-sort** option to sort in alphanumeric order, or the **-no_sort** option to order cells in the same way as specified on the command line.

This command requires the design to be linked. If an attempt to link the design fails, the command terminates. If any of the cells in *object_list* already belong to a multibit component, an error is issued and the command terminates.

EXAMPLES

In the following example, a multibit component is created for four registers:

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 1998.02
Date  : Fri Aug 29 10:01:19 1997
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- u - contains unmapped logic

Total 0 Multibit Components

```
prompt> create_multibit -name y_reg {y_reg*}
1
```

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 1998.02
Date  : Fri Aug 29 10:01:19 1997
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- u - contains unmapped logic

Cell	Reference	Library	Area	Width	Attributes
y_reg[3]	**SEQGEN**		0.00	1	n, u
y_reg[2]	**SEQGEN**		0.00	1	n, u
y_reg[1]	**SEQGEN**		0.00	1	n, u
y_reg[0]	**SEQGEN**		0.00	1	n, u
Total 4 cells			0.00	4	

Total 1 Multibit Components

In the next example, the command is run on a list of registers and uses the **-no_sort** option:

```
prompt> create_multibit -name y_reg \
    -no_sort {y_reg[0] y_reg[2] y_reg[1] y_reg[3]}
1
```

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 1998.02
Date  : Fri Aug 29 10:01:19 1997
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- s - synthetic operator
- u - contains unmapped logic

Multibit Component : y_reg					
Cell	Reference	Library	Area	Width	Attributes
y_reg[0]	**SEQGEN**		0.00	1	n, u
y_reg[2]	**SEQGEN**		0.00	1	n, u
y_reg[1]	**SEQGEN**		0.00	1	n, u
y_reg[3]	**SEQGEN**		0.00	1	n, u
Total 4 cells			0.00	4	

Total 1 Multibit Components

In the next example, the command is run on a list of MUX_OP cells:

```
prompt> create_multibit {U4, U7}
1
```

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 1998.02
Date  : Fri Aug 29 10:01:19 1997
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- s - synthetic operator
- u - contains unmapped logic

Multibit Component : y_reg					
Cell	Reference	Library	Area	Width	Attributes
U4	*MUX_OP_4_2.2		0.00	2	s, u
Total 1 cells			0.00	4	

Multibit Component : U7_multibit					
Cell	Reference	Library	Area	Width	Attributes

```
-----  
U7          *MUX_OP_4_2.2      0.00 2  s, u  
-----  
Total 1 cells                      0.00 2
```

Total 2 Multibit Components

In the next example, the command is run using cell instances U1/test1 and U1/test2. In this case the instance U1 corresponding to design MID is unique.

```
prompt> create_multibit {U1/test1 U1/test2} -name mult  
1
```

```
prompt> report_multibit
```

```
*****
```

```
Report : multibit  
Design : subtest  
Version: 1998.02  
Date  : Fri Aug 29 10:01:19 1997  
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- s - synthetic operator
- u - contains unmapped logic

Multibit Component : mult					
Cell	Reference	Library	Area	Width	Attributes
U1/test1	**SEQGEN**		0.00	1	n, u
U1/test2	**SEQGEN**		0.00	1	n, u
Total 2 cells			0.00	2	

Total 1 Multibit Components

create_mw_lib

Creates a Milkyway library.

SYNTAX

```
status create_mw_lib
      [-technology technology_file_name]
      [-bus_naming_style style]
      [-mw_reference_library lib_list]
      [-reference_control_file rc_file_name]
      [-open]
      libName
```

Data Types

<i>technology_file_name</i>	string
<i>style</i>	string
<i>lib_list</i>	string
<i>rc_file_name</i>	string
<i>libName</i>	string

ARGUMENTS

-technology *technology_file_name*

Specifies the name of the technology file for the newly created Milkyway library. This option and **-plib** are mutually exclusive.

-bus_naming_style *style*

Specifies the bus naming style for the library. The default bus naming style is [%d].

-mw_reference_library *lib_list*

Specifies a list of reference libraries to be used for the new library.

-reference_control_file *rc_file_name*

Specifies the reference control file used to set reference library information for the new library.

-open

Opens the library after creation.

libName

Specifies the name of the Milkyway library to be created.

DESCRIPTION

This command creates a Milkyway library.

The **-technology** and **-plib** options are mutually exclusive, and at least one of them must be specified.

Some advanced technologies require more than the default 255 layers. In these cases, you can extend the number of layers to 4095 by executing the **extend_mw_layers** command before you execute the **create_mw_lib** command. Once created in the default 255-layer mode or extended 4095-layer mode, the Milkyway library must remain in that layer mode. For details, see the man page for the **extend_mw_layers** command.

By default, the newly created Milkyway library is not open in the current session. To manipulate it, first run the **open_mw_lib** command. The library can also be opened by using the **-open** option, but to make the scripts more reusable, use **open_mw_lib**.

All strings stored in this library, as well as in designs belonging to it, are case-sensitive, and all string operations are performed as case-sensitive.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a Milkyway design library with a technology file and bus naming style as [%d].

```
prompt> create_mw_lib design -technology test.tf \
           -bus_naming_style {[%d]}
1
```

SEE ALSO

`close_mw_lib(2)`
`extend_mw_layers(2)`
`open_mw_lib(2)`

create_net

Creates nets in the current design or its subdesign.

SYNTAX

```
status create_net
      [-power | 
       -ground]
      net_list
```

Data Types

net_list list

ARGUMENTS

-power

Creates a power net. By default, the tool creates a signal net. This option is available only in Design Compiler topographical mode.

The **-power** and **-ground** options are mutually exclusive; you can specify only one.

-ground

Creates a ground net. By default, the tool creates a signal net. This option is available only in Design Compiler topographical mode.

The **-power** and **-ground** options are mutually exclusive; you can specify only one.

net_list

Specifies the names of the created nets. If you specify a hierarchical net name, the net is created in the specified instance. The net name must be unique within the current design or the subdesign where it is created. If you use a hierarchical net name, the parent instance must be unique; it cannot be an instance of a multiply-instantiated design.

This option is required.

DESCRIPTION

The **create_net** command creates new net objects in the current design or its subdesign based on the *net_list* argument. The **create_net** command creates only scalar (single bit) nets.

To bundle scalar nets into buses, use the **create_bus** command.

Nets connect pins and ports in a design. When you create nets with **create_net**, they are not connected. To establish this connection, use the **connect_net** command. To remove nets from the current design, use the **remove_net** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **create_net** to create net objects in the current design:

```
prompt> current_design  
prompt> create_net {N1 N2 N3 N4}  
prompt> get_nets *
```

The following example uses **create_net** to create net objects in the mid subdesign. Note that mid1 is an instance of the mid design. The mid design must be unique for the **create_net** command to succeed.

```
prompt> current_design  
prompt> create_net {mid1/N1 mid1/N2 mid1/N3 mid1/N4}  
prompt> get_nets mid1*
```

[disconnect_net\(2\)](#)
[remove_bus\(2\)](#)
[remove_net\(2\)](#)

create_net_search_pattern

Defines a net pattern.

SYNTAX

```
pattern_id create_net_search_pattern
  [-fanout_upper_limit number]
  [-fanout_lower_limit number]
  [-bbox_half_perimeter_upper_limit length]
  [-bbox_half_perimeter_lower_limit length]
  [-net_length_upper_limit length]
  [-net_length_lower_limit length]
  [-blocked_area_ratio_upper_limit percentage]
  [-blocked_area_ratio_lower_limit percentage]
  [-aspect_ratio_upper_limit ratio]
  [-aspect_ratio_lower_limit ratio]
  [-centered_within {{llx lly urx ury}]}
  [-connect_to_port]
  [-connect_to_macro]
  [-setup_slack_lower_limit number]
  [-setup_slack_upper_limit number]
```

Data Types

<i>number</i>	integer
<i>length</i>	float
<i>percentage</i>	float
<i>ratio</i>	float
<i>llx</i>	float
<i>lly</i>	float
<i>urx</i>	float
<i>ury</i>	float

ARGUMENTS

-fanout_upper_limit *number*

Identifies nets with fanouts that are less than the specified value.

-fanout_lower_limit *number*

Identifies nets with fanouts that are greater than or equal to the specified value.

-bbox_half_perimeter_upper_limit *length*

Identifies nets whose bounding box width and height have a sum that is less than the specified value. A net's bounding box is the smallest rectangle that contains all of its pins. The measurement unit is microns.

-bbox_half_perimeter_lower_limit *length*

Identifies nets whose bounding box width and height have a sum that is greater than or equal to the specified value. A net's bounding box is the smallest rectangle that contains all of its pins. The measurement unit is microns.

-net_length_upper_limit length

Identifies nets that have a total length that is less than the specified value. If a net is only virtually routed, the sum of its x_length and y_length attributes is checked; however, if a net is detail routed, its route_length attribute is checked. The measurement unit is microns.

-net_length_lower_limit length

Identifies nets that have a total length that is greater than or equal to the specified value. If a net is only virtually routed, the sum of its x_length and y_length attributes is checked; however, if a net is detail routed, its route_length attribute is checked. The measurement unit is microns.

-blocked_area_ratio_upper_limit percentage

Identifies nets whose bounding boxes are covered with blockages by a fractional amount that is less than the specified value. For example, if you want to create a collection of nets that have less than 1% of their bounding box area covered by some kind of blockage polygon (such as hard or soft placement blockages), use **-blocked_area_ratio_upper_limit 0.01**. Note that cells returned by the **all_macro_cells** command are considered sources of blockage. Also, partial placement blockages are NOT considered for this calculation. A net's bounding box is the smallest rectangle that contains all of its pins.

-blocked_area_ratio_lower_limit percentage

Identifies nets whose bounding boxes are covered with blockages by a fractional amount that is greater than or equal to the specified value. For example, if you want to create a collection of nets that have at least 50% of their bounding box area covered by some kind of blockage polygon (such as hard or soft placement blockages), then specify **-blocked_area_ratio_lower_limit 0.5**. Note that cells returned by the **all_macro_cells** command are considered sources of blockage. Also, partial placement blockages are NOT considered for this calculation. A net's bounding box is the smallest rectangle that contains all of its pins.

-aspect_ratio_upper_limit ratio

Identifies nets whose bounding boxes have aspect ratios that are less than the specified value. A net's aspect ratio is its bounding box (horizontal) width divided by its (vertical) height. A net's bounding box is the smallest rectangle that contains all of its pins. If a bounding box's width or height is less than 0.05, it is replaced with 0.05 for this specific calculation.

-aspect_ratio_lower_limit ratio

Identifies nets whose bounding boxes have aspect ratios that are greater than or equal to the specified value. A net's aspect ratio is its bounding box (horizontal) width divided by its (vertical) height. A net's bounding box is the smallest rectangle that contains all of its pins. If a bounding box's width or height is less than 0.05, it is replaced with 0.05 for this specific calculation.

-centered_within {llx lly urx ury}

Identifies nets whose bounding boxes have a center x and center y that fall within the specified region. A net's bounding box is the smallest rectangle that contains all of its pins. The coordinate values must be in microns.

-connect_to_port

Identifies all nets that are connected to a design's primary I/Os (all the ports of the top module of the netlist). If this option is specified with **-connect_to_macro**, a collection of all nets connected to BOTH primary and macro I/Os is derived.

-connect_to_macro

Identifies all nets that are connected to the I/Os of a design's macro pins. If this option is specified with **-connect_to_port**, a collection of all nets connected to BOTH primary and macro I/Os is derived.

-setup_slack_lower_limit number

Identifies nets in the specified pattern ID that have a setup slack that is greater than or equal to the specified value. A net's setup slack is the worst setup slack seen across all its sinks. To select all of the nets in pattern 1 that have a setup slack of more than 100, use **get_matching_nets_for_pattern -setup_slack_lower_limit 100 -pattern 1**.

-setup_slack_upper_limit number

Identifies nets in the specified pattern ID that have a setup slack that is less than the specified value. A net's setup slack is the

worst setup slack seen across all its sinks. To select all of the nets in pattern 2 that have a setup slack of less than 0, use **get_matching_nets_for_pattern -setup_slack_upper_limit 0 -pattern 2**.

DESCRIPTION

The **create_net_search_pattern** command defines a net pattern, which is a matching constraint that simultaneously uses several different physical attributes.

After they are created, net patterns can be used in the following ways:

- Net identification, to establish collections of nets.
- Specifies minimum and maximum layers when you run **compile_ultra -spg -layer_optimization** to alter the unit resistance and capacitance of the matched nets in the pattern-based collections.

Other commands can use patterns, such as **set_net_search_pattern_delay_estimation_options** and **get_matching_nets_for_pattern**, both of which have the **-pattern** option.

Whenever a pattern is created, it is assigned an integer ID. If the command fails, a -1 is returned. If the command succeeds, the assigned pattern ID is returned. The ID must be referenced for subsequent operations. For example, if you create a pattern of all nets with lengths between 5 and 10 um (for example **create_net_search_pattern -fanout_lower_limit 5 -fanout_upper_limit 10**) and it is assigned a pattern ID of 1, you can then enter **get_matching_nets_for_pattern -pattern 1** to collect nets that match the pattern.

Note that pattern IDs always start at 1 and can never be reused even if a pattern ID is removed. Each time a pattern is created, the pattern ID count always increases by 1. Although there is no hard-coded upper limit, it is strongly recommended to keep the pattern count under 5,000. Note that all net search pattern-related data is saved in the Milkyway database for future reference.

Multicorner-Multimode Support

This command uses information from all active scenarios. For setup slack, the worst value from all active scenarios is always used.

EXAMPLES

In the following example, the **create_net_search_pattern** command creates a collection of all nets that have a length of 200 um or more and also touch primary I/O pins:

```
prompt> create_net_search_pattern -net_length_lower_limit 200  
-connect_to_port
```

create_net_shape

Creates a new net shape.

SYNTAX

```
status create_net_shape
  [-type wire | path | rect]
  [-origin point
   | -bbox rect
   | -points list_of_points
  [-length length]
  [-width width]
  [-path_type square | round | extend_half_width | octagon]
  -layer layer
  [-mask_constraint constraint]
  -net net_name
  [-vertical]
  [-route_type route_type]
  [-net_type ground | power | clock | signal]
  [-datatype int]
  [-avoid_short_segment]
```

Data Types

<i>point</i>	point
<i>rect</i>	rectangle
<i>list_of_points</i>	list of points
<i>length</i>	float
<i>width</i>	float
<i>layer</i>	collection
<i>constraint</i>	string
<i>net_name</i>	string
<i>route_type</i>	string
<i>int</i>	integer

ARGUMENTS

-type wire | path | rect

Specifies the type of the net shape. Valid values are **wire**, **path**, and **rect** (rectangle).

If you do not specify this option, the tool determines the type by using the following rules, in order of precedence:

1. If you use the **-origin** option, the net shape is **wire**.
The wire is horizontal, unless you also specify the **-vertical** option.
2. If you use the **-bbox** option, the net shape is **wire** if you also use the **-path_type**, **-route_type**, or **-vertical** options. If you do not use any of these additional options, the net shape is **rect**.
3. If you use the **-points** option, the net shape is **path**.

-origin point

Specifies the origin of the net shape for wires.

When you specify this option, you must also specify the **-length** and **-width** options.

The **-origin**, **-points**, and **-bbox** options are mutually exclusive. You must specify one of these options.

-bbox rect

Specifies the bounding box of the net shape.

You must specify the lower-left and upper-right corners of the rectangle by using the following syntax: $\{\{lx ly\} \{urx ury\}\}$.

The **-origin**, **-points**, and **-bbox** options are mutually exclusive. You must specify one of these options.

-points list_of_points

Specifies the point sequence of the net shape for paths.

When you specify this option, you must also specify the **-width** option.

The **-origin**, **-points**, and **-bbox** options are mutually exclusive. You must specify one of these options.

-length length

Specifies the length of the net shape for wires in user units.

This option is required when you specify the **-origin** option and ignored otherwise.

-width width

Specifies the width of the net shape for wires in user units.

This option is required when you specify the **-origin** or **-points** option and ignored otherwise.

-path_type square | round | extend_half_width | octagon

Specifies the alignment type of a wire or path end.

The default is **square**.

You can specify one of the following values:

- **square** (square, no extension)
- **round** (round, half-width extension)
- **extend_half_width** (square, half-width extension)
- **octagon** (octagon, half-width extension)

This option can be used only for wire or path shapes.

-layer layer

Specifies the layer for the net shape. You can specify the layer by using the layer name from the technology file.

This option is required.

-mask_constraint constraint

Specifies the mask constraint for the net shape.

The valid mask constraints are **any_mask**, **mask1_soft**, **mask1_hard**, **mask2_soft**, **mask2_hard**, **same_mask**, **mask3_soft**, and **mask3_hard**.

-net net_name

Specifies the net associated with the net shape.

This option is required.

-vertical

Indicates that the net shape is vertical.

By default, the net shape is horizontal.

-route_type route_type

Specifies the route type of the net shape.

By default, the route type is **signal_route**.

You can specify one of the following values:

- **user_enter** (user entered)
- **signal_route** or **signal_route_detail** (detail routing)
- **signal_route_global** (global routing)
- **pg_ring** (power or ground ring)
- **pg_strap** (power or ground strap)
- **pg_macro_io_pin_conn** (power or ground net that connects to the power or ground pin of an I/O pad cell or a macro cell)
- **pg_std_cell_pin_conn** (power or ground net that connects to the power or ground pin of a standard cell)
- **clk_ring** (clock ring)
- **clk_strap** (clock strap)
- **clk_zero_skew_route** (clock zero-skew route)
- **bus** (bus)
- **shield** or **shield_fixed** (fixed shield)
- **shield_dynamic** (dynamic shield)
- **fill_track** or **clk_fill_track** (fill track)

This option can be used only for wire, path, or rectangle shapes.

-net_type ground | power | clock | signal

Specifies the type of the net on which to create the net shape. The valid net types are **ground**, **power**, **clock**, or **signal**.

-datatype int

Specifies the data type number in the range 0-255.

By default, the data type is 0.

-avoid_short_segment

Avoids creating segments shorter than a half width for paths.

DESCRIPTION

This command creates a shape object that is attached to the specified net. It returns 1 if success or 0 if command fails. Shapes will be created during compile.

The valid shape types are wire (horizontal or vertical), path, and rectangle.

Note: For wires, the shape must be symmetrical about the center line. If you specify the width as an odd value, either explicitly by using the **-width** option or implicitly by using the **-bbox** option, the tool rounds the width down to an even value.

For example, the following command specifies a width of 9995 database units. If the technology file defines the lengthPrecision as 1000, the tool rounds this down to 9994, resulting in a bounding box with the coordinates (100.000, 100.000) (**109.994**, 169.895).

```
prompt> create_net_shape -net VDD -type wire -route_type pg_strap \
    -layer M6 -bbox {100.000 100.000} {109.995 169.895} -vertical
```

If the **lengthPrecision** attribute is set to 1000 in the technology file, the width in database units is 9995. The tool rounds this down to 9994, which results in a bounding box of {100.000 100.000} **{109.994 169.895}**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a wire net shape:

```
prompt> create_net_shape -type wire -net VSS \
    -origin {0 0} -length 10 -width 2 -layer M1
```

The following example creates a path net shape:

```
prompt> create_net_shape -type path -net {VSS} \
    -path_type extend_half_width -layer M3 \
    -points {{845 715} {845 710} {860 710}} -width 0.230
```

The following example creates a rectangle net shape:

```
prompt> create_net_shape -type rect -net {CLOCK_Net27} \
    -bbox {76 110} {82 115} -layer METAL1
```

`create_route_guide(2)`
`create_terminal(2)`
`create_user_shape(2)`
`create_via(2)`

create_operating_conditions

Creates a new set of operating conditions in a library.

SYNTAX

```
status create_operating_conditions
  -name name
  -library library_name
  -process process_value
  -temperature temperature_value
  -voltage voltage_value
  [-tree_type tree_type]
  [-calc_mode calc_mode]
  [-rail_voltages rail_value_pairs]
```

Data Types

<i>name</i>	string
<i>library_name</i>	string
<i>process_value</i>	float
<i>temperature_value</i>	float
<i>voltage_value</i>	float
<i>tree_type</i>	string
<i>calc_mode</i>	string
<i>rail_value_pairs</i>	list

ARGUMENTS

-name *name*

Specifies the name of the new set of operating conditions.

-library *library_name*

Specifies the name of the library for the new operating conditions.

-process *process_value*

Specifies the process scaling factor for the operating conditions. Allowed values are 0.0 through 100.0.

-temperature *temperature_value*

Specifies the temperature value, in degrees Celsius, for the operating conditions. Allowed values are -300.0 through +500.0.

-voltage *voltage_value*

Specifies the voltage value for the operating conditions. Allowed values are 0.0 through 1000.0.

-tree_type *tree_type*

Specifies the tree type for the operating conditions. Allowed values are **balanced_tree** (the default), **best_case_tree**, or

worst_case_tree. The tree type is used to estimate interconnect delays by providing a model of the RC tree.

-calc_mode calc_mode

For use only with DPCM libraries. Specifies the DPCM delay calculator mode for the operating conditions. Allowed values are **unknown** (the default), **best_case**, **nominal**, or **worst_case**. If you use the default value, the **worst_case** value will be used during analysis. If **-rail_voltages** is specified, the command sets corresponding (**worst_case**, **nominal**, and **best_case**) voltage values.

-rail_voltages rail_value_pairs

Specifies a list of name-value pairs that defines the voltage for each specified rail. The name is one of the rail names defined in the library; the value is the voltage to be assigned to that rail. By default, rail voltages are determined by the values given to them in the library. Use this option to override the default voltages for the specified rails.

DESCRIPTION

The **create_operating_conditions** command creates a new set of operating conditions in the specified library. A technology library contains a fixed set of operating conditions. This command allows you to create new and additional operating conditions.

To see the operating conditions defined for a library, use the **report_lib** command.

To set operating conditions on the current design, use the **set_operating_conditions** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a new set of operating conditions called *WC_CUSTOM* in the library named *tech_lib*, specifying new values for process, temperature, voltage, parameter1, and tree type. By default, rail voltages remain as defined in the library.

```
prompt> create_operating_conditions -name WC_CUSTOM \
    -library tech_lib -process 1.2 -temperature 30.0 -voltage 2.8 \
    -parameter1 1.2 -tree_type worst_case_tree
```

The following example creates a new set of operating conditions called *OC3* in the library named *IBM_CMOS5S6_SC*, specifying new values for process, temperature, voltage, and rail voltages for rails VTT and VDDQ. By default, the tree type **balanced_tree** is used.

```
prompt> create_operating_conditions -name OC3 \
    -lib IBM_CMOS5S6_SC -proc 1.0 -temp 100.0 -volt 4.0 \
    -rail_voltages {VTT 3.5 VDDQ 3.5}
```

SEE ALSO

[report_lib\(2\)](#)
[set_operating_conditions\(2\)](#)

create_pin_guide

Creates a pin guide for top-level ports to constrain the terminals to a specified bounding box.

SYNTAX

```
collection create_pin_guide
  -bbox bounding_box_rect
  | -boundary rectilinear_boundary
  [ -parents soft_macro_or_plan_group]
  [ -name pin_guide_name]
  [ -exclusive]
  objects
```

Data Types

<i>bounding_box_rect</i>	list of points
<i>rectilinear_boundary</i>	list of points
<i>soft_macro_or_plan_group</i>	collection
<i>pin_guide_name</i>	string
<i>objects</i>	collection

ARGUMENTS

-bbox *bounding_box_rect*

Specifies the bounding box of a rectangular pin guide. The format of the bounding box specification is $\{\{lx\; ly\} \{urx\; ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle. The unit is in microns.

The **-boundary** and **-bbox** options are mutually exclusive. You must specify one of these options.

-boundary *rectilinear_boundary*

This option is not supported in Design Compiler in topographical mode and is ignored if specified.

-parents *soft_macro_or_plan_group*

This option is not supported in Design Compiler in topographical mode and is ignored if specified.

-name *pin_guide_name*

Specifies the name of the pin guide to be created.

If this option is not used, a default name is given to the pin guide.

-exclusive

Prevents the placement of terminals or soft macro pins within the pin guide, except for those that are specified to be placed inside the pin guide at the time it is created.

If nets are specified at the time of pin guide creation, the only pins allowed inside the pin guide are those that are connected to the nets or to the feedthrough pins derived from the global routes of these nets.

objects

Specifies the port objects to be placed into the pin guides.

DESCRIPTION

This command creates a pin guide for a plan group or soft macro to constrain the terminals generated by pin assignment to a specified region. The command returns a collection that contains the created pin guide.

Pin guide shapes can be used to define feedthroughs, that is, added ports that do not correspond to existing logical ports, to route a net through a plan group or soft macro. When used in this way, the collection of objects supplied to the command should consist only of nets.

If a parent block of the pin guide contains a connection to the net and the pin guide crosses the block boundary more than once, a port is associated with each crossing. One of the ports corresponds to the original port. Any additional ports created are feedthrough ports.

If a parent block of the pin guide does not contain any connection to the net, the pin guide must cross the block boundary in at least two separate locations. The net is forced to route through this block and has a feedthrough port in each of the areas where the guide crosses the block boundary. If a pin guide only crosses an unconnected block in one place, it is considered an error and this portion of the pin guide is ignored. The pin guide should be a single contiguous shape (not disjoint), and can be either rectangular or rectilinear.

You should ensure that the pin guide represents a reasonable path for the feedthrough routing. For any pin guide, the number of crossings of the block boundary must be less than or equal to the number of net targets outside the block. For example, if the pin guide is an irregular shape that crosses the block boundary in three disjoint areas, there must be at least three separate targets (ports) on the net outside the block, so that each new feedthrough port can be connected to at least one external target. If there are fewer external targets, say two in this example, it is considered an error and this portion of the pin guide is ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a pin guide named abc for all ports whose name contains the string "clk" on the plan group named mem1.

```
prompt> set pin_guide \
[create_pin_guide -bbox {0 0 100 100} -name abc \
[get_ports *clk*]]
```

SEE ALSO

create_placement_blockage

Creates a new placement blockage.

SYNTAX

```
status create_placement_blockage
  -bbox {llx1 lly1 urx1 ury1}
  [-type hard | soft | partial]
  [-blocked_percentage percentage]
  [-no_register]
  [-buffer_only]
  [-category attribute_name]
  [-no_rp_group]
  [-no_pin]
  [-blocked_layers layers]
  [-no_hard_macro]
  [-name blockage_name]
```

Data Types

<i>llx1</i>	float
<i>lly1</i>	float
<i>urx1</i>	float
<i>ury1</i>	float
<i>percentage</i>	integer
<i>layers</i>	string
<i>blockage_name</i>	string

ARGUMENTS

-bbox {llx1 lly1 urx1 ury1}

Specifies the coordinates of the bounding box of the blockage.

-type hard | soft | partial

Specifies the type of blockage to be created.

Valid values are:

- **hard**

With a hard blockage, the placer does not place any standard cells or hard macros in the specified region. This is the default value.

- **soft**

With a soft blockage, the coarse placer does not place any standard cells or hard macros in the specified region. However, cells might be placed there during optimization or legalization.

- **partial**

With a partial blockage, the amount of area used to place cells is limited to the specified percent of the blockage area.

Note that when you create a partial blockage, you must also specify the blocked percentage value by using the **-blocked_percentage** option.

This option is mutually exclusive with the **-no_hard_macro** and **-no_pin** options.

-blocked_percentage percentage

Specifies the percentage blockage for a partial blockage. To allow cell density of 100 percent in the specified partial blockage area, specify the **-blocked_percentage 0** option.

This option can only be used with the **partial** blockage type.

-no_register

Creates a register blockage, which prevents the coarse placer from placing any register cells within the specified blockage area.

The **-no_register** option must be used with the **-type partial** option. The coarse placer honors the attribute set by this option.

This option is mutually exclusive with the **-type hard**, **-type soft**, **-no_hard_macro**, **-no_rp_group**, **-buffer_only**, **-category**, and **-no_pin** options.

-buffer_only

Creates a buffer-only blockage, which prevents the coarse placer from placing any non-buffer cells within the specified blockage area.

The **-buffer_only** option must be used with the **-type partial** option. The coarse placer honors the attribute set by this option. In addition, the **placer_enable_redefined_blockage_behavior** variable must have a value of **true**, which is the default value.

This option is mutually exclusive with the **-type hard**, **-type soft**, **-no_hard_macro**, **-no_rp_group**, **-no_register**, **-category**, and **-no_pin** options.

-category attribute_name

Creates a category blockage, which prevents the coarse placer from placing a user-specified category of cells within the specified blockage area.

You specify the category for a cell by creating a Boolean user attribute named *attribute_name* on instances or references. If the attribute is true for an instance or its reference, the instance is prohibited within the blockage area. If the attribute is present on both the instance and the reference, the tool uses the instance value.

The **-category** option must be used with the **-type partial** option. The coarse placer honors the attribute set by this option. In addition, the **placer_enable_redefined_blockage_behavior** variable must have a value of **true**, which is the default value.

This option is mutually exclusive with the **-type hard**, **-type soft**, **-no_hard_macro**, **-no_rp_group**, **-no_register**, **-buffer_only**, and **-no_pin** options.

-no_rp_group

Creates a relative placement group blockage, which prevents the placement of relative placement groups within the specified area. This option affects only cells that belong to relative placement groups.

The **-no_rp_group** option must be used with the **-type partial** option.

This option is mutually exclusive with the **-type hard**, **-type soft**, **-no_hard_macro**, **-no_register**, **-buffer_only**, **-category**, and **-no_pin** options.

-no_pin

Specifies the pin blockage area where the global router does not route and the pin placer does not assign pins during pin assignment.

Note that when you create a pin blockage, you can also specify the blocked layers by using the **-blocked_layers** option. If you do not specify this option, the default is to block all layers.

This option is mutually exclusive with the **-no_hard_macro**, **-no_rp_group**, **-no_register**, **-buffer_only**, **-category**, and **-type** options.

The **-no_pin** option can be read, written and reported in Design Compiler Topographical mode, but it does not impact placement and floorplan estimation in Design Compiler Topographical mode.

-blocked_layers layers

Specifies the layers for which routing to pins is blocked.

This option can only be used with the **-no_pin** option.

The **-blocked_layers** option can be read, written and reported in Design Compiler Topographical mode, but it does not impact placement and floorplan estimation in Design Compiler Topographical mode.

-no_hard_macro

Specifies the hard macro blockage area where the placer does not place hard macros.

This option is mutually exclusive with the **-no_pin**, **-no_rp_group**, **-no_register**, **-buffer_only**, **-category**, and **-type** options.

The **-no_hard_macro** option can be read, written and reported in Design Compiler Topographical mode, but it does not impact placement and floorplan estimation in Design Compiler Topographical mode.

-name blockage_name

Specifies the optional name of the blockage. If you specify a name for the blockage, you can get the blockage by the name later in the flow.

DESCRIPTION

This command creates a new placement blockage that is used to control the placement of cells in a specified rectangular area.

Snapping to the bounding box is done automatically using global snap settings.

See the description of the **-type** option and the relevant placer documentation for more information.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a soft placement blockage.

```
prompt> create_placement_blockage -bbox {0 0 100 100} -type soft
```

The following example creates a category blockage that prohibits instance U1 and any instances that reference my_lib/sdffx1 within the specified region, but allows instance U2.

```
prompt> define_user_attribute -type boolean -class cell my_attr
prompt> define_user_attribute -type boolean -class lib_cell my_attr
prompt> set_attribute U1 my_attr true
prompt> set_attribute U2 my_attr false
prompt> set_attribute my_lib/sdffx1 my_attr true
prompt> create_placement_blockage -type partial -category my_attr
      -blocked_percentage 30 -bbox {0 0 100 100} -name my_category_blockage
```

SEE ALSO

`create_net_shape(2)`
`create_route_guide(2)`
`create_terminal(2)`
`create_user_shape(2)`
`create_via(2)`
`placer_enable_redefined_blockage_behavior(3)`

create_port

Creates ports in the current design or its subdesign.

SYNTAX

```
status create_port
      port_list
      [-direction dir]
```

Data Types

<i>port_list</i>	list
<i>dir</i>	string

ARGUMENTS

port_list

Specifies names of ports created in the current design. Each port name must be unique within the current design.

-direction *dir*

Specifies the signal flow of the created port. The possible values are **in**, **out**, or **inout**.

The default is **in**.

DESCRIPTION

The **create_port** command creates new port objects in the current design or its subdesign. The **create_port** command creates only scalar or single bit ports.

To bundle scalar ports into buses, use the **create_bus** command.

Ports are the external connection points on a design. To connect ports to nets inside a design, use the **connect_net** command. To remove ports from the current design, use the **remove_port** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **create_port** to create ports in the current design:

```
prompt> current_design  
Current design is 'TOP'.  
{TOP}  
  
prompt> create_port -direction "in" {A1 A2 A3 A4}  
Creating port 'A1' in design 'TOP'.  
Creating port 'A2' in design 'TOP'.  
Creating port 'A3' in design 'TOP'.  
Creating port 'A4' in design 'TOP'.  
1  
  
prompt> get_ports *  
{A1 A2 A3 A4}
```

The following example uses **create_port** to create ports in the *MID* subdesign. *U1* is a unique instance of the design named *MID*.

```
prompt> current_design  
Current design is 'TOP'.  
{TOP}  
  
prompt> create_port -direction "in" {U1/A1 U1/A2 U1/A3 U1/A4}  
Creating port 'A1' in design 'MID'.  
Creating port 'A2' in design 'MID'.  
Creating port 'A3' in design 'MID'.  
Creating port 'A4' in design 'MID'.  
1  
  
prompt> get_pins U1/*  
{U1/A1 U1/A2 U1/A3 U1/A4}
```

The **create_port** command created ports in the *MID* design. To confirm that the ports are created, use the **get_pins** command on the pins of the instance of the *MID* design.

remove_port(2)

create_power_domain

Creates a power domain, which provides a power supply distribution network.

SYNTAX

```
string create_power_domain
  domain_name
  [-elements cells]
  [-exclude_elements cells]
  [-include_scope]
  [-scope instance_name]
  [-supply {supply_set_handle_name [supply_set_name]})]*]
  [-available_supplies {supply_set_name_list}]
  [-update]
```

Data Types

<i>domain_name</i>	string
<i>cells</i>	collection
<i>instance_name</i>	string
<i>supply_set_handle_name</i>	string
<i>supply_set_name</i>	string
<i>supply_set_name_list</i>	collection

ARGUMENTS

domain_name

Specifies the name of the power domain to be created. It must be a simple (nonhierarchical) name.

The power domain cannot be created if there is an existing power domain, hierarchical cell instance, leaf cell instance, or port with the same name in the specified scope.

-elements *cells*

Specifies a collection of cells (hierarchical, black box, macro, buffer/inverter, or I/O pad cells) that are added as an extent of the power domain. The specified cells cannot be added to other power domains of the same scope.

If you do not use either the **-elements** or the **-include_scope** option, the power domain consists of the current scope and any of its children not specified as elements in another **create_power_domain** command.

-exclude_elements *cells*

Specifies a collection of cells (hierarchical, black box, macro, buffer/inverter, or I/O pad cells) that should not be considered as part of this power domain. Specified cells should also appear in -elements list of this power domain to be excluded. And the excluded cells should be defined as a root cell in another power domain, because each cell must have a power domain.

-include_scope

Causes the scope of the power domain (the entire hierarchical level of the domain) to be included in the extent of the domain (the set of logic elements that belong to the power domain). This option is deprecated in IEEE Std. 1801-2013. Define the extent of the

domain to include the current scope and, by default, all of its descendant scopes.

-scope *instance_name*

Specifies the scope (level of logic hierarchy) in which the power domain is created. The instance name is the name of a hierarchical cell. By default, the power domain is created in the current scope. This option is deprecated in IEEE Std. 1801-2013. Create the power domain within the current scope.

-supply {*supply_set_handle_name supply_set_name*}

Creates a user-specified supply set handle or restricts the supply sets available for use in the power domain. You can use this option multiple times in one command.

A supply set handle is an abstract supply set created for a power domain. By default, a power domain has supply set handles for the domain's primary supply set, a default isolation supply set, and a default retention supply set. These supply set handles let you synthesize a design even before you create any supply sets, supply nets, and supply ports for the power domain. Before such a design can be physically implemented, its supply set handles must be associated with actual supply sets. Those supply sets must be associated with actual supply nets.

If you specify a supply set handle name alone, without a supply set, the command creates a supply set handle having the specified name for the power domain. Supply nets named *domain_name.handle_name.power* and *domain_name.handle_name.ground* can then be used as supplies.

If you specify a supply set handle name with a supply set name, the command associates that supply set with the supply set handle, so that the specified supply set becomes equivalent to the supply set handle.

The following supply set handle names have special meaning in the command syntax:

```
primary
default_isolation
default_retention
extra_supplies_# (where # is a unique numeral)
extra_supplies
```

This is how the special-purpose supply set handle names are used:

- **primary**: The primary supply set of this power domain.
- **default_isolation**: The default isolation supply set for any isolation strategy applied to this power domain, if the isolation power or ground is not otherwise specified in this strategy.
- **default_retention**: The default retention supply set for any retention strategy applied to this power domain, if the retention power or ground is not otherwise specified in this strategy.
- **extra_supplies_#**: Extra supply sets that are available for the power domain to use in level shifter insertion and always-on synthesis.
- **extra_supplies**: When this supply set handle is used with an empty string for the *supply_set_name* parameter, **-supply {**extra_supplies** ""}**, it prevents any domain-independent extra supplies from being used in the power domain. In this case, only domain-dependent supply nets can be used, which are supply nets created with the **-domain** option of the **create_supply_net** command.

-available_supplies {*supply_set_name_list*}

A list of additional supply sets that are available for use by implementation tools to power cells inserted in this domain.

- The **-available_supplies** option specifies any additional supplies which are available for use.
- If **-available_supplies** is not specified, all supply sets and supply set handles defined in or above the scope of the power domain are available for use by tools to power cells inserted into the power domain.
- If **-available_supplies** is specified with an empty string argument, only the locally available supplies are available for use by tools to power cells inserted into the power domain.
- If **-available_supplies** is specified with a non-empty string, use a list of names of additional supply sets or supply set handles defined at or above the scope of the power domain in addition to the locally available supplies.

NOTE: The option **-available_supplies** cannot be used together with the keywords **extra_supplies** or **extra_supplies_#** of the **-supply** option.

-update

Updates the specification of an existing power domain. This option can be used only to update the supply set association or elements of a power domain, using the following other options of the command:

- **-supply**: Updates the supply set association of an existing power domain.
- **-available_supplies**: Updates the supply set association of an existing power domain.
- **-elements**: Updates the set of root cells that comprise the power domain extent.
- **-exclude_elements**: Updates the set of excluded cells from the root cells of the power domain extent.

The **-update** option is used along with the *domain_name* and **-supply** or **-elements** options. It is an error to use the **-update** option with any other options.

The **-supply** option allows you to

- Add a new supply set handle name without explicitly defining a supply set association
- Add a supply set to be associated with a previously declared supply set handle
- Add a new supply set handle and a supply set association in a single command

NOTE: You cannot update a supply set handle that you have already associated with a supply set.

The **-elements** option allows you to

- Add new root cells to an existing power domain extent

NOTE: You cannot add a root cell which is already a root cell of an existing power domain.

DESCRIPTION

This command creates a power domain in the specified scope. A power domain is a collection of design elements that share a primary power net and a ground power net. The logic hierarchy level where a power domain is created is called the *scope* of the power domain. The set of design elements that belong to a power domain is called the *extent* of that power domain. A hierarchical cell is an example of an element. Although a design element can be in the scope of several power domains, it can be in the extent of only one power domain.

A power domain can have several supply nets, which are connected to a power domain via a supply port. A power switch of a power domain can be used to turn on and off the power supply of part or all of the power domain. You can create a supply net, supply port, or power switch by using the **create_supply_net**, **create_supply_port**, or **create_power_switch** command, respectively.

When this command succeeds, it returns the full name of the power domain (from the current scope). When it fails, it returns a null string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates two power domains in the scope named INST1.

```
prompt> create_power_domain PD1 -elements INST1/SUB_INST -scope INST1  
INST1/PD1  
prompt> create_power_domain PD2 -elements INST1/SUB_INST -scope INST1  
Error: Could not add cell 'INST1/SUB_INST' to power domain 'PD2'.  
(MWUI-402)  
prompt> create_power_domain PD2 -scope INST1 -include_scope  
INST1/PD2
```

The following example creates a power domain with the **-supply** option with the **extra_supplies_#** keyword.

```
prompt> create_power_domain PD_MID -scope mid1 \  
-supply {extra_supplies_1 supply_set1} \  
-supply {extra_supplies_2 supply_set1}  
mid1/PD_MID
```

The following example creates a power domain with the **-supply** option with the **extra_supplies** keyword.

```
prompt> create_power_domain PD_MID -scope mid1 \  
-supply {extra_supplies ""}  
mid1/PD_MID
```

The following example updates an existing power domain with the **-supply** option.

```
prompt> create_power_domain PD_MID -scope mid1 -supply {abc}  
mid1/PD_MID  
prompt> create_power_domain PD_MID -scope mid1 -update \  
-supply {primary SS1} -supply {abc SS1}  
mid1/PD_MID
```

[report_power_domain\(2\)](#)

create_power_state_group

Defines a group name to be used in the **add_power_state** command.

SYNTAX

```
status create_power_state_group  
      group_name
```

Data Types

group_name string

ARGUMENTS

group_name

Specifies the name of the group to create. It must use a simple name.

DESCRIPTION

The **create_power_state_group** command defines a group in the active scope that can be used with the **-group** option of the **add_power_state** command.

Use a group to collect related power states defined by the **add_power_state** command. The legal power states of a group define the legal combinations of power states of other objects in this scope or the descendant subtree, that is, those combinations of states of those objects that can exist at the same time during operation of the design.

It is an error if the specified group name already exists in the active scope.

The group name should be in the same namespace as the other UPF objects (power domains/supply sets/supply nets/supply ports/PSTs).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a power state group.

```
prompt> create_power_state_group GROUP
```

SEE ALSO

[add_power_state\(2\)](#)

create_power_switch

Creates a power switch in the specified power domain.

SYNTAX

```
string create_power_switch
  switch_name
  -domain domain_name
  -output_supply_port {port_name supply_net_name}
  -input_supply_port {port_name supply_net_name}
  -control_port {port_name net_name}
  -supply_set supply_set_name
  [-ack_port {port_name net_name [{boolean_function}]}]
  [-ack_delay {port_name delay}]
  -on_state {state_name input_supply_port {boolean_function}}
  [-off_state {state_name {boolean_function}}]
  [-on_partial_state {state_name {boolean_function}}]
  [-error_state {state_name {boolean_function}}]
```

Data Types

<i>switch_name</i>	string
<i>domain_name</i>	string
<i>port_name</i>	string
<i>supply_net_name</i>	string
<i>net_name</i>	string
<i>supply_set_name</i>	string
<i>boolean_function</i>	list
<i>delay</i>	string
<i>state_name</i>	string
<i>input_supply_port</i>	string

ARGUMENTS

switch_name

Specifies the name of the power switch to be created. The name should be a simple (nonhierarchical) name. If a power switch with the same name already exists in the specified power domain, the power switch cannot be created.

This option is required.

-domain *domain_name*

Specifies the power domain that contains the power switch. If the power domain with the specified name does not exist in the current scope, the command fails.

This option is required.

-output_supply_port {*port_name supply_net_name*}

Specifies the name of the output port of the power switch and the supply net to which the port connects. On the power switch, if a port with the same name exists, the command fails. In the current scope, if there is no supply net with the same name, the command fails.

This option is required.

-input_supply_port {port_name supply_net_name}

Specifies the name of the input port of the power switch and the supply net to which the port connects. On the power switch, if a port exists with the same name, the command fails. In the current scope, if there is no supply net with the same name, the command fails.

This option is required and can be specified more than once. One power switch can have multiple input supply ports.

-control_port {port_name net_name}

Specifies the name of the control port of the power switch and the logical net to which this port connects. If a port with the specified name already exists on the power switch, the command fails. If a net with the specified name does not exist, the command fails.

This option is required and can be specified more than once. One power switch can have multiple control ports.

-supply_set supply_set_name

Specifies a related supply set for both the control and acknowledge signals of the created power switch.

When specified, this supply set is assumed to be the related supply of control and acknowledge ports of the switch.

The specified supply set must exist and be visible from the switch location. If it is not available on the switch location, then it is NOT automatically made available by means of this command

This argument is optional if the switch declares only one input port. For multiple input supply switches -supply_set is mandatory.

-ack_port {port_name net_name {boolean_function}}

Specifies the name of the acknowledge port of the power switch and the logical net to which this port connects. If a port with the specified name already exists on the power switch, the command fails. If a net with the specified name does not exist, the command fails.

If this option is not specified, the power switch does not have an acknowledge port. Optionally, a Boolean function can also be specified. The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-ack_delay {port_name delay}

Specifies the acknowledge port on the switch and the corresponding acknowledge delay.

This option can be specified multiple times.

-on_state {state_name input_supply_port {boolean_function}}

Specifies a named on-state, the relevant input supply port, and its Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-off_state {state_name {boolean_function}}

Specifies a named off state and its relevant Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else.

This option can be specified multiple times.

-on_partial_state {state_name {boolean_function}}

Specifies a named partial_on state and its relevant Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else. The **-on_partial_state** option does not affect implementation and is intended to be used by simulation, so the tool reads and writes the information specified with this option transparently.

This option can be specified multiple times.

-error_state {state_name {boolean_function}}

Specifies a named error state and its relevant Boolean function.

The *boolean_function* should be defined in terms of the specified control ports, and nothing else. The **-error_state** option does not affect implementation and is intended to be used by simulation, so the tool reads and writes the information specified with this option transparently.

This option can be specified multiple times.

DESCRIPTION

The *create_power_switch* command enables you to create a power switch at the specified power domain. The switch is created within the scope of the power domain. Each power switch must be connected with an input supply net and an output supply net. The power switch can be connected with an acknowledge (logical) net and several control (logical) nets. Each net is connected with a power switch via a switch port. The switch ports are automatically created if the power switch is created successfully.

Upon success, this command returns the full name of the power switch (from the current scope). The command returns a null string upon failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates power switch *SW1* within the power domain *PD1*:

```
prompt> create_power_switch SW1 -domain PD1 \
      -output_supply_port {vout VNO2} \
      -input_supply_port {vin1 VNI1} \
      -input_supply_port {vin2 VNI2} \
      -control_port {ctrl_small ON1} \
      -control_port {ctrl_large ON2} \
      -ack_port {ack_p ACKN {ctrl_small & !ctrl_large}} \
      -ack_delay {ack_p 1} \
      -on_state {full_s vin1 {ctr_small}} \
      -off_state {off_s {!ctr_small}} \
```

SEE ALSO

[report_power_switch\(2\)](#)

create_pst

Creates a power state table (PST), using a specific order of supply nets.

SYNTAX

```
string create_pst
  table_name
  -supplies list
```

Data Types

<i>table_name</i>	string
<i>list</i>	list

ARGUMENTS

table_name

Specifies the name of the power state table.

This argument is required.

-supplies *list*

Specifies a list of supply nets or ports to include in each power state table in the design.

This option is required.

DESCRIPTION

The **create_pst** command creates a power state table using a specific order of supply nets. A power state table is used for implementation specifically for synthesis, analysis, and optimization. The power state table defines the legal combinations of states, which are those combinations of states that can exist at the same time during the operation of the design.

The power state table has no simulation semantics. It is tool-dependent as to whether the simulation tools report an error if an illegal (unspecified) combination of states occurs.

An error occurs if a specified supply net has not been created before the **create_pst** command is run.

This command returns the name of the power state table if it is created, or the null string if the power state table is not created.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of the **create_pst** command:

```
prompt> create_pst MyPowerStateTable -supplies {PN1 PN2 SOC/OTC/PN3}
```

SEE ALSO

`add_port_state(2)`
`add_pst_state(2)`
`report_pst(2)`

create_qor_snapshot

Generates a quality-of-results report for active scenarios of the current design and stores the report into a set of files.

SYNTAX

```
status create_qor_snapshot
  -name name
  [-power]
  [-clock_tree]
  [-show_all]
  [-route]
  [-save_mw]
  [-significant_digits digits]
  [-zero_wire_load]
  [-max_paths number]
  [-nworst number]
  [-scenarios list_of_scenarios]
  [-infeasible_paths]
  [-nosplit]
```

Data Types

<i>name</i>	string
<i>digits</i>	integer
<i>number</i>	integer
<i>list_of_scenarios</i>	string

ARGUMENTS

-name *name*

Specifies the name of the QoR snapshot, which can be used to identify a particular snapshot. The name should start with a letter.

-power

Records dynamic and static power.

-clock_tree

Records clock tree information. This option is supported only in icc_shell, not dc_shell or de_shell.

-show_all

Shows all clock groups, including those without violations. By default, the command only shows clock groups that have violations.

-route

Shows route data of the design. This option is supported only in icc_shell, not dc_shell or de_shell.

-save_mw

Saves the Milkyway design using the snapshot name appended with "_ss". This option is supported only in icc_shell, not dc_shell or de_shell.

-significant_digits *digits*

Specifies the number of significant digits for the values generated in the reports. This setting can affect the numbers of violating paths in the histogram of minimum and maximum violations might, as demonstrated in the EXAMPLES section.

-zero_wire_load

Uses zero wire load models for timing reporting.

-max_paths *number*

Specifies the maximum number of paths for the **report_timing** command to report per path group.

-nworst *number*

Specifies the maximum number of worst paths for the **report_timing** command to report per timing endpoint.

-scenarios *list_of_scenarios*

Specifies the list of active scenarios to get a QoR snapshot. The default behavior is to report all active scenarios.

-infeasible_paths

Stores the data of paths which have been marked as infeasible during compile exploration. To access the stored data, specify the **-infeasible_paths** option with the **query_qor_snapshot** command.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **create_qor_snapshot** command generates a quality-of-results report for the active scenarios of the current design and stores the report into a set of files. You can extract information from snapshot reports by using the **query_qor_snapshot** command. A QoR snapshot contains information about quality metrics such as timing, area, DRC, clocks, power, and routing.

When you use the **-zero_wire_load** option, the timing report is generated using zero interconnect delay mode. The timing report is also affected by the **set_zero_interconnect_delay_mode** command.

The command supports both multicorners-multimode designs as well as designs that are not multicorners-multimode.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following command creates a QoR snapshot named "preroute" from the current design and saves the snapshot files under the "snapshot" directory under in the current working directory.

```
prompt> create_qor_snapshot -name preroute
```

The following example shows how the number of significant digits can affect the output of the minimum and maximum violation histogram.

```
prompt> create_qor_snapshot -name atest -significant_digits 4
```

```
...
```

```
Histogram: s1
```

```

create_qtm_constraint_arc

Creates a constraint arc for a quick timing model (QTM).

SYNTAX

```
status create_qtm_constraint_arc
  [-name arc_name]
  [-setup | -hold]
  [-from port_name]
  [-to port_spec]
  [-edge rise | fall]
  [-signal_edge rise | fall]
  [-input_transition_rise rise_time]
  [-input_transition_fall fall_time]
  [-path_type name [-path_factor factor]
  | -value constraint_value
```

Data Types

<i>arc_name</i>	string
<i>port_name</i>	string
<i>port_spec</i>	list
<i>rise_time</i>	float
<i>fall_time</i>	float
<i>name</i>	string
<i>factor</i>	float
<i>constraint_value</i>	float

ARGUMENTS

-name *arc_name*

Specifies the name of the constraint arc.

If you do not specify the **-name** option, the command constructs a default name based on the port names and edge names.

-setup

Creates a setup arc.

This option and the **-hold** option are mutually exclusive; you must specify one.

-hold

Creates a hold arc.

This option and the **-setup** option are mutually exclusive; you must specify one.

-from *port_name*

Specifies the constraining port name. Define this port as a clock port.

This is a required option.

-to port_spec

Specifies the constrained port. Define this port as an input, inout, or internal port.

This is a required option.

-edge rise | fall

Specifies the triggering edge of the clock specified by the **-from** option.

This is a required option.

-signal_edge rise | fall

Specifies the direction of the signal at the constrained port specified by the **-to** option.

If you do not specify this option, the tool creates constraints for both signal rise and signal fall.

-input_transition_rise rise_time

Specifies the rise transition time used for delay calculation at the input pin specified by the **-to** option.

This option works together with the **setup** or **hold** global QTM parameter specified by the **set_qtm_global_parameter** command, depending on whether you are specifying a setup or hold constraint. This delay and the delay specified by the **-value** option are applied to the arc. The **-input_transition_rise** option is ignored if there is no global setup or hold parameter specified by the **set_qtm_global_parameter** command.

The default is 0.0.

-input_transition_fall fall_time

Specifies the fall transition time used for delay calculation at the input pin specified by the **-to** option.

This option works together with the **setup** or **hold** global QTM parameter specified by the **set_qtm_global_parameter** command, depending on whether you are specifying a setup or hold constraint. This delay and the delay specified by the **-value** option are applied to the arc. The **-input_transition_fall** option is ignored if there is no global setup or hold parameter specified by the **set_qtm_global_parameter** command.

The default is 0.0.

-path_type name

Specifies the path type to use to set the delay. The specified type must be defined by a previous call to the **create_qtm_path_type** command.

This option and the **-value** option are mutually exclusive; you must specify one.

-path_factor factor

Specifies the multiplication factor for the path type.

This option is valid only with the **-path_type** option.

-value constraint_value

Specifies the delay value in the time units used in the design.

This option and the **-path_type** option are mutually exclusive; you must specify one.

DESCRIPTION

This command creates a constraint arc in a quick timing model. The **-from** option specifies the constraining port and the **-to** option

specifies the constrained port. The **-from** port must be defined as a clock port and the **-to** port must be an input, inout, or internal port.

If the constraint arc is a setup arc, the tool adds the QTM global setup time to the value specified by the **-setup** option. If the constraint arc is a hold arc, the tool adds the QTM global hold time to the value specified by the **-hold** option. You define the global setup time and global hold time by using the **set_qtm_global_parameter** command.

To display information about the current QTM model, use the **report_qtm_model** command.

For a basic description of quick timing models, see the **create_qtm_model** man page. For a more detailed description, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command creates a setup arc from the positive edge of the constraining pin CLK to the constrained pin IN1. The delay is 2 times the delay for path1.

```
prompt> create_qtm_constraint_arc -setup -edge rise \
      -from CLK -to IN1 -path_type path1 -path_factor 2
```

The following command creates a hold arc from the positive edge of the constraining pin CLK to the constrained pin IN1. The delay is 2 times the delay for path1.

```
prompt> create_qtm_constraint_arc -hold -edge rise \
      -from CLK -to IN1 -path_type path1 -path_factor 2
```

The following command creates a hold arc from the positive edge of the constraining pin CLK to the constrained pin IN1. The delay is 3 time units.

```
prompt> create_qtm_constraint_arc -hold -edge rise \
      -from CLK -to IN1 -value 3.0
```

SEE ALSO

`create_qtm_delay_arc(2)`
`create_qtm_model(2)`

`save_qtm_model(2)`
`set_qtm_global_parameter(2)`

create_qtm_delay_arc

Creates a delay arc for a quick timing model (QTM).

SYNTAX

```
status create_qtm_delay_arc
  [-name arc_name]
  -from ports
  -to ports
  [-from_edge rise | fall]
  [-to_edge rise | fall]
  [-input_transition_rise rise_time]
  [-input_transition_fall fall_time]
  -path_type name [-path_factor factor]
    | -value delay_value
    | -total_value total_value
  [-max_insertion_delay]
  [-min_insertion_delay]
```

Data Types

<i>arc_name</i>	string
<i>ports</i>	collection
<i>rise_time</i>	float
<i>fall_time</i>	float
<i>name</i>	string
<i>factor</i>	float
<i>delay_value</i>	float
<i>total_value</i>	float

ARGUMENTS

-name *arc_name*

Specifies the name of the delay arc.

If you do not specify the **-name** option, the command constructs a default name based on the port names and edge names.

-from *ports*

Specifies the QTM ports that are the startpoints of the delay arc. The port type must be clock, input, inout, or internal.

-to *ports*

Specifies the QTM ports that are the endpoints of the delay arc. The port type must be output, inout, or internal.

-from_edge rise | fall

Specifies the triggering edge (rise or fall) for clock startpoints or the signal direction for data startpoints. If you do not use this option, the command creates delay arcs from both rise and fall edges at the startpoints.

-to_edge rise | fall

Specifies the signal direction at the data endpoints. If you do not use this option, the command creates delay arcs to both rise and fall edges at the endpoints.

If you omit both the **-from_edge** and **-to_edge** options, the command creates rise-to-rise and fall-to-fall delay arcs.

-input_transition_rise rise_time

Specifies the rise transition time used for delay calculation at the input pin specified by the **-to** option. The default is 0.0.

-input_transition_fall fall_time

Specifies the fall transition time used for delay calculation at the input pin specified by the **-to** option. The default is 0.0.

When you specify a delay arc from a clock port, the **-input_transition_rise** or **-input_transition_fall** option works together with the **clk_to_output** global QTM parameter specified by the **set_qtm_global_parameter** command. This delay and the delay specified by the **-value** or **-total_value** option are applied to the arc. If there is no global **clk_to_output** parameter specified by the **set_qtm_global_parameter** command, the **-input_transition_rise** option or **-input_transition_fall** option setting is ignored.

-path_type name

Specifies the name of the path type to use to set the delay. The specified type must be defined by previous usage of the **create_qtm_path_type** command.

The **-path_type**, **-value**, and **-total_value** options are mutually exclusive; you must use one of them.

-path_factor factor

Specifies the multiplication factor for the path type. The delay value for this path is the delay of the specified path type multiplied by this factor. This option is used only with the **-path_type** option.

-value delay_value

Specifies the delay value in terms of the time units used for the design. The total delay value for the arc is computed by adding the specified value to the delay computed for the drive arc at the output port. The drive arc delay is defined by the **create_qtm_drive_type** and **set_qtm_port_drive** commands.

-total_value total_value

Specifies the total delay value in terms of the time units used for the design. The drive arc delay and load are not considered when determining the total delay value for the arc.

-max_insertion_delay

Specifies the insertion delay value for the maximum operating condition.

-min_insertion_delay

Specifies the insertion delay value for the minimum operating condition.

When you specify the **-max_insertion_delay** or **-min_insertion_delay** option, the **-from** and **-to** option must be the same port and must be a clock port. When you use these options, the command creates the insertion delay on that clock port of QTM model.

The **-max_insertion_delay** and **-min_insertion_delay** options must be specified with the **-value** option. In addition, these options are mutually exclusive with the **-path_type**, **-path_factor**, **-total_value**, **-from_edge**, **-to_edge**, **-name**, **-input_transition_rise**, and **-input_transition_fall** options.

DESCRIPTION

This command creates delay arcs in a quick timing model. If you specify a list of ports for the **-from** and **-to** options, the tool creates delay arcs from each startpoint to each endpoint.

For an edge-triggering arc from a clock port to a data port, the value of the **clk_to_output** global QTM parameter is added to the specified delay value.

You can specify the delay value of the arc by specifying a path type, by specifying a value that is added to the computed delay for the drive arc, or by specifying a total delay value explicitly. You must use exactly one of the options **-path_type**, **-value**, or **-total_value** to specify the delay value.

If the delay defined by **create_qtm_delay_arc** for the port is the maximum delay budgeted for the output, use the **-total_value** option to prevent the command from adding any more delay. If you use the **-value** option, the drive arc delay might be added to the budget. Note that with a smaller load at the output port, the delay might be smaller than the budgeted maximum delay.

To show the information for the current quick timing model, use the **report_qtm_model** command.

For a basic description of quick timing models, see the **create_qtm_model** man page. For a more detailed description, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command creates rise-to-fall delay arcs from the A, B, and C input ports to output port D with a delay value of 2.0 time units. The total delay for each arc is computed by adding 2.0 to the drive arc delay.

```
prompt> create_qtm_delay_arc -from_edge rise -to_edge fall \
    -from {A B C} -to D -value 2.0
```

The following command creates rise-to-rise and fall-to-fall delay arcs from the clock port named CLK to the OUT output port with a delay equivalent to three times that of path type "path1", which was defined earlier by the **create_qtm_path_type** command.

```
prompt> create_qtm_delay_arc -from CLK -to OUT \
    -path_type path1 -path_factor 3
```

The following command uses a wildcard to create rise-to-rise and fall-to-fall delay arcs from all input ports whose names start with CL to the OUT output port, with a delay equivalent to three times that of path type "path1".

```
prompt> create_qtm_delay_arc -from CL* -to OUT \
    -path_type path1 -path_factor 3
```

The following command sets the insertion delay on the clock port named CLK to be 4.5 for both the maximum and minimum operating conditions.

```
prompt> create_qtm_delay_arc -from CLK -to CLK -value 4.5 \
    -max_insertion_delay -min_insertion_delay
```

SEE ALSO

create_qtm_constraint_arc(2)
create_qtm_model(2)
create_qtm_path_type(2)
report_qtm_model(2)
save_qtm_model(2)

create_qtm_drive_type

Creates a drive type in a quick timing model (QTM).

SYNTAX

```
status create_qtm_drive_type
  -lib_cell lib_cell_name
  [-input_pin pin_name]
  [-output_pin pin_name]
  [-input_transition_rise rtrans]
  [-input_transition_fall ftrans]
  drive_type_name
```

Data Types

<i>lib_cell_name</i>	string
<i>rtrans</i>	float
<i>ftrans</i>	float
<i>drive_type_name</i>	string

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the library cell name in the technology library.

This is a required option.

-input_pin *pin_name*

Specifies the input pin in the lib_cell that is the startpoint of the arc that ends in the output pin.

-output_pin *pin_name*

Specifies the output pin in the lib_cell that specifies the drive.

-input_transition_rise *rtrans*

Specifies the input rising transition time associated with the input pin to compute the delay for the drive arc.

If you do not use this option, the delay table for the rising input of the drive arc is loaded from the library as-is.

Use the **-input_transition_rise** and **-input_transition_fall** options to capture the transition time associated with the input pin. This can provide more accurate information on the transition time and delay time for the defined drive arc.

-input_transition_fall *ftrans*

Specifies the input falling transition time associated with the input pin to compute the delay for the drive arc.

If you do not use this option, the delay table for the falling input of the drive arc will be loaded from library as-is.

drive_type_name

Specifies the name given to the defined drive type.

DESCRIPTION

This command can be used to create a drive type. The defined drive type can be used to set the drives on output ports. The drive type is specified by referring to a library cell in the technology library. The library cell is specified by using the **-lib_cell** option. This library cell must be present in the technology library.

The output pin that drives the port is specified by using the **-output_pin** option. In addition, you can specify the input pin by using the **-input_pin** option. This option selects an arc that drives the output pin of the library cell.

If you do not specify the input pin or the output pin, the tool chooses an arbitrary arc to define the drive type. If you specify the input pin but not the output pin, the tool chooses an arbitrary arc starting from the input pin to define the drive type. If you specify the output pin but not the input pin, the tool chooses an arbitrary delay arc coming into the output pin to define the drive type. If you specify both the input and the output pin, the library cell must have a combinational arc from the input pin to the output pin.

To use this command, you must read in the technology library and then specify it by using the **set_qtm_technology** command.

To show the information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTMs, see the **create_qtm_model** man page. For a more detailed description, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following examples it is assumed that you have loaded the technology library and the QTM technology is set. Do this by using the following the sequence of commands as a guide, substituting the name of your technology library.

```
prompt>read_lib my_technology_library.db  
prompt>set_qtm_technology -library my_technology_library
```

The following command creates a drive type equivalent to the BUF1 library cell.

```
prompt> create_qtm_drive_type -lib_cell BUF1 drive1
```

The following command creates a drive type named drive2 that is equivalent to the BUF2 library cell and specifies the output pin to use.

```
prompt> create_qtm_drive_type -lib_cell BUF2 -output_pin Y drive2
```

create_qtm_generated_clock

Creates a generated clock for a quick timing model (QTM).

SYNTAX

```
status create_qtm_generated_clock
      -source master_clock_name
      [-divide_by divide_factor
       | -multiply_by multiply_factor]
      [-invert]
      generated_clock_name
```

Data Types

<i>master_clock_name</i>	string
<i>divide_factor</i>	int
<i>multiply_factor</i>	int
<i>generated_clock_name</i>	string

ARGUMENTS

-source *master_clock_name*

Specifies the name of the clock defined as the master source of the generated clock. The master source must be defined as a clock or a generated clock prior to the generated clock definition.

-divide_by *divide_factor*

Specifies the frequency division factor. If the *divide_factor* value is 2, the generated clock period is twice as long as the master clock period.

-multiply_by *multiply_factor*

Specifies the frequency multiplication factor. If the *multiply_factor* value is 3, the generated clock period is one-third as long as the master clock period.

-invert

Inverts the generated clock signal (in the case of frequency multiplication and division).

generated_clock_name

Specifies the name of the generated clock.

If a QTM port or internal pin with the specified name already exists, the generated clock is defined on the existing port or internal pin. Otherwise, a new internal pin is created to be the source of the generated clock.

DESCRIPTION

This command creates a QTM generated clock. A generated clock can be defined on an external port of the QTM, as well as on an internal pin in the QTM. After you define a generated clock, the source port or pin can be used in other QTM commands the same way as those ports and pins defined by the **create_qtm_port** command. For example, the delay arcs from or to the generated clock source pin can be defined with the **create_qtm_delay_arc** command and constraint arcs related to the generated clock can be defined with the **create_qtm_constraint_arc** command.

For a basic description about QTMs, see the **create_qtm_model** man page. For a more detailed description about QTMs, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates a divide-by 2 generated clock using the master clock CLK on an internal pin named GCLK_int (assuming that there is no QTM port named GCLK_int).

```
prompt> create_qtm_generated_clock GCLK_int -source CLK -multiply_by 2
```

The following example creates a generated clock on port GCLK (assuming that GCLK has already been defined as a QTM port).

```
prompt> create_qtm_generated_clock GCLK -source CLK -divide_by 2 -invert
```

SEE ALSO

`create_qtm_model(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`create_qtm_delay_arc(2)`
`create_qtm_constraint_arc(2)`

create_qtm_insertion_delay

Specifies the insertion delay on the clock port of a quick timing model (QTM).

SYNTAX

```
string create_qtm_insertion_delay
  [-max]
  [-min]
  [-value insertion_delay]
  port_list
```

Data Types

```
insertion_delay    float
port_list          list
```

ARGUMENTS

-max

Specifies whether to generate insertion delay for Maximum operating condition.

-min

Specifies whether to generate insertion delay for Minimum operating condition.

-value *insertion_delay*

Specifies the insertion delay in terms of the time units you use for the model.

port_list

Specifies a list of clock ports on which to set internal clock latency. Each element in the list is either a collection of QTM ports or a pattern that matches QTM ports.

DESCRIPTION

This command creates the insertion delay for a clock port on the QTM model. The insertion delay is the network latency from the clock port to a (hypothetical) FlipFlop inside the QTM model.

If the CTS has been done on the design, then there would be network latency for all the clock pins of the FlipFlops. If some of the hierarchical blocks in the design are replaced by blackboxes, then the user can generate QTM models for the blackboxes to represent their timing model.

If the user generates the QTM models for the blackboxes, then *create_qtm_insertion_delay* command can be called to set the network delay from clock port of the hierarchical block to FlipFlop inside the hierarchical block, as the insertion delay.

To show the information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTM, see the **create_qtm_model** man page. For a more detailed description about QTM, see the design planning chapter of the *IC Compiler User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command sets the insertion delay on CLK to be 2.0 for Max mode.

```
prompt> create_qtm_insertion_delay -max -value 2.0 CLK
```

The following command sets the insertion on CK to be 4.5 for both Max and Min modes.

```
prompt> create_qtm_insertion_delay -value 4.5 CK
```

`create_qtm_port(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`create_qtm_clock(2)`

create_qtm_load_type

Creates a load type for a quick timing model (QTM) description.

SYNTAX

```
string create_qtm_load_type
    -lib_cell lib_cell_name
    [-input_pin pin_name]
    load_type_name
```

Data Types

<i>lib_cell_name</i>	string
<i>pin_name</i>	string
<i>load_type_name</i>	string

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of the library cell in the technology library.

-input_pin *pin_name*

Specifies the input pin in the lib_cell to specify capacitance.

load_type_name

Specifies the name given to the defined load type.

DESCRIPTION

This command creates a load type. A load type can be used to define the load on a QTM input port. The load type is specified by referring to a library cell in the technology library. The cell is specified using the **-lib_cell** option. The cell must be present in the specified technology library.

The input pin can be specified by using the **-input_pin** option. If the input pin is not specified, an arbitrary input pin is chosen to define the load type.

To use this command you must first read in the technology library, then specify the technology library by using the **set_qtm_technology** command.

To display information for the current QTM model, use the **report_qtm_model** command.

For a basic description about QTMs, see the **create_qtm_model** man page. For a more detailed description about QTM, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example loads the technology library and sets the QTM technology.

```
prompt>read_db my_technology_library.db  
prompt>set_qtm_technology -library my_technology_library
```

The following command creates a load type 'load1' using cell OR1. Since the input pin name is not specified, QTM selects an arbitrary input pin.

```
prompt> create_qtm_load_type -lib_cell OR1 load1
```

The following command creates a load type 'load2' using cell OR1, input pin A.

```
prompt> create_qtm_load_type -lib_cell OR1 -input_pin A load2
```

SEE ALSO

```
create_qtm_drive_type(2)  
create_qtm_model(2)  
create_qtm_path_type(2)  
report_qtm_model(2)

set_qtm_port_load(2)
```

create_qtm_model

Begins the definition of a quick timing model (QTM) description.

SYNTAX

```
string create_qtm_model
      model_name
```

Data Types

model_name string

ARGUMENTS

model_name

Specifies the name of the generated model.

DESCRIPTION

Specifies the name of a new quick timing model (QTM) to be created by ICC Design Planning. QTMs are temporary timing models that can be created quickly for a block using ICC Design Planning commands. The purpose of these commands is to provide timing information without the necessity of writing a detailed timing model.

QTMs are intended to be used early in the design cycle to describe rough initial timing of a block. These models will eventually be replaced, either by some other detailed timing model or by the netlist of the block, to obtain more accurate timing. For a more detailed description of QTMs, see the *ICC Design Planning User Guide*.

A QTM model can be saved as a Synopsys DB file, which can be instantiated in a design in the same way library cells or ITS models are instantiated. Both Design Compiler and JupiterXT accept designs with instantiated QTMs. To save a QTM model, use the **save_qtm_model** command.

Other commands in the QTM command set must be placed between a **create_qtm_model** and **save_qtm_model** command. Many QTM commands exist for specifying, configuring and examining QTMs. The following is not an exhaustive list, but gives examples of tasks you can perform using QTM commands:

- To create a QTM port, use the **create_qtm_port** command.
- To create constraint arcs and delay arcs, use the **create_qtm_constraint_arc** and the **create_qtm_delay_arc** commands, respectively.
- To set the drive of a QTM output port, use the **set_qtm_port_drive** command.
- To set the load of a QTM input port, use **set_qtm_port_load** command.
- To show the information about the current QTM model, use the **report_qtm_model** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command creates a new QTM model with the name adder.

```
prompt> create_qtm_model adder
```

SEE ALSO

set_qtm_technology(2)
```

create_qtm_path_type

Creates a path type in a quick timing model (QTM) description.

SYNTAX

```
string create_qtm_path_type
    -lib_cell lib_cell_name
    [-input_pin input_pin_name]
    [-output_pin output_pin_name]
    [-fanout count]
    path_type_name
```

Data Types

```
lib_cell_name    string
input_pin_name   string
output_pin_name  string
count           integer
path_type_name   string
```

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of the library cell in the technology library.

-input_pin *input_pin_name*

Specifies the input pin in the lib_cell. This is the startpoint of the arc for which to define the path type.

-output_pin *output_pin_name*

Specifies the output pin in the lib_cell. This is the endpoint of the arc for which to define the path type.

-fanout *count*

Specifies the average number of fanout pins to consider while computing the delay of the path type. The fanout count can range from 1 to 1000. By default, this is 1.

path_type_name

Specifies the name given to the defined path type.

DESCRIPTION

This command creates a path type. A path type mimics an arc in a library cell. An arc in the QTM model is defined in terms of the

delays of the path type. The path type is specified by referring to a lib_cell in the technology library. The lib_cell is specified using the **-lib_cell** option. This lib_cell must be present in the technology library specified.

You can specify the average fanout count to which the arc fans out while defining the path type. It is assumed the arc fans out to the first input pin of the same library cell, while calculating the delays. The input pin is specified by using the **-input_pin** option. The output pin is specified by using the **-output_pin** option.

If neither input pin nor the output pin is specified, an arbitrary delay arc in the lib_cell is chosen to define the path type.

If the input pin is specified and output pin is not specified, an arbitrary delay arc starting from the input pin defines the path type.

If the output pin is specified and input pin is not specified, an arbitrary delay arc coming into the output pin defines the path type.

If both input and output pins are specified, the lib_cell must have an arc from the input pin to the output pin.

To use this command, you must read in the technology library. Next, specify the technology library by using the **set_qtm_technology** command.

To show information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTM, see the **create_qtm_model** man page. For a more detailed description about QTM, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following examples load the technology library and set the QTM technology.

```
prompt>read_lib my_technology_library.db  
prompt>set_qtm_technology -library my_technology_library
```

The following example creates a path type path1 by using lib_cell AN2, with an average fanout count of 2 (uses default input, output pins).

```
prompt> create_qtm_path_type -lib_cell AN2 -fanout 2 path1
```

The following example creates a path type path2 by using cell AN2, with an average fanout count of 2, and using pin 'A' as the starting point for the path type.

```
prompt> create_qtm_path_type -lib_cell AN2 -input_pin A -fanout 2 path2
```

The following example creates a path type path3 by using cell AN2, with an average fanout count of 2, using 'A' as the startpoint of the arc, and pin 'Z' as the endpoint of the arc.

```
prompt> create_qtm_path_type -lib_cell AN2 -input_pin A -output_pin Z -fanout 2 path3
```

create_qtm_port

Creates a quick timing model (QTM) port.

SYNTAX

```
string create_qtm_port
    -type port_type
        port_list
```

Data Types

```
port_type   string
port_list   list
```

ARGUMENTS

-type *port_type*

Specifies the type of port. The port can be one of the following types: input, output, inout, internal or clock. If you want a port to be a clock, define it as a clock port.

port_list

Specifies the list of QTM ports you want created.

DESCRIPTION

This command creates QTM port. You can create a single port or a list of ports with this command. The ports can be input, output, inout, internal or clock. Any port that constrains another port or has a edge triggered launch arc originating from it, has to be defined to be of the type 'clock'.

Bused ports are also defined by giving the start and end index (A[0:5]). Bused ports cannot be internal.

To show the information about the current QTM model, use **report_qtm_model** command.

For a basic description about QTM, please refer to **create_qtm_model** man page. For a more detailed description about QTM, please refer to the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates an input bused QTM port A[0:5].

```
prompt> create_qtm_port A[0:5] -type input
```

The following example creates a clocked QTM port CLK.

```
prompt> create_qtm_port CLK -type clock
```

The following example creates QTM output ports A, B, C, and D.

```
prompt> create_qtm_port {A B C D} -type output
```

The following example creates QTM internal pin D_int.

```
prompt> create_qtm_port D_int -type internal
```

SEE ALSO

`create_qtm_model(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`set_qtm_port_drive(2)`
`set_qtm_port_load(2)`

create_register_bank

Creates a multibit register bank from a list of single-bit registers.

SYNTAX

```
status create_register_bank
  object_list
  [-name bank_name]
  -lib_cell library_name/lib_cell_name
```

Data Types

<i>object_list</i>	list
<i>bank_name</i>	string

ARGUMENTS

object_list

Specifies a list of single-bit registers or latches in the current design from which a multibit register bank is created. The specified registers or latches are removed from the netlist and replaced by the multibit register bank. The order in which the registers are listed determines the order in which the nets are connected to the inserted register bank.

-name *bank_name*

Specifies the name of the new multibit register bank. If this option is omitted, the command derives a bank name by concatenating the names of *object_list*.

-lib_cell *library_name/lib_cell_name*

Specifies the name of the library reference cell used for the new register bank. The bit-width of the specified library cell must be at least as large as the total bit-width of the registers specified in the *object_list*. You can specify only one library cell name. Specifying the library name along with the cell name (for example, my_lib/my_cell) is mandatory in the Design Compiler tool and optional in the IC Compiler too.

DESCRIPTION

The **create_register_bank** command creates a new multibit bank from a list of registers or latches in the current design. All the single-bit registers or latches in *object_list* are replaced by one bank.

The command verifies that the registers in the *object_list* exist in the design and have valid locations, and do not have a "dont_touch" or "fixed" attribute.

The order of the specified registers determines the pin connection order of the new bank. For example, a net connected to the third specified register in the *object_list* is connected to the third bit of the multibit register inserted by the command.

In the Design Compiler tool, the bank bit-width has to be equal to the totalbit-width of the specified registers.

To automatically generate a script containing **create_register_bank** bank commands based on specified banking criteria, use the **identify_register_banks** command in the Design Compiler tool or the **set_banking_guidance_strategy** command in the IC Compiler tool.

In the Design Compiler tool, you can use the **create_register_bank** and **split_register_bank** commands only before scan insertion. If you want to use these commands after scan insertion, use them later in the IC Compiler tool.

Multicorner-Multimode Support

In case of designs with multiple scenarios, to properly transfer scenario-specific information during banking operations, you need to activate all scenarios before you run the **create_register_bank** commands .

EXAMPLES

The following example creates a multibit register bank from 4 single-bit registers:

```
prompt> create_register_bank -name group0_0 \
{reg_1 reg_2 reg_3 reg_4} -lib_cell multibit_lib/REG_4_BIT
```

SEE ALSO

`identify_register_banks(2)`
`split_register_bank(2)`

create_route_guide

Creates a new route guide.

SYNTAX

```
collection create_route_guide
  -coordinate rectangle
  [-no_signal_layers layers]
  [-no_preroute_layers layers]
  [-standard_cell_region]
  [-zero_min_spacing]
  [-preferred_direction_only_layers layers]
  [-switch_preferred_direction_layers layers]
  [-repair_as_single_sbox]
  [-horizontal_track_utilization percentage]
  [-vertical_track_utilization percentage]
  [-track_utilization_layers layers]
  [-name guide_name]
  [-single_layer_routing layers]
  [-access_preference {access_preference_spec}]
```

Data Types

<i>rectangle</i>	list of points
<i>layers</i>	list of strings
<i>percentage</i>	integer
<i>guide_name</i>	string
<i>access_preference_spec</i>	list

ARGUMENTS

-coordinate *rectangle*

Specifies the coordinates of the lower-left and upper-right corners of the bounding box of the route guide. The coordinate unit is specified in the technology file.

This option is required.

-no_signal_layers *layers*

Specifies the layers that cannot contain signals. Specify the layers by using the layer names from the technology file.

-no_preroute_layers *layers*

This option is not supported in Design Compiler.

-standard_cell_region

Specifies that the type of route guide is standard_cell_region.

-zero_min_spacing

This option is not supported in Design Compiler.

-preferred_direction_only_layers *layers*

This option is not supported in Design Compiler.

-switch_preferred_direction_layers *layers*

This option is not supported in Design Compiler.

-repair_as_single_sbox

This option is not supported in Design Compiler.

-horizontal_track_utilization *percentage*

Specifies the horizontal track utilization rate in the area covered by the route guide.

You must specify an integer value between 0 and 100 for the *percentage* argument. If you do not specify this option or if you specify a value greater than 100, it is set to 100.

The following example specifies 90% horizontal track utilization route guide.

```
create_route_guide -horizontal_track_utilization 90
```

If an area has 10 horizontal tracks for routing, and Global Router puts 10 horizontal tracks here, with 90% horizontal utilization route guide, Global Router will now think the area is 1 track overflow.

-vertical_track_utilization *percentage*

Specifies the vertical track utilization rate in the area covered by the route guide.

You must specify an integer value between 0 and 100 for the *percentage* argument. If you do not specify this option or if you specify a value greater than 100, it is set to 100.

The following example specifies 90% vertical track utilization route guide.

```
create_route_guide -vertical_track_utilization 90
```

If an area has 10 vertical tracks for routing, and Global Router puts 10 vertical tracks here, with 90% vertical utilization route guide, Global Router will now think the area is 1 track overflow.

-track_utilization_layers *layers*

Specifies the layers on which track utilization is set by the **-horizontal_track_utilization** or **-vertical_track_utilization** option. Specify the layers by using the layer names from the technology file.

The direction of the track utilization is determined from the preferred direction of the specified layers. If the preferred direction of a specified layer is horizontal, the horizontal track utilization is set on that layer. If you specify more than one utilization in the same area, the router uses the minimum utilization.

-name *guide_name*

Specifies the name of the created route guide.

If you do not specify this option, the tool assigns a name to the route guide using the naming convention RG#x, where x is an integer value.

-single_layer_routing *layers*

This option is not supported in Design Compiler.

DESCRIPTION

This command creates a new route guide and returns a collection that contains the created route guide.

The tool uses the global snap settings to snap the bounding box of the route guide.

To remove a route guide, use the **remove_route_guide** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a route guide.

```
prompt> create_route_guide -coordinate {0.0 0.0 100.0 100.0} \
-no_signal_layers M1 -no_preroute_layers M2 \
-preferred_direction_only_layers M4
```

`create_placement_blockage(2)`
`create_terminal(2)`
`create_user_shape(2)`
`create_via(2)`
`remove_route_guide(2)`

create_rp_group

Creates relative placement groups.

SYNTAX

```
collection create_rp_group
  group_list
  [-design design_name]
  [-columns num_cols]
  [-rows num_rows]
  [-alignment bottom-left | bottom-pin | bottom-right]
  [-pin_align_name pin_name]
  [-utilization percentage]
  [-ignore]
  [-x_offset float]
  [-y_offset float]
  [-cts_option fixed_placement | size_only]
  [-route_opt_option fixed_placement | in_place_size_only]
  [-psynopt_option fixed_placement | size_only | all_optimization]
  [-move_effort low | medium | high]
  [-allow_keepout_over_tapcell false | true]
  [-allow_non_rp_cells]
  [-place_around_fixed_cells standard | physical_only | none | all]
  [-anchor_corner bottom-left | bottom-right | top-left | top-right | rp-location [-anchor_row integer] [-anchor_column integer]]
  [-placement_type bit_slice | compression | vertical_compression]
  [-group_orient default | N | FN | S | FS]
  [-cell_orient_opt]
  [-auto_blockage]
  [-disable_buffering]
  [-ignore_rows ignore_row_names_list]
  [-max_rp_width float]
  [-max_rp_height float]
```

Data Types

<i>group_list</i>	list
<i>design_name</i>	design
<i>num_cols</i>	integer
<i>num_rows</i>	integer
<i>pin_name</i>	string
<i>percentage</i>	float
<i>float</i>	percentage
<i>integer</i>	num_rows
<i>ignore_row_names_list</i>	list of strings

ARGUMENTS

group_list

Specifies the names for the relative placement (RP) groups you want to create in the specified design. Within a design, each group name must be unique. The tool generates a warning if you try to create a group that does not have a unique name.

The **create_rp_group** command creates one relative placement group for each item in the *group_list*.

-design *design_name*

Specifies the name of the design in which to create the new groups. If you do not specify a value for this option, the groups are created in the current design.

-columns *num_cols*

Specifies the number of columns into which objects can subsequently be placed, relative to each other.

If you do not specify a value for this option, the group is created with 1 column.

-rows *num_rows*

Specifies the number of rows into which objects can be subsequently placed, relative to each other.

If you do not specify a value for this option, the group is created with 1 row.

-alignment bottom-left | bottom-pin | bottom-right

Specifies the default alignment method to use when placing leaf cells and relative placement groups in the specified relative placement groups. If you do not specify this option, the tool uses bottom-left alignment.

You can override the default alignment method for a specific leaf cell or relative placement group when you add it to a relative placement group by using the **add_to_rp_group** command.

-pin_align_name *pin_name*

Specifies the default alignment pin for the created relative placement groups. During placement, the tool uses the alignment pin's location to align the cells within a column.

You can override the alignment pin for a specific leaf cell when you add the cell to the group by using the **add_to_rp_group** command.

-utilization *percentage*

Specifies the utilization percentage to use for placement of this relative placement group. Utilization is represented as a floating-point number between 0.0 (representing 0%) and 1.0 (the default, representing 100%).

-ignore

Indicates that the tool is to ignore this relative placement group during placement and not treat it as a relative placement group. Instead, the tool places all of the group's parts individually, as it would normally do when there is no relative placement.

-x_offset *float*

Specifies a left coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area, for top-level relative placement group. It is ignored for a lower level relative placement group. Specifying only an x-offset allows the group to slide in the y-direction.

-y_offset *float*

Specifies a lower coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area, for top-level relative placement group. It is ignored for a lower level relative placement group. Specifying only a y-offset allows the group to slide in the x-direction.

-cts_option fixed_placement | size_only

Specifies how to treat the cells in the relative placement group during clock tree synthesis and clock tree optimization. If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during **compile_clock_tree**, **optimize_clock_tree**, and **clock_opt** actions and cannot be sized or moved.

If you specify **size_only**, the cells in the relative placement group can only be sized. This option is applicable to the **compile_clock_tree**, **optimize_clock_tree**, and **clock_opt** commands.

The default of the option is fixed_placement.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-route_opt_option fixed_placement | in_place_size_only

Specifies how to treat the cells in the relative placement group during the **route_opt** and **psynopt on_route** stages.

If you specify fixed_placement, the cells in the relative placement group are treated as fixed during the **route_opt** and **psynopt on_route** stages and cannot be sized or moved.

If you specify in_place_size_only, sizing changes are constrained for minimal engineering change order (ECO) placement changes. For example, a cell is sized to improve timing or design rule costs only if the newly sized cell can fit into any available space adjacent to the original cell location. The resulting transformation is verified to ensure it is legal.

The default is fixed_placement.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-psynopt_option fixed_placement | size_only | all_optimization

Specifies how to treat the cells in the relative placement group during **psynopt** and **place_opt**.

If you specify fixed_placement, the cells in the relative placement group are treated as fixed during **psynopt** and cannot be sized or moved. This value is not recommended for **place_opt**.

If you specify size_only, the cells in the relative placement group can only be sized.

If you specify all_optimization, all the preroute optimization capabilities can be applied to cells in the relative placement group. This might result in losing some cells from the relative placement group as cells can be decomposed or deleted from the netlist.

The default is size_only.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-move_effort low | medium | high

Controls the extent to which a relative placement group can be moved from its initial location to preserve the relative placement without violating relative placement constraints. The size of the region searched for placement of a relative placement group is progressively reduced as you reduce the effort from high to medium to low.

Coarse placement estimates an initial location for every top-level relative placement group. If those groups are placed at the same locations returned by coarse placement, the relative placement groups might need to be broken, which would violate the relative placement constraints for those groups.

Specifying high effort allows the higher movement of a relative placement group from its initial location in search of a location compared to low and medium efforts to maintain the relative placement constraints and potentially avoid breaking the relative placement group. The tradeoff for maintaining the relative placement group is reduced QoR because the group is moved from the location initially determined by coarse placement.

Specifying low effort indicates that the relative placement group is placed as close as possible to the initial location returned by coarse placement. The tradeoff for maintaining the location is a higher potential for breaking the relative placement groups and violating the relative placement constraints for some relative placement groups.

By default, the tool uses medium effort.

This option is not supported in Design Compiler topographical mode and will be ignored.

-allow_keepout_over_tapcell false | true

Specifies that the hard keepout in the relative placement group should be overlapped with tap cells if needed.

By default, the value is **false**.

This option is not supported in Design Compiler topographical mode and will be ignored.

-allow_non_rp_cells

Applying this option allows nonrelative placement cells to come in the unused area of relative placement groups during **place_opt** and **refine_placement**.

-place_around_fixed_cells standard | physical_only | none | all

Specifies how to treat fixed cells in the floorplan during legalization of relative placement groups.

If you specify standard, the relative placement groups are legalized around fixed standard cells and the legalization engine avoids fixed physical-only cells.

If you specify physical_only, the relative placement groups are legalized around fixed physical-only cells, and the legalization engine avoids fixed standard cells.

If you specify all, the relative placement groups are legalized around both fixed standard and fixed physical-only cells.

If you specify none, the legalization engine avoids both fixed standard and fixed physical-only cells during legalization of relative placement groups.

The default is all.

This option applies to top-level relative placement groups only and is ignored for hierarchical relative placement groups.

-anchor_corner bottom-left | bottom-right | top-left | top-right | rp-location

Specifies the corner for the anchor point that is set by using the **-x_offset** and **-y_offset** options.

If you specify **bottom-left** (the default), the anchor point corner is the lower-left corner of the relative placement group.

If you specify **bottom-right**, the anchor point corner is the lower-right corner of the relative placement group.

If you specify **top-left**, the anchor point corner is the upper-left corner of the relative placement group.

If you specify **top-right**, the anchor point corner is the upper-right corner of the relative placement group.

If you specify **rp-location**, the anchor point corner is the starting location of object at the row and column specified by the **-anchor_row** and **-anchor_column** options. When you specify **rp-location**, the **-anchor_row** and **-anchor_col** options are required and the specified location must not be empty.

This option applies to top-level relative placement groups only and is ignored for hierarchical relative placement groups. When you specify **-anchor_corner bottom-right**, the relative placement group is anchored at the bottom-right corner at the specified x- and y-coordinates during legalization.

When many blockages are present, a slight deviation from the anchor point might occur.

-anchor_row integer

Specifies the row of the object for which the **-anchor_corner rp-location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp-location** option and is not accepted for other values of the **-anchor_corner** option.

-anchor_column integer

Specifies the column of the object for which the **-anchor_corner rp-location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp-location** and is not accepted for other values of the **-anchor_corner** option.

-placement_type bit_slice | compression | vertical_compression

Specifies how to place cells in relative placement groups. The default is bit_slice.

When you specify the bit_slice keyword, the next row starts after the tallest object in the row and the next column starts after the widest object in the column. Both the row and column alignments are preserved.

When you specify the vertical_compression keyword, columns are compressed such that no gap is between leaf cells, lower-level hierarchical relative placement groups, and keepouts in a column. Row alignment is not preserved.

When you specify the compression keyword, rows are compressed such that no gap is between leaf cells, lower-level hierarchical relative placement groups, and keepouts in a row. Column alignment is not preserved. If you set the **-alignment** option to bottom-right or bottom-pin and set this option to compression, the tool issues an error and does not create relative placement groups.

If both the **-utilization** and **-placement_type compression** options are specified, the utilization constraints are observed with gaps between leaf elements in a relative placement row.

The setting of this option does not propagate to child relative placement groups.

-group_orient default | N | FN | S | FS

Specifies the orientation of a relative placement group. If this value is not specified or is specified as **default** for any relative placement group, the tool chooses a suitable orientation for that relative placement group.

-cell_orient_opt

Applies automatic orientation on the cells in a relative placement group for optimizing wire length.

-auto_blockage

Disallows buffer insertion inside the area of relative placement groups during **psynopt** and **route_opt** activity.

-disable_buffering

Disallows buffer insertion on nets within relative placement groups during **psynopt** and **route_opt** activity.

-ignore_rows ignore_row_names_list

Specifies the site rows that must be ignored for the relative placement group cells.

To ignore site rows during relative placement, you must first define the **rp_ignore_row_name** attribute on the site rows to be ignored. The *ignore_row_names_list* argument is a list that includes the **rp_ignore_row_name** attribute value for each site row to be ignored.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups.

-max_rp_width float

Specifies the maximum allowable width in microns for the top-level relative placement groups. It is ignored for the lower-level relative placement groups. If you specify this option, the tool tries to restrict the width of the top-level relative placement groups to the specified maximum value during **psynopt**, **place_opt** and **route_opt**.

-max_rp_height float

Specifies the maximum allowable height in microns for the top-level relative placement groups. It is ignored for the lower-level relative placement groups. If you specify this option, the tool tries to restrict the height of the top-level relative placement groups to the specified maximum value during **psynopt**, **place_opt** and **route_opt**.

DESCRIPTION

The **create_rp_group** command creates new relative placement groups. The new groups are created empty and contain no items. Add items to a group using the **add_to_rp_group** command. Remove groups using the **remove_rp_groups** command.

This command returns a collection containing the relative placement groups that are created. If no objects are created, the empty string is returned.

Relative placement groups provide for explicit user control of placement for a group of cells. A relative placement group is placed as a whole while maintaining the relative placement (or tiling) of the cells within the group as specified with the **add_to_rp_group** command. Relative placement is also known as "structured placement."

When placing a relative placement group, the placer automatically chooses the orientation for the group. For example, if the placer chooses the north orientation for a relative placement group, the first column of that relative placement group is placed at the left and subsequent columns are placed toward the right. If the placer chooses the flip-north orientation for a relative placement group, the first column of that relative placement group is placed at the right and subsequent columns are placed toward the left.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **create_rp_group** to create a relative placement group:

```
prompt> create_rp_group grp_ripple -design ripple -rows 8
{ripple::grp_ripple}

prompt> get_rp_groups grp_ripple
{ripple::grp_ripple}

prompt> add_to_rp_group *ripple -leaf carry_in_1 -row 2
{ripple::grp_ripple}

prompt> define_user_attribute -type string \
    -class site_row rp_ignore_row_name
prompt> set_attribute [get_site_rows STD_ROW_112] \
    rp_ignore_row_name clock
prompt> create_rp_group rp -design d -ignore_rows { clock }
```

create_safety_core_group

Creates one safety_core_group

SYNTAX

```
status create_safety_core_group
    -rule safety_core_rule
    -cores objects
    [-name group_name]
    [-logic cells]
    -error_signal pin or port
    [-split_pins pins]
```

Data Types

<i>safety_core_rule</i>	string
<i>objects</i>	collection
<i>group_name</i>	string
<i>cells</i>	collection
<i>pin</i>	or port object
<i>or</i>	pin
<i>pins</i>	collection

ARGUMENTS

-rule *safety_core_rule*

Specifies the safety core rule based on which this safety core group will be created.

-cores *objects*

Specifies the collection of safety cores which should be part of this safety core group. Only logical hierarchical cells are allowed as safety cores.

-name *group_name*

Name of the new safety_core_group. If not specified, the name will be automatically generated by the tool

-logic *cells*

Specifies the collection of logic cells which form a part of the voting logic circuit. These must be combinational cells.

-error_signal *pin or port*

Specifies the pin or port by which compare error will be connected.

-split_pins *pins*

Specifies the set of pins which should be split so as to be a part of different branches of high-fanout tree.

DESCRIPTION

This command creates one safety_core_group based on the given parameters. It stores the reference to the original safety core rule which was honored to create it.

EXAMPLES

The following example creates a safety_core_group consisting of 2 cores and some voting logic combinational cells.

```
prompt> create_safety_core_group -rule rule1 \
    -cores [get_cells {cntrl alu}] \
    -logic {land1 land2 Ixor1} \
    -error_signal [get_ports MemData[6]] \
    -name group1
```

SEE ALSO

```
get_safety_core_groups(2)
remove_safety_core_groups(2)
report_safety_core_groups(2)
```

create_safety_core_rule

Creates one safety_core_rule

SYNTAX

```
status create_safety_core_rule
  [-name rule_name]
  [-update]
  [-num_cores count]
  [-distance values]
  [-routing_separation]
  [-routing_guardband distance]
  [-logic_module reference]
  [-logic_mapping lib_cell_list]
```

Data Types

<i>rule_name</i>	string
<i>count</i>	int
<i>reference</i>	collection
<i>lib_cell_list</i>	collection

ARGUMENTS

-name *rule_name*

Optionally specifies the name of the rule to be created. If not specified, a name will be automatically generated and assigned.

-update

Specifies that existing safety core rule need to be updated. This option need to be provided with **-name**.

-num_cores *count*

Optionally specifies the number of copies of core need to be created. Count should be greater than or equal to 1. If option is not provided, it will take default value as 2.

-distance *values*

Specifies the distance values for safety cores. It could be either in the form of an {x y} pair or a single number denoting radial distance. The values are in user units. The values cannot be negative. The distances are measured edge-to-edge, or in other words, from the position of one core to the position of another core.

Specifying the {x y} distance pair means that either "x" or "y" separation must be honored. In other words, cores in the group should be either "x" distance apart measured on X-axis, or "y" distance apart measured on Y-axis. This will effectively create a rectangular keep-out region around each core, in which it is forbidden to place another core of the same group. It is allowed to specify a distance of zero for "x" or "y", but not for both simultaneously.

Specifying the single "r" value means that the Manhattan distance between each pair of cores in the group should be at least "r". The Manhattan distance between two cores is defined as the sum of the vertical distance and horizontal distance between their closest edges. Specifying a radial distance thus creates an octagonal keep-out region around each core, wherein another core of

the same group must not be placed. For cells in the same column, the horizontal distance is 0. For cells in the same row, the vertical distance is 0. This "r" value cannot be zero.

-routing_separation

Specify if routing separation is required or not. Default value will be false.

-routing_guardband *distance*

Specifies the guard band widths for the routing in the form of radial distance value {r}, or an {x,y} value pair. If you do not specify this option, the guard band width is considered to be zero. If you specify this option, The *-distance* option must be specified as well. The specified values must be positive floating point numbers. When specified, the format of *-routing_guardband* must be same as that of *-distance*. Either both of them should be {r}, or both should be {x,y}.

-logic_module *reference*

Specifies the module containing the combinational logic which will be driven by safety cores output. This option is mutually exclusive with **-logic_mapping**.

-logic_mapping *lib_cell_list*

Specifies one or more lib_cells that can be instantiated for implementing the comparison logic. This option is mutually exclusive with **-logic_module**.

DESCRIPTION

This command creates a new safety_core_rule based on the options specified. This rule can be then applied to safety cores. The minimum separations between the cores can be specified which can be considered by the placement and legalizer engines.

EXAMPLES

The following example creates a safety_core_rule.

```
prompt> create_safety_core_rule -routing_guardband 1.1 \
    -routing_separation \
    -logic_mapping [get_lib_cells {A B}] \
    -name rule1
```

The following example defines a rule that requires cores to be separated by at least 20u horizontally, or, at least 5u vertically.

```
prompt> create_safety_core_rule -routing_guardband 1.1 \
    -distance {20 5} \
    -name rule2
```

The following rule defines a required Manhattan distance of 8u between the cores that should follow this rule.

```
prompt> create_safety_core_rule -name rule3 -distance 8
```

Note: All examples above assume the length unit to be microns.

SEE ALSO

[create_safety_core_group\(2\)](#)

```

remove_safety_core_rules(2)
report_safety_core_rules(2)
set_safety_core_rule(2)
```

create_safety_error_code_group

Creates one safety_error_code_group.

SYNTAX

```
status create_safety_error_code_group
  -rule safety_error_code_rule
  [-name group_name]
  -data pins_or_ports
  -checkbits pins_or_ports
  [-error_signal pin_or_port]
  [-requirement_id requirement_id_string]
```

Data Types

<i>safety_error_code_rule</i>	object
<i>group_name</i>	string
<i>pins_or_ports</i>	collection
<i>pin_or_port</i>	object

ARGUMENTS

-rule *safety_error_code_rule*

Specifies the safety_error_code_rule based on which this safety_error_code_group should be created. This is mandatory.

-name *group_name*

Specifies the name of the new safety_error_code_group. If not specified, the tool generates the name for the safety_error_code_group.

-data *pins_or_ports*

Specifies the collection of pins or ports of data signal to be encoded or decoded for this safety_error_code_group. This is mandatory.

-checkbits *pins_or_ports*

Specifies the collection of pins or ports, where the checkbits from the encoder output are connected for this safety_error_code_group. This is mandatory.

-error_signal *pin_or_port*

Specifies the existing pin or port in the design to which the decoder error output is connected to. This can be specified for all types, when mode is decode or encode_decode.

DESCRIPTION

This command creates one safety_error_code_group based on the given parameters. It stores the reference to the original safety_error_code_rule, which was honored to create it. This command supports undo or redo operations. The command shows error, if the *data* or *checkbits* pins or ports list is empty. The command shows error, if any of the *data* or *checkbits* pins or ports belong to existing safety error code groups. In the list, all elements should be either pin or port, combination of pins and ports in the list is not allowed.

EXAMPLES

The following example creates a safety_error_code_group with data and checkbits pins

```
prompt> create_safety_error_code_group -rule rule1 \
      -data {cell_1/pin1 cell_1/pin2 cell_1/pin3 cell_1/pin4} -checkbits {cell_2/pin} \
      -name group1
```

[report_safety_error_code_groups\(2\)](#)

create_safety_error_code_rule

Creates one safety_error_code_rule object

SYNTAX

```
status create_safety_error_code_rule
  -type type
  [-name rule_name]
  [-slice_size size]
  [-mode mode]
  [-sequential]
  [-update]
```

Data Types

<i>type</i>	string
<i>rule_name</i>	string
<i>size</i>	int
<i>mode</i>	string

ARGUMENTS

-type *type*

Specifies the encoding type of the safety error code rule. Valid values are *even_parity*, *odd_parity*, *ecc* and *edc*.

-name *rule_name*

Specifies the name of the rule to be created. If not specified, a name is automatically generated and assigned.

-slice_size *size*

Specifies the number of bits of data to be encoded as a group. If unspecified, all data bits are encoded as a single group.

-mode *mode*

Specifies the encoding mode of the safety error code rule. Currently the valid values is only *encode_decode*.

-sequential

Specifies sequential encoding.

-update

Specifies that the existing safety error code rule needs to be updated. The *-name* must be specified and the rule with that name must exist. Specified rule should not be part of safety error code group. The encoding type and slice_size property of the rule can be updated.

DESCRIPTION

This command creates a new safety_error_code_rule based on the options specified. This rule can be set on a set of data bits using the *set_safety_error_code_rule* command.

EXAMPLES

The following example creates a simple safety_error_code_rule with even_parity ncoding type.

```
prompt> create_safety_error_code_rule -type even_parity -name rule1 -sequential
```

SEE ALSO

create_safety_error_code_group(2)

remove_safety_error_code_rules(2)
report_safety_error_code_rules(2)
set_safety_error_code_rule(2)

create_safety_register_group

Creates one safety_register_group

SYNTAX

```
status create_safety_register_group
    -rule safety_register_rule
    [-name group_name]
    [-registers registers]
    [-logic cells]
    [-split_pins pins]
    [-error_signal pin_or_port]
```

Data Types

<i>safety_register_rule</i>	string
<i>group_name</i>	string
<i>registers</i>	collection
<i>pins</i>	collection

ARGUMENTS

-rule *safety_register_rule*

Specifies the safety registry rule based on which this redundancy group was created

-name *group_name*

Name of the new safety_register_group. If not specified, the name will be automatically generated by the tool

-registers *registers*

Specifies the collection of registers cells or the output pins of the register cells which should be part of this register redundancy group. You can either group register cells or output pins of multibit registers. It is not allowed to group mixture of register cells and output of registers. The object type passed in must be the same: either all register cells or all output pins of registers.

-logic *cells*

Specifies the collection of logic cells which form a part of the voting logic circuit. These must be combinational cells.

-split_pins *pins*

Specifies the set of pins which should be split so as to be a part of different branches of high-fanout tree.

DESCRIPTION

This command creates one safety_register_group based on the given parameters. It stores the reference to the original safety register rule which was honored to create it.

EXAMPLES

The following example creates a safety_register_group consisting of 3 registers and some voting logic combinational cells.

```
prompt> create_safety_register_group -rule rule1 \
    -registers {flop1 flop2 flop3} \
    -logic {land1 land2 ixor1} \
    -name group1
```

SEE ALSO

create_safety_register_rule

Creates one safety_register_rule

SYNTAX

```
status create_safety_register_rule
  -type rule_type
  [-name rule_name]
  [-distance values]
  [-register_mapping lib_cell_list]
  [-logic_module lib_cell]
  [-tap_mapping lib_cell_list]
  [-split_pin_types pin_type_list]
  [-update]
```

Data Types

<i>rule_type</i>	string
<i>rule_name</i>	string
<i>values</i>	list
<i>lib_cell_list</i>	collection
<i>lib_cell</i>	object
<i>pin_type_list</i>	list

ARGUMENTS

-type *rule_type*

Specifies whether the register should be mapped to another fault-tolerant variant, or should be replaced by a group of redundant flops (redundancy group). Valid values are "fault_tolerant", "dual_mode" and "triple_mode"

In case of redundancy group, it specifies the module that the register should be replaced by.

-name *rule_name*

Optionally specifies the name of the rule to be created. If not specified, a name will be automatically generated and assigned.

-distance *values*

Specifies the distance values for repelling bound constraint for redundancy group. It could be either in the form of an {x y} pair or a single number denoting radial distance. The values are in user units. The values cannot be negative. The distances are measured edge-to-edge, or in other words, from the boundary of one register to the closest boundary of another. For -type dual_mode or triple_mode, this option must be specified. For -type fault_tolerant, this option is unnecessary and will be ignored.

Specifying the {x y} distance pair means that either "x" or "y" separation must be honored. In other words, each pair of registers in the group should be either "x" distance apart measured on X-axis, or "y" distance apart measured on Y-axis. This will effectively create a rectangular keep-out region around each register, in which it is forbidden to place another register of the same group. It is allowed to specify a distance of zero for "x" or "y", but not for both simultaneously.

Specifying the single "r" value means that the Manhattan distance between each pair of registers in the group should be at least "r".

The Manhattan distance between two redundancy registers is defined as the sum of the vertical distance and horizontal distance between their closest edges. Specifying a radial distance thus creates an octagonal keep-out region around each register, wherein another register of the same group must not be placed. For cells in the same column, the horizontal distance is 0. For cells in the same row, the vertical distance is 0. This "r" value cannot be zero.

-register_mapping lib_cell_list

Optionally specifies the list of lib_cells for mapping. This option only works for type "fault_tolerant".

-logic_module lib_cell

Optionally specifies the voting logic module. This option only works for type "dual_mode" or "triple_mode".

-tap_mapping lib_cell_list

The list of lib cells, out of which the appropriate one will be used for instantiating tap cells for the safety registers.

-split_pin_types pin_type_list

The pin types which should be considered for splitting so as to be a part of different branches of clock tree or high fanout net trees. Allowed values are *clock*, *reset* and *scan*. List of one or more such types can be specified.

DESCRIPTION

This command creates a new safety_register_rule based on the options specified. This rule can be then applied to safety-critical registers. The rule can specify replacement of the register either to another fault-tolerant register, or by a group of redundant registers. In latter case, the minimum separations between the redundant registers can be specified which can be considered by the placement engine. If the pins of the redundant registers should be split to different branches of trees, the types to be considered can also be specified.

EXAMPLES

The following example creates a safety_register_rule.

```
prompt> create_safety_register_rule -type fault_tolerant \
    -distance {20 30} \
    -split_pin_types {scan clock} \
    -name rule1
```

The following example defines a rule that requires redundancy registers to be separated by at least 20u horizontally, or, at least 5u vertically.

```
prompt> create_safety_register_rule -type triple_mode \
    -name RULE1 -distance {20 5}
```

Assuming that the width of current block is smaller than 2000u, following rule states that redundancy registers must be placed into separate rows. Because the specified y distance is zero, adjacent rows are allowed.

```
prompt> create_safety_register_rule -type triple_mode \
    -name RULE2 -distance {2000 0}
```

Assuming that the width of current block is smaller than 2000u, following rule states that redundancy registers must be placed into separate rows. The vertical between the two redundancy registers must be at least 10u.

```
prompt> create_safety_register_rule -type dual_mode \
    -name RULE3 -distance {2000 10}
```

The following rule defines a required Manhattan distance of 8u between the redundancy registers that should follow this rule.

```
prompt> create_safety_register_rule -type triple_mode -name RULE4 -distance 8
```

Note: All examples above assume the length unit to be microns.

create_scenario

Creates a scenario in memory.

SYNTAX

```
status create_scenario
      scenario_name
```

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the name of the scenario created. A *scenario_name* must be unique within the current session.

DESCRIPTION

This command creates a new scenario in memory. The newly-created scenario has no scenario-specific constraints.

The creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command creates a new scenario for use with multicorner-multimode designs.

EXAMPLES

The following example uses the **create_scenario** command to create a scenario:

```
prompt> create_scenario MODE1
prompt> all_scenarios
```

SEE ALSO

```
all_scenarios(2)
all_active_scenarios(2)
create_scenario(2)
current_scenario(2)
remove_scenario(2)
set_active_scenarios(2)
```

create_site_def

Creates a site definition.

SYNTAX

```
create_site_def
  -name site_name
  -height site_height
  -width site_width
  -type site_type
  -symmetry site_symmetry
```

Data Types

site_name	string
site_height	integer
site_width	integer
site_type	string
site_symmetry	string

ARGUMENTS

-name site_name

Specifies the name of the site, such as *unit*, *bigSite*, and so forth. If the site already exists, the old site will be replaced. This is a required argument.

-height site_height

Specifies the height of this site. This is a required argument that must be > 0.

-width site_width

Specifies the width of this site. This is a required argument that must be > 0.

-type site_type

Specifies the type of site being defined. Options are *core* or *pad*. Default behavior is *core*.

-symmetry site_symmetry

Specifies if the site definition is symmetrical about X and/or Y and/or 90 degree rotation. By default there is no symmetry. Valid symmetry is a set or combination of the following values o X (symmetrical about the X-axis) o Y (symmetrical about the Y-axis) o R90 (symmetrical for 90 degrees rotation)

DESCRIPTION

The **create_site_def** command creates a site definition.

EXAMPLES

The following command creates a site called unit with width and height attributes of 10.

```
prompt> create_site_def -name unit -width 10 -height 10
```

SEE ALSO

[create_site_row\(2\)](#)
[extract_physical_constraints\(2\)](#)
[report_physical_constraints\(2\)](#)
[write_physical_constraints\(2\)](#)

create_site_row

Creates a row of sites.

SYNTAX

```
collection create_site_row
  -coordinate {X Y}
  [-name row_name]
  -kind site_type
  -space space
  -count site_count
  [-orient orientation]
  [-dir direction]
```

Data Types

X	float
Y	float
row_name	string
site_type	string
space	string
site_count	integer
direction	string

ARGUMENTS

-coordinate {X Y}

Specifies the lower-left corner of the row, regardless of the orientation. The values are specified in microns relative to the chip origin.

-name row_name

Specifies the name of the site row, such as *ROW1*, *ROW2*, and so forth. If a row name is not specified, the tool names the newly-created site row.

-kind site_type

Specifies the type of site being defined.

-space space

Specifies the space for each site, from the lower-left corner of the site to the lower-left corner of the next site. The value is specified in microns.

-count site_count

Specifies the number of sites in the row.

-orient orientation

Specifies the orientation of sites. The following values are allowed:

0
90
180
270
0-mirror
90-mirror
180-mirror
270-mirror

Alternatively, you can use the following values:

N
W
S
E
FN
FW
FS
FE

The default value is either **0** or **N**.

-dir direction

Specifies the direction of the row. The following values are allowed:

h
v
horizontal
vertical
VERTICAL
HORIZONTAL
V
H

The default value is **horizontal**.

DESCRIPTION

The **create_site_row** command creates a row of sites at the specified location.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command creates a horizontal row of 3 sites spaced by 5 units, and originating at {10,10}:

```
prompt> create_site_row -coordinate {10,10} -kind CORE -space 5 -count 3
{SITE_ROW#12345}
```

SEE ALSO

`report_physical_constraints(2)`
`write_physical_constraints(2)`

create_supply_net

Creates a supply net for the specified power domain. The supply net is created in the logic hierarchy at the same scope as the specified power domain.

SYNTAX

```
string create_supply_net
    supply_net_name
    [-domain domain_name]
    [-reuse]
    [-resolve unresolved | parallel | one_hot | parallel_one_hot | resolution_function_name]
```

Data Types

<i>supply_net_name</i>	string
<i>domain_name</i>	string

ARGUMENTS

supply_net_name

Specifies the name of the supply net to be created. The name should be a simple (nonhierarchical) name.

In the scope of specified power domain, if there is a supply net, logical hierarchical net, or logical port with the same name, the supply net cannot be created. An exception to this rule is when you use the **-reuse** option. In this case the net name must be same as an existing supply net in the same scope; name; check is not performed.

This argument is required.

-domain *domain_name*

Specifies the power domain for which this supply net is defined. The power domain must exist.

This argument is optional. If **-domain** is not specified, the supply net is available for all power domains at the current scope and below.

-reuse

Reuses an existing supply net instead of creating a new one. One supply net can be associated with several power domains. If this option is used, the specified supply net must already exist.

-resolve *unresolved* | *parallel* | *one_hot* | *parallel_one_hot* | *resolution_function_name*

Specifies how the state and voltage of the supply net are resolved when the supply net is driven by a power switch or multiple power switches. Specifying *unresolved* means that this supply net can have only a single driver. Specifying *parallel* means that this supply net can be driven by multiple power switches. When the supply net is connected to the output of multiple power switches, any number of outputs might be ON at the same time, if the voltage value is same. Specifying *one_hot* means that this supply net can be driven by multiple power switches. A supply net with *one_hot* resolution has a deterministic state only when no more than one source drives the net at any particular point in time. Specifying *parallel_one_hot* means that this supply net can be driven by multiple power switches. The *parallel_one_hot* resolution allows resolution of a supply net that has multiple root supply drivers where each driver might have more than one path through supply sources to the supply net. Each unique root supply driver is

identified and one_hot resolution is applied to the drivers. *Parallel* resolution is then applied to each supply source connecting the one_hot root supply driver to the supply net. Resolution semantics may also be specified by a user-defined resolution function. When a user-defined resolution function is specified, there are no restrictions on the number of input sources or the number of root supply drivers involved, and the function is responsible for defining any restrictions on the values of inputs as well as the algorithm for determining the output result.

The default is **unresolved**.

DESCRIPTION

The **create_supply_net** command enables you to create a supply net defined in the specified power domain. A supply net presents the intention of the power supply in the power domains. A supply net connects supply ports and, or pins.

Each power domain has a primary power supply net and a primary ground supply net, and could have several other supply nets. If the command succeeds, a supply net is created in the scope of the power domain. The new supply net is neither a primary power net nor a primary ground net of the power domain. Use the **set_domain_supply_net** command to set the supply net as the primary power or ground net.

On success this command returns the full name of the supply net (from the current scope). On failure, it returns a null string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a supply net named A_VDD in the power domain PD1, and re-creates supply net A_DD in the power domain PD2 using the **-reuse** option:

```
prompt> create_power_domain PD1 -element INST1  
PD1  
  
prompt> create_power_domain PD2 -element INST2  
PD2  
  
prompt> create_supply_net A_VDD -domain PD1  
A_VDD  
  
prompt> create_supply_net A_VDD -domain PD2 -reuse  
A_VDD
```

SEE ALSO

[report_supply_net\(2\)](#)

create_supply_port

Creates a supply port in the specified power domain. If a power domain is not specified, creates the port in the current scope.

SYNTAX

```
string create_supply_port
      supply_port_name
      [-domain domain_name]
      [-direction in | out | inout | internal]
```

Data Types

<i>supply_port_name</i>	string
<i>domain_name</i>	string

ARGUMENTS

supply_port_name

This is a required argument.

Specifies the name of the supply port to be created. The name should be a simple (non-hierarchical) name. This argument can be used with the **-domain** option to avoid hierarchical names.

If a supply port, logical port, or logical hierarchical net with the same name exists in the scope of the power domain, the supply port cannot be created.

-domain *domain_name*

Specifies the power domain where this port defines a supply net connection point. If the specified power domain does not exist in the current scope, the command fails.

-direction *in* | *out* | *inout* | *internal*

Defines how the state information is propagated through the supply network when connected to the port. If the port is an input port, the state information of the external supply net connected to the port is propagated into the domain. Similarly, for an output port, the state information of the internal supply net connected to the port is propagated outside the domain. Similarly, for an inout port, the state information of the internal supply net connected to the port is propagated into/outside the domain. An internal-direction port is for use with library models that have internal-direction supply pins. Supply nets connected to an internal port are considered virtual nets and will not be used during implementation.

The default value of this option is **in**.

DESCRIPTION

The *create_supply_port* command creates a supply port at the scope of the specified power domain or at the current scope. A supply

port provides a connection point for the supply net.

On success, the command returns the full name of the supply port (from the current scope). Otherwise, returns a null string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates the supply port *VN1* at the scope of power domain *PD1*:

```
prompt> create_power_domain PD1 -element INST1
PD1
prompt> create_supply_port VN1 -domain PD1
VN1
```

SEE ALSO

[report_supply_port\(2\)](#)

create_supply_set

Creates a set of supplies that can be used to define the power network. A supply set is created in the current logic hierarchy.

SYNTAX

```
string create_supply_set
  [-function {function_name supply_net_name}]
  [-update]
  supply_set_name
```

Data Types

<i>function_name</i>	string
<i>supply_net_name</i>	string
<i>supply_set_name</i>	string

ARGUMENTS

-function {*function_name* *supply_net_name*}

Specifies the functionality to which an actual supply net should be associated.

This option takes a list of two parameters as input. The first parameter is the name of the function, which is either **power** or **ground**. The second parameter is the name of the supply net that is in the same hierarchical scope as the supply set.

You can specify the **-function** option multiple times in a single run of the **create_supply_set** command; once to define the power supply net and once to define the ground supply net.

This is a required argument when the **-update** option is used.

-update

Instructs the tool to associate an actual supply net to the **power** and **ground** functions of an existing supply set. It is an error if the supply set specified does not exist. Only one update is allowed for each function of the supply set. If your update is not successful, the tool issues an error message. You can continue to update the function, until your update is successful.

This is an optional argument. When the **-update** argument is used, the **-function** argument must also be used.

supply_set_name

Specifies the name of the supply set to be created. The name should be a simple (non-hierarchical) name.

If a supply set with the same name exists in the current scope, the supply set is not created. An exception to this rule is when you use the **-update** option. In this case the supply set name must be same as an existing supply set in the same scope.

This is a required argument.

DESCRIPTION

The **create_supply_set** command creates a supply set in the current scope. A supply set eliminates the requirement of a supply net and supply ports in the design, in the front-end tool. However, actual supply nets must be associated with the supply sets, later in the flow, before running physical synthesis.

A supply set supports the use of the following functions in the design:

- **power**
- **ground**

These functions, when unassociated with any supply net, can be used as supply nets for any purpose. They can be accessed by referencing them through the name of the supply set. To access the **power** function, you must specify *supply_set_name.power*. To access the **ground** function, you must specify *supply_set_name.ground*.

The functions of a supply set can be used just as any other supply net in the UPF design, with no domain restrictions. However, domain restrictions are applicable when you run the command with the **-update** option. This means that after you run the command with the **-update** option, the association of a supply net with a supply set is checked in the domains where the supply set is used.

When you run the command with the **-update** option on an existing supply set, the command replaces the supply set functions with actual supply nets. After doing an update, the actual supply net can be referenced through the supply set or by its actual name.

EXAMPLES

The following example creates a supply set named primary_sset in the current logical hierarchy:

```
prompt> create_supply_set primary_sset
primary_sset
```

The following example illustrates how a supply set function can be used:

```
prompt> create_supply_set primary_sset
primary_sset

prompt> create_power_domain PD_TOP
PD_TOP

prompt> set_domain_supply_net PD_TOP A \
    -primary_power_net primary_sset.power \
    -primary_ground_net primary_sset.ground \
1

prompt> set_retention ret_cstr -domain PD_TOP \
    -retention_power_net primary_sset.power \
    -retention_ground_net primary_sset.ground
1

prompt> set_isolation iso_cstr -domain PD_TOP \
    -isolation_power_net primary_sset.power \
    -isolation_ground_net primary_sset.ground \
1
```

The following example illustrates how to associate a supply set with actual supply nets.

```
prompt> create_supply_set primary_sset
primary_sset
```

```
prompt> create_power_domain PD_TOP  
PD_TOP  
  
prompt> set_domain_supply_net PD_TOP \  
-primary_power_net primary_sset.power \  
-primary_ground_net primary_sset.ground  
1  
  
prompt> set_retention ret_cstr -domain PD_TOP \  
-retention_power_net primary_sset.power \  
-retention_ground_net primary_sset.ground  
1  
  
prompt> set_isolation iso_cstr -domain PD_TOP \  
-isolation_power_net primary_sset.power \  
-isolation_ground_net primary_sset.ground \  
1  
  
prompt> create_supply_net TOP_VDD -domain PD_TOP  
TOP_VDD  
  
prompt> create_supply_net TOP_VSS -domain PD_TOP  
TOP_VSS  
  
prompt> create_supply_set primary_sset \  
-function {power TOP_VDD} \  
-function {ground TOP_VSS} \  
-update  
1
```

create_terminal

Creates a new terminal for a logical port.

SYNTAX

```
collection create_terminal
  -bbox rect | -bounding_box rect
  -layer layer
  [-mask_constraint constraint]
  -port port_name
  [-direction {pin_directions}]
  [-name terminal_name]
```

Data Types

<i>rect</i>	list of two points
<i>layer</i>	collection
<i>constraint</i>	string
<i>port_name</i>	string
<i>terminal_name</i>	string

ARGUMENTS

-bounding_box rect | -bbox rect

Specifies the bounding box of the terminal in the format $\{x1\ y1\ x2\ y2\}$. These options are equivalent; you can specify only one of them. In addition, these options are mutually exclusive; you must specify one of them.

-layer layer

Specifies the layer of the terminal.

This option is required.

-mask_constraint constraint

Specifies the mask constraint for the terminal.

The valid mask constraints are **any_mask**, **mask1_soft**, **mask1_hard**, **mask2_soft**, **mask2_hard**, **same_mask**, **mask3_soft**, and **mask3_hard**.

-port port_name

Specifies the name of the associated logical port of the terminal.

This option is required.

-direction {pin_directions}

Specifies a list of allowable access directions for the terminal.

You can specify one or more of the following values: **left**, **right**, **up**, or **down**.

If you do not specify this option, no access direction is assumed.

-name *terminal_name*

Specifies the name of the created terminal.

If you do not specify this option, the tool automatically generates a terminal name from the port name.

In most cases, you should not specify this option and allow the tool to automatically generate the terminal name, because some operations require that the terminal name conforms to the terminal naming conventions. For information about the terminal naming conventions, see the DESCRIPTION section.

If the specified terminal name does not match the terminal naming conventions, the tool issues a warning.

DESCRIPTION

The **create_terminal** command creates a new terminal for a logical port and returns a collection containing the created terminal.

By convention, the terminal name is the same as the name of the associated port; however, this is not a strict requirement. For electrically equivalent (EEQ) pins, where there are multiple terminals associated with the same port, the first terminal has the same name as the port and subsequent terminal names have the format *port_name number* where *port_name* is the port name and *number* is a unique number which, when automatically generated, starts from one and increments for each new terminal on that port.

Snapping of the bounding box is done automatically using the global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a terminal for the A1 port on the M3 layer:

```
prompt> create_terminal -bbox {0 0 10 10} -port A1 -layer M3
```

SEE ALSO

`create_net_shape(2)`
`create_placement_blockage(2)`
`create_route_guide(2)`
`create_user_shape(2)`
`create_via(2)`

create_test_protocol

Creates a test protocol based on user specifications.

SYNTAX

```
status create_test_protocol
  [-infer_asynch]
  [-infer_clock]
  [-capture_procedure single_clock | multi_clock]
```

ARGUMENTS

-infer_asynch

Infers asynchronous set and reset signals in the design.

-infer_clock

Infers test clocks in the design.

-capture_procedure single_clock | multi_clock

Specifies the capture procedure type. The **multi_clock** type creates a protocol file that uses generic capture procedures for all capture clocks. The **single_clock** type creates a protocol file that uses the legacy 3-vector capture procedures for all capture clocks.

The default is **multi_clock**.

DESCRIPTION

The **create_test_protocol** command creates a test protocol for the current design based on user specifications issued prior to running this command. The specifications are made using commands such as **set_dft_signal**.

This command removes any protocol that is present in memory due to a previous execution of **create_test_protocol**. However, if the protocol is present in memory due to a previous execution of **read_test_protocol**, it issues a warning and does not create a new test protocol.

This command checks whether the user-specified values are consistent with each other. If they are not, it issues an error and does not generate a protocol.

If **-infer_asynch** is specified, **create_test_protocol** infers asynchronous set and reset signals in the design, and places them at off state during scan shifting.

If **-infer_clock** is specified, **create_test_protocol** infers test clock pins from the design, and pulses them during scan shifting. The timing of the test clock is based on the **test_default_period**, **test_default_delay**, **test_default_strobe**, and **test_default_strobe_width** variables.

Both **-infer_asynch** and **-infer_clock** take previous user specifications into account.

When the default **-capture_procedure multi_clock** is specified, the protocol file contains four capture procedures: multiclock_capture, allclock_capture, allclock_launch, and allclock_launch_capture. This single protocol file can be used for ATPG stuck-at, transition delay, and path delay testing.

The **create_test_protocol** command automatically generates a master_observe procedure for LSSD designs in STIL format. However, to use this feature, you must set the scan style to LSSD design by using the **set_scan_configuration -style** command.

The **create_test_protocol** command should be executed before running the **dft_drc** command because design rule checking requires a test protocol.

If the interface of a design changes, for example, a port is created or removed, after a test protocol is created, there is no need to rerun **create_test_protocol** because the interface change is automatically taken into account in the protocol.

However, if you change any test specification of the design, for example, if you use **set_dft_signal** to specify a test clock, the protocol present in the memory is deleted. In this case, you need to rerun **create_test_protocol** to create a test protocol. The commands that change the test specifications of the existing design include **set_dft_signal** and **set_scan_path**.

The **insert_dft** command automatically updates the protocol after inserting scan circuitry into the design, and the **dft_drc** command can be executed afterward without rerunning **create_test_protocol**.

EXAMPLES

The following example creates a test protocol in memory for the current design:

```
prompt> create_test_protocol
```

The following example creates a test protocol in memory for the current design, inferring both asynchronous set and reset signals, as well as test clocks:

```
prompt> create_test_protocol -infer_clock -infer_asynch
```

SEE ALSO

```

create_track

Creates tracks for a routing layer or poly layer.

SYNTAX

```
int create_track
    -layer layer
    [-space track_pitch]
    [-count number_of_tracks]
    [-coord start_x_or_y]
    [-dir X | Y]
    [-bounding_box track_boundary_box]
    [-mask_constraint constraint]
```

Data Types

<i>layer</i>	string
<i>track_pitch</i>	float
<i>number_of_tracks</i>	integer
<i>start_x_or_y</i>	float
<i>track_boundary_box</i>	rectangle

ARGUMENTS

-layer *layer*

Specifies the layer to use the tracks. You can specify the layer name, the layer number, or a collection containing one layer object.

-space *track_pitch*

Specifies the pitch between tracks. The pitch is the center-to-center distance between two routing wires in adjacent tracks. By default, this distance is the same as the routing pitch from the unit tile in the Milkyway reference library. The pitch unit size is specified in technology file, typically microns.

-count *number_of_tracks*

Specifies how many tracks to create. By default, the tracks use the entire die area. If you do not specify this option, the value is automatically calculated from the available area of the die or bounding box.

-coord *start_x_or_y*

Specifies the x-coordinate or y-coordinate of the first track, depending on whether the tracks are vertical or horizontal, as determined by the **-dir** option. The unit size for the coordinate is specified in the technology file, typically microns. By default, the coordinate is the left or bottom coordinate of the bounding box, or one-half the pitch inside of the die area.

-dir X | Y

Specifies the direction in which the tracks are placed, either **X** (horizontal) or **Y** (vertical). By default, the direction is the preferred routing direction of the layer, which is specified by the unit tile in the Milkyway reference library.

-bounding_box *track_boundary_box*

Specifies the lower-left and upper-right coordinates of the bounding box that encloses all the tracks, in the form of {{x1 y1} {x2 y2}}. The unit size for the coordinates is specified in the technology file, typically microns. By default, there is no bounding box and the tracks cover the available die area.

-mask_constraint constraint

Specifies the mask constraint for the terminal.

The valid mask_constraints are **any_mask**, **mask1_soft**, **mask1_hard**, **mask2_soft**, **mask2_hard**, **same_mask**, **mask3_soft**, **mask3_hard**.

DESCRIPTION

This command creates a group of tracks on the floorplan so the router can use them to perform detail routing, or the **insert_metal_filler** command can use them to fill the poly layer at the chip finishing stage.

You must specify either a routing layer or poly layer for the tracks. The option of creating tracks for a poly layer is intended for fill purposes only, not routing.

By default, the command creates tracks the preferred routing direction and fills the available die area, starting from one-half the pitch from the die corner. You can optionally specify the track direction (X or Y), the coordinate of the first track, the number of tracks to create, or a bounding box to be filled with tracks.

The tracks created by this command are part of the design database. They are saved in the Milkyway database when you use the **save_mw_cel** command and in DEF format when you use the **write_def** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates routing tracks for a routing layer named "m3" on the floorplan and reports the newly created routing tracks.

```

prompt> create_track -layer m3
Warning: Space is not specified. Using pitch. (MWUI-124)
Warning: Direction is not specified. Using the layer preferred direction.
(MWUI-125)
Warning: Coordinate value is not specified. Defaulting to the left(bottom)
coordinate of the track's bounding box. (MWUI-126)
Warning: Count value is not specified. Covering the bounding box of track,
depending on its space value. (MWUI-127)
1
prompt> report_track -layer m3
...
Layer      Direction   Start    Tracks   Pitch   Attr
-----
Attributes :
  usr : User defined
  def : DEF defined
m3          Y        0.280    3696    0.560   usr
1

```

The following example creates reserved tracks for a routing layer named "m2" with width of 0.06, using a nondefault routing rule, and reports the newly created tracks.

```
prompt> create_track -layer m2 -dir Y -coord 0.438 -space 0.57 \
    -width 0.06 -bounding_box [list "0.000 0.12" "190.260 341.88"] \
    -reserved_for_width true
Warning: Count value is not specified. Covering the bounding box of track,
depending on its space value. (MWUI-127)
1
prompt> report_track -layer m2
...
Layer      Direction   Start   Tracks   Pitch   Attr
-----
Attributes :
  usr : User defined
  def : DEF defined
m2          Y          0.438    790     0.570   usr,width=0.060,reserved_for_width
1
```

SEE ALSO

`get_tracks(2)`
`remove_track(2)`
`report_track(2)`

create_user_shape

Creates a new user shape. A user shape is a metal shape that is not associated with a net.

SYNTAX

```
collection create_user_shape
  [-type wire | path | trap | rect | poly]
  -origin point
  | -points list_of_points
  | -bbox rect
  | -boundary boundary
  [-length length]
  [-width width]
  [-path_type square | round | extend_half_width | octagon]
  -layer layer
  [-mask_constraint constraint]
  [-vertical]
  [-route_type route_type]
  [-datatype int]
  [-avoid_short_segment]
```

Data Types

<i>point</i>	point
<i>list_of_points</i>	list of points
<i>rect</i>	rectangle
<i>boundary</i>	polygon
<i>length</i>	float
<i>width</i>	float
<i>layer</i>	collection
<i>constraint</i>	string
<i>route_type</i>	string
<i>int</i>	integer

ARGUMENTS

-type wire | path | trap | rect | poly

Specifies the type of the user shape. Valid values are **wire**, **path**, **trap** (trapezoid), **rect** (rectangle), and **poly** (polygon).

The default is **poly**.

-origin *point*

Specifies the origin of the user shape for wires.

When you specify this option, you must also specify the **-length** and **-width** options.

The **-origin**, **-points**, **-bbox**, and **-boundary** options are mutually exclusive. You must specify one of these options.

-points *list_of_points*

Specifies the points of the user shape for paths.

When you specify this option, you must also specify the **-width** option.

The **-origin**, **-points**, **-bbox**, and **-boundary** options are mutually exclusive. You must specify one of these options.

-bbox *rect*

Specifies the bounding box of the user shape. You must specify the lower-left and upper-right corners of the bounding box by using the following syntax: `{llx llx} {urx urx}`.

The **-origin**, **-points**, **-bbox**, and **-boundary** options are mutually exclusive. You must specify one of these options.

-boundary *boundary*

Specifies the boundary of the user shape. You must specify at least three nonoverlapping points.

The **-origin**, **-points**, **-bbox**, and **-boundary** options are mutually exclusive. You must specify one of these options.

-length *length*

Specifies the length of the user shape for wires in user units.

This option is required when you specify the **-origin** option and is ignored otherwise.

-width *width*

Specifies the width of the user shape for wires or paths in user units.

This option is required when you specify the **-origin** or **-points** option and is ignored otherwise.

-path_type *square | round | extend_half_width | octagon*

Specifies the alignment type of a wire or path end.

The default is **square**.

You can specify one of the following values:

- **square** (square, no extension)
- **round** (round, half-width extension)
- **extend_half_width** (square, half-width extension)
- **octagon** (octagon, half-width extension)

This option can be used only for wire or path shapes.

-layer *layer*

Specifies the layer for the user shape. You can specify the layer by using the layer name from the technology file or by using the **get_layers** command.

This is a required option.

-mask_constraint *constraint*

Specifies the mask constraint for the user shape.

The valid mask constraints are **any_mask**, **mask1_soft**, **mask1_hard**, **mask2_soft**, **mask2_hard**, **same_mask**, **mask3_soft**, and **mask3_hard**.

-vertical

Indicates that the user shape is vertical.

By default, the user shape is horizontal.

-route_type route_type

Specifies the route type of the user shape.

By default, the route type is **signal_route**.

You can specify one of the following values:

- **user_enter** (user entered)
- **signal_route** or **signal_route_detail** (detail routing)
- **signal_route_global** (global routing)
- **pg_ring** (power or ground ring)
- **pg_strap** (power or ground strap)
- **pg_macro_io_pin_conn** (power or ground net that connects to the power or ground pin of an I/O pad cell or a macro cell)
- **pg_std_cell_pin_conn** (power or ground net that connects to the power or ground pin of a standard cell)
- **clk_ring** (clock ring)
- **clk_strap** (clock strap)
- **clk_zero_skew_route** (clock zero-skew route)
- **bus** (bus)
- **shield** or **shield_fixed** (fixed shield)
- **shield_dynamic** (dynamic shield)
- **fill_track** or **clk_fill_track** (fill track)

This option can be used only for wire, path, or rectangle shapes.

-datatype int

Specifies the data type number in the range 0-255.

By default, the data type is 0.

-avoid_short_segment

Avoids creating segments shorter than a half width for paths.

DESCRIPTION

This command creates a shape object that is not attached to a net and returns a collection that contains the created user shape.

The valid shape types are wire (horizontal or vertical), path, trapezoid, rectangle, and polygon.

Note: For wires, the shape must be symmetrical about the center line. If you specify the width as an odd value, either explicitly by using the **-width** option or implicitly by using the **-bbox** option, the tool rounds the width down to an even value.

For example, the following command specifies a width of 9995 database units. If the technology file defines the lengthPrecision as 1000, the tool rounds this down to 9994, resulting in a bounding box with the coordinates (100.000, 100.000) (**109.994**, 169.895).

```
prompt> create_user_shape -type wire -route_type pg_strap \
    -layer M6 -bbox { {100.000 100.000} {109.995 169.895} } -vertical
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a wire user shape.

```
prompt> create_user_shape -type wire \
    -origin {0 0} -length 10 -width 2 -layer M1
```

SEE ALSO

```
create_net_shape(2)
create_placement_blockage(2)
create_route_guide(2)
create_via(2)
create_terminal(2)
```

create_via

Creates a new via at a specified location.

SYNTAX

```
collection create_via
  -at point
  [-name name]
  [-master via_master | -auto]
  [-net net_name | -no_net]
  [-allow_multiple]
  [-route_type route_type]
  [-orient orientation]
  [-type via | via_array]
  [-row num_rows]
  [-col num_columns]
  [-x_pitch x_distance]
  [-y_pitch y_distance]
```

Data Types

<i>point</i>	point
<i>name</i>	string
<i>via_master</i>	collection
<i>net_name</i>	string
<i>route_type</i>	string
<i>orientation</i>	string
<i>num_rows</i>	integer
<i>num_columns</i>	integer
<i>x_distance</i>	float
<i>y_distance</i>	float

ARGUMENTS

-at *point*

Specifies the location of the center of the created via or via array in the format {*x* *y*}. The units for the coordinates are microns.

This argument is required.

-name *name*

Specifies the name of the created via or via array.

If you do not specify this option, the tool assigns a name using the naming convention VIA#*n*.

-master *via_master*

Specifies the via master. You can specify the via master by using its name or a collection of one via master.

To determine the available via masters, use the **get_via_masters** command.

When you use this option, you must also use either the **-net** or **-no_net** option.

-auto

This option is not supported in Design Compiler topographical mode.

-net net_name

Specifies the name of the net to connect to the via.

This option and the **-no_net** option are mutually exclusive; you must specify one of these options when you use the **-via_master** option.

-no_net

Specifies that no net should be connected to the via.

This option and the **-net** option are mutually exclusive; you must specify one of these options when you use the **-via_master** option.

-allow_multiple

This option is not supported in Design Compiler topographical mode.

-route_type route_type

Specifies the route type of the via.

Specify one of the following values:

user_enter	User entered
signal_route, signal_route_detail	Detail routing
signal_route_global	Global routing
pg_ring	Power or ground (PG) ring
pg_strap	PG strap
pg_macro_io_pin_conn	PG net that connects to the PG pin of an I/O pad cell or a macro cell
pg_std_cell_pin_conn	PG net that connects to the PG pin of a standard cell
clk_ring	Clock ring
clk_strap	Clock strap
clk_zero_skew_route	Clock zero skew route
bus	Bus
shield, shield_fixed	Fixed shield
shield_dynamic	Dynamic shield
fill_track, clk_fill_track	Fill track

By default, the route type is **signal_route**.

-orient orientation

Specifies the orientation of the via or via array using either DEF notation or the tool notation.

Specify one of the following values (values listed in the same bullet are synonymous):

- N, NE, 0
- W, WN, 90
- S, SW, 180
- E, ES, 270
- FN, NW, 0-mirror
- FS, SE, 180-mirror

- FE, EN, 270-mirror
- FW, WS, 90-mirror

By default, the orientation is **N**.

-type via | via_array

Specifies the type of via to create.

By default, a single-cut via is created unless you specify another command option that is specific to via arrays.

-row num_rows

Specifies the number of via array rows.

-col num_columns

Specifies the number of via array columns.

-x_pitch x_distance

Specifies the x-distance in microns between cut centers in the via array.

-y_pitch y_distance

Specifies the y-distance in microns between cut centers in the via array.

This pitch values must be greater than or equal to the sum of the via cut dimension and the minimum cut spacing specified in the technology file for the specified via master. If the value is less than this threshold, a warning is issued and the value is adjusted to the minimum allowable value.

DESCRIPTION

The **create_via** command creates a new via or via array and returns a collection that contains the created object.

Snapping is performed automatically by using the global snap settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an instance of a VIA12 via master at location (100,100) without connecting the via to any net, and identifies the route type as "clock ring":

```
prompt> create_via -at {100 100} -route_type clk_ring \
    -master VIA12 -no_net
{VIA#89088}
```

SEE ALSO

```
create_net_shape(2)
create_placement_blockage(2)
create_route_guide(2)
create_terminal(2)
create_user_shape(2)
```

create_via_master

Creates a design via master using parameters or a geometry list.

SYNTAX

```
status create_via_master
  -name via_master_name
  -cut_layer_name cut_layer_name
  -lower_layer_name low_layer_name
  -upper_layer_name up_layer_name
  [-rectangles {{layer_name {llx lly urx ury}} ...}]
  [-cut_width cut_width]
  [-cut_height cut_height]
  [-lower_layer_enc_width low_enc_width]
  [-lower_layer_enc_height lo_enc_height]
  [-upper_layer_enc_width up_enc_width]
  [-upper_layer_enc_height up_enc_height]
  [-min_cut_spacing min_cut_spacing]
  [-quiet]
```

Data Types

via_master_name	string
cut_layer_name	string
low_layer_name	string
up_layer_name	string
layer_name	string
cut_width	float
cut_height	float
low_enc_width	float
lo_enc_height	float
up_enc_width	float
up_enc_height	float
min_cut_spacing	float

ARGUMENTS

-name *via_master_name*

Specifies the name of the created via master.

-cut_layer_name *cut_layer_name*

Specifies the cut layer for the via master.

-lower_layer_name *low_layer_name*

Specifies the lower metal layer for the via master.

-upper_layer_name *up_layer_name*

Specifies the upper metal layer for the via master.

-rectangles {{layer_name {llx lly urx ury}} ...}

Specifies the list of rectangles that describe the geometry of the via master.

If you use this option, the command ignores the following options: **-cut_width**, **-cut_height**, **-lower_layer_enc_width**, **-lower_layer_enc_height**, **-upper_layer_enc_width**, **-upper_layer_enc_height**, and **-min_cut_spacing**.

-cut_width cut_width

Specifies the cut width in microns of the via master.

You cannot use this option if you use the **-rectangles** option.

-cut_height cut_height

Specifies the cut height in microns of the via master.

You cannot use this option if you use the **-rectangles** option.

-lower_layer_enc_width low_enc_width

Specifies the lower metal layer enclosure width in microns of the via master. The value can be either positive or negative. The negative range is down to -25% of cut size.

You cannot use this option if you use the **-rectangles** option.

-lower_layer_enc_height lo_enc_height

Specifies the lower metal layer enclosure height in microns of the via master. The value can be either positive or negative. The negative range is down to -25% of cut size.

You cannot use this option if you use the **-rectangles** option.

-upper_layer_enc_width up_enc_width

Specifies the upper metal layer enclosure width in microns of the via master. The value can be either positive or negative. The negative range is down to -25% of cut size.

You cannot use this option if you use the **-rectangles** option.

-upper_layer_enc_height up_enc_height

Specifies the upper metal layer enclosure height in microns of the via master. The value can be either positive or negative. The negative range is down to -25% of cut size.

You cannot use this option if you use the **-rectangles** option.

-min_cut_spacing min_cut_spacing

Specifies the minimum spacing in microns between cuts when the via master is used to form an array.

You cannot use this option if you use the **-rectangles** option.

-quiet

Suppresses error and warning messages.

DESCRIPTION

This command creates a new via master. You use this command when the technology file does not already have a via master that matches the required geometry. The working design in which you want to use the via must be open before you create the new via master.

You can create the new via master either by specifying its geometry as a list of rectangles or by specifying the width, height, lower-layer enclosure, upper-layer enclosure, and minimum cut-spacing characteristics of the via, similar to a technology file definition.

To create a single-cut, symmetrical via master, use the height, width, enclosure, and minimum spacing options. To create a multi-cut via master such as an H-shape, use the **-rectangles** option.

When you save the current working cell, the via master is saved with the current cell. You can use the new via master any number of times.

If you specify a geometry list using the **-rectangles** option and you also specify parameters such as width, height, enclosure, and minimum spacing, the tool ignores the parameter settings and issues a warning.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command creates a single-cut via master using parameters:

```
prompt> create_via_master \
-name VIA1 \
-cut_layer_name CUT \
-lower_layer_name METAL1 \
-upper_layer_name METAL2 \
-cut_width 0.22 \
-cut_height 0.22 \
-lower_layer_enc_width 0.1 \
-lower_layer_enc_height 0.1 \
-upper_layer_enc_width 0.01 \
-upper_layer_enc_height 0.01 \
-min_cut_spacing 0.25
```

Using parameters always creates a symmetric, single-cut via master.

The following command creates an H-shaped via master by specifying a geometry list:

```
prompt> create_via_master \
-name VIA1 \
-cut_layer_name CUT \
-lower_layer_name METAL1 \
-upper_layer_name METAL2 \
-rectangles { \
{METAL1 {-0.130 -0.035 0.130 0.035}} \
{CUT {0.035 -0.035 0.100 0.035}} \
{CUT {-0.100 -0.035 -0.035 0.035}} \
{METAL2 {-0.100 -0.065 -0.035 0.065}} \
{METAL2 {0.035 -0.065 0.100 0.065}} \
}
```

SEE ALSO

`create_via(2)`

create_via_rule

Creates a via_rule.

SYNTAX

```
collection create_via_rule
  -name via_rule_name
  [-cut_layer_names {name_list}]
  [-cut_names {name_list}]
  [-cut_rows {int_list}]
  [-cuts_per_row {int_list}]
```

Data Types

<i>name_list</i>	<i>cut_names</i>
<i>int_list</i>	<i>cuts_per_row</i>

ARGUMENTS

-name *via_rule_name*

Specifies the name of the via_rule to be created.

-cut_layer_names {*name_list*}

Defines the cut layer's names. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cut_names {*name_list*}

Defines the cut table names. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cut_rows {*int_list*}

Defines the number of cut rows. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same as of other via_ladder related attributes.

-cuts_per_row {*int_list*}

Defines the number of cuts per row. This is must for defining a via_ladder. If specified then other via_ladder related attributes are must and length of this list attribute should be same for other via_ladder related attributes.

RETURN VALUE

The command returns the created via_rule (as a collection), an empty string if it fails, or a TCL_ERROR if there is a command syntax

error.

DESCRIPTION

This command creates a new via_rule.

EXAMPLES

The following example creates a via_rule in current lib.

```
prompt> create_via_rule -name VR1
```

The following example creates a via_ladder type of via_rule.

```
prompt> create_via_rule -name VL1 -cut_layer_names {VIA1 VIA2} \cut_names {cut1 cut2} -cut_rows {2 2} -cuts_per_row {2 2}
```

SEE ALSO

`get_via_rules(2)`

create_voltage_area

Creates a voltage area at a specified region that constrains the placement of specified hierarchical cells. This command is supported only in topographical mode.

SYNTAX

```
int create_voltage_area
  modules -name voltage_area_name
  | -power_domain {power_domain_name}
  -coordinate {{llx1 lly1 urx1 ury1 ...}}
  [-guard_band_x guard_band_width]
  [-guard_band_y guard_band_width]
  [-is_fixed]
  [-color color | -cycle_color]
  [-target_utilization float]
```

Data Types

<i>modules</i>	list
<i>voltage_area_name</i>	string
<i>power_domain_name</i>	string
<i>llx1</i>	float
<i>lly1</i>	float
<i>urx1</i>	float
<i>ury1</i>	float
<i>guard_band_width</i>	float
<i>color</i>	string

ARGUMENTS

modules

Specifies a list of hierarchical cells that are constrained to be placed in the specified area. A given cell cannot be assigned to two different voltage areas. Leaf-level cells (standard cells) cannot be specified in this option.

In UPF mode, voltage areas may only be created if they contain all of the hierarchical cells from one or more power domains. The **-power_domain** argument should be used instead of this argument.

-name *voltage_area_name*

Specifies the name of the voltage area to be created. It cannot be the name of an existing voltage area or the name "DEFAULT_VA", which is reserved for the default voltage area.

If this option is used with the **-power_domain** option, you can put multiple compatible power domains into the same voltage area. Otherwise, this option can be used only with the **modules** argument.

-power_domain {*power_domain_name*}

Creates a voltage area from an existing power domain previously created by the **create_power_domain** command. By default, the name of the new voltage area is identical to the name of the power domain. All hierarchical cells in the power domain are

associated with the voltage area. After the voltage area is successfully created, the power domain contains the corresponding boundary information. You cannot create a voltage area from a top-level power domain.

-coordinate {llx1 lly1 urx1 ury1 ...}

Specifies a list of lower-left and upper-right coordinates of a voltage area, in microns. Each set of $\{llx\ lly\ urx\ ury\}$ defines a target rectangular placement area. The voltage area geometry can be a rectangle or a rectilinear polygon.

-guard_band_x guard_band_width

Specifies the horizontal (left and right) margin around the voltage area where objects are not allowed to be placed, a positive floating-point value.

-guard_band_y guard_band_width

Specifies the vertical (top and bottom) margin around the voltage area where objects are not allowed to be placed, a positive floating-point value.

-is_fixed

Specifies that the voltage area is in a fixed location and cannot be changed by shaping. By default, the voltage area can be changed by shaping.

-color color

Specifies the color for the voltage area and its cells in the GUI display. The value can be either a color string such as "red" or "blue" or a color index, an integer between 0 to 63, each number representing a different color.

-cycle_color

Automatically chooses the next color in the color table for successive new voltage areas. This option is mutually exclusive with the **-color** option.

-target_utilization float

Specifies the target utilization for this voltage area during shaping. The target voltage area is the total area of cells placed in the voltage area divided by the target utilization for the voltage area. The default is the design utilization. The value specified must be between 0.1 and 1.0.

DESCRIPTION

The **create_voltage_area** command creates a voltage area of a specific geometry and location on the core area of the chip. The voltage area is associated with a list of one or more power domains previously created by the **create_power_domain** command or a list of specified hierarchical cells. The placer considers the voltage area an exclusive, hard move bound; it tries to place all the cells associated with the voltage area within the that area, and to place all other cells outside of that area.

Voltage areas can be physically nested, with one voltage area completely enclosing another voltage area. When considering the area or utilization of the outside voltage area, the area of inner voltage area is excluded.

Voltage areas can also be logically nested, with one hierarchical cell belonging to one voltage area while one or more of its descendants belonging to other voltage areas. When considering area utilization, the tool excludes all descendants belonging to other voltage areas.

Any nested voltage area must be fully enclosed by another voltage area; partially overlapping voltage areas are not allowed. Any move bound must be completely enclosed inside a voltage area; a voltage area cannot partially overlap or be enclosed by a move bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example constrains the hierarchical instance INST_1 to lie within the voltage area whose coordinates are lower-left corner (100,100) and upper-right corner (200,200):

```
prompt> create_voltage_area -name VA1 \
    -coordinate {100 100 200 200} INST_1
```

The following example creates a voltage area of disjoint polygons using the **-coordinate** option:

```
prompt> create_voltage_area -power_domain PD1 -coordinate \
    { {100 100} {300 100} {300 200} {200 200} \
    {200 300} {100 300} {100 100} } \
    { {400 400} {500 400} {500 500} {400 500} {400 400} } }
```

Each power domain must be fully contained within a single voltage area. To restrict placement of elements that are a subset of a power domain, see the **create_bounds** command.

SEE ALSO

[create_power_domain\(2\)](#)
[remove_voltage_area\(2\)](#)
[report_voltage_area\(2\)](#)
[create_bounds\(2\)](#)

create_wiring_keepouts

Creates a wiring keepout.

SYNTAX

```
status create_wiring_keepouts
      -name name
      -layer layer
      -coordinate list_of_float_values
```

Data Types

<i>name</i>	string
<i>layer</i>	string
<i>list_of_float_values</i>	list

ARGUMENTS

-name *name*

Specifies the name of the wiring keepout to be created.

-layer *layer*

Specifies the name of the layer on which the routing obstruction is to lie.

-coordinate *list_of_float_values*

Specifies a list of float values that serve as the coordinates of the wiring keepout. These coordinates are relative to the design origin at (0 0) and are in units of micron.

DESCRIPTION

The **create_wiring_keepouts** command creates a wiring keepout.

A wiring keepout is not created if the given keepout name matches with any other existing wiring keepout name. However, a wiring keepout is created if its name matches the name of an existing placement keepout.

EXAMPLES

The following is an example of the **create_wiring_keepouts** command:

```
prompt> create_wiring_keepouts -name "my_keep1" -layer "METAL1" \
-coord {12 12 100 100}
```

SEE ALSO

`extract_physical_constraints(2)`
`report_physical_constraints(2)`
`reset_physical_constraints(2)`

cross_probing_filter

Filters a collection based on file name and line number criteria.

SYNTAX

```
collection cross_probing_filter
  -source source_patterns
  objects
```

Data Types

<i>source_patterns</i>	string
<i>objects</i>	collection

ARGUMENTS

-source *source_patterns*

This string is the matching criteria used for filtering. Filter a collection by specifying a source file and line number in the "file_pattern[:line_pattern]" format. You can specify multiple patterns by delimiting them with a space character, such as "file_pattern1[:line_pattern1] file_pattern2[:line_pattern2] ...". Objects that match any of the specified file/line patterns are returned in the resulting collection.

The asterisk (*) and question mark (?) wildcard patterns are allowed in the pattern.

objects

Specifies the base collection to be filtered. The base collection may contain cell or port objects.

DESCRIPTION

Allows you to filter a collection by specifying a source file and line number. This command functions similar to **filter_collection** except the filtering criteria is specific to cross-probing.

You must have a design that was analyzed and elaborated or synthesized using Design Compiler version I-2013.12 or later. The tool provides information about where the cell or port was created, specifying which file and line number the object came from. These objects can be filtered based on file name and/or line number.

Some objects in the design might have been merged, resulting in an object that can potentially have multiple source locations. In this case, the object is returned in the result collection if any of its source positions match any of the specified source patterns specified by *source_patterns*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the result from the **cross_probing_filter** command, returning cells that originated from a source file ending in m.v, and on line 21:

```
prompt> cross_probing_filter [get_cells -hierarchical] -source "*m.v:21"  
{mid1/bot1/c1 mid1/bot2/c1}
```

SEE ALSO

`report_cross_probing(2)`
`get_cross_probing_info(2)`

current_design

Sets the working design.

SYNTAX

```
string current_design
      [design]
```

Data Types

design string

ARGUMENTS

design

Specifies the working or focal design for many commands.

If you do not specify a design or specify a period (.), the tool returns the current working design. If you specify a design that cannot be found, the tool issues an error and the working design remains unchanged.

DESCRIPTION

The **current_design** command sets the working design for many commands. If you do not specify any arguments, the **current_design** command returns the name of the current working design.

To display designs currently available in memory, use the **list_designs** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **current_design** command to show the current context and to change the context from one design to another:

```
prompt> current_design .
Current design is 'TOP'.
{TOP}
```

```
prompt> list_designs
ADDER      FULL_SUBTRACTOR HALF_SUBTRACTOR TOP (*)
FULL_ADDER  HALF_ADDER   SUBTRACTOR
```

```
prompt> current_design ADDER
Current design is 'ADDER'.
{ADDER}
```

```
prompt> current_design
Current design is 'ADDER'.
{ADDER}
```

You can use the **current_design** command as an argument to other commands. In the following example, the **remove_design** command is used to delete the working design from memory:

```
prompt> current_design
Current design is 'TOP'.
```

```
prompt> remove_design [current_design]
Removing design 'TOP'
```

```
prompt> current_design
Error: Current design is not defined. (UID-4)
```

SEE ALSO

[current_instance\(2\)](#)
[list_designs\(2\)](#)
[list_instances\(2\)](#)

current_design_name

Returns the current design name.

SYNTAX

string **current_design_name**

DESCRIPTION

This command returns the string of the current design name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **current_design_name** to save the current design name to a variable:

```
prompt> current_design
Current design is 'TOP'.
{TOP}

prompt> set design_name [current_design_name]
Information: Defining new variable 'design_name'. (CMD-041)
TOP
Current design is 'TOP'.
```

SEE ALSO

[current_design\(2\)](#)

current_dft_partition

Sets or gets the design partition for the current specification.

SYNTAX

```
status current_dft_partition
      [design_partition_label]
```

Data Types

design_partition_label string

ARGUMENTS

design_partition_label

Specifies the working design partition for many commands. If the *design_partition_label* is not specified, the tool uses the last design partition specified. If the *design_partition_label* specifies a partition name that is not defined in the CTL model for the current design and that has not been specified previously using the **define_dft_partition** command, an error is issued and the working test mode remains unchanged.

DESCRIPTION

The **current_dft_partition** command sets the design partition for many specification commands, such as **set_dft_signal**, **set_scan_configuration**, **set_scan_compression_configuration**, and **set_scan_path**. When no arguments are specified, **current_dft_partition** returns the name of the current DFT partition.

To display the names of all of the design partitions in the test model for the current design, use the **report_dft_partition** command.

EXAMPLES

The following example sets the required number of scan chains to 3 and 2 to the partitions *part1* and *part2*, respectively:

```
prompt> define_dft_partition part1 -include {U1 U2}
prompt> define_dft_partition part2 -include {U3 U4}

current_instance

Sets the working instance object and enables other commands to be used on a specific cell in the design hierarchy.

SYNTAX

```
string current_instance
      [instance]
```

Data Types

instance string

ARGUMENTS

instance

Specifies the working cell.

The **current_instance** command operates with a variety of *instance* arguments:

- If you do not specify the *instance* argument, the focus is returned to the top level of the hierarchy.
- If you specify "." or "./", the current instance is returned and no change is made.
- If you specify ".." or "../", the current instance is moved up one level in the design hierarchy. You can also nest the ".." directive in complex instance specifications. For example, ../../MY_INST attempts to move the context up two levels of hierarchy, and then down one level to the MY_INST cell.
- If you specify a valid cell at the current level of the hierarchy, the current instance is moved down to that level of the design hierarchy.
- You can traverse multiple levels of hierarchy in a single call to the **current_instance** command by separating multiple cell names with slashes. A trailing slash can be added to the end of the last cell, though the behavior is the same as without the trailing slash.
For example, if you specify U1/U2, the current instance is moved down two levels of hierarchy if both cells exist at the current levels in the design hierarchy.

More complex examples of *instance* arguments are described below in EXAMPLES.

DESCRIPTION

The **current_instance** command sets the working instance. An instance is a cell embedded in the hierarchy of a design. Usually you define an instance to set or get attributes on a cell.

To display the instances available at the current level of a design hierarchy, use the **list_instances** command.

The **current_design** command changes the working design, setting the current instance to the top level of the new current design.

The **current_instance** command traverses the design hierarchy similar to the way the UNIX **cd** command traverses the file hierarchy.

Note that the **current_instance** command does not work on leaf cells. If you attempt to run the **current_instance** command on a leaf cell, an error occurs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **current_instance** command to move up and down the design hierarchy and the **list_instances** command to show the available instances at each point in the hierarchy:

```
prompt> current_design .
Current design is 'TOP'.
{TOP}

prompt> current_design ../
Current design is 'TOP'.
{TOP}

prompt> list_instances
U1 (ADDER)    U2 (SUBTRACTOR)

prompt> current_instance U1
Current instance is 'TOP/U1'.
/TOP/U1

prompt> current_instance .
Current instance is 'TOP/U1'.
/TOP/U1

prompt> list_instances
U1 (FULL_ADDER) U2 (FULL_ADDER) U3 (FULL_ADDER) U4 (FULL_ADDER)

prompt> current_instance U3
Current instance is 'TOP/U1/U3'.
/TOP/U1/U3

prompt> current_instance "../U4"
Current instance is 'TOP/U1/U4'.
/TOP/U1/U4

prompt> current_instance
Current instance is the top-level of design 'TOP'.
```

In the following example, changing the current design resets the **current_instance** to the top level of the new design hierarchy:

```
prompt> current_design
Current design is 'TOP'.
{TOP}

prompt> current_instance "U2/U1/"
Current instance is 'TOP/U2/U1'.
/TOP/U2/U1

prompt> current_design ADDER
```

```
Current design is 'ADDER'.
{ADDER}
```

```
prompt> current_instance.
Current instance is the top-level of design 'ADDER'.
```

The following example uses **current_instance** to go to an instance of another design. The current design is set by the new design whose name is the name after the first slash of the given instance name.

```
prompt> current_design.
Current design is 'TOP'.
{TOP}
```

```
prompt> current_instance U1
Current instance is 'TOP/U1'.
/TOP/U1
```

```
prompt> current_instance /TOP/U2
Current instance is 'TOP/U2'.
/TOP/U2
```

```
prompt> current_instance /ALARM_BLOCK/U6
Current instance is 'ALARM_BLOCK/U6'.
/ALARM_BLOCK/U6
```

current_lib

Sets or returns the current library.

SYNTAX

```
string current_lib
    [-quiet]
    [library_name]
```

Data Types

library_name string

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

DESCRIPTION

The **current_lib** command gets or sets the current library.

Many library-related commands use the current library by default. The current library is automatically set when the **create_lib** command creates a new library or the **open_lib** command opens a library.

This command returns the current library if successful, or 0 otherwise. If an illegal name is given, a Tcl error is issued.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example returns the current library in the current session:

```
prompt> current_lib
design
```

The following example sets the current library in the current session:

```
prompt> current_lib top_design
top_design
```

current_mw_lib

Gets the current Milkyway library.

SYNTAX

collection **current_mw_lib**

ARGUMENTS

The **current_mw_lib** command has no arguments.

DESCRIPTION

The **current_mw_lib** command gets the current Milkyway library. The **current_mw_lib** command returns a collection of the current Milkyway library, if one exists.

Many Milkyway library-related commands use the current Milkyway library by default. The current Milkyway library is automatically set when the **open_mw_lib** command opens a Milkyway library to use.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns the current Milkyway library in the current session:

```
prompt> current_mw_lib
{design}
```

current_scenario

Sets the current scenario.

SYNTAX

```
string current_scenario
      [scenario_name]
```

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the name of the current scenario. If *scenario_name* is not specified, the tool returns to the current scenario.

DESCRIPTION

The **current_scenario** command sets the current scenario for many commands. Without arguments, **current_scenario** returns the name of the current scenario.

The creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example uses the **current_scenario** command to set the current scenario:

```
prompt> create_scenario MODE1
Warning: Discarding all scenario-specific information previously defined
      in this session. (UID-1008)
Current scenario is: MODE1
1

prompt> create_scenario MODE2
Current scenario is: MODE2
```

1

prompt> **create_scenario MODE3**

Current scenario is: MODE3

1

prompt> **current_scenario MODE2**

Current scenario is: MODE2

MODE2

SEE ALSO

[all_scenarios\(2\)](#)

[create_scenario\(2\)](#)

[remove_scenario\(2\)](#)

current_test_mode

Sets or gets the current working test mode for the current design.

SYNTAX

```
status current_test_mode
      [test_mode_label]
```

Data Types

test_mode_label string

ARGUMENTS

test_mode_label

Specifies the working test mode for many commands.

If the *test_mode_label* is not specified, the tool prints the current test mode.

DESCRIPTION

The **current_test_mode** command sets the current working mode. This is the default test mode used for many DFT commands, such as **set_dft_signal** and **dft_drc**.

To display the names of all the modes in the test model data for the current design, use the **report_test_model** command.

To display the names of all the test modes of the current design defined with the **define_test_mode** command, use the **list_test_modes** command.

EXAMPLES

The following example sets the test mode to "Internal_scan" for the current design:

```
prompt> current_test_mode Internal_scan
1
```

The following example gets the test mode for the current design:

```
prompt> current_test_mode
Current test mode is 'Internal_scan'.
1
```

SEE ALSO

`current_design(2)`
`dft_drc(2)`
`list_test_modes(2)`
`report_test_model(2)`

cut_row

Removes rows from the current design.

SYNTAX

status **cut_row**
[-all | -within {coordinates}]

Data Types

coordinates list

ARGUMENTS

-all

Removes all rows from the current design. This option and the **-within** option are mutually exclusive.

-within {coordinates}

Removes all rows in the specified region. For a rectangular region, specify the coordinates for the lower-left and upper-right corners as $\{\{ll_x\ ll_y\} \{ur_x\ ur_y\}\}$. For a rectilinear region, specify a list of rectilinear coordinates in either clockwise or counterclockwise order. This option and the **-all** option are mutually exclusive.

This option is not supported in Design Compiler topographical mode and will be ignored.

DESCRIPTION

This command removes rows from the current design. If you specify the **-all** option, the command removes all rows from the design. If you specify the **-within** option, the command removes rows within the specified region.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **-all** option to remove all rows from the current design.

```
prompt> cut_row -all  
1
```

SEE ALSO

`add_row(2)`

date

Returns a string containing the current date and time.

SYNTAX

string **date**

DESCRIPTION

The **date** command generates a string containing the current date and time, and returns that string as the result of the command. The format is fixed as follows:

ddd mmm nn hh:mm:ss yyyy

Where:

ddd is an abbreviation for the day
mmm is an abbreviation for the month
nn is the day number
hh is the hour number (24 hour system)
mm is the minute number
ss is the second number
yyyy is the year

The **date** command is useful because it is native. It does not fork a process. On some operating systems, when the process becomes large, no further processes can be forked from it. With it, there is no need to call the operating system with **exec** to ask for the date and time.

EXAMPLES

The following command prints the date.

```
prompt> echo "Date and time: [date]"  
Date and time: Thu Dec 9 17:29:51 1999
```

SEE ALSO

[exec\(2\)](#)

dc_allocate_budgets

Allocates budgets to specified cells.

SYNTAX

```
string dc_allocate_budgets
  [cell_list]
  [-write_script]
  [-file_format_spec format_spec]
  [-format dctcl | dcsh]
  [-separator hierarchy_separator]
  [-mode rtl | gate | mixed]
  [-budget_design_ware]
  [-levels budget_levels]
  [-no_interblock_logic]
  [-min_register_to_output minimum_budget]
  [-min_input_to_output minimum_budget]
  [-min_input_to_register minimum_budget]
```

Data Types

<i>cell_list</i>	list
<i>format_spec</i>	string
<i>hierarchy_separator</i>	string
<i>budget_levels</i>	string
<i>minimum_budget</i>	float

ARGUMENTS

cell_list

Specifies the list of cells to budget. The list of cells is required when you do not use the **-levels** option.

-write_script

Specifies that the context of each budgeted cell or design is to be written into a constraint file.

-file_format_spec *format_spec*

Specifies the format for the names of constraint files generated for each budgeted cell, if the **-write_script** option is used. The default is /%C.dctcl. For details, see the DESCRIPTION section.

-format *dctcl* | *dcsh*

Specifies the output format for script files. Allowed values are **dctcl** (the default) or **dcsh**.

-separator *hierarchy_separator*

Specifies a single character to use as a separator in deriving the names of constraint files generated for each cell. All characters are allowed except slash (/), percent (%), and double backslash \e|. The default is the at sign (@).

-mode rtl | gate | mixed

Specifies whether the design to be budgeted is an RTL or a gate-level design, or a design that is mixed with RTL and gates. The default is **gate**. For details on the **-mode** option, see the *Budgeting for Synthesis User Guide*.

-budget_design_ware

Specifies that DesignWare components are to be budgeted. By default, Design Budgeter considers these components fixed.

-levels budget_levels

Specifies the number of levels of hierarchy for which to allocate budgets starting from the specified cells. Allowed values are **all**, **1**, **2**, **3**..., and **n**. The default is **all**, which allocates budgets down all levels of hierarchy.

-no_interblock_logic

Specifies that interblock logic is not to be budgeted. By default, the design budgeter considers interblock logic not fixed.

-min_register_to_output minimum_budget

Specifies a positive floating-point number that indicates the minimum budget for any path segment from an internal register to an output pin of a budgeted cell.

-min_input_to_output minimum_budget

Specifies a positive floating-point number that indicates the minimum budget for any path segment from an input pin to an output pin of a budgeted cell.

-min_input_to_register minimum_budget

Specifies a positive floating-point number that specifies the minimum budget for any path segment from an input pin to an internal register of a budgeted cell.

The **-min_register_to_output**, **-min_input_to_output**, and **-min_input_to_register** options allow you to avoid overconstraining noncompressible path segments, such as segments to registered output pins or segments from registered input pins. Use these options carefully to avoid creating mutually inconsistent constraints. If necessary, the budgeter assigns path delays less than these minimum budget values to prevent negative slack in the budget.

DESCRIPTION

The **dc_allocate_budgets** command distributes the timing constraints among the specified cells. The command allows you to specify cells by either non-hierarchical budgets allocation or the hierarchical budgets allocation.

The non-hierarchical budgets allocation is the default method. Only cells specified with *cell_list* are budgeted. Designs are not budgeted.

The hierarchical budgets allocation is enabled by the **-levels** option. When activated, the tool allocates budgets hierarchically. If you specify *cell_list*, budgets are hierarchically allocated starting from these cells. If you do not specify *cell_list*, budgets are allocated starting from cells in the top level of the design. If a design has several instances, a constraint file can be written out for each instance for cell-based file format specification (%C). For design-based file format specification (%D), the last instance of the design is used to generate the constraint file.

The **-file_format_spec** option specifies the format for the names of constraint files generated for each budgeted cell. The format contains the directory in which files are to be written, and the prefix, the suffix, and the extension to use. The format specification must contain only one conversion specification: either %D, which indicates a design name, or %C, which indicates a cell name.

For the %D conversion specification, the constraint file name is obtained by replacing the conversion specification by either the name of the cell design if the design is referenced once (uniquified design), or by the concatenation of the design name and the full cell name.

For the %C conversion specification, the constraint file name is obtained by replacing the conversion specification by the full cell name.

The default value of **-file_format_spec** depends on the **-format** option.

The default value is `./%C.dctcl` if the **-format** option is not specified, `./%C.dctcl` if the **-format** option value is **dctcl**, or `./%C.dscl` if the **-format** option is **dscl**.

By default, budget allocation is performed automatically. You can optionally specify user budgets or budget ratios using the **set_user_budget** command.

EXAMPLES

The following command allocates budgets to cells *I1* and *I2*, and writes a constraint file in dcsh format to files named *I1.dscl* and *I2.dscl*. The report shows the results.

```
prompt> dc_allocate_budgets -write_script \
    -file_format_spec %C.dscl -format dscl {I1 I2}
```

```
prompt> report_path_budget
```

decrypt_lib

Decrypts a Milkyway library containing locked technology information.

SYNTAX

```
status decrypt_lib
  [-format {mwlib}]
  -key key_string
  lib_name
```

Data Types

<i>key_string</i>	string
<i>lib_name</i>	string

ARGUMENTS

-format {mwlib}

Specifies the format of the file to be decrypted. By default, the format is **mwlib**, which means Milkyway library.

-key *key_string*

Specifies the key string to unlock the Milkyway library technology information. The library can be decrypted only by supplying the correct key string.

lib_name

Specifies the name of the Milkyway library to decrypt.

DESCRIPTION

This command can decrypts an encrypted mw library if the library was encrypted by command "**encrypt_lib -format mwlib -key keyStr**".

A library encrypted natively by creation from an encrypted technology file cannot be decrypted by this command.

EXAMPLES

The following example decrypts the Milkyway library "my_lib" with a key string.

```
prompt> decrypt_lib -key {ki08$#98fa?ipo} my_lib
```

SEE ALSO

`encrypt_lib(2)`

define_design_lib

Maps a design library to a UNIX directory.

SYNTAX

```
status define_design_lib
      library_name
      -path directory
```

Data Types

library_name string
directory string

ARGUMENTS

library_name

Specifies the library to be mapped.

-path *directory*

Specifies the directory to which the library is mapped.

DESCRIPTION

The **define_design_lib** command maps a design library to a UNIX directory. The directory is used to store intermediate representations of designs.

When **define_design_lib** is used with the **design_library_file** command, the file is automatically reread when it is changed. As a result, if the file contains a library definition that was manually defined with **define_design_lib**, the manual definition is overridden.

EXAMPLES

The following example uses **define_design_lib** to map the *MY_LIB* library to the *~/library* directory:

```
prompt> define_design_lib MY_LIB -path ~/library
```

SEE ALSO

`analyze(2)`
`elaborate(2)`
`get_design_lib_path(2)`
`read(2)`
`report_design_lib(2)`
`write_design_lib_paths(2)`

define_dft_design

Characterizes a design as a DFT design to be used for DFT insertion.

SYNTAX

```
status define_dft_design
  -design_name design_name
  [-type design_type]
  [-interface access_list]
  [-test_model model_path_name]
  [-params param_list]
  [-validate true | false]
```

Data Types

<i>design_name</i>	string
<i>design_type</i>	string
<i>access_list</i>	list
<i>model_path_name</i>	string
<i>param_list</i>	list

ARGUMENTS

-design_name *design_name*

Identifies the design to be instantiated during DFT insertion.

This option is required.

-type *design_type*

Specifies the type of the DFT design to which the design corresponds. Valid design types are:

DECODE	CONTROL_FORCE	Z_CONTROL_FORCE	OBSERV_DGEN
SHIFT_REG	BC_1	BC_2	BC_3
BC_4	BC_5	BC_7	BC_8
BC_9	BC_10	WC_D1	WC_D1_S
WC_S1	WC_S1_S	INSTRREG	TAP
TAP_UC	LBIST_CONTROLLER	LBIST_CODEC	LBIST_XCONTROLLER
LBIST_XCODEC	CLK_MUX	CLK_CHAIN	MBIST_CONTROLLER
MBIST_WRAPPER	PAD	AC_1	AC_2
AC_7	AC_SELU	AC_SELX	

There is no default for this option. When the option is not specified, the tool creates a new DFT design type from the specified design name and the specified interface access list.

-interface *access_list*

Specifies the list of signal mapping triplets relating a signal type to a pin of the design specified with **-design_name *design_name***. The valid format of a signal mapping triplet is as follows:

signal_type_name pin_name pin_polarity

The *signal_type_name* specifies the signal type name of the latest of DesignWare version of the DFT design pin name. The *pin_name* specifies the pin name of the design specified with **-design_name** *design_name*. The *pin_polarity* specifies the polarity of the specified design pin with respect to the *signal_type_name*.

Valid values for *pin_polarity* are **h** for normal polarity and **l** for negative polarity.

There is no default for this option. When the option is not specified, it is assumed that the design does not have interface access pins for use with DFT insertion.

-test_model model_path_name

Identifies the path name of the test model for the specified DFT design.

There is no default for this option.

-params param_list

Specifies the list of parameter triplets for the specified DFT design. The valid format of a parameter triplet is as follows:

param_name param_type param_value

The *param_name* specifies the name of the parameter, *param_type* specifies the type of the parameter, and *param_value* specifies the value of the parameter. Valid values for *param_type* are **integer**, **float**, **boolean**, and **string**.

These parameters are stored on the specified DFT design for use with DFT insertion.

There is no default for this option.

-validate true | false

Validates connectivity in netlist DFT designs.

When set to **true**, the **define_dft_design** command validates that each output/inout port in the interface specification reaches at least one input port in the interface specification. Port direction is determined by the design netlist specified with the **-design** option. The check is a simple topological fanin check that does not analyze cell functionality or design constants. If the validation fails, the tool issues an error and discards the specification.

The default is **false** so that specifications relying on inferred ports do not cause validation failures.

This option is considered only for design netlist representations; it is ignored for black box or library cell representations.

DESCRIPTION

The **define_dft_design** command characterizes a design as a DFT design of a certain type for use with DFT insertion. Ensure that the specified design functionality matches the standard design of the specified type. The specified design is used to instantiate an IP instead of a DesignWare IP during DFT insertion.

EXAMPLES

The following example instructs **insert_dft** to use the *my_des* design as a WC_D1 for wrapper insertion:

```
prompt> read_db my_des.db
1

prompt> define_dft_design -design_name my_des -type WC_D1 \
    -interface {shift_clk capture_clk h capture_en capture_en \}
```

```
h shift_en shift_dr h cti si h cto so h cfi data_in \
h cfo data_out h}
1
```

The following example instructs **insert_dft** to use the *my_des1* design as a BC_4 for BSD insertion:

```
prompt> read_db my_des1.db
1

prompt> define_dft_design -design_name my_des1 -type BC_4 \
    -interface {capture_clk cap_clk h capture_en cen h \
    shift_dr shift h si ti h so to h data_in di h data_out do h}
1
```

The following example instructs **insert_dft** to use the *ip_pad_des1* design as an input pad design for BSD insertion:

```
prompt> read_db ip_pad_des1.db
1

prompt> define_dft_design -design_name ip_pad_des1 -type PAD \
    -interface {port di h data_out do h} \
    -params {$pad_type$ string input}
1
```

The following example instructs **insert_dft** to use the *op_pad_des1* design as a tristate output pad design with an inverted enable pin for BSD insertion:

```
prompt> read_db op_pad_des1.db
1

prompt> define_dft_design -design_name op_pad_des1 -type PAD \
    -interface {port do h data_in di h enable en l} \
    -params {$pad_type$ string tristate_output}
1
```

The following example instructs **insert_dft** to use the *bidi_pad_des1* design as a bidirectional differential pad design library cell with observe/high/low pins for BSD insertion:

```
prompt> read_db bidi_pad_des1.db
1

prompt> define_dft_design -design_name bidi_pad_des1 -type PAD \
    -interface {port ZP h port ZM l data_in di h \
    data_out do h observe IE h high TM h low TE h} \
    -params {$pad_type$ string bidirectional \
    $differential$ string true $lib_cell$ string true}
1
```

The following example instructs **insert_dft** to use the *ip_op_pad_des1* design as an differential input as well as a differential output pad design for BSD insertion:

```
prompt> read_db ip_op_pad_des1.db
1

prompt> define_dft_design -design_name ip_op_pad_des1 -type PAD \
    -interface {port dop h port don l data_in di h} \
    -params {$pad_type$ string output $differential$ string true}
1
prompt> define_dft_design -design_name ip_op_pad_des1 -type PAD \
    -interface {port dip h port din l data_out do h} \
    -params {$pad_type$ string input $differential$ string true}
1
```

The following example instructs **insert_dft** to use the *ip_op_pad_des1* design as a differential hybrid pad design for BSD insertion:

```
prompt> read_db ip_op_pad_des1.db
```

```
1  
prompt> define_dft_design -design_name ip_op_pad_des1 -type PAD \  
-interface {si si_pin H so so_pin H shift_dr shift_dr_pin H} \  
-params {$pad_type$ string hybrid $differential$ string true \  
$diff_port_pairs$ list string \  
"dop don" "dip din" $end_list$ \  
$bsr_segment$ list string \  
"0 BC_1 - dop X -" \  
"1 BC_4 dip - X -" "2 BC_2 dip - X -" "3 BC_4 din - X -" \  
$end_list$}

define_dft_partition

Defines a design DFT partition to be created during DFT synthesis.

SYNTAX

```
status define_dft_partition
  design_partition_label
  [-default false | true]
  [-include list_of_design_objects]
  [-clocks list_of_clocks]
  [-rising_edge_clocks list_of_clocks]
  [-falling_edge_clocks list_of_clocks]
  [-extest_cells list_of_wrapped_cores]
  [-wrapper enable | disable]
```

Data Types

```
design_partition_label  string
list_of_design_objects  list
list_of_clocks         list
list_of_wrapped_cores  list
```

ARGUMENTS

design_partition_label

Specifies a user-defined text string containing only alphanumeric characters (a-z, A-Z, 0-9) and the underscore (_).

-default false | true

Specifies whether the defined partition is also the default partition.

By default, the tool creates a default partition named **default_partition** for any design logic not explicitly included in a user-defined partition.

If you set this option to **true**, this defined partition is the default partition. Any unallocated logic is included in this partition along with any design logic explicitly included using other options of this command.

Only one partition can be defined as the default partition.

-include list_of_design_objects

Specifies the list of leaf or hierarchical cells, design references, or core scan segments that belong to the defined partition.

In DFTMAX shared codec I/O flows, you can also specify subpartition names to define sharing groups. Partition names are not supported in other flows.

You can mix object types in the list. Wildcards and collections are supported.

-clocks list_of_clocks

Specifies the list of clocks that belongs to the defined partition.

-rising_edge_clocks *list_of_clocks*

Specifies the list of rising clocks that belongs to the defined partition.

-falling_edge_clocks *list_of_clocks*

Specifies the list of falling clocks that belongs to the defined partition.

-extest_cells *list_of_wrapped_cores*

Specifies that the outward-facing wrapper chains from the specified cores should be included in the defined partition.

The referenced cores can exist in other DFT partitions. This option provides more control over how the outward-facing chains of wrapped cores are compressed by a top-level codec in a DFT partition flow.

This option affects all test modes that use the specified cores in outward-facing modes, including uncompressed scan modes. Test modes that use the cores in inward-facing modes are unaffected by this option.

DESCRIPTION

The **define_dft_partition** command allows you to define a specific design partition during DFT synthesis. The partition is referenced to the top level in a top-down flow.

The partition information is then used during the DFT architect and insertion process, while running the **preview_dft** or the **insert_dft** command. Each design partition will be DFT-inserted based on its DFT constraints.

You can use multiple option types (**-include**, **-clocks**, **-rising_edge_clocks**, and **-falling_edge_clocks**) in a single partition definition.

You can include clock-gating cells in DFT partition definitions. Although clock-gating cells are not stitched into scan chains, they will use partition-specific scan-enable signals for their test pins (if defined). Clock-gating cells can be included by leaf cell, enclosing hierarchical cell, or clock. When referencing a Power Compiler clock-gating cell by leaf cell, reference the mapped clock-gating cell inside the hierarchical clock-gating cell wrapper.

EXAMPLES

The following example defines 2 design partitions for use in a DFT insertion. The design contains at the top level 4 hierarchical cells named *U1*, *U2*, *U3* and *U4*, respectively.

```
prompt> define_dft_partition part_1\
           -include {U1 U2}

prompt> define_dft_partition part_2\
           -include {U3 U4}
```

The following example defines 2 design partitions for use in a DFT insertion. The design contains at the top level 4 hierarchical cells. The cells *U1* and *U2* are instantiated from the *ref1* design reference and cells *U3* and *U4* are instantiated from design reference *ref2*:

```
prompt> define_dft_partition part_1\
           -include {ref1}

prompt> define_dft_partition part_2\
           -include {ref2}
```

define_libcell_subset

Defines a subset of library cells to restrict the optimization of sequential and instantiated combinational cells.

SYNTAX

```
status define_libcell_subset
  [-libcell_list lib_cells]
  [-family_name name]
```

Data Types

<i>lib_cells</i>	list
<i>name</i>	string

ARGUMENTS

-libcell_list *lib_cells*

Specifies a list of library cells to be a family. These library cells must abide by the following rules: First, the library cells cannot belong to another family. Second, they must have the same functional identification. Third, they must be either sequential library cells or instantiated combinational cells.

-family_name *name*

Specifies a name for the subset of library cells.

DESCRIPTION

The **define_libcell_subset** command defines a subset of target library cells to be used for the **set_libcell_subset** command. After the library cells are grouped into a family, they are not available for use during the compile run. However, cells that are specified by the **set_libcell_subset** command can be optimized. A library cell can only belong to one family. Therefore, if you need to change the family of a library cell, the family should be removed first using the **remove_libcell_subset** command.

This command is supported only in topographical mode.

The exclusiveness restriction applies only to the new cells that are created or mapped during optimization. This restriction does not affect cells that are already mapped.

To remove a family, use the **remove_libcell_subset -family_name** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, **define_libcell_subset** groups logic library cells SDFLOP1 and SDFLOP2 into a family called special_flops. Next, **set_libcell_subset** sets the target family for instances u1 and u2 to the defined special cell family, special_flops, which consists of the cells SDFLOP1 and SDFLOP2.

```
prompt> define_libcell_subset -libcell_list "SDFLOP1 SDFLOP2" -family_name special_flops
prompt> set_libcell_subset -object_list [get_cells u1 u2] -family_name special_flops
```

```

define_name_maps

Defines object name mapping for an application and design.

SYNTAX

```
status define_name_maps
  -application application_name
  -design_name design_name
  -columns column_list
  entries
```

Data Types

<i>application_name</i>	string
<i>design_name</i>	string
<i>column_list</i>	list
<i>entries</i>	list_of_lists

ARGUMENTS

-application *application_name*

Specifies the targeting application name. Currently only *golden_upf* is supported. *application_name* and *design_name* jointly specify a unique in-memory name map instance for the current session.

-design_name *design_name*

Specifies the name of the design. The *application_name* and *design_name* values jointly specify a unique in-memory name map instance for the current session.

-columns *column_list*

Specifies the column names of the name map for the *application_name*.

entries

Specifies name mapping entries conforming to the definition of *column_list*.

DESCRIPTION

The **define_name_maps** command allows you or the tool to specify a list of object name mapping entries for a specified application. Usually a name map is associated with a particular design name. The *application_name* value is predefined by the tool.

The object name map can help in certain constraint applications where the default object query or even the rule-based query algorithms cannot succeed in finding the correct objects. The typical case is when trying to apply RTL constraints to the post-optimization netlist.

Note that it is the specific application that defines the content format and the usage model of its name map. To fully understand the functionality of a name map, see the related documentation for the specific application.

APPLICATION golden_upf

golden_upf is the application name assigned to the golden UPF flow. The command **define_name_maps** for *golden_upf* can appear in the golden UPF name mapping file, although other commands, such as **set_query_rules** can also exist in the golden UPF name mapping file. The *golden_upf* name map has four columns. They are *class*, *pattern*, *options*, and *names*.

Columns *class*, *pattern*, and *options* are used jointly to locate the entry in the map; the *names* column is the mapping result.

The following example illustrates the map contents and columns.

```
prompt> define_name_maps
      \ 
      -application golden_upf
      -design TOP
      -columns {class pattern options names} \
{cell mid/inst/U3 {} {mid_inst/U4 mid_inst/U5}} \
{cell mid/inst/bot+U5 {} {mid_inst/bot/U9}}
```

The preceding name map is for the application *golden_upf* and a design named TOP. Four columns are predefined for the application as follows:

- *class* specifies an object class name, such as cell or port. The supported class names are cell, port, pin, net, power_domain, power_switch, supply_net, supply_port, and supply_set.
- *pattern* specifies the object matching pattern string. This is one of the object name patterns from the user golden UPF file. The optional delimiter character '+' is used to indicate that a pattern is composed of a matching string (for example, "U5") and a scope (for example, scope "mid/inst/bot") for that matching string.
- *options* specifies a list of matching options for the map entry. It is derived from the user golden UPF file. The supported *options* is a list of the following elements: {nocase transitive leaf|noleaf in|out|inout}. The *nocase* option specifies that the string in the *pattern* column should be treated case-insensitively during name lookups. See the documentation for the **find_objects** command for descriptions of the other options. Note that *leaf* and *noleaf* are mutually exclusive, and *in*, *out*, and *inout* are mutually exclusive. In the preceding example, no option is used.
- *names* is a list of object names where every name element is a full-path name relative to the top scope of the specified design. Column *names* is the name mapping target.

The preceding name map would result in the following query behavior under the *golden_upf* application, although in a real golden UPF flow, the queries are executed through the **load_upf** command:

```
prompt> find_objects . -pattern mid/inst/U3 -object_type inst
{mid_inst/U4 mid_inst/U5}

prompt> find_objects mid/inst/bot -pattern U5 -object_type inst
{mid_inst/bot/U9}
```

<i>output_format</i>	string
<i>prefix_name</i>	string
<i>map_string</i>	string

```
object_type      string
dummy_nets_format  string
```

ARGUMENTS

name_rules

Specifies the name of the rules being defined. If named rules called *name_rules* do not exist, they are created.

-max_length *length*

Specifies the maximum length of a name, which must be 8 or more characters, except that a value of 0 resets the maximum length to its default (any length).

-target_bus_naming_style *bus_naming_style*

Specifies the target bus naming style for all object types, to which the current bus naming style is to be changed. For this option to succeed, set the **bus_naming_style** variable with the current bus naming style. For an example, see the section entitled "Changing the Bus Naming Style." By default, the target bus naming style is set to be the same as the current bus naming style. If the target bus naming style is different from the current bus naming style, after the rule is applied through the **change_names** command, the bus naming style becomes the target bus naming style, but this does not occur automatically. If more **change_names** commands need to be issued later, be careful that the bus naming style is in transition from one rule to another rule and needs to be set manually to reflect the real bus style inside the .db file during the transition.

-allowed *allowed_chars*

Specifies the set of characters allowed in names, which must be 10 or more characters. The format of the *allowed_chars* string is provided in the "DESCRIPTION" section. By default, any printable character is allowed in a name.

-restricted *restricted_chars*

Specifies the set of characters not allowed in names. The format of the *chars* string is provided in the "DESCRIPTION" section. By default, any printable character is allowed in a name.

-first_restricted *first_chars*

Specifies a set of characters that are not allowed as the first character in a name. The format of the *chars* string is provided in the "DESCRIPTION" section. By default, any printable character is allowed as the first character of a name.

-last_restricted *last_chars*

Specifies a set of characters not allowed as the last character in a name. The format of the *chars* string is described in the "DESCRIPTION" section. By default, any printable character is allowed as the last character of a name.

-reserved_words *reserves*

Specifies a list of words that cannot be used as a name. The *reserves* value contains words that are considered reserved in your target system. By default, there are no reserved words.

-replacement_char *char*

Specifies the character used to replace characters not allowed in names, as specified by the **-allowed** or **-restricted** option. By default, the replacement character is the underscore character (_).

-remove_chars

Specifies that characters not allowed in names, as specified by the **-allowed** or **-restricted** option, are removed rather than replaced. By default, illegal characters are replaced by the character specified with **-replacement_char**.

-equal_ports_nets

Specifies that nets connected to non-inout ports must have the same name as their connecting port. If a net is connected to more than one port, the net's name is not changed and a warning is issued. By default, nets are not required to match the names of the

non-inout ports to which they are connected.

-inout_ports_equal_nets

Specifies that nets connected to inout ports must have the same name as their connecting port. If a net is connected to more than one port, the net's name is not changed and a warning is issued. By default, nets are not required to match the names of the inout ports to which they are connected.

-collapse_name_space

Specifies that the name space of ports, cells, and nets is the same. No port, cell, or net in a design can have the same name. By default, ports, cells, and nets each have their own name space.

-case_insensitive

Specifies that the case of characters is not significant when comparing names. For example, the name *example* (lowercase) is equivalent to *EXAMPLE* (uppercase). If two names are equivalent within a name space, one of the names must be changed. By default, the case of a name is significant.

-special *output_format*

Specifies to use special rules pertaining to a specific target system when changing names. By default, no special rules apply. The possible values for *output_format* are as follows:

```
verilog  
vhdl  
sge  
vhdl93  
sge_vhdl  
siffl
```

-prefix *prefix_name*

Specifies a prefix used when changing a name. By default, the prefixes are **P** for ports, **U** for cells, and **N** for nets.

Use this option only when the **change_names** command needs to create a completely new name to ensure the name's uniqueness. See Step 3 of the "Naming Rules" section for more information.

-map *map_string*

Provides a way to change objects in addition to the previously specified name rules. This option specifies the name mapping and replacement rules as defined in the *map_string*. See "Mapping Rules" under the "Naming Rules" section for details.

-type *object_type*

Specifies that the rules being defined apply only to the given type of objects. Allowed values for *object_type* are **port**, **cell**, or **net**. By default, the defined rules apply to all object types.

-reset

Resets all rules to their default values. When all rules are set to the defaults, no restrictions are imposed on the names.

-remove_internal_net_bus

Bit-blasts all internal net buses.

-remove_port_bus

Bit-blasts all port buses. Net buses that connect to ports are also bit-blasted. This option overrides the **-preserve_struct_ports** option, setting its value to the default value.

-check_bus_indexing

Checks the indices of buses and bit-blasts the incomplete buses.

-check_bus_indexing_use_type_info

Checks bus indexing based on the bus type information and bit-blast for incomplete port buses.

-rename_three_state_port_net

Renames three-state port nets so they have different names from the ports on the inout port connections.

-check_internal_net_name

Checks and renames nets that have the same name as some ports, but the nets are not connected to these ports.

-remove_irregular_port_bus

Bit-blasts any port bus that contains irregular members.

-remove_irregular_net_bus

Bit-blasts any net bus that contains irregular members.

-flatten_multi_dimension_busses

Flattens multi-dimension ports, net buses, and arrays so writing out is easier.

-preserve_struct_ports

Specifies to avoid bit-blasted ports inferred from SystemVerilog structures or VHDL records.

-dont_change_bus_members

Specifies not to change the elements that are in either a port bus or a net bus. This option overrides the previous four options (**-remove_irregular_port_bus**, **-remove_irregular_net_bus**, **-flatten_multi_dimension_busses**, and **-preserve_struct_ports**). If this option is set, these four options are reset to the default value of **false**. In most cases, this option should remain **false**.

-dont_change_ports

Specifies not to change elements that are set by the **-type** option to **port**.

-add_dummy_nets

Adds dummy nets for unconnected pins. The **-dummy_net_prefix** option specifies the format to name dummy nets. The format defaults to **SYNOPSYS_UNCONNECTED_%d**.

-dummy_net_prefix dummy_nets_format

Sets the prefix for the dummy net naming convention. The **dummy_nets_format** value specifies the format to name the dummy nets.

-dir_inout_as_in

Instructs the tool to treat all instances with the INOUT direction as if they were set to IN. The default behavior is to treat them as direction OUT.

DESCRIPTION

The **define_name_rules** command defines a set of rules for naming design objects. Name rules are used by the **change_names** and **report_names** commands. The **report_name_rules** command displays a listing of the name rules currently defined in the shell.

Name rules can be defined in multiple calls to the **define_name_rules** command. For an example of multiple calls, see the "EXAMPLES" section.

The **-type** option enables you to define rules that apply to a specific object type, such as port, cell, or net). Each call to **define_name_rules** is additive or overrides previous calls for a specific name rules.

Naming Rules

This section describes the effects of specific options when defining name rules with **define_name_rules**.

Maximum Length Rules

The maximum number of characters in a name can be restricted with the **-max_length** option.

Names shorter than the specified maximum length remain unchanged. Names longer than the specified maximum length are modified so that their lengths are less than or equal to the maximum.

Fixed names are guaranteed to be unique within the design. The following steps are applied in succession to fix a name to meet the uniqueness criteria:

- Step 1
Truncation - Names are truncated to meet the maximum length. The truncated name is accepted if it is unique within the design. For example, if the name is THIS_NAME_IS_TOO_LONG_TO_BE_ACCEPTABLE and the maximum number of characters is 16, the resulting name is THIS_NAME_IS_TOO.
- Step 2
Truncation with index - Names are truncated. The truncated name is appended with an index in an attempt to make it unique. If a unique name is found, it is accepted. If the name from the previous example, THIS_NAME_IS_TOO, is not unique, this the tool tries THIS_NAME_IS_T1, THIS_NAME_IS_T2, and continues up to, THIS_NAME_IS_T99. The first unique name is accepted.
- Step 3
Basic names - If both previous steps fail, the original name is deleted and names of the form <prefix><index> are generated until a unique name is found. The <prefix> is defined using the **-prefix** option. Examples are N1, N2, and so on.

If all three steps fail to generate a unique name, the original name is retained and a warning message is issued.

Character Restriction Rules

Specify characters that make up names with the **-allowed**, **-restricted**, **-first_restricted**, and **-last_restricted** options.

To specify the character set allowed, use **-allowed** or **-restricted**. Either of these options overrides the previous values of **-allowed**, **-restricted**, **-first_restricted**, and **-last_restricted**.

In conjunction with **-allowed** or **-restricted**, use **-first_restricted** and **-last_restricted** to further restrict the available characters for the first and last character of a name. The **-first_restricted** and **-last_restricted** options depend on **-allowed** and **-restricted**, and modify the set of available characters for their special cases. The set of characters available for first and last characters cannot exceed that defined for all other characters.

The *allowed_chars*, *restricted_chars*, *first_chars*, and *last_chars* strings contain characters that can be used (they are **-allowed**), or cannot be used (they are **-restricted**) in design object names. The dash (-) character indicates a range of ASCII characters. To include a literal dash character in a *chars* parameter, precede it with 2 backslashes (\-\). Blank spaces are disregarded. A minimum of 10 characters must be allowed or an error is reported. The order of the characters in the *chars* string parameters is not significant.

The following example specifies a character set consisting of uppercase characters and an underscore.

```
prompt> define_name_rules -allowed "A-Z _"
```

In the following example, some punctuation characters are restricted. The dash (-) character is restricted with the character sequence \-. The double quotation marks ("") are restricted with the sequence \". First characters cannot be lowercase.

```
prompt> define_name_rules -restricted "!@#$%^&*()\\-\" \
    -first_restricted "a-z"
```

The following example attempts to restrict the character set to fewer than 10 characters. An error is reported.

```
prompt> define_name_rules -allowed "ABCDE"
```

If a design object name contains a character that is restricted for its object type, the following steps are taken to fix the name:

- Step 1
Remove the character - If **-remove_chars** is specified in the name rules, the offending character is removed.
- Step 2
Change the case - The case of characters is changed to meet character restrictions. The change is accepted if the new character is allowed. For example, if names are restricted to uppercase characters, the name sum_port is changed to

- SUM_PORT.
- Step 3
Replace the character - A restricted character is changed to the value of **-replacement_char**. For example, if punctuation characters are not allowed and the replacement character is an underscore, the name U\$1 is changed to U_1.
 - Step 4
Uniquify the name - If the name created in either Step 1 or Step 2 is not unique, an index is appended to the new name.

Reserved Word Rules

Prohibit specific names from becoming design object names by using the **-reserved_words**. The parameter to this option is a list of names that are not allowed as design object names.

The following example uses **-reserved_words**. The words DESIGN, MODULE, START, and END are designated as reserved. The case of the names in this list is significant.

```
prompt> define_name_rules \
    -reserved_words {"DESIGN", "MODULE", "START", "END"}
```

Case Insensitive Rules

If **-case_insensitive** is specified, the case of the characters in a name is not significant when comparing names.

If **-case_insensitive** is specified, the case of characters in reserved words is not significant. For example, if **-case_insensitive** is used and the string MODULE is specified as a reserved word, the name module is also considered a reserved word and changed.

Port and Net Rules

Make the name of a net connected to a port equal to the name of that port with **-equal_ports_nets**. If this substitution causes a conflict, no names are changed and a warning message is issued. If a net is connected to more than one port, no names are changed and a warning message is issued.

Name Space Rules

By default, name spaces of ports, cells, and nets are separate. Names of ports and cells must be unique within a design. A port, a cell, and a net within a design can share the same name.

Name spaces for ports, cells, and nets can be shared using the **-collapse_name_space** option. Ports, cells, and nets within a design must be unique across all objects. Conflicting names are modified by appending digits to their name.

If the **-collapse_name_space** option is specified with **-equal_ports_nets**, **-equal_ports_nets** has priority over **-collapse_name_space**. So you may still have a net that is named same as the connected port.

Type-Specific Rules

Name rules can be tailored for ports, cells, and nets object types with the **-type** option. The options to **define_name_rules** that can be specified by object type are as follows:

- max_length**
- allowed**
- restricted**
- first_restricted**
- last_restricted**
- replacement_char**
- remove_chars**
- prefix**

To specify the maximum length restriction on ports different than the maximum length for cells, make multiple calls to **define_name_rules**.

In the following example, the maximum length of ports is set to 12. The maximum length of cells is set to 8. The maximum length of nets is unrestricted.

```
prompt> define_name_rules EXAMPLE -max_length 12 -type port
prompt> define_name_rules EXAMPLE -max_length 8 -type cell
```

Special Rules

Define name rules that are for a specific target system and cannot be modeled with the general **define_name_rules** options. The systems supported by the **-special** option are **sge**, **verilog**, **vhdl**, **vhdl93**, **sge_vhdl**, and **siff**.

Specifying **-special verilog** adds one rule to make names conform to the rules of Verilog.

The difference between **-special verilog** and **-rules verilog** is as follows:

- For **-special verilog**, **verilog** means the output format for a specific target system. The following rules will be specified automatically along with [-special verilog]:

```
-collapse_name_space
-equal_ports_nets
-inout_ports_equal_nets
-remove_irregular_port_bus
-remove_irregular_net_bus
```

- For **-rules verilog**, **verilog** means the name of the rule. The verilog rule is a predefined name rule in **change_names** and the recommended rule. The following rules are already defined in verilog rule:

```
-special verilog
-target_bus_naming_style {%-s[%d]}
-flatten_multi_dimension_busses
-check_internal_net_name
-check_bus_indexing
...
```

You can add other rules to the verilog rule set.

- Specifying **-special vhdl** adds one rule to make names conform to the rules of VHDL. This option does not allow consecutive underscores in a name.
- Specifying **-special vhdl93** adds one rule to make names conform to the rule of VHDL93. This option adds support for an extended identifier. An extended identifier is a sequence of characters that are defined by the VHDL93 character set and are written between two backslashes (\ \).
- Specifying **-special sge** adds one rule to make names conform to the rules of the SGE system. This option does not allow net names that start with the characters BBBB_ and NNNN_. These names are reserved by the SGE system.
- Specifying **-special sge_vhdl** is a combination of the previous two rules. The **change_names** command enforces **-collapse_name_space** and **-equal_ports_nets**, but because these two rules conflict with each other, the **sge_vhdl** rule applies under the following conditions:
 - The **-collapse_name_space** rule first checks the object class type. If the object is a port, it checks to see if the name is used by any port names. Since the ports are processed first, there are no collisions with the other name spaces. If the object is a cell or a design, it verifies that the name is not used previously by any port. If the object is a net, it checks the port, and cell name spaces. If there is a name conflict, it changes the name so that it is unique. See the **-collapse_name_space** rule description for details.
 - The **-equal_ports_nets** rule is applied to a scalar net or a net object whose owning bus is not of a single width. See the **-equal_ports_nets** rule description for details.
- Specifying **-special siff** adds one rule to make names conform to the rules for the "Synopsys Integrator For Falcon Framework."

All of the special rules previously given share the same name rules in addition to their own name rules:

- The names of bused ports or nets follow the **bus_naming_style**, except that **sge_vhdl** always uses "%s(%d)" instead of **bus_naming_style**.
- The names of bused ports or nets owned by the same bus have the same base name. The bus index order follows the index part defined in the owning bus.
- If a net does not belong to a busbag and it contains a separator character defined in the **bus_naming_style** variable,

this separator character changes to _ (underscore) and the ending separator is removed. For example, the net name *sample[24][3]* changes to the name *sample_24_3*.

Specifying **-special** does not create all of the rules necessary for VHDL, SGE, or SIFF compliance. Only the non-general rules previously described are created. To make **define_name_rules** to constrain names to fully meet the requirements of SGE and VHDL, use the other options in conjunction with **-special**.

To avoid conflict, do not merge special name rules with name rules that you defined. When defined name rules conflict, **change_names** could generate names that are not compliant to your name rule. When there is a conflict among name rules, define each one of those name rules using a different name in **define_name_rules** and apply each of them using **change_names**. The last rule applied generates names that override names generated by previous rules.

Mapping Rules

The **-map** option specifies the name mapping and replacement rules as defined in the *map_string*. The mapping string has the following format:

```
{"pattern", "replacement"} [, {"pattern", "replacement"}]* }
```

The mapping string is grouped into pairs. There can be any number of pairs in a mapping string. Each pair is enclosed by {} (curly braces) and separated by a , (comma). The **change_names** and **report_names** commands apply all of them according to the order specified in the *map_string*.

The first member of each pair is the *pattern* string, which is used to match against the object name. The second member is the *replacement* string, which is used to replace the matched portion of the object name. Both the *pattern* and *replacement* string must begin and end with " (double quotation marks). There is a , (comma) between *pattern* and *replacement* string.

The following example has the first occurrence of any portion of an object name that contains **_reg** replaced by an empty string and the first occurrence of any portion of a object name that contains **A** replaced by **a** in the new name.

```
prompt> define_name_rules my_rule -map {"_reg", ""}, {"A", "a"}}
```

The pattern string also provides limited regular expression capability. The following 4 special characters are supported to make the mapping strings more specific:

- The \$ (dollar sign) indicates the end of string.
- The ^ (caret) indicates the beginning of string.
- The * (asterisk) indicates a wildcard matching 0 or more characters.
- The ? (question mark) indicates a wildcard matching 1 character.

The following example defines a rule that any name ending with **_reg** is replaced by **in** at the end of the string:

```
prompt> define_name_rules my_rule0 -map {"_reg$", "in"}}
```

The following example defines a rule that any name beginning with **_reg** is replaced by **in** at the beginning of the string:

```
prompt> define_name_rules my_rule1 -map {"^_reg", "in"}}
```

The following example defines a rule that the first occurrence of any substring of a name that begins with **_r** and ends with **g** is replaced by the **in** string:

```
prompt> define_name_rules my_rule2 -map {"_r*g", "in"}}
```

The following example defines a rule that the first occurrence of any substring of a name that begins with **_r** followed any one character, then ending with **g** is replaced by **in**:

```
prompt> define_name_rules my_rule3 -map {"_r?g", "in"}}
```

Once a mapping rule is defined, you can only use **-reset** to reset the mapping rule. You cannot redefine the same matching pattern within the same rule. For example, assume you define the following rule:

```
prompt> define_name_rules my_rule4 -map {"A", "X"}}
```

If you then decide to replace all occurrences of **A** with **Z**, you must first execute a reset and then redefine the name rules as follows:

```
prompt> define_name_rules my_rule4 -reset
prompt> define_name_rules my_rule4 -map {"A", "Z"}
```

To insert escape characters into names, you can also use the **-map** option. This is useful prior to generating reports, if the report output is processed by a program that requires certain characters to be escaped. For example, if names contain the / (slash) character, the tool cannot differentiate between a / used in a name and a / that denotes a change in hierarchy. Defining a rule with the following command replaces any / in a name with \ (backslash slash).

```
prompt> define_name_rules -map {"/", "\\"}
```

The name **HAS/SLASH** inside hierarchy **A** writes out as **A/HAS\SLASH**.

Default Rules Values

Once defined, you can reset name rules to their default values with the **-reset** option. Name rules with all default values impose no restrictions on design object names.

Default values for specific rules are shown below. A set of name rules called ALL_DEFAULTS is defined with no options. The **report_name_rules** command displays the default value of each specific rule.

```
prompt> define_name_rules ALL_DEFAULTS
prompt> report_name_rules ALL_DEFAULTS
*****
Report : name_rules
Name Rules : ALL_DEFAULTS
Version: v3.0
Date : Fri Sep 27 09:36:52 1991
*****
Rules Name: ALL_DEFAULTS
  Equal port and net names: false
  Collapse name space: false
  Case insensitive: false
  Special rules: none
  Reserved words: none

  Max Repl Rem
  Rules Type Len Char Chrs Prefix Allowed Chars
  -----
  Port Rules none '_' no P    No restrictions
  Cell Rules none '_' no U    No restrictions
  Net Rules  none '_' no N    No restrictions
```

Many rules can be reset individually by specifying empty values for the option. The following table shows how to specify the default value for these fields. Options not listed in the table must be reset with the **-reset** option.

Option	Default Value
-max_length	0
-restricted	""
-allowed	""
-first_restricted	""
-last_restricted	""
-reserved_words	{}
-replacement_char	""
-prefix	""

Applying Name Rules

When names are changed using the **change_names** or **report_names** command, name rules are applied sequentially even though they are specified concurrently in the **define_name_rules** command. Name rules are applied in order, so rules applied later might overwrite previous names rules and there will be cases where names after **change_names** or **report_names** do not conform to all

rules specified.

This section describes the order in which name rules are applied, and the results you can expect.

The name rules are applied in the following order:

1. Map rule: rules that are applied to an object name string. The rule in this category is **-map_rule**.
2. Character rules: rules that are applied to object name characters. Rules in this category are **-allowed**, **-restricted**, **-first_restricted**, and **-last_restricted**. To support the character rules, use **-remove_char** and **-replacement_chars**.
3. Design rules: rules that are applied to object names in terms of whole design naming methodology. Rules in this category are **-equal_ports_nets** (for net objects only), **-special**, **-max_length**, and **-reserve_words**.
4. Meta rules: rules that extend beyond one of the previous single categories. Rules in this category are **-collapse_name_space**, **-case_insensitive**, **-prefix**, and **-type**.

Since rules applied earlier might be overwritten by later rules, apply the "must have" rule last. The name rules are applied to object names according to the order shown above. That is, the string rules are applied first, then the character rules, and the design rules are last. Meta rules are used for supporting those rules during name changes. Rules within the same category are applied following the same order as the prior list. Because later rules might override previous ones, to preserve the priority it is better to use those rules that cause conflict separately. Among these rules, use mapping primarily.

During name changes, the objects are categorized into three types: port, cell, and net. Port objects are changed first, then cell objects, then net objects. When there is a name conflict among a port name, a cell name, and a net name, the port name has highest priority (it is not changed). The net and port names must be changed to unique names.

Changing the Bus Naming Style

When **define_name_rules** changes the bus naming style, use the **bus_naming_style** variable to identify the bus naming style used by the current database.

For example, the following script changes the bus naming style from [] to < >:

```
prompt> define_name_rules change_bus_naming_style \
    -target_bus_naming_style "%s<%d>" \
    bus_naming_style="%s[%d]"

prompt> change_names -rule change_bus_naming_style -hierarchy
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines a name rule called *SIMPLE* that requires design names in uppercase. The *SIMPLE* name rule is used as the default name rule by **change_names**.

```
prompt> define_name_rules SIMPLE -allowed "A-Z _"

prompt> default_name_rules = SIMPLE

prompt> change_names
Information: Using name rules 'SIMPLE'.
Information: 153 names changed in design 'MY_DESIGN'.
```

The following example defines name rules called *MY_RULES* using multiple calls to **define_name_rules**. The length of names is restricted to 16 characters. The example defines the allowed character set and a replacement character:

```
prompt> define_name_rules MY_RULES -max_length 16
```

```
prompt> define_name_rules MY_RULES -replacement_char "X"
```

```
prompt> define_name_rules MY_RULES -allowed "A-Z _"
```

In the following example, multiple calls to **define_name_rules** use most of the options. The **report_name_rules** command displays the effect of these calls.

```
prompt> define_name_rules SMORG -collapse_name_space
```

```
prompt> define_name_rules SMORG -case_insensitive
```

```
prompt> define_name_rules SMORG -reserved_words {IN,OUT,INOUT}
```

```
prompt> define_name_rules SMORG -case_insensitive
```

```
prompt> define_name_rules SMORG -type port -max_length 16 \
    -allowed "A-Z a-z 0-9_**" \
    -replacement_char "**"
```

```
prompt> define_name_rules SMORG -type cell -prefix "CELL" \
    -restrict "()[]{}"
```

```
prompt> define_name_rules SMORG -type net -allowed "A-Za-z_**" \
    -first_restrict "0-9" -last_restrict "0-9" \
    -replacement_char "**"
```

```
prompt> report_name_rules SMORG
```

```
*****

define_power_model

Defines a power model which describes the power intent of a reference library cell.

SYNTAX

```
status define_power_model
    power_model_name
    [-for library_cells]
    {UPF_commands}
```

Data Types

```
power_model_name   string
library_cells      list
UPF_commands       command list
```

ARGUMENTS

power_model_name

Specifies the name of the power model to be defined. The name should be a simple (non-hierarchical) name.

The name is scope-based, i.e., the power model cannot be defined if there is another power model with the same name in the scope where the define_power_model command is executed.

-for *library_cells*

Specifies a collection of library cells that this power model can be applied to.

If this option is not specified, the power model can then be applied to any library cell.

DESCRIPTION

The define_power_model command defines a power model containing other UPF commands contained within curly braces. A power model is used to define the power intent of a model and shall be used in conjunction with one or more model representations. The opening and closing curly braces encapsulating the UPF commands that describe the power model must be present in the same UPF file.

A power model can be referenced by its simple name from anywhere in a power intent description. It shall be an error to have two power models with the same name and at the same scope.

A power model can be applied to specific instances using apply_power_model.

A power model that is not referenced by an apply_power_model command does not have any impact on the power intent of the design.

The define_power_model command provides a protected environment to the power model. Any Tcl variable used in the power model is not affected by the global variables defined outside the define_power_model command. Also, any Tcl variable defined inside the power model will not affect the environment outside the power model.

A power model can be parameterized by creating parameters using the add_parameter command. These parameters are represented as special Tcl variables which can be referenced within the power model. The parameters can be overridden with -parameters option of the apply_power_model command.

A power model cannot have a nested definition of power models, i.e. a nested define_power_model command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a power model for two library cells. Notice that there is a parameter for the top power domain name in the power model.

```
prompt> define_power_model MODEL -for {lib_cell_A lib_cell_B} {
    add_parameter DOMAIN -default domain -description "top power domain in model"
    create_supply_net VDD
    create_supply_net VSS
    create_supply_set SS -function {power VDD} -function {ground VSS}
    create_power_domain PD_$DOMAIN -supply {primary SS} -include_scope
}
```

define_preserve_user_attribute

Use the **define_preserve_user_attribute** command to specify which user-defined attributes to preserve on sequential cells in synthesis flows.

SYNTAX

```
status define_preserve_user_attribute  
  [attribute_preservation_list]  
  | [-reset]
```

Data Types

attribute_preservation_list list

ARGUMENTS

attribute_preservation_list

Specifies the list of user-defined attributes to preserve during the synthesis flow.

DESCRIPTION

This command is used to specify which user-defined attributes to preserve on sequential cells in synthesis flows. The command **define_preserve_user_attribute** is not additive. The command needs to be repeated to replace a previous attribute preservation list.

The attribute preservation list applies for the present session only. The list is not saved as part of the design data. There is no restriction on the type of attribute to preserve.

EXAMPLES

The following is an example of the **define_preserve_user_attribute** command.

```
prompt> define_preserve_user_attribute {my_attribute_1 my_attribute_2}  
1  
  
prompt> report_preserve_user_attribute  
my_attribute_1 my_attribute_2  
  
prompt> define_preserve_user_attribute -reset  
1
```

```
prompt> report_preserve_user_attribute  
prompt>
```

SEE ALSO

[report_preserve_user_attribute\(2\)](#)

define_proc_attributes

Defines attributes of a Tcl procedure, including an information string for help, a command group, a set of argument descriptions for help, and so on. The command returns the empty string.

SYNTAX

```
string define_proc_attributes  
  proc_name  
  [-info info_text]  
  [-define_args arg_defs]  
  [-define_arg_groups group_defs]  
  [-command_group group_name]  
  [-return type_name]  
  [-hide_body]  
  [-hidden]  
  [-dont_abbrev]  
  [-permanent]  
  [-deprecated]  
  [-obsolete]
```

Data Types

```
proc_name    string  
info_text    string  
arg_defs     list  
group_defs   list  
group_name   string  
type_name    string
```

ARGUMENTS

proc_name

Specifies the name of the existing procedure.

-info *info_text*

Provides a help string for the procedure. This is printed by the **help** command when you request help for the procedure. If you do not specify *info_text*, the default is "Procedure".

-define_args *arg_defs*

Defines each possible procedure argument for use with **help -verbose**. This is a list of lists where each list element defines one argument.

-define_arg_groups *group_defs*

Defines argument checking groups. These groups are checked for you in `parse_proc_arguments`. Each list element defines one group

-command_group group_name

Defines the command group for the procedure. By default, procedures are placed in the "Procedures" command group.

-return type_name

Specifies the type of value returned by this proc. Any value may be specified. Some applications use this information for automatically generated dialogs etc. Please see the type_name option attribute described below.

-hide_body

Hides the body of the procedure from **info body**.

-hidden

Hides the procedure from **help** and **info proc**.

-dont_abbrev

Specifies that the procedure can never be abbreviated. By default, procedures can be abbreviated, subject to the value of the **sh_command_abbrev_mode** variable.

-permanent

Defines the procedure as permanent. You cannot modify permanent procedures in any way, so use this option carefully.

-deprecated

Defines the procedure as deprecated i.e. it should no longer be called but is still available.

-obsolete

Defines the procedure as obsolete i.e. it used to exist but can no longer be called.

DESCRIPTION

The **define_proc_attributes** command associates attributes with a Tcl procedure. These attributes are used to define help for the procedure, locate it in a particular command group, and protect it.

When a procedure is created with the **proc** command, it is placed in the Procedures command group. There is no help text for its arguments. You can view the body of the procedure with **info body**, and you can modify the procedure and its attributes. The **define_proc_attributes** command allows you to change these aspects of a procedure.

Note that the arguments to Tcl procedures are all named, positional arguments. They can be programmed with default values, and there can be optional arguments by using the special argument name **args**. The **define_proc_attributes** command does not relate the information that you enter for argument definitions with **-define_args** to the actual argument names. If you are describing anything other than positional arguments, it is expected that you are also using **parse_proc_arguments** to validate and extract your arguments.

The **info_text** is displayed when you use the **help** command on the procedure.

Use **-define_args** to define help text and constraints for individual arguments. This makes the help text for the procedure look like the help for an application command. The value for **-define_args** is a list of lists. Each element has the following format:

arg_name option_help value_help data_type attributes

The elements specify the following information:

- *arg_name* is the name of the argument.
- *option_help* is a short description of the argument.
- *value_help* is the argument name for positional arguments, or a one word description for dash options. It has no meaning for a Boolean option.

- *data_type* is optional and is used for option validation. The *data_type* can be any of: string, list, boolean, int, float, or one_of_string. The default is string.
- *attributes* is optional and is used for option validation. The *attributes* is a list that can have any of the following entries:
 - "required" - This argument must be specified. This attribute is mutually exclusive with optional.
 - "optional" - Specifying this argument is optional. This attribute is mutually exclusive with "required."
 - "value_help" - Indicates that the valid values for a one_of_string argument should be listed whenever argument help is shown.
 - "values {<list of allowable values>}" - If the argument type is one_of_string, you must specify the "values" attribute.
 - "type_name <name>" - Give a descriptive name to the type that this argument supports. Some applications may use this information to provide features for automatically generated dialogs, etc. Please see product documentation for details. This attribute is not supported on boolean options.
 - "merge_duplicates" - When this option appears more than once in a command, its values are concatenated into a list of values. The default behavior is that the right-most value for the option specified is used.
 - "remainder" - Specifies that any additional positional arguments should be returned in this option. This option is only valid for string option types, and by default the option is optional. You can require at least one item to be specified by also including the required option.
 - "deprecated" - Specifying this option is deprecated i.e. it should no longer be used but is still available. A warning will be output if this option is specified. This attribute cannot be combined with obsolete or required.
 - "obsolete" - Specifying this option is obsolete i.e. it used to exist but can no longer be used. A warning will be output if this option is specified. This attribute cannot be combined with deprecated or required.
 - "min_value" <value> - Specify the minimum value for this option. This attribute is only valid for integer and float types.
 - "max_value" <value> - Specify the maximum value for this option. This attribute is only valid for integer and float types.
 - "default" <value> - Specify the default value for this option. This attribute is only valid for string, integer and float option types. If the user does not specify this option when invoking the command this default value will be automatically passed to the associated tcl procedure.

The default for *attributes* is "required."

Use the **-define_arg_groups** to define argument checking groups. The format of this option is a list where each element in the list defines an option group. Each element has the following format:

```
{<type> {<opt1> <opt2> ...} [<attributes>]}
```

The types of groups are

- "exclusive" Only one option in an exclusive group is allowed. All the options in the group must have the same required/optional status. This group can contain any number of options.
- "together" If the first option in the group is specified then the second argument is also required. This type of group can contain at most two options.
- \fi"related" These options are related to each other. An automatic dialog builder for this command may try to group these options together.

The supported attributes are:

- {"label" <text>} An optional label text to identify this group. The label may be used by an application to automatically build a grouping in a generated dialog.
- "bidirectional" This is only valid for a together group. It means that both options must be specified together.

Change the command group of the procedure using the **-command_group** command. Protect the contents of the procedure from being viewed by using **-hide_body**. Prevent further modifications to the procedure by using **-permanent**. Prevent abbreviation of the procedure by using **-dont_abbrev**.

EXAMPLES

The following procedure adds two numbers together and returns the sum. For demonstration purposes, unused arguments are defined.

```

prompt> proc plus {a b} { return [expr $a + $b]}

prompt> define_proc_attributes plus -info "Add two numbers" \
? -define_args {
  {a "first addend" a string required}
  {b "second addend" b string required}
  {"-verbose" "issue a message" "" boolean optional}}

prompt> help -verbose plus
Usage: plus  # Add two numbers
      [-verbose] (issue a message)
      a          (first addend)
      b          (second addend)

prompt> plus 5 6
11

```

In the following example, the argHandler procedure accepts an optional argument of each type supported by `define_proc_attributes`, then displays the options and values received. Note the only one of -Int, -Float, or -Bool may be specified to the command:

```

proc argHandler {args} {
  parse_proc_arguments -args $args results
  foreach argname [array names results] {
    echo $argname = $results($argname)
  }
}

define_proc_attributes argHandler \
-info "Arguments processor" \
#define_args {
  {-Oos "oos help" AnOos one_of_string
   {required value_help {values {a b}}}}
  {-Int "int help" AnInt int optional}
  {-Float "float help" AFloat float optional}
  {-Bool "bool help" "" boolean optional}
  {-String "string help" AString string optional}
  {-List "list help" AList list optional}
  {-IDup "int dup help" AIDup int {optional merge_duplicates}}
} \
#define_arg_groups {
  {exclusive {-Int -Float -Bool}}
}

```

number_of_layers integer

ARGUMENTS

rule_name

Specifies the name for the new nondefault routing rule.

This is a required argument.

-reference_rule_name *ref_rule_name*

Specifies the name of the reference (source) rule to use.

The **-reference_rule_name** and **-default_reference_rule** options are mutually exclusive; you can specify only one. If you do not specify either option, the command uses the default routing rule as the reference rule.

-default_reference_rule

Specifies that the default routing rule is used as the reference rule.

The **-reference_rule_name** and **-default_reference_rule** options are mutually exclusive; you can specify only one. If you do not specify either option, the command uses the default routing rule as the reference rule.

-widths {*layer_name_and_width_pairs*}

Specifies the routing width for each named routing layer. Each entry in the list contains a routing layer name and its width in microns, separated by a space. The width portion of the pair is a floating point number. You can specify only a single width per layer.

If you do not specify the width for a layer, the tool sets the width based on the reference rule.

-spacings {*layer_name_and_spacing_pairs*}

Specifies the minimum different-net spacing allowed between wires for each named routing layer.

For Zroute, each entry in the list contains a routing layer name and a list of one or more spacing values in microns. The spacing values are floating point numbers. If you specify more than one spacing value, you must also use the **-spacing_weights** or **-spacing_weight_levels** option. The spacing values in the **-spacings** option and the weights in the **-spacing_weights** or **-spacing_weight_levels** option must have a one-to-one correspondence.

For the classic router, each entry in the list contains a routing layer name and its spacing in microns. You can specify only a single spacing per layer. The spacing value is a floating point number.

If you do not specify the minimum spacing for a layer, the tool sets the minimum spacing based on the reference rule.

-spacing_weights {*layer_name_and_weight_pairs*}

Sets the weight for the corresponding spacing that is specified in the **-spacings** option.

Each entry in the list contains a routing layer name and its weight list, separated by a space. Each weight value must be a floating point number between 0.0 and 1.0. A value of 1 indicates that the spacing is a hard rule. Smaller values indicate that the corresponding spacing is softer. 0.0 is not a valid value.

The weight values in the **-spacing_weights** argument and the spacing values in the **-spacings** argument must have a one-to-one correspondence.

The **-spacing_weights** and **-spacing_weight_levels** options are mutually exclusive; you can specify only one of these options for a given rule.

This option is supported only by Zroute.

This option is not supported in Design Compiler topographical mode.

-spacing_weight_levels {*layer_name_and_weight_level_pairs*}

Sets the weight level for the corresponding spacing that is specified in the **-spacings** option. This option is an alternative to the **-spacing_weights** option.

Each entry in the list contains a routing layer name and its weight level list, separated by a space. Each weight level value must be one of low, medium, high, or hard.

- **low**
Treat the spacing rule as a soft rule with low weight.
- **medium**
Treat the spacing rule as a soft rule with medium weight.
- **high**
Treat the spacing rule as a soft rule with high weight.
- **hard**
Treat the spacing rule as a hard rule.

The weight level values in the **-spacing_weight_levels** option and the spacing values in the **-spacings** option must have a one-to-one correspondence.

The **-spacing_weights** and **-spacing_weight_levels** options are mutually exclusive; you can specify only one of these options for a given rule.

This option is supported only by Zroute.

This option is not supported in Design Compiler topographical mode.

-spacing_length_thresholds {*layer_name_and_length_threshold_pairs*}

Sets the length threshold for the corresponding spacing that is specified in the **-spacings** option. Each entry in the list contains a routing layer name and its length threshold list in microns, separated by a space.

Each length threshold value is a floating point number between 0 and 16.3, inclusive. If you specify a length threshold value outside of this range, the command fails.

The length threshold values in the **-spacing_length_thresholds** argument and the spacing values in the **-spacings** argument must have a one-to-one correspondence.

If you do not specify the length threshold values for a layer, the default threshold value is 0.

Zroute reports and tries to fix only those DRC violations where the parallel length of the metal involved in the violation overlaps by at least the specified threshold. Zroute calculates the parallel length using a shape-based formulation. The purpose of this option is to increase the flexibility of DRC convergence but not hurt crosstalk in a significant way.

This option is supported only by Zroute.

This option is not supported in Design Compiler topographical mode.

-shield

Defines shielding with default spacing and default width for the new nondefault routing rule.

This option is not supported in Design Compiler topographical mode.

-shield_widths {*layer_name_and_shield_width_pairs*}

Specifies the shielding width for each named routing layer. Each entry in the list contains a routing layer name and its shielding width in microns, separated by a space. The shielding width portion of the pair is a floating point number. You can specify only a single width per layer.

If you do not specify the shielding width for a layer, the tool sets the shielding width based on the reference rule.

This option is not supported in Design Compiler topographical mode.

-shield_spacings {*layer_name_and_shield_spacing_pairs*}

Specifies the minimum shield spacing allowed between wires for each named routing layer. Each entry in the list contains a routing layer name and its shield spacing in microns, separated by a space. The shield spacing portion of the pair is a floating point number. You can specify only a single spacing per layer.

If you do not specify the shield spacing for a layer, the tool sets the shield spacing based on the reference rule.

This option is not supported in Design Compiler topographical mode.

-snap_to_track

Snaps the shielding wires to the track.

This option is not supported in Design Compiler topographical mode.

-via_cuts {*via_definition_list*}

Creates vias automatically during routing using the via definitions.

For Zroute, each entry in the *via_definition_list* argument consists of the routable via name, its horizontal and vertical site count numbers, and its rotation setting, separated by spaces. The site count portion of the triplet is in the format mXn or mxn, where *m* is the horizontal site count and *n* is the vertical site count, separated by the X or x character. For a normal via array, all via sites are occupied by cuts, so the total number of cuts is equal to total number of via sites. For a via array with a special pattern, such as a staggered pattern, some via sites are empty, so the total number of cuts is smaller than the total number of via sites. Zroute figures out how many cuts are needed from the specified via array size mXn and the required via array pattern. The rotation portion of the triplet is specified by R or NR, where R indicates a rotated via and NR indicates an unrotated via. The default rotation value is NR. Only those modes and rotations that are explicitly specified are allowed by the nondefault routing rule. For example, to allow all via array modes (swapped and unswapped) and rotations (rotated and unrotated) for a 1x2 via array named VIAHH, you must enter the following definition:

```
-via_cuts {{VIAHH 1x2 NR} {VIAHH 1x2 R} {VIAHH 2x1 NR} {VIAHH 2x1 R}}
```

For the classic router, each entry in the *via_definition_list* argument consists of the routable via name and its horizontal and vertical cut count numbers, separated by a space. The cut number is in the format mXn or mxn, where *m* is the horizontal cut number and *n* is the vertical cut number. The classic router supports only a single via definition for each layer; if you specify multiple vias for a given layer, the first definition is used and additional definitions are ignored. If you specify rotation information, it is ignored by the classic router.

You must ensure that the specified vias exist in the reference routing rule; otherwise, the command fails.

The **-via_cuts** and **-cuts** options are mutually exclusive; you can specify only one.

This option is not supported in Design Compiler topographical mode.

-cuts {*cut_definition_list*}

Creates vias automatically during routing using the general cut definitions.

Each entry in the *cut_definition_list* argument consists of the cut layer name and the cut pair lists, separated by spaces. Each cut pair consists of the cut name and the number of cuts, separated by spaces. The cut name is defined in the Layer section of the technology file along with the width and height information for the cut. The **define_routing_rule** command searches for proper {via, rowXcolumn, rotation} solutions (the description for the **-via_cuts** option for more information) without violating any nondefault rules or technology file rules.

The solutions must satisfy the following conditions:

1. The cut sizes of the vias match the width and height of the specified cut name.
2. The solutions are a subset of the contact codes defined in the fatTblFatContactNumber attribute in the Layer section of the technology file required by the metal width and number of cuts.
3. The cut number is the larger of the number defined in the nondefault routing rule and the number defined in the fatTblFatContactMinCuts attribute in the Layer section of the technology file.

For example, assume the following information is defined in the technology file:

```
Layer "VIA1" {
```

```

fatTblThreshold      = ( 0, 0.181, 0.411 )
fatTblFatContactNumber = ( "2,3,4,5,6 ","5,6,20", "5,6,20" )
fatTblFatContactMinCuts = ( "1,1,1,1,1", "1,1,1", "2,2,2" )

cutNameTbl          = ( Vsq, Vrect )
cutWidthTbl         = ( 0.05, 0.05 )
cutHeightTbl        = ( 0.05, 0.13 )
...
}

```

To specify all cuts that match the size requirement of Vrect, meet the fat table rules according to the upper and lower metal widths, and the cut number is at least 1, enter the following definition:

```
define_routing_rule ruleA -widths { M1 0.2 M2 0.25 } -cuts {VIA1 {Vrect 1}}
```

The **define_routing_rule** command automatically populates all cuts that meet the requirements.

The **-via_cuts** and **-cuts** options are mutually exclusive; you can specify only one.

This option is supported only by Zroute.

This option is not supported in Design Compiler topographical mode.

-taper_level tapering_level

Defines the tapering level.

Valid values for the tapering level are

- 0 (the default)
Enables pin-based tapering.
- 1
Disables tapering on all pins.
- Positive integer greater than 1 (classic router only)
For the classic router, specifying a positive integer greater than one enables fanout-based tapering with up to the specified number of widths. In this case, the router uses the default width at the input pin and the maximum width, as defined in the routing rule, is used at the output pin and at the top-level pin.

Zroute does not support this value. To specify the tapering wire width for Zroute, use the **set_route_zrt_detail_options** command to set the **-pin_taper_mode** Zroute detail route option. To specify the tapering distance for Zroute, use the **-taper_distance** option.

This option is not supported in Design Compiler topographical mode.

-taper_distance tapering_distance

Sets the maximum length in microns for tapering wires.

To disable tapering, set this option to 0.

If you do not specify this option, the default tapering distance is 10 times the mean number of tracks for all routing layers and the default tapering wire width is the default width for the respective layer.

For Zroute, you can change the tapering wire width to the pin width instead, by using the **set_route_zrt_detail_options** command to set the **pin_taper_mode** Zroute detail route option to **pin_width**.

For the classic router, you can change the tapering wire width by using the **-pin_taper** option.

The tapering wire width is the default width for the respective layer, unless you set the **pin_taper_mode** Zroute detail route option.

This option is not supported in Design Compiler topographical mode.

-driver_taper_distance driver_tapering_distance

Sets the maximum length in microns for tapering wires from driver pins.

This option is not supported in Design Compiler topographical mode.

-multiplier_width *layer_width*

Defines the layer width multiplier. You do not have to know the units or exact metal width currently defined in the library.

For example, to define double width, specify **-multiplier_width 2.0**.

-multiplier_spacing *layer_spacing*

Defines the layer spacing multiplier. You do not have to know the units and exact layer spacing currently defined in the library.

For example, to define double spacing, specify **-multiplier_spacing 2.0**.

-double_pattern_mask_constraints *layer_and_constraint_pairs*

Defines the double-patterning mask constraint for each double-patterning routing layer.

Each pair in the list contains a routing layer name and its double-patterning mask constraint. The routing layer name must be one of the double-patterning layers specified in the technology file. The valid double-patterning mask constraints are **mask1_hard**, **mask1_soft**, **mask2_hard**, **mask2_soft**, **same_mask**, and **any_mask**.

The usage of the mask constraint values is as follows:

- Use both **mask1_xxx** and **mask2_xxx** if routes must be mapped to two different masks. Otherwise, choose either **mask1_xxx** or **mask2_xxx**.
- The **mask1_hard** and **mask1_soft** values are treated exactly the same by router. The names hard and soft give you the flexibility to denote different hardnesses of mask constraints, if needed. Likewise for the **mask2_hard** and **mask2_soft** values.
- The **any_mask** value means no double-patterning mask constraint is set.
- The **same_mask** value means that mask mapping is required, but the mask number is yet to be determined.

When you set a double-patterning constraint (except for **any_mask**) on a net, it must meet the double-patterning minimum spacing rule; otherwise, the tool reports a "Double pattern hard/soft mask spacing" violation.

This option is not supported in Design Compiler topographical mode.

-via_spacings *via_layer_name_pairs_and_spacing*

Specifies the via spacing between two via layers using the following format:

```
{ {layer1 layer2 spacing} ... }
```

The two via layers can be the same layer or different layers.

The minimum spacing between vias on any layer combinations not specified in this option is determined from the Milkyway technology file. For vias on the same layer, the router uses the minimum spacing defined in the Layer section for the via layer. For vias on different layers, the router uses the minimum spacing defined in the DesignRule section for the via layer combination.

This option is supported only by Zroute.

This option is not supported in Design Compiler topographical mode.

-rdl_taper_distance *rdl_tapering_distance*

Specifies the maximum length in microns for tapering wires in the redistribution layer.

The default is 0 and the wires are not tapered.

This option is supported only by the flip-chip router.

This option is not supported in Design Compiler topographical mode.

-rdl_taper_widths {*layer_name_and_rdl_tapering_width_pairs*}

Specifies the tapering width for each redistribution layer using the following format:

```
{ {layer width} ... }
```

If you do not specify this option, the flip-chip router uses the size of the via or pin as the wire width.

This option is supported only by the flip-chip router.

This option is not supported in Design Compiler topographical mode.

-taper_over_pin_layers number_of_layers

Enables layer-based pin tapering and specifies the number of metal layers over the pin layer that the router can use for tapering.

For example, if pin is on M1 and you specify **-taper_over_pin_layers 2**, the tool uses the M1 and M2 layers for tapering, but not the M3 layer.

The default is 0. If both the **-taper_over_pin_layers** and **-taper_under_pin_layers** options are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

Layer-based pin tapering takes precedence over distance-based pin tapering. If you specify the **-taper_distance** option with this option, the tool ignores the taper distance and issues a ZRT-548 warning message.

This option is not supported in Design Compiler topographical mode.

-taper_under_pin_layers number_of_layers

Enables layer-based pin tapering and specifies the number of metal layers under pin layer that the router can use for tapering.

The default is 0. If both the **-taper_over_pin_layers** and **-taper_under_pin_layers** layers are set to zero, pin tapering is disabled on the pin layer. If either option is set to a nonzero value, the pin layer is considered a taper layer.

Layer-based pin tapering takes precedence over distance-based pin tapering. If you specify the **-taper_distance** option with this option, the tool ignores the taper distance and issues a ZRT-548 warning message.

-single_side_spacing

Specifies to create the rule with single-side spacing, which limits spacing to one side of the net.

DESCRIPTION

This command defines design-specific, nondefault routing rules that are stored in the design database.

Use the **define_routing_rule** command to define width and spacing rules and the via types associated with them, as needed, without predefining them in the physical library.

Use the **set_net_routing_rule** command to assign nondefault routing rules to specific nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines a nondefault routing rule named new_rule that uses the default routing rules as the reference rule:

```
prompt> define_routing_rule new_rule -default_reference_rule \
           -widths {m1 0.8 m4 0.9} -spacings {m1 1.0 m4 1.0}
```

The following example defines a nondefault routing rule named new_rule that specifies multiple contacts with both rotated and

unrotated vias for certain layers. Note that multiple contacts and rotation are supported only for Zroute.

```
prompt> define_routing_rule new_rule \
-via_cuts {{VIA1_HH 2x1 NR} {VIA1_HH 2x1 R} \
{VIA1_HV 2x1 NR} {VIA1_HV 2x1 R}}
```

The following example reports the nondefault rule named new_rule:

```
prompt> define_routing_rule new_rule
prompt> report_routing_rules new_rule
```

The following example defines a nondefault rule named new_rule that specifies spacings, spacing weights, and spacing length thresholds:

```
prompt> define_routing_rule new_rule \
-spacings {m1 {0.09 0.15 0.2} m2 {0.09 0.15 0.2} m3 {0.09 0.15 0.2}} \
-spacing_weights {m1 {1 0.5 0.2} m2 {1 0.5 0.2} m3 {1 0.5 0.2}} \
-spacing_length_thresholds {m1 {0.01 0 0} m2 {0.01 0 0} m3 {0.01 0 0}}
```

The following example defines double-patterning mask constraints for the double-patterning layers.

```
prompt> define_routing_rule color1 \
-double_pattern_mask_constraints {M01 same_mask M02 mask1_hard \
M03 mask1_soft M04 mask2_hard M05 mask2_soft}
```

The following example defines via spacing between same via layers and different via layers.

```
prompt> define_routing_rule -via_spacings {{v1 v1 2.3} {v1 v2 3.2}}
```

The following example enables layer-based tapering. When routing a pin with this routing rule, if the pin is on M2, M2 and M3 are the taper layers; there is no tapering on any layer below the pin layer.

```
prompt> define_routing_rule CLK_NDR \
-taper_over_pin_layers 2 -taper_under_pin_layers 0
```

define_scaling_lib_group

Defines a scaling library group to support voltage and/or temperature scaling.

SYNTAX

```
status define_scaling_lib_group
  [-name name]
  [lib_file_names]
```

Data Types

<i>name</i>	string
<i>lib_file_names</i>	list

ARGUMENTS

-name *name*

Specifies a name for the scaling library group. The name can be used in a subsequent **set_scaling_lib_group** command.

lib_file_names

Specifies the set of library files that comprise the scaling library group. Specify the names of files that can be found using the **search_path** variable.

DESCRIPTION

The **define_scaling_lib_group** command defines a group of libraries that the tool uses for interpolation to perform voltage and/or temperature scaling.

You can define more than one group to cover different portions of a design, but the groups cannot share libraries. Each library can belong to no more than one scaling library group.

A minimum of two libraries is required for one-dimensional scaling, such as voltage or temperature. A minimum of four libraries is required for two-dimensional scaling, such as voltage and temperature.

The scaling library group defined in the current session is not written back to the design. In a new session, the same scaling library group settings must be defined again.

You should use the **set_scaling_lib_group** command to set the scaling library group defined on the design objects, so that the tool can perform interpolation between libraries in this group for voltage and/or temperature. You should define a scaling library group only if you intend to use it in the current session.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines a scaling library group for two voltage domains about the nominal:

```
prompt> define_scaling_lib_group -name g1 { 0.9.db 1.1.db 1.3.db }
```

[set_scaling_lib_group\(2\)](#)

define_test_mode

Defines a test mode to be created during DFT synthesis.

SYNTAX

```
status define_test_mode
  test_mode_label
  [-encoding {port_name 0 | 1, ...}]
  [-usage mode_purpose]
  [-target core_mode_pair_list]
  [-transparent_mode_of parent_mode_name]
```

Data Types

<i>test_mode_label</i>	string
<i>mode_purpose</i>	string
<i>core_mode_pair_list</i>	list
<i>parent_mode_name</i>	string

ARGUMENTS

test_mode_label

Specifies a user-defined text string containing only alphanumeric characters (a-z, A-Z, 0-9) and the underscore (_).

-encoding {port_name 0 | 1, ...}

Specifies a list of ports and the binary values that select a particular test mode. The encoding argument consists of a port name and a binary value pair that specify the test-mode port and the bit values to be used in a particular test mode. The encoding port pairs for a test mode must contain all pairs to be used in the design. See the EXAMPLES section for more information.

Before a port can be used for a test-mode port, it must be defined as a test-mode port using the **set_dft_signal** command:

```
set_dft_signal -type TestMode
```

-usage mode_purpose

Specifies the mode type for a test mode. The supported mode types are **scan_compression**, **scan**, **wrp_if**, **wrp_of**, **wrp_safe**, and **logicbist**.

- **scan** is the basic scan mode operation. The scan chains are driven directly by top-level scan-in ports and they in turn drive top-level scan-out ports. This mode is used for testing all logic internal to the core. This is the default mode if none is specified.
- **scan_compression** is the DFTMAX compressed scan mode of operation. In this mode, the compressed scan chains are driven by the load compressors and the scan chains drive the unload compressors. This mode is used for testing all logic internal to the core.

For backward compatibility, you can also use this usage to define DFTMAX Ultra compression modes if the design does not also contain DFTMAX compression modes.

- **streaming_compression** is the DFTMAX Ultra compressed scan mode of operation. In this mode, the compressed scan

chains are driven by the streaming load compressors and the scan chains drive the streaming unload compressors. This mode is used for testing all logic internal to the core.

- **wrp_if** is the inward facing, or **INTEST** mode of wrapper operation. This mode is used for testing all logic internal to the core. In this mode, wrappers are enabled and configured to drive and capture data within the design in conjunction with the internal scan chains.
- **wrp_of** is the outward facing, or **EXTEST** mode of wrapper operation. This mode is used for testing all logic external to the design. Wrappers are enabled and configured to drive and capture data outside of the design. In this mode the internal chains are disabled.
- **wrp_safe** is the safe wrapper mode. In this mode the internal chains are disabled and the internal core is protected from toggle activity. This mode is optional and provides isolation of the core while other cores are being tested. When active, safe mode enables driving steady states into or out of the design.
- **logicbist** is the LogicBIST self-test compression mode, which implements a digital logic built-in self-test capability. In this mode, the compressed scan chains are driven by a pseudo-random pattern generator for a fixed number of patterns. A multiple-input signature register (MISR) captures the resulting scan data, then compares it against an expected signature value to generate a PASS/FAIL result.

-target core_mode_pair_list

Specifies test-mode assignments to use for DFT-inserted cores.

This option overrides the default test-mode assignment for DFT-inserted cores. Specify a list of core and test-mode pairs to use for the top-level test mode being defined; each pair consists of a core instance name and a core test-mode name separated by a colon (:). For designs with scan compression, you can also include the name of the current design, without a colon or test-mode name, to specify that the top-level logic should be active and tested.

If a core is targeted in some test modes but not others, it is inactive in the test modes where it is not targeted. This is known as sparse targeting. (To completely exclude a core from all top-level test modes, use the **-exclude_elements** option of the **set_scan_configuration command**.)

Untargeted cores (not included in any target list across all test modes) are tested in top-level modes where the top-level logic is tested.

-transparent_mode_of parent_mode_name

Specifies the parent mode for the transparent test mode being defined.

A transparent mode is derived from an inward-facing parent test mode of a core-wrapped design. It is identical to its parent mode, except that

- Wrapper chains are treated as regular scan chains.
- Dedicated wrapper cells are logically transparent, although their flip-flops remain in the wrapper chains and act as observe test points on I/O paths.
- Any scan compression codecs from the referenced inward-facing mode are reused.
- Feedthrough chains drive the outward-facing wrapper scan I/Os in transparent mode.

A transparent mode allows a core-wrapped design to be tested top-down flat from a higher hierarchy level.

A transparent mode inherits all DFT configuration information from its parent mode. Do not apply any other DFT configuration commands specifically to a transparent test mode; they are ignored. Do not specify a base mode for a transparent compressed scan mode.

DESCRIPTION

The **define_test_mode** command allows you to define a test mode for DFT synthesis. Inference for existing scan multimode designs is not supported at this time.

The information associated with a *spec* mode is interpreted as a specification of a test mode to be synthesized. This information is used during the DFT architect and insertion process, while running the **preview_dft** or the **insert_dft** command. The specification information for a mode consists of protocols, port attributes, and the configuration information specific to the DFT to be inserted.

Perform multimode specifications in the following order:

1. Define TestMode signals with **set_dft_signal -test_mode all**.
2. Define all test modes, their usage, and their encoding with **define_test_mode**.
3. Define clocks, asynchronous signals, and constants common to all test modes with **set_dft_signal -test_mode all**.
4. Define mode-specific signals with **set_dft_signal -test_mode test_mode_name**.
5. Specify scan paths to be used in all test modes with **set_scan_path -test_mode all**.
6. Specify scan paths to be used in specific test modes with **set_scan_path -test_mode test_mode_name**.

Note that when the **define_test_mode** command is used, it will set the current *test_mode*. Then if any of the commands listed below are used without the **-test_mode** option, the spec will not be applied to all test modes. Instead, the spec will be applied only to the mode that was last defined with **define_test_mode**. The affected commands are

set_scan_configuration

set_scan_path

set_dft_signal

set_scan_configuration_compression

Be sure to use the **-test_mode** option with all of these commands once the **define_test_mode** command has been issued. If the spec is to be applied to all modes use **-test_mode all**. If the spec is to be applied to a specific test mode, use **-test_mode test_mode_name**.

Use the **remove_test_mode** command to remove a test mode and all associated information.

EXAMPLES

The following example defines three test modes in a DFTMAX compressed scan flow. The modes are ScanCompression_mode, Internal_scan1, and Internal_scan2. The encoding values are also specified.

```

prompt> set_dft_signal -view spec -type TestMode \
    -port [list i_trdy_de i_trdy_dd i_cs]

prompt> define_test_mode ScanCompression_mode \
    -usage scan_compression \
    -encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1}

prompt> define_test_mode Internal_scan1 -usage scan \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0}

prompt> define_test_mode Internal_scan2 -usage scan \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1}

```

The following example defines 9 wrapper modes:

```

prompt> set_dft_signal -view spec -type TestMode \
    -port [list i_trdy_de i_trdy_dd i_cs]

prompt> define_test_mode burn_in -usage scan \
    -encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 0 i_wr 1}

```

```
prompt> define_test_mode domain -usage scan \
    encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1 i_wr 0}

prompt> define_test_mode my_wrp_if -usage wrp_if \
    encoding {i_trdy_de 0 i_trdy_dd 0 i_cs 1 i_wr 1}

prompt> define_test_mode my_wrp_if_delay -usage wrp_if \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0 i_wr 0}

prompt> define_test_mode my_wrp_if_scl_delay -usage wrp_if \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 0 i_wr 1}

prompt> define_test_mode my_wrp_of -usage wrp_of \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1 i_wr 0}

prompt> define_test_mode my_wrp_of_delay -usage wrp_of \
    -encoding {i_trdy_de 0 i_trdy_dd 1 i_cs 1 i_wr 1}

prompt> define_test_mode my_wrp_of_scl_delay -usage wrp_of \
    -encoding {i_trdy_de 1 i_trdy_dd 0 i_cs 0 i_wr 0}

prompt> define_test_mode my_wrp_safe -usage wrp_safe \
    -encoding {i_trdy_de 1 i_trdy_dd 0 i_cs 0 i_wr 1}
```

The following example uses the **-target** option to override default name-based test-mode assignment for DFT-inserted cores:

```
prompt> define_test_mode STD -usage scan \
    -target {IPcore:STD MMcore:STD top}

prompt> define_test_mode COMP1 -usage scan_compression \
    -target {IPcore:DFTMAX1 MMcore:CMP top}

prompt> define_test_mode COMP2 -usage scan_compression \
    -target {IPcore:DFTMAX2 MMcore:CMP top}
```

define_user_attribute

Defines a new user-defined attribute.

SYNTAX

```
string define_user_attribute
  -type string | int | float | double | boolean
  -classes class_list
  [-range_min min]
  [-range_max max]
  [-one_of values]
  [-quiet]
  attr_name
  [-import]
```

Data Types

<i>class_list</i>	list
<i>min</i>	double
<i>max</i>	double
<i>values</i>	list
<i>attr_name</i>	string

ARGUMENTS

-type string | int | float | double | boolean

Specifies the data type of the attribute.

-classes *class_list*

Specifies the classes for the new user-defined attribute. Valid classes are design, port, cell, net, etc.

-range_min *min*

This option is only for PT compatibility.

-range_max *max*

This option is only for PT compatibility.

-one_of *values*

This option is only for PT compatibility.

-quiet

Turns off the warning message that would otherwise be issued if the attribute or classes are improper.

attr_name

Specifies the name of the attribute.

DESCRIPTION

This command defines a new attribute. Use the **list_attributes** command to list the attributes that you have defined.

The definition for a user-defined attribute can be persistent if it has been set on a specified design object and stored in the database.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example defines an attribute named attr_1, which has a data type of double with a minimum value of 2 and a maximum value of 3.2 and can be set on cells or nets.

```
prompt> define_user_attribute -class {cell net} -type double \
    -range_max 3.2 -range_min 2 attr_1
attr_1
```

The following example defines an attribute named attr_2, which has a data type of string with valid values of true or false and can be set on nets.

```
prompt> define_user_attribute -class net -type string \
    -one_of {true false} attr_2
attr_2
```

The following example shows how to list the attribute definitions using the **list_attributes** command:

```
prompt> list_attributes
*****
Report : attribute definition
Design :
Version: E-2010.12
Date  : Tue Sep 28 19:23:55 2010
*****  
  
Attributes:
r - read-only
u - user-defined  
  
Attribute name      Class     Type     Attributes
-----
attr_1             cell      float    u
attr_1             net       float    u
attr_2             net       string   u
-----
1
```

set_attribute(2)
```

delete_operating_conditions

Deletes a specific set of operating conditions from a library.

SYNTAX

```
status delete_operating_conditions
  -library library_name
  -name op_cond_name
```

Data Types

library_name string
op_cond_name string

ARGUMENTS

-library *library_name*

Specifies the name of the library that stores the operating conditions.

-name *op_cond_name*

Specifies the name of the set of operating conditions.

DESCRIPTION

The **delete_operating_conditions** command deletes a specific set of operating conditions from the specified library.

To create a new set of operating conditions, use the **create_operating_conditions** command.

To set operating conditions on the current design, use the **set_operating_conditions** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example deletes a specific set of operating conditions called *BEST* in the *a_lib* library:

```
prompt> delete_operating_conditions -library a_lib -name BEST
```

SEE ALSO

`create_operating_conditions(2)`
`set_operating_conditions(2)`

derive_constraints

Propagates design environment, constraints, and attribute settings from the top-level design to the specified subdesigns.

SYNTAX

```
status derive_constraints
      [-attributes_only]
      [-verbose]
      [-budget]
      cell_list
```

ARGUMENTS

-attributes_only

Propagates only the attributes. By default, both constraints and attributes are propagated.

-verbose

Enables additional messages during propagation.

-budget

Performs RTL budgeting to come up with delay constraints.

cell_list

Specifies the list of cells to which the environment is to be propagated. The following validations are performed on the specified cells:

- Cell is hierarchical
- Cell is unique or is a master instance
- Reference design is in Design Compiler memory

DESCRIPTION

This command propagates design environment, constraints, and attribute settings from the top-level design to the specified subdesigns. Although this command works on both mapped and unmapped designs, design budgeting provides more accurate constraints for mapped designs.

This command uses the **target_library** variable. Ensure that this variable is set before running the command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

SEE ALSO

`write_environment(2)`
`MasterInstance(3)`
`target_library(3)`

describe_state_transition

Defines named state transitions for an object.

SYNTAX

```
status describe_state_transition
  transition_name
  [-object object]
  [-from from_list]
  [-to to_list]
  [-paired {{from_state to state}*}]
  [-through through_list]
  [-legal | illegal]
  [-illegal]
```

Data Types

<i>transition_name</i>	string
<i>from_list</i>	list
<i>to_list</i>	list
<i>from_state</i>	string
<i>to_state</i>	string
<i>through_list</i>	list

ARGUMENTS

transition_name

Specifies the name of the transition that will be defined.

-object *object*

Specifies the name of the object for which the state transitions will be defined.

-from *from_list*

Consists of an unordered list of power state names active before a state transition. An empty list expands to all named power states for the specified object.

-to *to_list*

Consists of an unordered list of power state names active after a state_transition. An empty list expands to all named power states for the specified object.

-paired {{*from_state* to *state*}*}

Consists of a list of from-state and to-state name pairs.

-through *through_list*

List of intermediate states. This option is only applicable when -from and -to options are specified. The effective transition

sequence is **-from**, **-through**, **-to**. This is a Synopsys specific extension.

-legal | -illegal

These options specify the legality of the transition being defined as either legal or illegal. The default is **-legal**.

DESCRIPTION

This command defines named state transitions between power states of an object. The allowed object types are as follows:

- Power Domain
- Supply Set
- Power State Group
- Power State Table
- Supply Port
- Supply Net
- Power Switch

If the specified object does not exist or is not any of the types indicated above, the command issues an error.

The initial and final states of each transition can be specified either using two separate **-from** and **-to** lists or a **-paired** list. If none of these are specified the command issues an error. Furthermore, the same state cannot be an initial and final state of the same transition, and specifying this will cause the command to return an error.

Synopsys has a specific extension consisted of the **-through** option, which is a list of intermediate states to the **-from** and **-to** lists. If this option is specified without the **-from** or **-to** option, the command issues an error.

Design Compiler doesn't preserve this command through hierarchical flow, and a warning will be issued from characterize when this command is seen.

Design Compiler only parses and preserves this command.

EXAMPLES

Following examples show different usages of **describe_state_transition** command and the outcome.

```

prompt> describe_state_transition TURN_ON -object MID_SS \
    -from [list OFF PWR_OFF] -to [list ON PWR_ON] -legal
1

prompt> describe_state_transition FAILED1 -object TOP_SS \
    -from [list ON PWR_OFF] -to [list ON PWR_ON]
Error: The same state can't be both an initial and final state in a transition.
State ON is in both -from and -to state lists. (UPF-898)

prompt> describe_state_transition FAILED2 -object mid_true/PST2 \
    -from [list OFF PWR_OFF] -through [list ON PWR_ON]
Error: State list -through can't be defined if -from or -to lists are empty. (UPF-897)

prompt> describe_state_transition FAILED3 -object mid_sttrue/MID2_SS
Error: State lists -from and -to can't be empty if -paired state list is not defined. (UPF-896)

prompt> describe_state_transition FAILED4 -object NE \
    -from [list OFF PWR_OFF] -to [list ON PWR_ON] -legal
Error: Object NE wasn't found (UPF-899)

```

SEE ALSO

`add_state_transition(2)`

dft_drc

Checks the current design against test design rules.

SYNTAX

```
status dft_drc
  [-pre_dft]
  [-verbose]
  [-coverage_estimate]
  [-sample percentage]
```

ARGUMENTS

-pre_dft

Specifies that only pre-DFT rules (D rules) are checked. By default, the state of the design determines the rules that are checked. The state of the design is automatically determined using attributes. For scan-routed designs, post-DFT rules are checked; otherwise pre-DFT rules are checked.

-verbose

Controls the amount of detail when displaying violations. If specified, every violation instance is displayed. By default, only the first instance and the number of instances are displayed.

-coverage_estimate

Generates a test coverage estimate at the end of post-DFT DRC design rule checking.

-sample *percentage*

Specifies a sample percent of faults to be considered when estimating test coverage. This option must be used in conjunction with the **-coverage_estimate** option.

DESCRIPTION

This command checks the current design against the test design rules of the scan test implementation specified by the **set_scan_configuration -style** command. If there are unconnected test modes and functional Autofix clocks, they are constrained as needed.

If design rule violations are found, the appropriate messages are generated.

Perform test design rule checking on a design before performing any other DFT Compiler operations, such as **insert_dft**.

This command requires the existence of a valid test protocol. The test protocol can be generated using the **create_test_protocol** command or read using the **read_test_protocol** command.

The severity of violations falls under one of the following categories:

- Information indicates no action is required.
- Warning indicates that you should analyze the violations. These might violate sequential cells resulting in their exclusion from scan chains. However, they do not prevent you from running certain DFT Compiler commands.
- Fatal violations stop you from proceeding. Certain DFT Compiler commands cannot be run.

If you start with a design with pre-existing scan structures, the scan information for inference must be specified with **-view** as **existing_dft** for the **set_dft_signal** and **set_scan_path** commands and run the **create_test_protocol** command.

The **\fb-coverage** option generates test coverage statistics for the current design. The option does not allow you to save or write out test patterns. The number generated is only an estimate and might be different from the one generated by an ATPG tool.

If you are running the command in the Design Vision environment, you can use the violation browser to analyze violations.

EXAMPLES

The following command performs test design-rule checking for the current design, and illustrates the types of messages that are printed:

```

prompt> current_design des1

prompt> set_scan_configuration -methodology full_scan \
    -style multiplexed_flip_flop

prompt> set_dft_signal -view existing_dft -type Constant \
    -port TM1 -active_state
Accepted dft signal specification.
1

prompt> set_dft_signal -view existing_dft -type Constant \
    -port TM2 -active_state
Accepted dft signal specification.
1

prompt> set_dft_signal -view existing_dft -type MasterClock \
    -port CLK1 -timing [list 45 55]
Accepted dft signal specification.
1

prompt> create_test_protocol -infer_asynch

disconnect_net

Disconnects a net from pins or ports.

SYNTAX

```
status disconnect_net
    net
    object_list | -all
```

Data Types

<i>net</i>	string
<i>object_list</i>	list

ARGUMENTS

net

Specifies the net name or net instance name to disconnect. A net must exist in the current design.

object_list

Specifies the pins and ports disconnected from the net. Only pins and ports existing in the current design are specified. Either *object_list* or **-all** must be specified.

-all

Specifies to break all connections on the net. Either **-all** or *object_list* must be specified.

DESCRIPTION

The **disconnect_net** command breaks the connections between a net or a net instance and its pins or ports. The net, pins, and ports are not removed.

This command accepts only scalar (single bit) nets, and not bused nets.

To connect nets, use the **connect_net** command. To display the pins and ports connected to a net, use the **all_connected** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples disconnect nets using the **disconnect_net** command:

```
prompt> disconnect_net NET0 [get_ports A1]  
Disconnecting net 'NET0' from port 'A1'.
```

```
prompt> disconnect_net NET0 [get_pins U1/A]  
Disconnecting net 'NET0' from pin 'U1/A'.
```

The following example breaks all connections on a net using the **disconnect_net** command:

```
prompt> disconnect_net MY_NET_1 -all  
Disconnecting net 'MY_NET_1' from port 'PORT1'.
```

```
prompt> all_connected [get_nets MY_NET_1]
```

SEE ALSO

[create_net\(2\)](#)
[current_design\(2\)](#)
[remove_net\(2\)](#)

distance

Describes basic command types for describing mask geometry.

SYNTAX

distance

ARGUMENTS

The **distance** command has no arguments.

DESCRIPTION

This command describes basic types of distance for describing mask geometry.

A *distance* is a basic command syntax unit, such as strings and floating-point numbers.

Distances are returned by some commands and some attributes are distances. Distances can be used as arguments to some commands.

Distances can be grouped into lists to form points. A *point* is a Tcl list of two distances, which are interpreted as the x- and y-values of the coordinate. For example, the origin is {0 0}.

A *rectangle* is a Tcl list of two points, which are interpreted as the lower-left and upper-right corners. For example, the unit square is {{0 0} {1 1}}.

To access a distance when given a point, you might want to use the **lindex** command.

EXAMPLES

The following examples show how to set several uses of distance:

```
prompt> set spacing 12.25  
prompt> set lower_left_x 2.5  
prompt> set lower_left_y 44.125  
prompt> set corner {22.54 1235.75}  
prompt> set base [list $lower_left_x $lower_left_y]  
prompt> set box [list $base [list 222.14 [expr 200.2 * 7]]]
```

```
prompt> get_attribute $cell1 bbox
prompt> {241.5 700.1} {246.4 703.1}
```

SEE ALSO

`move_objects(2)`

drive_of

Returns the drive resistance value of the specified library cell pin.

SYNTAX

```
float drive_of
    library_cell_pin
    [-rise | -fall]
    [-piece best | worst | average
     | [-min]]
```

Data Types

library_cell_pin string

ARGUMENTS

library_cell_pin

Specifies the name of the library cell pin whose drive value is to be returned. Use the following format to specify this option:

library_name/lib_cell_name/pin_name

The specified library must already be loaded into the shell.

-rise

Specifies that the command is to return the *library_cell_pin* rise drive resistance.

-fall

Specifies that the command is to return the *library_cell_pin* fall drive resistance.

-piece **best** | **worst** | **average**

Specifies to return the **best**, **worst**, or **average_value** of all of the pieces. The **average_value** corresponds to the **average_value** integer index value. This option can be used only with piecewise-linear libraries.

-min

Gets the wire's drive value.

DESCRIPTION

This command returns the drive or wire_drive resistance of the specified library cell pin. The resistance is primarily used as an argument to the **set_drive** command. The **set_driving_cell** command provides a more convenient and accurate method of describing the drive capability of a port.

If you do not use either the **-rise** or **-fall** option, the command returns the largest of the rise or fall drive resistances.

If the command cannot find the specified *library_cell_pin*, it issues an error message and returns 0.0.

Because drive resistances are associated with timing arcs, it is possible to have more than one distinct rise and fall drive associated with a specified library pin. In this case, the command returns the largest resistance.

If the specified library uses the nonlinear (table-lookup) delay model, the command returns an estimated linear drive value. The **set_driving_cell** command handles nonlinear drives and produces more accurate results than the **set_drive** command for these libraries.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command returns the rise drive of the *my_pin* pin of the *lib_cell* cell from the *tech_lib* library:

```
prompt> drive_of -rise tech_lib/lib_cell/pin
```

The following command searches through all of the pieces of the **rise_pin_resistance** attribute on the *my_pin* pin of the *lib_cell* cell. The command returns the worst value for all of the pieces. This assumes that the *tech_lib* library is modeled as a piecewise-linear library; otherwise, the command returns the normal *rise_resistance*.

```
prompt> drive_of -piece "worst" \
    -rise tech_lib/lib_cell/pin
```

SEE ALSO

```
set_drive(2)
set_driving_cell(2)
```

duplicate_logic

Duplicates combinational logic paths, given a startpoint pin, an endpoint pin, and, optionally, a list of intermediate (through) pins.

SYNTAX

```
status duplicate_logic
  -from      start_points
  [-through   mid_points]
  -to        end_points
  [-location  location]
  [-suffix    suffix]
  [-report_only]
```

Data Types

<i>start_points</i>	collection
<i>mid_points</i>	collection
<i>end_points</i>	collection
<i>location</i>	string
<i>suffix</i>	string

ARGUMENTS

-from *start_points*

Lists the startpoint pins where the paths to be duplicated start. The startpoint pins are expected to be drivers of their paths. It can be a single pin, a list of pins, or a list of pin lists (when the argument is instantiated multiple times in a single call of the command).

-through *mid_points*

Lists the midpoint pins where the paths are passing through. This argument is optional, which means there is no midpoint checking for the paths.

-to *end_points*

Lists the endpoint pins where the paths to be duplicated end. The endpoint pins are expected to be loads of their paths. It can be a single pin, a list of pins, or a list of pin lists (when the argument is instantiated multiple times in a single call of the command).

-location *location*

Specifies the name of a hierarchical cell, inside of which you want the duplicated cells and nets to be located (in a hierarchical context). If not specified, the duplicated cells and nets are located in the same hierarchical units where their originals belonged.

-suffix *suffix*

Specifies an optional suffix that you can append to the names of the original cells, nets, or ports for the construction of the duplicated cell, net, or port name. The default suffix string is "_dup". However, the command automatically appends a two-digit index to whatever suffix is used in order to differentiate multiple duplications of the same original cell in different calls of the command.

-report_only

Reports only the duplicate logic path finder results without any duplication being done. There are cases where many paths are found between the startpoint and endpoint. The idea of this optional report is to give you enough feedback to help in the choosing of midpoint alternatives to reduce the scope of the duplication.

DESCRIPTION

Duplicates the combinational paths from startpoint pins, passing through optional midpoint pins, to endpoint pins.

If there are multiple paths found for a single **duplicate_logic** command call, the default behavior is to duplicate each involved cell and net only once.

This command can be invoked whenever there is a Design Compiler netlist present. However, only mapped netlists are officially supported.

Be aware that after duplication, the endpoint pins are disconnected from their original driver net, and therefore in some cases you could end up with unloaded logic path tails after the only load has been disconnected.

If you use the command in Design Compiler topographical mode, and physical information is available, duplicated cells are automatically placed in the same physical locations as their originals.

Restrictions

This command does not duplicate paths when any of the following situations occur:

1. When the intermediate cells are any of the following:
 - 1.1. Don't Touch
 - 1.2. ILM
 - 1.3. Black Box
 - 1.4. Macro Cell
 - 1.5. Sequential Cell
2. When the path crosses hierarchical boundaries and the child hierarchical cell does not allow hierarchical boundary optimization.
3. When the path crosses power domain boundaries.

EXAMPLES

The following example is typical usage. It specifies duplicated combinational paths between IN1 and \

OUT1 ports:"

```
prompt> duplicate_logic -from IN1 -to OUT1
1
```

The following example uses **-report_only** to test how many and how long the paths are between Port A and Port C:

```
prompt> duplicate_logic -from A -to C -report_only
Valid Path (1 of 2) (4 Nodes): { A/**inside** U2/A U2/Z C/**inside** }
Valid Path (2 of 2) (6 Nodes): { A/**inside** U3/B U3/Z U2/B U2/Z C/**inside** }
1
```

The following example uses the **-through** option to reduce the paths to be duplicated:

```
prompt> duplicate_logic -from A -to C -through U2/A -report_only
Valid Path (1 of 2) (4 Nodes): { A/**inside** U2/A U2/Z C/**inside** }
1
```

SEE ALSO

echo

Echos arguments to standard output.

SYNTAX

```
string echo  
  [-n]  
  [arguments]
```

Data Types

arguments string

ARGUMENTS

-n

Suppresses the new line. By default, **echo** adds a new line.

arguments

Specifies the arguments to be printed.

DESCRIPTION

The **echo** command prints out the value of the given arguments. Each of the arguments are separated by a space. The line is normally terminated with a new line, but if the **-n** option is specified, multiple **echo** command outputs are printed onto the same output line.

The **echo** command is used to print out the value of variables and expressions in addition to text strings. The output from **echo** can be redirected using the **>** and **>>** operators.

EXAMPLES

The following are examples of using the **echo** command:

```
prompt> echo  
"Running version" $sh_product_version  
Running version v3.0a  
  
prompt> echo -n "Printing to" [expr (3 - 2)] > foo
```

```
prompt> echo " line." >> foo
prompt> sh cat foo
Printing to 1 line.
```

SEE ALSO

[sh\(2\)](#)

elaborate

Builds a design from the intermediate format of a Verilog module, a VHDL entity and architecture, or a VHDL configuration.

SYNTAX

```
status elaborate
  design_name
  [-library library_name | -work library_name]
  [-architecture arch_name]
  [-parameters param_list]
  [-file_parameters file_list]
  [-update]
  [-ref]
```

Data Types

```
design_name    string
library_name   string
arch_name     string
param_list    list
file_list     list
```

ARGUMENTS

design_name

Specifies the name of the design to build. The design can be a Verilog module, a VHDL entity, or a VHDL configuration.

-library *library_name*

Specifies the library name to which **work** is to be mapped. By default, **elaborate** looks in the **work** library for the design to be built. Specifying **-library** allows you to temporarily change the library to which **work** is mapped.

-work *library_name*

Specifies an alias used for **-library**.

-architecture *arch_name*

Specifies the name of the architecture. In VHDL, the default architecture is the most recently analyzed architecture.

-parameters *param_list*

Specifies a list of design parameters enclosed in quotes. Parameters within the list must be separated by commas. A specification can be based on parameter order (for example, "8,7,5") or on parameter names (for example, "N=>8,M=>6"). It is acceptable to mix ordered and named parameter specifications, as long as the ordered parameters are listed first. The full *param_list* syntax is summarized in the "DESCRIPTION" section below.

-file_parameters *file_list*

Specifies a list of files that contain parameter specifications. The specifications are appended to the parameters listed in the -

parameters option (if present). The syntax of the parameter file is identical to the syntax between the parameter-delimiters (#) in the **-parameters** option, except that the backslashes (\) at the end of lines and the hashes (#) must be omitted. The specified files are searched for in the search_path.

-update

Reanalyzes out-of-date intermediate files if the source can be found.

-ref

Elaborates several reference designs that contain bottom design instantiations in the elaborated module, using a hierarchical elaboration flow. When the top design is instantiated, it includes all the linkage information, including interfaces, modports, and parameters, and the logic for the lower-level designs.

DESCRIPTION

The **elaborate** command builds a design from its intermediate representation using the specified parameters.

The syntax of the parameter specifications includes a subset of VHDL syntax plus the `h constant format of Verilog. VHDL accepts all but the `h format. Verilog accepts strings, integers, and `h values. Define each parameter only once; an error message is generated if a parameter is defined more than once.

Parameters are not case-sensitive, so NUM is the same as num.

For the **-parameters** option (but not in files specified by **-file_parameters**), the parameter specification must be specially delimited. The parameter specification can be enclosed in double quotation marks ("), but this is not advised if the specification itself includes string values. Instead, use the special parameter-delimiter, which brackets the parameter specification syntax. The parameter-delimiter starts and ends with '# (hash). For multi-line strings put backslashes (\) as the last character in the line. This is because "#" is properly recognized as a string constant.

Spaces can be inserted in the middle of the parameter string to make your script easier to read, but you must either enclose the parameter string in double quotation marks ("), or escape the spaces using backslashes (\).

In the following example, the same parameter is passed three times, one without intermediate spaces and two using the appropriate syntax. All three cases are equivalent.

```
prompt> elaborate TOP -param width=>32,ports=>8
prompt> elaborate TOP -param "width => 32, ports => 8"
prompt> elaborate TOP -param #width\ =>\ 32,\ ports\ =>\ 8#
```

In the following example, the second # in the first line does not terminate the parameter:

```
prompt> elaborate MY_DES -param #words=>4,str => "#",\
      name=>"my_name",\
      matrix=>"1010101010001"& \
      "0001010101010"#+
```

The formal syntax for the parameter specification is as follows:

```
parameter_list: parameter_spec [ , parameter_spec ]*
parameter_spec: parameter_name => value_spec
               parameter_name = value_spec
               value_spec
value_spec:   " string_value "
              ' character_value '
```

```
integer_value
enum_value
( value_spec [ , value_spec ]* )
integer_value 'h hex_value
```

When the **-ref** option is specified, the **elaborate** command scans the design and groups the bottom design instantiations into several reference designs. Each reference design contains all of the instantiations of a bottom design type.

For example, if a *top* design contains several instances of bottom designs, name *bot1* and *bot2*, the **-ref** option generates two reference designs named *top_bot1* and *top_bot2*, that contain all of the instantiations of each type of lower design, respectively. The instance parameters and SV interface specializations for SystemVerilog designs are preserved in the reference design information.

Later, the reference design can be loaded and linked, forcing the elaboration of all of the specialized information required from the *top* design. The already-elaborated bottom designs can be used in a hierarchical elaboration flow.

During elaboration, the **link** command is invoked to resolve all instances in the designs. When instances cannot be resolved, the **elaborate** command issues error messages for those instances, returning a 1 status, and continues to resolve all other instances without aborting the elaboration process. Link error messages issued during elaboration are considered as warning messages, and an explicit **link** command should be executed after reading the design.

For more information about the hierarchical elaboration flow for SystemVerilog designs with interfaces, see the *SystemVerilog User Guide*.

EXAMPLES

The following example builds the design *mult* with *N* parameter set to 8, and *M* set to 3. The **-update** switch causes all out-of-date HDL files to be automatically reanalyzed.

```
prompt> elaborate -update mult -parameters "N=8,M=3"
Information: Re-analyzing the out of date package 'USER_TYPES'. (LBR-15)
Information: Re-analyzing the out of date entity 'MULT'. (LBR-15)
Information: Re-analyzing the out of date architecture 'STRUCTURE(MULT)'. (LBR-15)
Current design is now 'MULT_N8_M3'.
1
```

The following example generates a reference design for hierarchical elaboration using the **-ref** switch. The resulting design is saved to a .ddc file.

```
prompt> elaborate -ref
Running PRESTO HDLC
Presto compilation completed successfully.
Elaborated 1 reference design. Use 'link' to elaborate the required down design.
Current design is now 'top_bottom'.
Ending elaborate -ref mode. Please link the generated designs later
1
```

```
prompt> write -f ddc -hier -o top_bottom.ddc top_bottom
Writing ddc file 'top_bottom.ddc'.
1
```

The following example uses a reference design previously generated with the **-ref** switch, links it to elaborate the bottom designs, includes specialized information required by the top module, and writes out a .ddc file:

```
prompt> analyze -f sverilog bottom.sv
Running PRESTO HDLC
Searching for ./bottom.sv
Compiling source file ./bottom.sv
Presto compilation completed successfully.
1
```

```
prompt> read_ddc top_bottom.ddc
```

```
Reading ddc file 'top_bottom.ddc'.
Loaded 1 design.
Current design is 'top_bottom'.
top_bottom
```

```
prompt> link
```

```
Linking design 'top_bottom'
Using the following designs and libraries:
-----
top_bottom      ./top_bottom.ddc
```

```
Information: Building the design 'bottom' instantiated from design 'top_bottom'
with the parameters "N=32,M=16". (HDL-193)
```

```
Presto compilation completed successfully.
```

```
Information: Building the design 'bottom' instantiated from design 'top_bottom'
with the parameters "M=64". (HDL-193)
```

```
Presto compilation completed successfully.
```

```
1
```

```
prompt> list_designs
```

```
bottom_M64    bottom_N32_M16  top_bottom (*)  
1
```

```
prompt> write -f ddc -hier -o bottom.ddc { bottom_M64 bottom_N32_M16 }
```

```
Writing ddc file 'bottom.ddc'.
```

```
1
```

enable_redirect_bg_commands

Specify the allowed command type for redirect background executable.

SYNTAX

```
string enable_redirect_bg_commands  
  [-all] [-read_only]
```

ARGUMENTS

-all

This is the default value. It allows all supported command for redirect background executable.

-read_only

Only allows read_only commands for redirect background executable.

DESCRIPTION

This command will specify the allowed command type for redirect background executable. If the command is not called or called with no option, all supported commands will be allowed for redirect background executable. If *-read_only* option is specified, only the *read_only* commands are allowed.

SEE ALSO

[redirect\(2\)](#)

enable_write_lib_mode

Enables usage of the **write_lib** command in the tool session.

SYNTAX

status **enable_write_lib_mode**

ARGUMENTS

None

DESCRIPTION

This command enables usage of the **write_lib** command in the tool. By default, the **write_lib** command is disabled to optimize for performance. To enable the **write_lib** functionality, you must run the **enable_write_lib_mode** command at the beginning of the tool session, before you load any .db library files. After it is enabled, using the **write_lib** command writes out the complete library file. You should not perform optimization on the design during the session and you need to exit the tool completely after the library operation is done.

EXAMPLES

The following command enables usage of the **write_lib** command:

```
prompt> enable_write_lib_mode
This icc_shell session is for library operations only. You should
not perform optimization on the design. Please exit when you are
finished with the library operation.
1

prompt> report_write_lib_mode
Information: write_lib mode is enabled.
1

prompt> write_lib my_lib
1
```

SEE ALSO

`report_write_lib_mode(2)`
`write_lib(2)`

encrypt_lib

Encrypts a VHDL source library file.

SYNTAX

```
status encrypt_lib
  file_name
  [-output encrypted_file]
  [-format {vhdl | tf | mwlib}]
  [-key string]
```

Data Types

<i>file_name</i>	string
<i>encrypted_file</i>	string

ARGUMENTS

file_name

Specifies the name of the VHDL file to encrypt.

-output *encrypted_file*

Specifies the output filename to which the encrypted output is to be written. By default, the output file is named *file_name.E* and is written to the current directory.

NOTE: If you specify an output filename that already exists, the command overwrites the file without warning.

DESCRIPTION

This command encrypts a VHDL source library file to protect ASIC vendors' VHDL models. The encrypted file is read and simulated by **vhdlan** and **vhdsim**, respectively, in the same way as a nonencrypted file.

EXAMPLES

The following example encrypts the technology library *my_file.vhd*. The output file is named *my_file.E* and is written to the current directory.

```
prompt> encrypt_lib my_file.vhd
```

SEE ALSO

`read_lib(2)`
`write_lib(2)`

error_info

Prints extended information on errors from the last command.

SYNTAX

string **error_info**

ARGUMENTS

This **error_info** command has no arguments.

DESCRIPTION

The **error_info** command is used to display information after an error has occurred. Tcl collects information showing the call stack of commands and procedures. When an error occurs, the **error_info** command can help you to focus on the exact line in a block that caused the error.

EXAMPLES

This example shows how **error_info** can be used to trace an error. The error is that the iterator variable "s" is not dereferenced in the 'if' statement. It should be '\$s == "a"'.

```
prompt> foreach s $my_list {  
?     if { s == "a" } {  
?       echo "Found 'a'!"  
?     }  
?  
}  
Error: syntax error in expression " s == "a" "  
    Use error_info for more info. (CMD-013)  
prompt> error_info  
Extended error info:  
syntax error in expression " s == "a" "  
    while executing  
"if { s == a } {  
    echo "Found 'a'"  
}"  
    ("foreach" body line 2)  
    invoked from within  
"foreach s [list a b c] {  
    if { s == a } {
```

```
    echo "Found 'a"  
}  
}"  
-- End Extended Error Info
```

estimate_fp_black_boxes

Sets the size of a black box based on an estimation of the objects that it will contain when replaced with real logic.

SYNTAX

```
status estimate_fp_black_boxes
  [-sm_size {width height}]
  | -polygon {{x1 y1} {x2 y2} ...}
  | -sm_gate_equiv gate_count]
  [-sm_util util]
  [-hard_macros names]
  [-fixed_shape]
  [-reset_shape]
  black_boxes
```

Data Types

<i>width</i>	float
<i>height</i>	float
<i>x1</i>	float
<i>y1</i>	float
<i>x2</i>	float
<i>y2</i>	float
<i>gate_count</i>	integer
<i>util</i>	float
<i>names</i>	string
<i>black_boxes</i>	collection

ARGUMENTS

-sm_size {*width height*}

Specifies the width and height of the black box. The estimated area is determined by multiplying width by height, given by a list of two floating point numbers. If you also use the **-sm_util** option, an equivalent gate count value is calculated internally based on the *util* value. Otherwise, the tool uses a value of 1.0 for utilization when the **-sm_size** option is used, but the **-sm_util** option is not used. The **-sm_size** and **-polygon** options are mutually exclusive: you can use only one. By default, this option is off.

-polygon {{*x1 y1*} {*x2 y2*} ...}

Creates a rectilinear black box based on the specified coordinates. The polygon is defined by specifying the coordinates of all its points. The format is {{*x1 y1*} {*x2 y2*} ... {*x1,y1*}}. Specify the points as absolute coordinates in microns. The **-sm_size** and **-polygon** options are mutually exclusive; you can use only one. When you use the **-polygon** option to estimate black box size, the **-sm_util** setting defaults to 1.0. By default, this option is off.

-sm_gate_equiv *gate_count*

Estimates the area as a soft macro with the specified number of equivalent gates. The command calculates an area by multiplying the specified *gate_count* with the area of the currently stored base gate area (either a default 2-input-nand gate area or one which has previously been updated using the **set_fp_base_gate** command) and then dividing by the currently-stored utilization factor (either the default value of 0.7 or the also-specified *sm_util* value).

Use the **set_fp_base_gate** command to change the area of the equivalent gate.

-sm_util util

Estimates the area as a soft macro with the specified utilization. You must also specify the **-sm_gate_equiv** option with a positive value for *gate_count* when you specify the **-sm_util** option. The default is 0.7 if the **-sm_size** or **-polygon** options are not specified.

-hard_macros names

Specifies a list of reference library hard macro names in a string with the names separated by spaces or commas. Each name can have an optional instance count. The instance count is specified as a number in parentheses () appended to the name. For example, to specify 10 instances of the mem macro use the **estimate_fp_black_boxes -hard_macros {mem(10)}** command.

The size estimation includes the area of all the hard macros in the specified list. This estimation mode does not consider the shapes of the actual hard macros.

-fixed_shape

Marks the black box as fixed shape after estimation.

-reset_shape

Resets the shape to rectangular if it is currently rectilinear.

black_boxes

Specifies the names of the black boxes to estimate.

DESCRIPTION

This command sets the estimated size of a black box based on the objects that it will contain when replaced with real logic. The estimation can be as a soft or hard macro. As a soft macro it has one, but not both, of the following characteristics:

- A size specified by using the **-sm_size** or **-polygon** option
- The number of gate-equivalent cells with utilization specified by using the **-sm_gate_equiv** option.

You can specify the utilization in any of the 3 cases: **-sm_size**, **-polygon**, or **-sm_gate_equiv**. As a hard macro the block has either a specified size set by using the **-sm_size** option, or a number of gate equivalent cells set by using the **-sm_gate_equiv** option.

If you do not use the **-hard_macros** option, then you must use the **-sm_size**, **-polygon**, or **-sm_gate_equiv** option. If you specify both the **-sm_size** and the **-sm_gate_equiv** options together, the *size* value takes precedence and the *gate_count* value is ignored; the *gate_count* value becomes a dependent variable that is calculated based on the *size* value. Similarly, if you specify both the **-polygon** and **-sm_gate_equiv** options together, the *polygon_area* value takes precedence and the *gate_count* value is ignored; the *gate_count* value becomes a dependent variable that is calculated based on the *polygon_area* value.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the 2-input NAND gate equivalent cell to nand2d1 and creates a black box estimate for macro alu1. The macro contains 12000 nand2d1 equivalents with a utilization of 0.7.

```
prompt> set_fp_base_gate -cell {nand2d1}
prompt> estimate_fp_black_boxes -sm_gate_equiv 12000 -sm_util 0.75 \
[get_cells -filter "is_physical_black_box==true" alu1]
```

The following example estimates a black box named alu1 to a rectilinear soft macro.

```
prompt> estimate_fp_black_boxes\  
-polygon {{1723.645 1925.365} {1723.645 1722.415} \  
{1803.595 1722.415} {1803.595 1530.535} \  
{799.915 1530.535} {799.915 1925.365} \  
{1723.645 1925.365}} \  
[get_cells -filter "is_physical_black_box==true" \  
I_ORCA_TOP/I_PCI_TOP] \  
[get_cells -filter "is_physical_black_box==true" alu1]
```

SEE ALSO

[get_cells\(2\)](#)
[set_fp_base_gate\(2\)](#)

exit

Terminates the application.

SYNTAX

```
integer exit  
  [exit_code]
```

Data Types

exit_code integer

ARGUMENTS

exit_code

Specifies the return code to the operating system. The default value is 0.

DESCRIPTION

This command exits from the application. You have the option to specify a code to return to the operating system.

EXAMPLES

The following example exits the current session and returns the code 5 to the operating system. At a UNIX operating system prompt, verify (**echo**) the return code as shown.

```
prompt> exit 5  
% echo $status  
5
```

SEE ALSO

[quit\(2\)](#)

extend_mw_layers

Extends Milkyway database layer number support to 4095 layers, using layers 4001 through 4095 as the system-reserved layers.

SYNTAX

status **extend_mw_layers**

DESCRIPTION

By default, the Milkyway database supports the usage of up to 255 layers, numbered 1 through 255. Layers 1 thorough 187 are available as user-defined layers and routing layers, while layers 188 through 255 are reserved for the Milkyway system layers.

Milkyway system layers are the layers used to define blockages, route guides, and other physical features that guide the router. The Milkyway system layer numbers are fixed and cannot be assigned or changed by the user. User-defined layers are layers defined in the technology (.tf) file, such as metal layers and text layers.

Some advanced process and routing technologies require more than 255 layers. In these cases, you can extend the number of layers supported in a Milkyway library by executing the **extend_mw_layers** command. In that case, layers 1 thorough 4000 are available as user-defined layers, while layers 4001 through 4095 are reserved for the Milkyway system layers.

In both the default and extended layer modes, routing layers are restricted to layer numbers 1 through 187. Routing layers are the standard layers used by the IC Compiler router to make interconnections, including wire routes, vias, and contacts.

To create a new Milkyway library using extended layers, you must execute the **extend_mw_layers** command before the **create_mw_lib** command. Once created in extended layer mode, the Milkyway library cannot be changed back to use the default layer mode.

In future sessions, the tool automatically recognizes the layer mode of the Milkyway library and uses the correct Milkyway system layer numbers, from 188 to 255 in the default mode or from 4001 to 4095 in the extended layer mode.

EXAMPLES

The following example shows the usage of the command to extend layer number support to 4095 layers and to use layers 4001 through 4095 as the system-reserved layers in a new Milkyway library.

```
prompt> extend_mw_layers
1
prompt> create_mw_lib -technology mytech.tf my_lib_2
Start to load technology file mytech.tf
...
```

SEE ALSO

`create_mw_lib(2)`

extract_physical_constraints

Extracts physical constraint information from one or more Design Exchange Format (DEF) files.

This command is supported only in Design Compiler in topographical mode.

SYNTAX

```
status extract_physical_constraints
  def_files
  [-verbose]
  [-no_incremental]
  [-exact]
  [-allow_physical_cells]
  [-standard_cell topo | spg]
```

Data Types

def_files list

ARGUMENTS

def_files

Specifies one or more DEF files from which the physical constraint information is extracted. This argument is required.

-verbose

Provides more detailed output during the process of extracting the physical constraints.

-no_incremental

Indicates that the command runs in non-incremental mode. By default, the command runs in incremental mode.

In incremental mode, the placement area is extracted based on the current core area and the site rows in the DEF file.

In non-incremental mode, the placement area is extracted based on the site rows in the DEF file. If there are no site rows in the DEF file, other constraints are not extracted, and the following physical constraints are reset:

- Core area
- Route guide
- Voltage area
- Layer preferred routing direction
- Die area
- Placement area
- Macro location and orientation

- Hard, soft, and partial placement blockages
- Wiring keepouts
- Placement bounds
- Port location
- Preroutes
- Site array information
- Vias
- Routing tracks
- Keepout margins

-exact

Specifies that an exact match is performed between the netlist and DEF file for cell and port names.

By default, a rule-based match is performed, with the underlying match rules determined by the **set_query_rules** command.

-allow_physical_cells

Specifies that physical-only cells are extracted from the DEF file and added to the design. A cell instance is considered a physical-only cell if the **cell_type** attribute of its library cell is **std_filler** or if it has only power and ground pins or no pins at all. Physical-only cells are not written to the ASCII netlist, and they are not passed to IC Compiler through the .ddc file. You can identify physical-only cells in the design by the **is_physical_only** attribute.

In addition to extracting physical-only cells from the DEF file, when you use the **-allow_physical_cells** option, the **extract_physical_constraints** command extracts any cell in the DEF file that is not found in the design if the cell has a fixed location. All other cells in the DEF file that are not considered to be physical-only cells are added to the design as logic cells. These cells can be ROM or RAM cells. When you run the **extract_physical_constraints -allow_physical_cells** command, the tool updates the current design with these new logic cells and includes them in your Verilog netlist.

The tool sets a **logical_cell_from_def** attribute on logic cells that are extracted from a DEF file. You can identify these logic cells by using the following command:

```
prompt> get_cells -hierarchical -filter "logical_cell_from_def == true"
```

By default, the tool ignores physical-only cells in the DEF file.

-standard_cell topo | spg

Reads the standard cell locations specified in the DEF file when you use the ASCII flow.

Specify **topo** if the DEF file was generated by using the Design Compiler topographical flow. Specify **spg** if the DEF file was generated by using the Design Compiler physical guidance flow.

DESCRIPTION

The **extract_physical_constraints** command extracts the physical constraint information from one or more DEF files and applies these constraints to the design.

The applied constraints are saved in the .ddc format and do not need to be reapplied in a new topographical mode session when the .ddc file is read in.

The saved constraints are recognized only by Design Compiler topographical mode; they have no effect in other tools, such as Design Compiler in wire load mode or IC Compiler.

Note that not all information in DEF files is extracted and applied to the design. Only the following types of information are extracted

and applied:

- Placement area
Placement area is computed based on the site array definition and is applied to the design.
- Port location
Each port with a location and port shape in the DEF file has the location and port shape set on the corresponding port in the design. Ports that do not exist in the design or do not have locations in the DEF file have no effect on the design.
- Cell location
Each cell with a location and a FIXED attribute in the DEF file has the location set on the corresponding cell in the design. Cells that do not exist in the design or do not have a location or FIXED attribute in the DEF file have no effect on the design.
- Placement blockage
Placement blockages are extracted as placement keepouts and are set on the design. For a single rectangle placement blockage in the DEF file, one placement keepout is created on the design. For placement blockages with multiple rectangles, one placement keepout is created for each rectangle. All created placement keepouts can be hard, soft, or partial keepouts.
- Site rows
The site row commands are extracted and applied if they exist in the DEF file.
- Bounds
If regions are defined in the DEF file, the placement bounds are extracted. Also, if there are cells in the related group attached to the region, the cells are matched using query rules with the ones in the design and the matched cells are attached to the bounds in the following ways:
 - If there are regions in the design with the same name in the DEF file, in incremental mode, the cells in the related group are attached to the region.
 - Otherwise, the region is created with the same name as in the DEF file and the matched cells in the related group are also attached.
- Wiring keepouts
Wiring keepouts are extracted in a manner similar to the way in which placement blockages are extracted.
- Preroutes
Preroutes are extracted from DEF and applied by default. Preroutes include net shapes, vias, and via arrays of matched contact codes, as well as via cells.

To check which physical constraints were applied to the design, use the **report_physical_constraints** command. To generate a Tcl script of the physical constraints, use the **write_physical_constraints** command.

EXAMPLES

The following example shows how to extract the physical constraints from a DEF file named in.def:

```
prompt> extract_physical_constraints in.def
```

```
write_physical_constraints(2)
update_bounds(2)
```

extract_rc

Executes virtual routing for nets in a design.

SYNTAX

```
status extract_rc  
-estimate
```

ARGUMENTS

-estimate

Performs RC estimation for nets in the design. For RC estimation, the command performs virtual routing and delay calculation and back-annotates the delay and capacitance on the current design. After running this command, you can use the **report_timing** command to see the estimated timing results. In Design Compile in Topographical mode, the **-estimate** option is required for the command to run.

DESCRIPTION

This command performs RC extraction for virtual routing of design nets. It calculates delay based on the Elmore delay model.

If you use the **set_tlu_plus_files** command to specify the TLUPlus technology files, the tool performs extraction based on TLUPlus technology.

If your physical library does not contain extraction parameters, the tool derives the resistance and capacitance values of routes from the available RC estimation method in your physical library. The tool issues the **RCEX-015** information message, which determines the RC estimation method that is used.

The command is available only in Design Compiler in topographical mode.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example performs virtual routing and updates back-annotated net delays.

```
prompt> extract_rc -estimate
```

SEE ALSO

`read_parasitics(2)`
`report_timing(2)`

filter

Returns a list of design objects that satisfy a conditional attribute expression.

SYNTAX

```
list filter
  object_list
  expression
  [-regexp]
  [-nocase]
```

Data Types

```
object_list    list
expression     string
```

ARGUMENTS

object_list

Specifies a list of design or library objects to filter.

expression

Specifies a conditional expression used to filter the object list in which attribute names are preceded by @ (at sign). For examples of typical expressions, see the "EXAMPLES" section. For a complete description of conditional expressions, refer to the dc_shell man page.

-regexp

Indicates that the real regular expressions are to be used by the =~ and !~ filter operators. By default, the =~ and !~ filter operators use simple wildcard pattern matching with the '*' and '?' wildcards.

-nocase

When used with the **-regexp** option, the pattern matching is case-insensitive. This option must be used with the **-regexp** option.

DESCRIPTION

The **filter** command selectively searches a group of objects and returns only those objects for which the conditional expression is true. The return of an empty list indicates that there are no objects in *object_list* for which the conditional expression is true. To use **filter** with Boolean values, the correct syntax is **true** and **false**. For a list of Synopsys attributes that can be used with **filter**, refer to the Design Compiler documentation.

The basic form of the conditional expression is a series of relations joined together with && and || operators. Parentheses are also supported. The basic relation contrasts an attribute name with a value through a relational operator. For example:

```
is_hierarchical == true && area <= 6
```

The relational operators are as follows:

==	Equal
!=	Not equal
>	Greater than
<	Less than
>=	Greater than or equal to
<=	Less than or equal to
=~	Matches pattern
!~	Does not match pattern

The basic relational rules are as follows:

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can only be compared with == and !=. The value can be only true or false.

Existence relations determine if an attribute is defined or not defined for the object. For example:

```
sense == setup_clk_rise && defined(@sdf_cond)
```

The existence operators are as follows:

defined
undefined

These operators apply to any attribute as long as it is valid for the object class.

For a complete description of conditional expressions, see the documentation for the tool.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care when you quote the filter expression. Using rigid quoting around regular expression pattern is recommended. See the "EXAMPLES" section for more details. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed. You can make the regular expression search case-insensitive by using the **-nocase** option.

EXAMPLES

The following example uses the **filter** command to return the bidirectional ports of the current design:

```
prompt> filter [get_ports *] \
    "@port_direction == inout"
{B1 B2}
```

The following example finds all of the designs in the system that are programmable logic arrays or state machines:

```
prompt> filter [get_designs *] \
    "@design_type == pla || @design_type == fsm"
{CONTROL COUNTER}
```

The following example finds all nets for which **dont_touch** is set to **true**:

```
prompt> filter [get_nets *] \
    "@dont_touch == true"
{N1 N9}
```

The following example finds all ports from in[18] to in[23]. The placement of double quotes and backslashes is necessary to avoid syntax errors.

```
prompt> filter [get_ports] \
    -regexp {@name=~ "in\[(([1][8-9]|2)[0-3])\]"}
{in[23] in[22] in[21] in[20] in[19] in[18]}
```

The following example finds the *U2* and *U4* cells, using the **-nocase** option:

```
prompt> filter [get_cells] -regexp \
    -nocase {@name =~ u[2,4]}
{U2 U4}
```

The following example uses wildcard characters to match the name. Wildcard characters can be used only with the `=~` and `!~` operators.

```
prompt> filter [get_cells] {@name =~ U?}
{U1 U2 U3 U4}
```

The following example finds all cells in the system that have the `**logic_0**` reference name. The `*` and `?` characters have special meanings when used with the `=~` and `!~` operators, allowing you to use the `==` operator for an exact match.

```
prompt> filter [get_cells] {@ref_name == **logic_0**}
```

filter_collection

Filters an existing collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

```
collection filter_collection
  [-regexp]
  [-nocase]
  collection1
  expression
```

Data Types

<i>collection1</i>	collection
<i>expression</i>	string

ARGUMENTS

-regexp

Specifies that the `=~` and `!~` filter operators will use real regular expressions. By default, the `=~` and `!~` filter operators use simple wildcard pattern matching with the `*` and `?` wildcards.

-nocase

Makes the pattern match case-insensitive.

collection1

Specifies the base collection to be filtered. This collection is copied to the result collection. Objects are removed from the result collection if they are evaluated as `false` by the conditional *expression* value. Substitute the collection you want for *collection1*.

expression

Specifies an expression with which to filter *collection1*. Substitute the string you want for *expression*.

DESCRIPTION

Filters an existing collection, resulting in a new collection. The base collection remains unchanged. In many cases, application commands that create collections support a `-filter` option that filters as part of the collection process, rather than after the collection has been made.

This type of filtering is almost always more efficient than using the **filter_collection** command after a collection has been formed. The **filter_collection** command is most useful if you plan to filter the same large collection many times using different criteria.

The **filter_collection** command results in either a new collection or an empty string. A resulting new collection contains the subset of

the objects in the input *collection1*. A resulting empty string (the empty collection) indicates that the *expression* filtered out all elements of the input *collection1*.

The basic form of the conditional expression is a series of relations joined together with AND and OR operators. Parentheses () are also supported. The basic relation compares an attribute name with a value through a relational operator.

For example,

```
is_hierarchical == true and area <= 6
```

If an attribute is a collection attribute, then you can query an attribute value from that object using "." to name the attribute on the other object. The "." operator can be chained. If the collection attribute refers to more than one object, then the expression is true if it is true for one of the objects referenced. While ":" is preferred, using ">" is also supported.

For example:

```
owner.is_hierarchical == true and owner.area <= 6
shape.net.name==reset
```

The value side of a relation can be a simple string, quoted string, or an attribute name prefixed with "@". For example:

```
input_delay<=@output_delay
input_delay<=0.24
name="@literal_name"
```

The relational operators are

==	Equal
!=	Not equal
>	Greater than
<	Less than
>=	Greater than or equal to
<=	Less than or equal to
=~	Matches pattern
!~	Does not match pattern

The basic relational rules are

- String attributes can be compared with any operator.
- Numeric attributes cannot be compared with pattern match operators.
- Boolean attributes can be compared only with == and !=. The value can be only either *true* or *false*.

Existence relations determine if an attribute is defined or not defined for the object. For example,

```
(sense == setup_clk_rise) and defined(sdf_cond)
```

The existence operators are

```
defined
undefined
!defined
```

These operators apply to any attribute as long as it is valid for the object class.

Collection attributes support a special sizeof(attrName) operator that returns the number of objects in the attribute. If the attribute is not set then 0 is returned.

The **filter_collection** command has a -regexp option that uses regular expressions when matching for string attributes. Regular expression matching is done in the same way as in the Tcl **regexp** command. When using the -regexp option, take care in the way you quote the filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended.

Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ":" to the beginning or end of the expressions as needed. You can make the regular expression search case-insensitive by using the -nocase option.

If the application variable filter_collection_extended_syntax is true then mathematical expressions are supported too. All function names must be prefixed with the '#' in order to disambiguate the function names from subscripted attribute names (i.e. "#sin(attr)"). In order to use a math expression on the right hand side of a comparison, the expression must be contained in parenthesis. This is required for backward compatibility with the legacy expression syntax as strings on the right do not require quoting.

When extended syntax is on filters can also match against glob style subscript patterns (i.e. "input_delay(*)<1.0"). In that case the term evaluates to true if any subscript satisfies the condition.

Additionally when extended syntax is on, a filter may refer to nested attributes that may imply multiple objects in a collection (i.e. "pins.capacitance==0.2"). In that case the term returns true if any of the objects referred to in the have an attribute value satisfying the condition.

EXAMPLES

The following example from PrimeTime creates a collection of only hierarchical cells.

```
prompt> set a [filter_collection [get_cells *] \
"is_hierarchical == true"]
{Adder1 Adder2}
```

The following example from PrimeTime uses existence operators to create a collection of all nonmoded cell timing_arc objects in the current design.

```
prompt> set b [filter_collection \
[get_timing_arcs -of_objects [get_cells *]] \
"undefined(mode)"]
```

The following example finds all cells from {U0(1) U1(1) U0(0) U1(0)} with the index (0). Notice the round brackets used for the index.

```
prompt> filter_collection -regexp [get_cells] {full_name =~ "U.*\((0\)"}
{U0(0) U1(0)}
```

The following example finds all ports from in[18] to in[23]. The placement of double quotes and backslashes is necessary to avoid syntax errors.

```
prompt> filter_collection [get_ports] -regexp {name=~ "in\[(1[8-9]|2[0-3])\]"}
{in[23] in[22] in[21] in[20] in[19] in[18]}
```

The following example finds the U2 and U4 cells, using the -nocase option:

```
prompt> filter_collection [get_cells] -regexp -nocase {name =~ u[24]}
{U2 U4}
```

find

Finds a design or library object.

SYNTAX

```
list find
  type
  [name_list]
  [-hierarchy]
  [-flat]
```

Data Types

<i>type</i>	one-of-string
<i>name_list</i>	list

ARGUMENTS

type

Specifies the type of object to find. The value of *type* can be any of the following:

design	clock
port	reference
cell	net
pin	cluster
rp_group	library
lib_cell	lib_pin
multibit	operator
module	implementation
file	

The value can also be **physnet**, **physcell**, or **physport** for physical objects.

name_list

Specifies a list of names of design or library objects in dc_shell to find. If you do not specify *name_list*, all objects of the specified type are returned.

-hierarchy

Specifies to return all objects matching *type* and *name_list* within the current design hierarchy. The full name of the object at a particular level must match the patterns. The search is similar to the UNIX **find** command. For example, if there is a cell named *block1/adder*, a hierarchical search finds it using *adder*. If you use the **-hierarchy** option, the *type* must be either **design**, **lib_cell**, **net**, **cell**, or **pin**.

-flat

Specifies that the command finds only objects in leaf cells. You must specify **-flat** with the **-hierarchy** option.

DESCRIPTION

The **find** command locates and returns a list of design or library objects in dc_shell. The command returns all of the design or library objects of the given *type* that match the names specified in the *name_list*. If no objects are found, the return value is an empty list ({}).

In Tcl-based dc_shell, the **find** command returns a collection.

The **find** command is generally used as a parameter to another dc_shell command. In this case, the parameters of **find** must be enclosed in parentheses to separate them from the parameters of the other command.

The **find** command is used to resolve name conflicts for commands that accept objects of more than one type. For example, the **set_dont_touch** command accepts design cells, nets, references, clusters, and library cells as arguments. If the current design contains both a net and cell named *interrupt* the name *interrupt* does not specify a unique object. Depending on the type of object expected, *interrupt* can mean the net interrupt or the cell interrupt. Resolve this explicitly with the following command:

```
prompt> set_dont_touch find (net, interrupt)
```

Naming Conventions

A consistent naming convention is used to refer to design and library objects by all of the commands in dc_shell. In most cases, the referenced object exists in the current design and can be identified by using its simple name. More complex cases can be handled by including a library specification prefix. This prefix allows you to reference objects in any library and objects in the current design. The design specification prefix is separated from the simple object name with a / (slash).

In the following example, the *MUX51HP* cell in the *lsi_10k* library is returned:

```
prompt> find cell lsi_10k/MUX51HP
{A}
```

You can uniquely identify any design or library object in dc_shell by also specifying the design file in the design specification prefix. This portion of the name is delimited by a : (colon). Do this only when you have two designs (or libraries) with the same name that originated from different file names, as in the following example:

```
prompt> find port /project/ADDER.db:ADDER/A
{A}
```

Objects are subordinate to a design or library object. The types of objects that are contained in a design object are ports, references, clocks, cells, nets, pins, clusters, and Relative Placement (RP) groups. The types of objects contained in a library object are lib_cells, modules, implementations, and pins.

To find an object that might exist in a design or a library, a search order is implied. The following example shows the search procedure that **find** uses to locate objects:

```
prompt> find cell ADDER/A
```

To determine the object that **find** returns depends on a two-step search:

1. Search the current design for a cell named *ADDER/A*. If one exists, return it.
2. Extract the library specification and search for the library *ADDER*. Search the *ADDER* library for a cell named *A*. If one exists, return that cell name. Otherwise, return an empty list.

You can use the wildcard character * (asterisk) to match any number of characters in a name, or you can use ? (question mark) to match a single character. For example, *u** specifies all object names that begin with the letter *u*. Specifying *u*z* returns all object names that begin with the letter *u* and end with the letter *z*. Specifying *u?v* returns all object names that begin with the letter *u* and end with letter *v* matching any single character in the middle.

Wildcard characters must be escaped using double backslashes (\\\) to remove their special regular expression meaning. For example, *u*z* specifies any object with the name *u*z*. For more details about escaping wildcards refer to the **wildcards** variable man page.

Implicit Find Command

Commands that accept design or library object arguments perform an implicit **find** for each argument that is not already an explicit find. For example, the **set_input_delay** command accepts only port objects. Therefore, the following two commands are equivalent:

```
prompt> set_input_delay IN1 10
prompt> set_input_delay find (port, IN1) 10
```

The implicit **find** operation is different for commands that accept more than one object type. In this case, each object type is searched (in order) for a match to the name. The search ends when a match is found. For example, the following command first looks for a cell named *X*, then a net named *X*, next a reference named *X*, and finally a library cell named *X*:

```
prompt> set_dont_touch X
```

The implicit **find** operation is different for commands that operate only on bus objects. In this case, each object type is searched (in order) for a match to the name. It first searches ports, and then searches nets. The search of object types ends when a match is found. If one of the objects found is a bus object, it is among the objects returned in the list. If one of the objects found is not a bus object, it is among the objects returned only if it is not a member of a bus object. For example, the following command first looks for ports with names that begin with the letter *X*, then for nets with names that begin with the letter *X*:

```
prompt> remove_bus X*
```

If there are ports named XJ1, XJ2, XK1, XK2, XL1, and XL2, and there are port buses named XJ (with members XJ1 and XJ2) and XK (with members XK1 and XK2), the objects returned are ports XL1, and XL2, and the port buses XJ and XK. Nets are not searched for because ports are found.

Hierarchical Find Command

The **-hierarchy** option to **find** returns all objects within the hierarchy of the current design that meet the *type* and *name_list* criteria.

The impact of each allowed *type* used in conjunction with the **-hierarchy** option is described as follows:

find design -hierarchy

Returns all design objects referenced within the hierarchy of the current design.

find lib_cell -hierarchy

Returns all lib_cell objects referenced within the hierarchy of the current design.

find net -hierarchy

Returns all instances of nets within the hierarchy of the current design.

find cell

Returns all instances of cells within the hierarchy of the current design.

find pin

Returns all instances of pins within the hierarchy of the current design.

Adding a *name_list* in each of the previous cases further restricts the returned objects to a given name.

EXAMPLES

The following example finds the *N1* net in the current design:

```
prompt> find net N1
{N1}
```

The following example uses the * (asterisk) wildcard character to find all cells in the current design that begin with *U*:

```
prompt> find cell U*
```

```
{U0, U1, U2, U3, U4, U5, U6, U7}
```

The following example finds the *CACHE/MEM* cluster in the current design:

```
prompt> find cluster CACHE/MEM
          {MEM}
```

The following example uses a library prefix to find the *IVA* cell in the *tech_lib* library and sets the **dont_use** attribute:

```
prompt> set_dont_use tech_lib/IVA
```

The following example finds all pins of the *U8* cell:

```
prompt> find pin U8/*
          {U8/A, U8/Z}
```

The following example sets the **dont_touch** attribute for design reference *adder* of the current design:

```
prompt> set_dont_touch find (reference, adder)
```

The following example sets the **dont_touch** attribute for *datapath* cluster of the current design:

```
prompt> set_dont_touch find (cluster, datapath)
```

In the following example, the specified object is not found and a warning is returned:

```
prompt> find port A1
          Warning: Can't find port 'A1' in design 'adder'
          {}
```

If you specify multiple names, **find** returns all of the objects found, and a warning is returned for those not found:

```
prompt> find design {add, hadd, fadd}
          Warning: Can't find design 'hadd'
          {add, fadd}
```

The following example shows how to prefix a name with a full file specification:

```
prompt> find cell /project/ripple/lookahead/TOP.db:MULTX
          {MULTX}
```

The following examples show the use of **find** where *type* has the value of **file**:

```
prompt> list -files
      File           Path
      ---           ---
      adder.db       /remote/usr4/joeuser/designs
      clock.db       /remote/usr4/joeuser/designs
      1
```

```
prompt> find file "adder.db"
          {adder.db}
```

```
prompt> find file "mux.db"
          Error: Can't find file 'mux.db'. (UID-109)
          {}
```

```
prompt> remove_design find(file,"clock.db")
          Removing file 'clock.db'
          design 'TOP'
          design 'MUX'
          design 'TIME_BLOCK'
          design 'TIME_STATE_MACHINE'
          design 'TIME_COUNTER'
          design 'TIME_COUNTER_DW01_inc_n6_0'
          design 'ALARM_BLOCK'
```

```

design 'ALARM_COUNTER'
design 'ALARM_COUNTER_DW01_inc_n6_0'
design 'ALARM_STATE_MACHINE'
design 'ALARM_SM_2'
design 'CONVERTOR_CKT'
design 'CONVERTOR'
design 'HOURS_FILTER'
design 'COMPARATOR'
1

```

If you specify **-hierarchy** using **design** as the value of **type**, all designs referenced within the current design are returned as shown in the following example:

```

prompt> find design -hierarchy
{HALF_SUBTRACTOR FULL_SUBTRACTOR SUBTRACTOR}

```

The following example returns all instances of cells that begin with the letter *U* in the hierarchy of the current design:

```

prompt> find -hierarchy cell "U*"
{U1MY_CELL/U1MY_CELL/U2U1/EXAMPLE/U33}

```

The following example returns all instances of leaf cells that begin with *U1* in the hierarchy of the current design:

```

prompt> find -flat -hierarchy cell "U1*"
{U4/U10 U4/U11 U4/U12 U1/U2/U132 U1/U2/U131 U6/U10}

```

The following example returns all multibit components that begin with *U1* in the current design:

```

prompt> find multibit "U*"
{U2 U4_multibit}

```

The following example in Tcl mode returns and displays a collection using the implicit query property:

```

prompt> find cell U*
{U1 U2 U345}

```

The following example in Tcl mode sets variable *a* to contain a collection. The implicit query property of **find** in Tcl mode returns the collection, even though the name assigned to the collection is *-se11*, as shown by using the **echo** command:

```

prompt> set a [find cell U*]
{U1 U2 U345}
prompt> echo $a
"_se11"

```

find_objects

Finds logical hierarchy objects within a scope. This is a UPF query command.

SYNTAX

```
list find_objects
  scope
  -pattern pattern_string
  -object_type inst | port | net | model | supply_port | process
  [-direction in | out | inout]
  [-transitive true | false]
  [-non_leaf]
  [-leaf_only]
  [-traverse_macros]
  [-ignore_case]
  [-regexp | -exact]
```

Data Types

<i>scope</i>	string
<i>pattern_string</i>	string

ARGUMENTS

scope

Specifies the scope within in to search for logical hierarchy objects.

-pattern *pattern_string*

Specifies a search pattern. By default, the pattern is treated as a Tcl glob expression.

-object_type **inst | **port** | **net** | **model** | **supply_port** | **process****

Searches only for the specified object type.

The keyword values have the following definitions:

- **inst** (cell instance)
- **port** (design port)
- **net** (net)
- **model** (model or lib cell)
- **supply_port** (UPF supply port or P/G pin)
- **process** (VHDL process)

If **object_type model** is specified, **find_objects** searches for instances of any model and lib cell whose name matches the

`search_pattern`. If **object_type** is specified with any other value then **find_objects** searches the logic hierarchy for the specified objects whose name matches the `search_pattern`.

-direction in | out | inout

Restricts the direction of the searched ports.

This option has an effect only when ports are included in the search.

-transitive true | false

Controls whether the descendants of the elements are included in the search.

By default (**false**), the descendants are not included in the search.

-non_leaf

Limits the search to only nonleaf design elements (elements that have child elements).

If you do not specify the **-non_leaf** or **-leaf_only** option, the command searches for both leaf and nonleaf design elements.

-leaf_only

Limits the search to only leaf-level design elements (elements without child elements).

If you do not specify the **-non_leaf** or **-leaf_only** option, both leaf and nonleaf design elements are searched.

-traverse_macros

By default, during a search, the tool will not descend past the boundary of hierarchy marked as "**terminal boundary**" or as "**soft macro**". The **-traverse_macros** option can be used to override the default behavior, allowing the tool to continue searching into said hierarchy.

When the **-traverse_macros** option is used, the search will be performed as if the **-transitive** option was set to TRUE.

-ignore_case

Performs case-insensitive pattern matching. By default, all pattern matches are case sensitive.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `.*` to the beginning or end of the expressions, as needed.

The **-regexp** and **-exact** options are mutually exclusive. You can specify only one of these options.

-exact

Disallow wildcard expansion on the specified `search_pattern`. When this option is not used, `search_pattern` is interpreted as a Tcl glob expression.

The **-regexp** and **-exact** options are mutually exclusive. You can specify only one of these options.

DESCRIPTION

The **find_objects** command finds logical hierarchy objects within a scope. It returns a list of the found hierarchical names relative to the active scope. When nothing is found, it returns a null string.

This is a UPF query command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Here are some examples of usage of the command with different options.

```
prompt> find_objects a -pattern * -object_type inst \
           -transitive TRUE -non_leaf
a/b1 a/b2

prompt> find_objects a/b2 -pattern b_? -object_type net
a/b2/b_i a/b2/b_o

prompt> find_objects a/b1 -pattern * -object_type port \
           -transitive TRUE -direction out
a/b1/c1/Z a/b1/c2/Z a/b1/b_o

prompt> find_objects . -object_type model -pattern b* -non_leaf \
           -transitive TRUE
a/b1 a/b2 b1

prompt> find_objects . -object_type model -pattern b* -non_leaf \
           -transitive TRUE -exact
Warning: Can't find module or lib cell 'b*' in design 'top'. (UID-95)

prompt> find_objects . -object_type model -pattern bot -non_leaf \
           -transitive TRUE -exact
a/b1 a/b2 b1
```

fix_mv_design

Fixes multivoltage and PVT violations of buffers in a design.

SYNTAX

```
status fix_mv_design
  [-buffer]
  [-from objects]
  [-lib_cells lib_cells]
  [-verbose]
```

Data Types

lib_cells list of library cells

ARGUMENTS

-buffer

Instructs the command to operate on buffers. In the current version, this is the only supported mode and the argument must be provided.

-from *objects*

Specify the buffer trees that the **fix_mv_design -buffer** command should work on. If input is a pin, it specifies the driver pin of a full or partial buffer tree. If input is a net, its driver pin specifies a full or partial buffer tree.

-lib_cells *lib_cells*

Specify a list of single-rail and dual-rail buffer or inverter library cells that the **fix_mv_design -buffer** command can use. The command does not use any library cells that are not in this list. The tool keeps the existing library cells used by buffers or inverters if they do not need to be fixed.

-verbose

Displays detailed information of each buffer tree modified by the command.

DESCRIPTION

The **fix_mv_design** command with the **-buffer** option will replace single-rail buffers and inverters with dual-rail equivalents, and vice versa, as necessary to match the backup connections that the tool has derived for the design. These mismatches, if they exist, will be reported as MV-076/MV-078/MV-080/MV-082 warnings in the **check_mv_design** report. If no such mismatches exist, no changes will be made.

This fixing operation is performed automatically as part of **compile_ultra**, so this command will have no effect on a design which has been compiled. However, if manual edits have been made to the netlist, or if an external netlist is loaded, then the command may be

useful.

EXAMPLES

When run on a design with no always-on violations, the command will make no changes and return no messages.

```
prompt> fix_mv_design -buffer  
1
```

If some violations existed, then changes will be reported:

```
prompt> fix_mv_design -buffer  
Information: 2 single-rail buffers have been replaced with dual-rail buffers. (MV-860)  
1
```

[set_always_on_strategy\(2\)](#)

foreach

Specifies the control structure for list traversal loop execution.

SYNTAX

status **foreach**

ARGUMENTS

The **foreach** command has no arguments.

DESCRIPTION

This command iteratively executes commands while successively setting the *variable_name* argument to each member of *list_expression*. Note that this changes the type of the *variable_name* argument for each iteration of the loop.

The *list_expression* argument is evaluated upon execution and converted to a list-type expression, as appropriate. Commands in *loop_statement_block* are executed once for each member in the list that results from evaluating the *list_expression* argument. On each loop iteration, the *variable_name* argument is set to each successive member in the list.

The variable specified by the *variable_name* argument and its value remain after the loop terminates. If the **foreach** command is used within a user-defined function, the *variable_name* variable is local to that function.

The return value of the **foreach** command is the return value of the last command executed. If no commands execute, the return value is 0.

The **break** and **continue** commands modify the standard execution of the **foreach** command. See the **break** and **continue** command man pages for more information.

You can redirect the output of the **foreach** command to a file. This file contains the output of any commands executed in the body of the **foreach** command.

EXAMPLES

The following example uses the **foreach** command to print the elements of a simple list:

```
prompt> set mylist {I1/FF3/D I1/FF4/D I1/FF5/D}
I1/FF3/D I1/FF4/D I1/FF5/D

prompt> foreach i $mylist {echo $i}
I1/FF3/D
```

I1/FF4/D
I1/FF5/D

SEE ALSO

`break(2)`
`continue(2)`
`if(2)`
`while(2)`

foreach_in_collection

Iterates over the elements of a collection.

SYNTAX

```
string foreach_in_collection
      itr_var
      collections
      body
```

Data Types

<i>itr_var</i>	string
<i>collections</i>	list
<i>body</i>	string

ARGUMENTS

itr_var

Specifies the name of the iterator variable.

collections

Specifies a list of collections over which to iterate.

body

Specifies a script to execute per iteration.

DESCRIPTION

The **foreach_in_collection** command is used to iterate over each element in a collection. You cannot use the Tcl-supplied **foreach** command to iterate over collections because the **foreach** command requires a list, and a collection is not a list. Also, using the **foreach** command on a collection causes the collection to be deleted.

The arguments for the **foreach_in_collection** command parallel those of the **foreach** command: an iterator variable, the collections over which to iterate, and the script to apply at each iteration. All arguments are required.

Note: The **foreach_in_collection** command does not allow a list of iterator variables.

During each iteration, the *itr_var* option is set to a collection of exactly one object. Any command that accepts *collections* as an argument also accepts *itr_var* because they are of the same data type (collection).

You can nest the **foreach_in_collection** command within other control structures, including another **foreach_in_collection** command.

Note that if the body of the iteration is modifying the netlist, it is possible that all or part of the collection involved in the iteration will be deleted. The **foreach_in_collection** command is safe for such operations. If a command in the body causes the collection to be removed, at the next iteration, the iteration ends with a message indicating that the iteration ended prematurely.

An alternative to collection iteration is to use complex filtering to create a collection that includes only the desired elements, then apply one or more commands to that collection. If the order of operations does not matter, the following are equivalent. The first is an example without iterators.

```
set s [get_cells {U1/*}]
command1 $s
command2 $s
unset s
```

The following is a similar approach using the **foreach_in_collection** command:

```
foreach_in_collection itr [get_cells {U1/*}] {
    command1 $itr
    command2 $itr
}
```

For collections with large numbers of objects, the non-iterator version is more efficient, though both produce the same results if the commands are order-independent.

EXAMPLES

The following example from PrimeTime removes the wire load model from all hierarchical cells in the current instance.

```
prompt> foreach_in_collection itr [get_cells *] {
?      if {[get_attribute $itr is_hierarchical] == "true"} {
?          remove_wire_load_model $itr
?      }
?  }
```

Removing wire load model from cell 'i1'.
Removing wire load model from cell 'i2'.

SEE ALSO

[collections\(2\)](#)
[foreach\(2\)](#)

generate_mv_constraints

Generates new isolation strategies for design elements.

SYNTAX

```
status generate_mv_constraints
  [-align_isolation_clamp_value]
  [-no_isolation]
  [-output output_file_name]
  [-include_elements]
  [-apply]
  [-elements element_list]
```

Data Types

<i>output_file_name</i>	string
<i>element_list</i>	list

ARGUMENTS

-align_isolation_clamp_value

Optional Argument. Enables the **generate_mv_constraints** command to try to align the isolation clamp value for the constant elements.

-no_isolation

Optional Argument. Enables the **generate_mv_constraints** command to create no isolation strategies for elements where redundant isolation cells would be inserted.

-output *output_file_name*

Optional argument which tells **generate_mv_constraints** where to write out the newly created strategies. If the file specified exists, it is overwritten.

-include_elements

Optional argument, used in conjunction with the **-align_isolation_clamp_value** option. By default, the **generate_mv_constraints** command does not attempt to correct any elements specified in the **-elements** option of the **set_isolation** command to align with the isolation clamp value. When specified, the tool modifies the user-defined isolation strategies having **-elements** by removing any constant elements not matching the isolation clamp value and adding them to the tool derived isolation strategies with the clamp value aligned to the constant value of the element. It is an optional argument.

-apply

If specified, applies all the newly created strategies to the design in memory. It is an optional argument.

-elements *element_list*

list of design objects that are going to be processed by the command. Accepts pins, ports and cells references.

DESCRIPTION

The purpose of this utility is to help refine the user UPF before inserting isolation cells.

The **-no_isolation** option helps reduce the number of redundant isolation cell that would be inserted by assigning **-no_isolation** isolation strategies to design elements where such redundant isolation cells would be inserted.

The **-elements** option is required when using the **-no_isolation** option and cannot be used without it

The **-align_isolation_clamp_value** option analyzes the isolation strategies and derives new isolation strategies for the elements whose driving constant value is different than the specified isolation clamp value.

The **-align_isolation_clamp_value** option must be used before isolation cell insertion takes place, otherwise back-to-back isolation cell might appear and/or previously associated isolation cells might become unassociated.

The **-align_isolation_clamp_value** option does not align the clamp value of elements where the current applying isolation strategy that was created using the **-no_isolation** (from the **set_isolation** command) or the **-force_isolation** option or with a **-clamp_value\dp other than 0 or 1**.

The **-align_isolation_clamp_value** option and the **-no_isolation** option are mutually exclusive.

generate_mv_constraints requires the design and UPF data to be loaded.

The tool derived strategies are written to the output file specified with the **-output** option. In addition to the **set_isolation** constraint, the utility also emits the **set_isolation_control** constraint for these new strategies. However, no **map_isolation_cell** constraint are emitted and the **UPF-442** message is printed. You need to add a relevant **map_isolation_cell** constraint.

The tool derived strategies can also be applied to the netlist in memory when **-apply** option is specified.

EXAMPLES

Following examples show different usages of **generate_mv_constraints** command and the outcome.

```
prompt> generate_mv_constraints
Error: Required argument '-align_isolation_clamp_value' was not found. (CMD-007)
```

```
prompt> generate_mv_constraints -align_isolation_clamp_value
Error: Either '-output' or '-apply' needs to be specified. (UPF-445)
```

Following shows the behavior when **generate_mv_constraints** command is called without loading any UPF constraint.

```
prompt> generate_mv_constraints -align_isolation_clamp_value
Error: Isolation clamp value is not aligned, as there is no UPF data. (UPF-440)
```

Following shows the behavior when **generate_mv_constraints** command identifies a constant with non-matching clamp value.

The user-provided UPF has the following isolation constraint where element u1/cin is driven by constant 0.

```
prompt> set_isolation iso1 \
    -domain CARRY -applies_to inputs \
    -isolation_power_net VDD -isolation_ground_net GND \
    -clamp_value 1
prompt> set_isolation_control iso1 \
    -domain CARRY -isolation_signal ctrl \
    -location self -isolation_sense low

prompt> generate_mv_constraints -align_isolation_clamp_value \
    -output align.upf
```

1

The output file align.upf is as follows:

```
# Created by DC Utility for non-matching isolation clamp and driving constant value.

# List of new strategies created with clamp value matching the constant isolating it, for strategies with no user specified element list
set_isolation iso1_clamp0 -domain CARRY -isolation_power_net VDD -isolation_ground_net GND -elements u1/cin -clamp_value 0 -
set_isolation_control iso1_clamp0 -domain CARRY -isolation_signal ctrl -isolation_sense low -location self
```

Following shows the behavior when **generate_mv_constraints** command identifies a constant with nonmatching clamp value.

The user-supplied UPF has the following isolation constraint where element u1/cin is driven by constant 0.

```
prompt> set_isolation iso1 \
           -domain CARRY -applies_to_inputs \
           -elements {u1/cin u1/carry} -clamp_value 1
prompt> set_isolation_control iso1 \
           -domain CARRY -isolation_signal ctrl \
           -location self -isolation_sense low

prompt> generate_mv_constraints -align_isolation_clamp_value \
           -output align.upf -include_elements
1
```

The output file align.upf is as follows:

```
# Created by DC Utility for non-matching isolation clamp and driving constant value.

# List of user strategies modified
set_isolation iso1_modified -domain CARRY -isolation_power_net VDD -isolation_ground_net GND -elements u1/carry -clamp_value
set_isolation_control iso1_modified -domain CARRY -isolation_signal ctrl -isolation_sense low -location self

# List of new strategies created with clamp value matching the constant isolating it, for strategies with user specified element list
set_isolation iso1_clamp0 -domain CARRY -isolation_power_net VDD -isolation_ground_net GND -elements u1/cin -clamp_value 0 -
set_isolation_control iso1_clamp0 -domain CARRY -isolation_signal ctrl -isolation_sense low -location self
```

generate rtl upf

Writes out the design's UPF power intent as a UPF command script in DC Explorer.

SYNTAX

```
status generate_rtl_upf  
    -path path_name
```

Data Types

path_name string

ARGUMENTS

DESCRIPTION

The **generate_rtl_upf** command creates a modified version of the input UPF file from the user. User-specified UPF commands that are not supported by DC Explorer are commented out, and UPF commands derived by the tool for auto-isolation insertion, such as **set_isolation**, **set_isolation_control**, **create_pst**, **add_pst_state**, and **add_power_state**, are added. The output UPF file reflects the power intent of the design as seen by DC Explorer for the **compile_exploration** command.

The **generate_rtl_upf** command should be called immediately after all of the user's UPF power intent has been loaded.

The tool appends the .de_upf_rtl suffix to the original UPF file names as the output file names generated by the **generate_rtl_upf** command.

EXAMPLES

The following example saves the full UPF power intent of the design in a file in the current directory. The resulting UPF file name is top.upf.de_upf_rtl.

```
prompt> load_upf top.upf  
prompt> generate_rtl_upf -path ./
```

SEE ALSO

[load_upf\(2\)](#)

```
save_upf(2)
```

get_alternative_lib_cells

Creates a collection of equivalent library cells for a specified cell or library cell.

SYNTAX

```
collection get_alternative_lib_cells
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-libraries libraries]
  pattern_or_objects
```

Data Types

<i>expression</i>	string
<i>libraries</i>	string
<i>pattern_or_objects</i>	string

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *pattern_or_objects* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns_or_objects* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each library cell in the collection, the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

To see the list of library cell attributes that you can use in the expression, use the **list_attributes -application -class lib_cell** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-libraries libraries

Specifies a list of libraries from which to select equivalent library cells. You can specify a list of library names or a collection of libraries loaded into memory.

If you do not specify this option, the command traverses the link path to find libraries. In this case, if a library is found with a minimum library relationship (which is determined from the setting in the **set_min_library** command), the minimum library is automatically included.

pattern_or_objects

Specifies the cells or library cells for which to return equivalent library cells.

Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

This is a required option.

DESCRIPTION

This command creates a collection of library cells that are logically similar to the specified cell or library cell and pass the filter, if specified. This collection can be used to replace or resize the specified cell in the current design.

If the command cannot find any logically similar library cells for the specified cell and the current design is not linked, the design automatically links.

The command returns a collection if any library cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the equivalent library cells for the slow/AND2X2 library cell.

```
prompt> set libcelsel [get_lib_cells slow/AND2X2]
{slow/AND2X2}

prompt> [get_alternative_lib_cells $libcelsel]
```

```
{slow/AND2X1 slow/AND2X6 slow/AND2X12}
```

The following example queries the equivalent library cells for the top/U21 cell instance.

```
prompt> set celsel [get_cell top/U21]
{top/U21}

prompt> [get_alternative_lib_cells $celsel]
{slow/AND2X1 slow/AND2X2 slow/AND2X6 slow/AND2X12}
```

get_always_on_logic

Returns a collection of cells and nets on the always-on paths in the design.

SYNTAX

```
collection get_always_on_logic
  [-cells]
  [-nets]
  [-all]
  [-boundary]
```

ARGUMENTS

-cells

Returns the buffers and inverters on the always-on paths.

-nets

Returns the nets on the always-on paths.

-all

Returns the nets, buffers, and inverters on the always-on paths. This is the default behavior when no argument is specified.

-boundary

Returns the isolation and level-shifter cells on the boundary of the always-on paths.

DESCRIPTION

This command creates a collection of nets and cells on the always-on paths. The always-on paths are paths that must always be powered up during the operation of the system. The always-on paths consist of logic cones that terminate on always-on pins in the design. Examples of always-on pins are the enable pin of isolation cells and special control pins of retention registers.

You can mark any pin of a cell instance with an always-on attribute by using the **set_attribute** command. You can create power-down regions by using the **create_power_domain** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns the always-on nets, buffers, and inverters in the design.

```
prompt> get_always_on_logic
```

The following example returns the always-on nets, buffers, inverters, boundary level-shifter cells, and isolation cells in the design.

```
prompt> get_always_on_logic -boundary
```

The following example returns the always-on nets, boundary level-shifter cells and isolation cells in the design.

```
prompt> get_always_on_logic -nets -boundary
```

The following example returns the always-on buffers, inverters, boundary level-shifter cells, and isolation cells in the design.

```
prompt> get_always_on_logic -cells -boundary
```

The following example returns the always-on nets, buffers, inverters, boundary level-shifter cells, and isolation cells in the design.

```
prompt> get_always_on_logic -nets -cells -boundary
```

`set_attribute(2)`

get_app_var

Gets the value of an application variable.

SYNTAX

```
string get_app_var
  [-default | -details | -list]
  [-only_changed_vars]
  var
```

Data Types

var string

ARGUMENTS

-default

Gets the default value.

-details

Gets additional variable information.

-list

Returns a list of variables matching the pattern. When this option is used, then the *var* argument is interpreted as a pattern instead of a variable name.

-only_changed_vars

Returns only the variables matching the pattern that are not set to their default values, when specified with **-list**.

var

Specifies the application variable to get.

DESCRIPTION

The **get_app_var** command returns the value of an application variable.

There are four legal forms for this command:

- **get_app_var <var>**
Returns the current value of the variable.

- `get_app_var <var> -default`
Returns the default value of the variable.
- `get_app_var <var> -details`

Returns more detailed information about the variable. See below for details.

- `get_app_var -list [-only_changed_vars] <pattern>`

Returns a list of variables matching the pattern. If `-only_changed_vars` is specified, then only variables that are changed from their default values are returned.

In all cases, if the specified variable is not an application variable, then a Tcl error is returned, unless the application variable `sh_allow_tcl_with_set_app_var` is set to true. See the `sh_allow_tcl_with_set_app_var` man page for details.

When `-details` is specified, the return value is a Tcl list that is suitable as input to the Tcl `array set` command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key, and each even-numbered element in the list is the value of the previous key.

The supported keys are as follows:

name

This key contains the name of the variable. This key is always present.

value

This key contains the current value of the variable. This key is always present.

default

This key contains the default value of the variable. This key is always present.

help

This key contains the help string for the variable. This key is always present, but sometimes the value is empty.

type

This key contains the type of the application variable. Legal values of for this key are: string, bool, int, real. This key is always present.

constraint

This key describes additional constraints placed on this variable. Legal values for this key are: none, list, range. This key is always present.

min

This key contains the min value of the application variable. This key is present if the constraint is range. The value of this key may be the empty string, in which case the variable only has a max value constraint.

max

This key contains the max value of the application variable. This key is present if the constraint is "range". The value of this key may be the empty string, in which case the variable only has a min value constraint.

list

This key contains the list of legal values for the application variable. This key is present if the constraint is "list".

EXAMPLES

The following are examples of the **get_app_var** command:

```
prompt> get_app_var sh_enable_page_mode
1

prompt> get_app_var sh_enable_page_mode -default
false

foreach {key val} [get_app_var sh_enable_page_mode -details] { echo "$key: $val"
}
=> name: sh_enable_page_mode
value: 1
default: false
help: Displays long reports one page at a time
type: bool
constraint: none

prompt> get_app_var -list sh_*message
sh_new_variable_message
```

SEE ALSO

[report_app_var\(2\)](#)
[set_app_var\(2\)](#)
[write_app_var\(2\)](#)

get_attribute

Returns the value of an attribute on a list of design or library objects.

SYNTAX

```
list get_attribute
  object_list
  attribute_name
  [-bus]
  [-quiet]
  [-return_null_values]
```

Data Types

object_list list
attribute_name string

ARGUMENTS

object_list

Specifies a list of the design or library objects for which the attribute value is returned.

attribute_name

Specifies the name of the attribute whose value is returned.

-bus

Returns the value of the attribute that is on the bus as a whole, and not on each individual bus member.

-quiet

Turns off the warning message that is otherwise issued if the attribute or objects are not found.

-return_null_values

Returns an empty string for failed objects when the *object_list* argument contains multiple objects.

DESCRIPTION

This command searches the *object_list* for the specified attribute and returns a list of attribute values. By default, if a specified object cannot be found or the attribute does not exist on the object, that object is ignored. If you use the **-return_null_values** option, the command returns an empty string.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example gets the value of the **rise_drive** attribute for the IN1 port.

```
prompt> get_attribute [get_ports IN1] rise_drive  
0.25
```

The following example gets the value of the **load** attribute for all ports whose names begin with OUT:

```
prompt> get_attribute get_ports OUT* load  
1.0 2.0 2.5 1.0
```

The following example gets the value of the **area** attribute for the G1 and G2 cells in the tech_lib library:

```
prompt> get_attribute {tech_lib/G1 tech_lib/G2 } area  
1.0 2.0
```

The following example sets a user-defined attribute named X on some cells and then uses **get_attribute** commands to retrieve this attribute value, as well as the value of an application attribute.

```
prompt> define_user_attribute -type int -class cell X  
X  
prompt> set_attribute [get_cells *] X 30  
Information: Attribute 'X' is set on 2 objects. (UID-186)  
i1 i2  
prompt> foreach_in_collection sel [get_cells *] {  
echo -n "On '[get_attribute $sel full_name]', "  
echo "X = [get_attribute $sel X]"  
}  
On 'i1', X = 30  
On 'i2', X = 30
```

In the following example, the **-return_null_values** option returns an empty string when the tool cannot find the attributes for some objects.

```
prompt> get_attribute [get_cells {cell1 cell2 cell3}] area  
Warning: Attribute 'area' does not exist on cell 'cell2' (ATTR-3)  
79.833600 79.833600  
  
prompt> get_attribute [get_cells {cell1 cell2 cell3}] area \  
-return_null_values  
Warning: Attribute 'area' does not exist on cell 'cell2' (ATTR-3)  
79.833600 {} 79.833600
```

The following example shows the warning that is issued because the U9 cell is not found:

```
prompt> get_attribute [get_cells {U1 U9}] dont_touch  
Warning: Can't find object 'U9' in design 'example'. (UID-95)  
true  
-0.25in
```

SEE ALSO

```

get_bounds

Creates a collection of bounds from the current design.

SYNTAX

```
collection get_bounds
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [patterns | -of_objects objects]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Does not suppress syntax error messages.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly brackets around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each bound in the collection, the expression is evaluated based on the bound's attributes. If the expression evaluates to true, the bound is included in the result.

To see the list of bound attributes that you can use in the expression, use the **list_attributes -application -class bound** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of bounds whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* argument and **-of_objects** option are mutually exclusive; you can use only one. If you do not use either one, the command uses the asterisk (*) as the default pattern.

-of_objects objects

Creates a collection of bounds that contain the specified objects. The objects must be leaf cells or ports.

The *patterns* argument and **-of_objects** option are mutually exclusive; you can use only one. If you do not use either one, the command uses the asterisk (*) as the default pattern.

DESCRIPTION

This command creates a collection of bounds from the current design that match the specified criteria.

The command returns a collection if any bounds match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects** or **report_bounds**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all bounds with names that start with my_bound.

```
prompt> get_bounds my_bound*
```

SEE ALSO

`collections(2)`
`filter_collection(2)`
`foreach_in_collection(2)`
`list_attributes(2)`
`query_objects(2)`
`collection_result_display_limit(3)`
`wildcards(3)`

get_buffers

Creates a collection of buffer cells.

SYNTAX

```
collection get_buffers
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-inverter]
  [-inverting_buffers]
  [-library lib_spec]
  [patterns]
```

Data Types

<i>expression</i>	string
<i>lib_spec</i>	collection
<i>patterns</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns_or_objects* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `"."` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each buffer cell in the collection, the expression is evaluated based on the buffer cell's attributes. If the expression evaluates to true, the buffer cell is included in the result.

To see the list of library cell attributes that you can use in the expression, use the **list_attributes -application -class lib_cell** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-inverter

Gets inverter cells only. By default, only buffer cells are returned. To include the library cells that have both inverting and noninverting outputs, use the **-inverting_buffers** option.

-inverting_buffers

Includes inverting buffer cells in addition to buffer cells (or inverter cells, if you use the **-inverter** option). Inverting buffers are library cells that have both inverting and noninverting outputs.

By default, only buffer cells are returned.

-library lib_spec

Specifies the libraries from which to collect the buffer cells. By default, the buffer cells are collected from all libraries in the link path.

patterns

Creates a collection of buffer cells whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page.

If you do not specify this option, the command uses the asterisk (*) as the default pattern.

DESCRIPTION

This command creates a collection of buffer cells that match the specified criteria.

The command returns a collection if any library cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries all buffer cells in the current library.

```
prompt> get_buffers
```

```
{slow/BUF2X2 slow/BUF2X4 slow/BUF2X12}
```

The following example queries all inverter cells in the misc_cmos library.

```
prompt> get_buffers -inverter -library misc_cmos
{misc_cmos/INV2X2 misc_cmos/INV2X4 misc_cmos/INVX12}
```

SEE ALSO

`filter_collection(2)`
`get_lib_cells(2)`
`list_attributes(2)`
`query_objects(2)`
`collection_result_display_limit(3)`
`wildcards(3)`

get_cells

Creates a collection of cells from the current design, relative to the current instance.

SYNTAX

```
collection get_cells
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [-rtl]
  [patterns
   | -of_objects objects
   | -within region
   | -touching region
   | -intersect region
   | -at point]
  [-all]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	collection
<i>region</i>	list
<i>point</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive. You can specify only one of these options.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the ==, =~, and !~ filter operators.

-filter expression

Filters the collection with the specified expression.

For each cell in the collection, the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

To see the list of cell attributes that you can use in the expression, use the **list_attributes -application -class cell** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-hierarchical

Searches for cells level-by-level, relative to the current instance. The name of the object at a particular level must match the patterns. For example, if there is a cell block1/adder, a hierarchical search finds it by using "adder".

By default, the search is not hierarchical.

-rtl

Creates a collection of cells with the **object_rtl_name** attribute.

patterns

Creates a collection of cells whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns*, **-of_objects**, **-object_id**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of cells connected to the specified objects. Each object can be a named pin or net, a collection of pins, a collection of nets, or a power domain. When the object is a power domain, the cells returned are the root cells of the power domain.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

In addition, you cannot use the **-hierarchical** option with the **-of_objects** option.

-within region

Creates a collection that contains all cells that are completely inside the specified region and do not overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is {{lx ly} {urx ury}} or {lx ly urx ury}, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is {{x1 y1} {x2 y2} ... {xN yN} {x1 y1}}, where each {x y} pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-object_id**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

In addition, you cannot use the **-hierarchical** option with the **-within** option.

-touching region

Creates a collection that contains all cells that are inside the specified region, including those that overlap the boundary. The region

boundary can be rectangle or polygon.

The format for specifying a rectangle is $\{\{llx\;ly\} \{urx\;ury\}\}$ or $\{\{llx\;ly\;urx\;ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\;y1\} \{x2\;y2\} \dots \{xN\;yN\} \{x1\;y1\}\}$, where each $\{x\;y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-object_id**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-touching** option.

-intersect region

Creates a collection that contains all cells that intersect the boundary of the specified region and at least part of the cell is outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is $\{\{llx\;ly\} \{urx\;ury\}\}$ or $\{\{llx\;ly\;urx\;ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\;y1\} \{x2\;y2\} \dots \{xN\;yN\} \{x1\;y1\}\}$, where each $\{x\;y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The *patterns*, **-of_objects**, **-object_id**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-intersect** option.

-at point

Creates a collection that contains all cells at the specified point. The format for specifying a point is $\{x\;y\}$.

The coordinate unit is specified in the technology file; typically it is microns.

The *patterns*, **-of_objects**, **-object_id**, **-within**, **-touching**, **-intersect**, and **-at** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the *pattern*.

In addition, you cannot use the **-hierarchical** option with the **-at** option.

-all

Includes physical-only cells in the collection. The following types of cells are considered physical-only cells:

- Standard cell fillers
- Pad fillers
- Corner cells
- Flip-chip pads (bumps)
- Chips
- Cover cells
- Tap cells
- Cells that have only power and ground ports

By default, physical-only cells are not included in the collection.

DESCRIPTION

This command creates a collection of cells that match the specified criteria. By default, the command creates the collection of cells from the current design, relative to the current instance.

If the command cannot find any cells that match the criteria and the current design is not linked, the design automatically links.

The command returns a collection if any cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the cells that begin with "o" and reference an FD2 library cell. Although the output looks like a list, it is only a display.

```
prompt> get_cells "o**" -filter "@ref_name == FD2"  
{o_reg1 o_reg2 o_reg3 o_reg4}
```

The following example queries the cells connected to a collection of pins.

```
prompt> set pinsel [get_pins o*/CP]  
{o_reg1/CP o_reg2/CP}  
  
prompt> get_cells -of_objects $pinsel  
{o_reg1 o_reg2}
```

The following example queries the cells connected to a collection of nets.

```
prompt> set netsel [get_nets tmp]  
{tmp}  
  
prompt> get_cells -of_objects $netsel  
{b c}
```

The following example removes the wire load model from the i1 and i2 cells.

```
prompt> remove_wire_load_model [get_cells {i1 i2}]  
Removing wire load model from cell 'i1'.  
Removing wire load model from cell 'i2'.  
1
```

get_clocks

Creates a collection of clocks from the current design.

SYNTAX

```
collection get_clocks
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [patterns]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each clock in the collection, the expression is evaluated based on the clock's attributes. If the expression evaluates to true, the clock is included in the result.

To see the list of clock attributes that you can use in the expression, use the **list_attributes -application -class clock** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of clocks whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this option, the command uses the asterisk (*) as the default pattern.

DESCRIPTION

This command creates a collection of clocks that match the specified criteria.

The command returns a collection if any clocks match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example applies the **set_max_time_borrow** command to all clocks in the design that match the PHI* pattern.

```
prompt> set_max_time_borrow 0 [get_clocks "PHI*"]
```

The following example sets the **clock_list** variable to the collection of clocks that have a period of 15:

```
prompt> set clock_list [get_clocks * -filter "@period==15"]
```

SEE ALSO

[collections\(2\)](#)
[filter_collection\(2\)](#)
[create_clock\(2\)](#)
[list_attributes\(2\)](#)
[query_objects\(2\)](#)
[report_clock\(2\)](#)
[collection_result_display_limit\(3\)](#)
[wildcards\(3\)](#)

get_clusters

Creates a collection of one or more clusters.

SYNTAX

```
collection get_clusters
  [-quiet]
  [-regexp [-nocase]]
  [-exact]
  [-filter expression]
  [-hier]
  [-flat]
  patterns | -of_objects objects
```

Data Types

expression	string
patterns	list
objects	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* option as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. The **-regexp** and **-exact** options are mutually exclusive; you can choose only one.

-nocase

Makes matches case-insensitive when combined with **-regexp**. You can use the **-nocase** option only when you also use **-regexp**.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * (asterisk) and ? (question mark) wildcard characters. The **-regexp** and **-exact** options are mutually exclusive; you can choose only one.

-filter expression

Filters the collection with the value of *expression*. For any clusters that match the *patterns* value, the expression is evaluated based on the attributes of the cluster. If the expression evaluates to *true*, the design is included in the result.

-hier

Specifies hierarchical.

-flat

Specifies flat.

patterns

Matches cluster names against patterns. Patterns can include the wildcard character * (asterisk) and ? (question mark), or regular expressions based on the **-regexp** option.

-of_objects objects

Get cells related to these objects.

DESCRIPTION

This command creates a collection of clusters that match certain criteria. It returns a collection handle (identifier) if any clusters match the *patterns* or *objects* and pass the filter (if specified). If no objects match your criteria, the command returns an empty string.

You can use the **get_clusters** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_clusters** result to a variable.

When issued from the command prompt, the **get_clusters** command behaves as though the **query_objects** command has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change the maximum using the **collection_result_display_limit** variable.

The "implicit query" property of **get_clusters** provides a fast, simple way to display clusters in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_clusters** as an argument to the **query_objects** command. Add the **-query** option to emulate the behavior of **query_objects**.

For information about collections and querying objects, see the **collections** man page.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example queries the clusters that begin without. *Although the output looks like a list, it is only a display.*

```
prompt> get_clusters out*
{out_reg}
```

SEE ALSO

`collections(2)`
`filter_collection(2)`
`query_objects(2)`
`regexp(2)`
`collection_result_display_limit(3)`

get_command_option_values

Queries current or default option values.

SYNTAX

```
get_command_option_values
  [-default | -current]
  -command command_name
```

Data Types

command_name string

ARGUMENTS

-default

Gets the default option values, if available.

-current

Gets the current option values, if available.

-command *command_name*

Gets the option values for this command.

DESCRIPTION

This command attempts to query a default or current value for each option (of the command) that has default and/or current-value-tracking enabled. Details of how the option value is queried depend on whether one of the **-current** or **-default** options is specified (see below).

A "Tcl array set compatible" (possibly empty) list of option names and values is returned as the Tcl result. The even-numbered entries in the list are the names of options that were enabled for default-value-tracking or current-value-tracking and had at least one of these values set to a not-undefined value). Each odd-numbered entry in the list is the default or current value of the option name preceding it in the list.

Any options that were not enabled for either default-value-tracking nor current-value-tracking are omitted from the output list. Similarly, options that were enabled for default-value-tracking or current-value-tracking, but for which no (not-undefined) default or current value is set, are omitted from the result list.

If neither **-current** nor **-default** is specified, then for each command option that has either default-value-tracking or current-value-tracking (or both) enabled, the value returned is as follows:

- The current value is returned if current-value-tracking is enabled and a (not-undefined) current value has been set;

- Otherwise the default value is returned if default-value-tracking is enabled and a (not-undefined) default value has been set;
- Otherwise the name and value pair for the option is not included in the result list.

If **-current** is specified, the value returned for an option is the current value if current-value-tracking is enabled, and a (not-undefined) current value has been set; otherwise the name and value pair for the option is omitted from the result list.

If **-default** is specified, the value returned for an option is the default value if default-value-tracking is enabled, and a (not-undefined) default value has been set; otherwise the name and value pair for the option is omitted from the result list.

The result list from **get_command_option_values** includes option values of both dash options and positional options (assuming that both kinds of options of a command have been enabled for value-tracking).

The command issues a Tcl error in a variety of situations, such as if an invalid command name was passed in with **-command**.

EXAMPLES

The following example shows the use of **get_command_option_values**:

```
prompt> test -opt1 10 -opt2 20
1
prompt> get_command_option_values -command test
-bar1 10 -bar2 20
```

SEE ALSO

get_cross_probing_info

Gets cross-probing information about cells and ports and returns the results as a string.

SYNTAX

```
string get_cross_probing_info
  [-unique_source]
  objects
```

Data Types

objects collection

ARGUMENTS

-unique_source

Prevents duplicate source file and line number combinations from being returned in the result.

If you specify this option, the string that is returned follows a different format; it does not use a pair of braces between the different source positions of an object or the results between different objects. Instead, the tool returns the results in the following format:
obj1_file1:obj1_line1 obj2_file1:obj2_line1 obj2_file2:obj2_line2

If an object has no known source position or valid file and line number, nothing is returned for the object.

objects

Specifies the cell and port objects to query.

DESCRIPTION

This command provides cross-probing information about specified cells and ports and returns the results as a string.

You must have a design that was analyzed and elaborated or synthesized using Design Compiler version I-2013.12 or later. The tool provides information about where the cell or port was created, specifying which file and line number the object came from. Some objects in the design might have been merged, which can result in an object with multiple source locations. In this case, multiple results are returned for the object.

The results of each object are separated by a pair of braces between each source position and between each object. For example, if you specify two objects with the **get_cross_probing_info** command, obj1 and obj2, where obj1 has one source position and obj2 has two source positions, the tool returns the results in the following format:

```
{ { obj1_file1:obj1_line1 } } { { obj2_file1:obj2_line1 } { obj2_file2:obj2_line2 } }
```

You can prevent duplicate file and line number combinations in the results by using the **-unique_source** option. In this case, the tool returns the results in the following format:

```
obj1_file1:obj1_line1 obj2_file1:obj2_line1 obj2_file2:obj2_line2
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows results from the **get_cross_probing_info** command:

```
prompt> get_cross_probing_info [get_cells -hierarchical]
{ {/usr/joe/design/m.v:21} } { {/usr/joe/design/m.v:22} } { {/usr/joe/design/m.v:21} }
{ {/usr/joe/design/m.v:22} } { {/usr/joe/design/m.v:28} } { {/usr/joe/design/m.v:12} }
{ {/usr/joe/design/m.v:13} } { {/usr/joe/design/m.v:14} } { {/usr/joe/design/m.v:4} }
```

The following example shows results from the **get_cross_probing_info** command with the **-unique_source** option:

```
prompt> get_cross_probing_info [get_cells -hierarchical] -unique_source
/usr/joe/design/m.v:21 /usr/joe/design/m.v:22 /usr/joe/design/m.v:28 /usr/joe/design/m.v:12
/usr/joe/design/m.v:13 /usr/joe/design/m.v:14 /usr/joe/design/m.v:4
```

SEE ALSO

[cross_probing_filter\(2\)](#)

get_defined_commands

Get information on defined commands and groups.

SYNTAX

```
string get_defined_commands
  [-details]
  [-groups]
  [pattern]
```

Data Types

pattern string

ARGUMENTS

-details

Get detailed information on specific command or group.

-groups

Search groups rather than commands

pattern

Return commands or groups matching pattern. The default value of this argument is "*".

DESCRIPTION

The **get_defined_commands** gets information about defined commands and command groups. By default the command returns a list of commands that match the specified pattern.

When **-details** is specified, the return value is a list that is suitable as input to the **array set** command. The returned value is a list with an even number of arguments. Each odd-numbered element in the list is a key name, and each even-numbered element in the list is the value of the previous key. The **-details** option is only legal if the pattern matches exactly one command or group.

When **-group** is specified with **-details**, the supported keys are as follows:

name

This key contains the name of the group.

info

This key contains the short help for the group.

commands

This key contains the commands in the group

When **-details** is used with a command, the supported keys are as follows:

name

This key contains the name of the command.

info

This key contains the short help for the command.

groups

This key contains the group names that this command belongs to.

options

This key contains the options defined for the command. The value is a list.

return

This key contains the return type for the command.

Each element in the *options* list also follows the key value pattern. The set of available keys for options are as follows:

name

This key contains the name of the option.

info

This key contains the short help for the option.

value_info

This key contains the short help string for the value

type

The type of the option.

required

The value will be 0 or 1 depending if the option is optional or required.

is_list

Will be 1 if the option requires a list.

list_length

If a list contains the list length constraint. One of any, even, odd, non_empty or a number of elements.

allowed_values

The allowed values if the option has specified allowed values.

min_value

The minimum allowed value if the option has specified one.

max_value

The maximum allowed value if the option has specified one.

EXAMPLES

```
prompt> get_defined_commands *collection
add_to_collection append_to_collection copy_collection filter_collection
foreach_in_collection index_collection sort_collection
prompt> get_defined_commands -details sort_collection
name sort_collection info {Create a sorted copy of the collection}
groups {} options {{name -descending info {Sort in descending order}
value_info {} type boolean required 1 is_list 0} {name -dictionary info
{Sort strings dictionary order.} value_info {} type boolean required 1
is_list 0} {name collection info {Collection to sort} value_info
collection type string required 0 is_list 0} {name criteria info {Sort
criteria - list of attributes} value_info criteria type list required 0
is_list 1 list_length non_empty}}
```

SEE ALSO

[help\(2\)](#)
[man\(2\)](#)

get_design_lib_path

Returns the directory to which the specified library is mapped.

SYNTAX

```
status get_design_lib_path  
    library_name
```

Data Types

library_name string

ARGUMENTS

library_name

Specifies the library whose directory mapping is returned.

DESCRIPTION

This command returns the directory to which the specified library is mapped.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the library named *MY_LIB* to the same directory as the *WORK* library:

```
prompt> define_design_lib MY_LIB \  
    -path get_design_lib_path("WORK")
```

SEE ALSO

`analyze(2)`
`define_design_lib(2)`

```
elaborate(2)
read_file(2)
report_design_lib(2)
```

get_designs

Creates a collection of one or more designs loaded into the tool.

SYNTAX

```
collection get_designs
  [-hierarchical]
  [-quiet]
  [-regexp]
  [-nocase]
  [-exact]
  [-filter expression]
  patterns
```

Data Types

expression string
patterns list

ARGUMENTS

-hierarchical

Searches for designs inferred by the design hierarchy relative to the current instance. The full name of the object at a particular level must match the patterns. The use of this option does not force an auto link.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * (asterisk) and ? (question mark) wildcard characters.

-filter *expression*

Filters the collection with *expression*. For any designs that match *patterns*, the expression is evaluated based on the design's attributes. If the expression evaluates to true, the design is included in the result.

patterns

Matches design names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more

details about using and escaping wildcards refer to the **wildcards** man page.

DESCRIPTION

The **get_designs** command creates a collection of designs from those currently loaded into the tool that match certain criteria. The command returns a collection if any designs match the *patterns* and pass the filter (if specified). If no objects match your criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Using rigid quoting with curly braces around regular expressions is recommended. Regular expressions are always anchored. The expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search simply by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_designs** command at the command prompt, or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the **get_designs** result to a variable.

When issued from the command prompt, **get_designs** behaves as though **query_objects** has been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum using the **collection_result_display_limit** variable.

The implicit query property of **get_designs** provides a fast, simple way to display designs in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_designs** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the designs that begin with *mpu*. Although the output looks like a list, it is just a display. A complete listing of designs is available using the **list_designs** command.

```
prompt> get_designs mpu*
{mpu_0_0 mpu_0_1 mpu_1_0 mpu_1_1}
```

The following example shows that, given a collection of designs, you can remove those designs:

```
prompt> remove_design [get_designs mpu*]
Removing design mpu_0_0...
Removing design mpu_0_1...
Removing design mpu_1_0...
Removing design mpu_1_1...
```

SEE ALSO

```

get_dft_hierarchical_pins

Returns a collection of ports and hierarchical pins created during DFT insertion.

SYNTAX

```
collection get_dft_hierarchical_pins
```

ARGUMENTS

The **get_dft_hierarchical_pins** command has no arguments.

DESCRIPTION

This command returns a collection of ports and hierarchical pins created during DFT insertion command in the current design.

EXAMPLES

The following example shows how to use the **get_dft_hierarchical_pins** command to report attributes for each port created during DFT insertion:

```
prompt> set ports [get_ports -quiet [get_dft_hierarchical_pins]]  
{data_source test_mode test_si1 test_si2 test_so2 test_se}
```

```
prompt> foreach _in_collection p $ports {report_attribute $p}
```

```

get_die_area

Returns a collection containing the die area of the current design.

SYNTAX

```
string get_die_area
```

ARGUMENTS

None

DESCRIPTION

This command returns a collection containing the die area of the current design. If the die area is not defined, the command returns an empty string. The die area is also known as the cell boundary. It represents the silicon boundary of a chip and typically encloses all objects of a design, such as pads, I/O pins, cells, and so on. There should be only one die area in a design. Use the **get_attribute** command to get information about the die area, such as the object class, bounding box information, coordinates of the die area for the current design, die area boundary, and die area name. You can use the **report_attribute** command to browse attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Use the **get_attribute** command to get information about the die area. The following example shows how to return the object class using the **object_class** attribute:

```
prompt> get_attribute [get_die_area] object_class  
die_area
```

The following example shows how to return the bounding box information and the coordinates of the die area for the current design using the **bbox** attribute:

```
prompt> get_attribute [get_die_area] bbox  
{0.000 0.000} {400.000 400.000}
```

The following example shows how to return the die area name using the **name** attribute:

```
prompt> get_attribute [get_die_area] name
```

```
{my_design_die_area}
```

SEE ALSO

[set_placement_area\(2\)](#)

get_dont_touch_cells

Creates a collection of dont_touch cells that meet the specified criteria.

SYNTAX

```
collection get_dont_touch_cells
  [-type type]
  [-hierarchical]
  patterns
```

Data Types

<i>type</i>	string
<i>patterns</i>	collection

ARGUMENTS

-type *type*

Matches the cell with the specified dont_touch type. You can use a wildcard.

To list the dont_touch types for cells, use the **list_dont_touch_type** command with the **-class cell** option.

-hierarchical

Searches for cells in the hierarchy, relative to the current instance. The full name of the object at a particular level must match the patterns. For example, if the specified cell name is block1/cell2, a hierarchical search finds a cell named cell2 in a block named block1.

patterns

Matches the cell names with the specified patterns. A collection of cells is also accepted.

DESCRIPTION

This command creates a collection of dont_touch cells in the current design, relative to the current instance, that match the specified criteria. If no cells match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as the **query_objects** command. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, the command displays a maximum of 100 objects. You can change this value by setting the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

For information about the dont_touch types that can be specified for cells, use the **list_dont_touch_type -class cells** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the dont_touch cells with an **ideal_network** setting under the block named InstDecode:

```
prompt> get_dont_touch_cells -type idn InstDecode/*  
{InstDecode/reset_UPF_LS InstDecode/U38 InstDecode/U36}
```

The following examples queries the dont_touch cells with a DFT-related dont_touch setting under the block named core:

```
prompt> get_dont_touch_cells -type dft* core/*  
{core/U34 core/U35 core/U89}
```

SEE ALSO

```
list_dont_touch_types(2)  
report_dont_touch(2)  
get_dont_touch_nets(2)  
set_dont_touch(2)  
set_dont_touch_network(2)  
collection_result_display_limit(3)
```

get_dont_touch_nets

Creates a collection of dont_touch nets that meet the specified criteria.

SYNTAX

```
collection get_dont_touch_nets
  [-type type]
  [-hierarchical]
  patterns
```

Data Types

<i>type</i>	string
<i>patterns</i>	collection

ARGUMENTS

-type *type*

Matches the net with the specified dont_touch type. You can use a wildcard.

To list the dont_touch types for nets, use the **list_dont_touch_type** command with the **-class net** option.

-hierarchical

Searches for nets in the hierarchy, relative to the current instance. The full name of the object at a particular level must match the patterns. For example, if the specified net name is block1/net2, a hierarchical search finds a net named net2 in block named block1.

patterns

Matches the net names with the specified patterns. A collection of nets is also accepted.

DESCRIPTION

This command creates a collection of dont_touch nets in the current design, relative to the current instance, that match the specified criteria. If no nets match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as the **query_objects** command. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** to report the objects in the collection. By default, the command displays a maximum of 100 objects. You can change this value by setting the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

For information about the dont_touch types that can be specified for nets, use the **list_dont_touch_type -class nets** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the nets whose names begin with NET in a block named block1.

```
prompt> get_dont_touch_nets -type mv* block1/NET*
{block1/NET1QNX block1/NET2QNX}
```

The following example queries the nets under the block named block1 that have a dont_touch type of dtn.

```
prompt> get_dont_touch_nets -type dtn block1/*
{block1/clk}
```

SEE ALSO

```
collections(2)

get_nets(2)
list_dont_touch_types(2)
report_dont_touch(2)
set_dont_touch(2)
set_dont_touch_network(2)
collection_result_display_limit(3)
wildcards(3)
```

get_flat_cells

Creates a collection of leaf cells that match certain criteria in the current design.

SYNTAX

```
collection get_flat_cells
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [patterns | -of_objects objects]
  [-all]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each cell in the collection, the expression is evaluated based on the cell's attributes. If the expression evaluates to true, the cell is included in the result.

To see the list of cell attributes that you can use in the expression, use the **list_attributes -application -class cell** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of cells whose full names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

When using the *patterns* argument, the command searches all leaf cells to match the *patterns* argument on their full names regardless of their hierarchical level.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

Creates a collection of cells connected to the specified objects. Each object must be a named cell, pin, net, or a collection of these objects.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

-all

Includes physical-only cells in the collection. The following types of cells are considered physical-only cells:

- Standard cell fillers
- Pad fillers
- Corner cells
- Flip-chip pads (bumps)
- Chips
- Cover cells
- Tap cells
- Cells that have only power and ground ports

By default, physical-only cells are not included in the collection.

DESCRIPTION

This command creates a collection of leaf cells from the current design that match the specified criteria. Leaf cells are those processed during place and route. They are shown and can be selected in the GUI layout window.

The command returns a collection if any leaf cells match the criteria. If no objects match the criteria, the command returns an empty string.

The **get_flat_cells** and **get_cells** commands both return cell objects. The collections returned by both commands are interchangeable and can be passed along to any command that accepts cell objects.

However, the **get_flat_cells** command differs from the **get_cells** command in several ways. The **get_cells** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis that have been in Design Compiler, Primetime, and SDC. The **get_flat_cells** command searches all leaf cells to match the *patterns* argument on their full names relative to the current design, it does not depend on the current instance. It provides pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the IC Compiler flow. You can use whichever command is easier depending on the type of search you are doing.

Note that the **get_flat_cells** command is not part of the SDC format standard and should not be used in timing constraint scripts if you want to apply them across other tools or by using the **read_sdc** command. Also, in a design with multiple physical hierarchies, the **get_flat_cells** command does not search cells in child blocks.

Due to the pattern matching behavior of this command, the search space is often larger than the corresponding **get_cells** command. As a result, the runtime might be much larger and you should limit the number of calls to this command that contain regular expressions or wildcards.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects** or **change_selection**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries all black box cells in the current design. Although the output looks like a list, it is only a display.

```
prompt> get_flat_cells * -filter {is_black_box == true }
{cornerur cornerul cornerul cornerll I_CLOCK_GEN/I_PLL_SD I_CLOCK_GEN/I_PLL_PCI
I_CLOCK_GEN/I_CLKMUL I_ORCA_TOP/I_BLENDER/latched_clk_en_reg I_ORCA_TOP/I_CONTEXT_MEM/CONTEXT_RAM_3 I_ORCA_TOP/I_CONTEXT_MEM/CONTEXT_RAM_2 ...}
```

The following example queries the leaf cells whose full name begins with "BLOCK/", as well as all leaf cells any number of logical levels below the BLOCK hierarchical cell.

```
prompt> get_flat_cells BLOCK/*
{BLOCK/SB/U1 BLOCK/SB/U2 BLOCK/SB/U3 BLOCK/SB/U4 BLOCK/U5 BLOCK/U6
BLOCK/U7 BLOCK/U8 BLOCK/U9}
```

As a comparison to the previous example, the following example finds only cells that are direct children of the BLOCK hierarchical cell.

```
prompt> get_cells BLOCK/*
{BLOCK/SB BLOCK/U5 BLOCK/U8 BLOCK/U7 BLOCK/U6}
```

The following example shows that, given a collection of nets, you can select the leaf cells connected to those nets. You can see that these cells are selected in the GUI layout view if there is one open for the current design.

```
prompt> set netsel [get_flat_nets r1_2_ ]
{r1_2_}
prompt> change_selection [get_flat_cells -of_object $netsel ]
```

wildcards(3)
```

get_flat_nets

Creates a collection of top-level nets of hierarchical net groups in the current design that match the specified criteria.

SYNTAX

```
collection get_flat_nets
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [patterns | -of_objects objects]
  [-all]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each net in the collection, the expression is evaluated based on the net's attributes. If the expression evaluates to true, the net is included in the result.

To see the list of net attributes that you can use in the expression, use the **list_attributes -application -class net** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of top-level nets of hierarchical net groups whose full names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

When using the *patterns* argument, the command searches all top-level nets of hierarchical net groups to match the *patterns* argument on their full name.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the asterisk (*) as the default pattern.

Creates a collection of top-level nets of hierarchical net groups that are connected to the specified objects. Each object is either a named pin, port, net, cell, or a collection of these objects.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the asterisk (*) as the default pattern.

-all

Includes power and ground nets.

DESCRIPTION

This command creates a collection of top-level nets of hierarchical net groups in the current design that match the specified criteria.

The **get_flat_nets** and **get_nets** commands return both return net objects. The collections returned by both commands are interchangeable and can be passed along to any command that accept net objects.

However, the **get_flat_nets** command differs from the **get_nets** command in several ways. The **get_nets** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis that have been in Design Compiler, PrimeTime, and SDC. The **get_flat_nets** command searches the top-level nets of hierarchical net groups to match the *patterns* argument on their full names relative to the current design, it does not depend on the current instance. It provides pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the IC Compiler flow. You can use whichever command is easier depending on the type of search you are doing.

Note that the **get_flat_nets** command is not part of the SDC format standard and should not be used in timing constraint scripts if you want to apply them across other tools or by using the **read_sdc** command. Also in a design with multiple physical hierarchies, the **get_flat_nets** command does not search nets in child blocks.

Due to the pattern matching behavior of this command, the search space is often larger than the corresponding **get_nets** command. As a result, the runtime might be much larger and you should limit the number of calls to this command that contain regular expressions or wildcards.

The command returns a collection if any nets match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects** or **change_selection**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the top-level nets whose full name begins with "BLOCK/". Although the output looks like a list, it is just a display.

```
prompt> get_flat_nets BLOCK/*
{BLOCK/SB/n76}
```

The following example shows that there is no top-level net whose full name begins with "BLOCK/" and ends with "n1".

```
prompt> get_flat_nets BLOCK/*n1
Warning: No nets matched 'BLOCK/*n1' (SEL-004)
```

As a comparison to the previous example, the following example shows that there is a net whose full name begins with "BLOCK/" and ends with "n1".

```
prompt> get_nets BLOCK/*n1
{BLOCK/n1}
```

The following selects the top-level nets of hierarchical net groups that connect to cells. You can see that these nets are selected in the GUI layout view if there is one open for the current design.

```
prompt> set cellsel [get_flat_cells I_ORCA_TOP/I_SDRAM_IF/U23276]
{I_ORCA_TOP/I_SDRAM_IF/U23276}

prompt> change_selection [get_flat_nets -of_objects $cellsel]
```

get_nets(2)
list_attributes(2)
query_objects(2)
wildcards(3)
```

get_flat_pins

Creates a collection of leaf-cell pins in the current design that match the specified criteria.

SYNTAX

```
collection get_flat_pins
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [patterns | -of_objects objects]
  [-all]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `"."` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each pin in the collection, the expression is evaluated based on the pin's attributes. If the expression evaluates to true, the pin is included in the result.

To see the list of pin attributes that you can use in the expression, use the **list_attributes -application -class pin** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of leaf-cell pins whose full names match the specified patterns. Patterns can include the asterisk (*) and question mark (?) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

When using the *patterns* argument, the command searches all pins of leaf cells to match the *patterns* argument on their full names regardless of their hierarchical level.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of leaf-cell pins connected to the specified objects. Each object is a named leaf cell, a net, or a collection of these objects.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the asterisk (*) as the default pattern.

-all

This option has no effect. Added for script compatibility.

DESCRIPTION

This command creates a collection of leaf-cell pins in the current design that match the specified criteria. Leaf cells are those processed during place and route. They are shown and can be selected in GUI layout window.

The **get_flat_pins** and **get_pins** commands both return pin objects. The collections returned by both commands are interchangeable and can be passed along to any command that accepts pin objects.

However, the **get_flat_pins** command differs from the **get_pins** command in several ways. The **get_pins** command performs the pattern search based on the logical hierarchy of the design and is consistent with the commands used for synthesis and timing analysis that have been in Design Compiler, PrimeTime, and SDC. The **get_flat_pins** command searches all pins of leaf cells to match the *patterns* argument on their full names relative to the current design; it does not depend on the current instance. It provides pattern search in a way that is consistent with the place-and-route view of the design, and thus is simpler for many tasks in the IC Compiler flow. You can use whichever command is easier depending on the type of search you are doing.

Note that the **get_flat_pins** command is not part of the SDC format standard and should not be used in timing constraint scripts if you want to apply them across other tools or by using the **read_sdc** command. Also, in a design with multiple physical hierarchies, the **get_flat_pins** command does not search pins in child blocks.

Due to the pattern matching behavior of this command, the search space is often larger than the corresponding **get_pins** command. As a result, the runtime might be much larger and you should limit the number of calls to this command that contain regular expressions or wildcards.

The command returns a collection if any pins match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects** or **change_selection**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the I pins of leaf cells that begin with "I_CLK". Although the output looks like a list, it is just a display.

```
prompt> get_flat_pins I_CLK*/I
{I_CLK_SOURCE_SDRAM_CLK/I I_CLK_SOURCE_SYS_2x_CLK/I
 I_CLK_SOURCE_SYS_CLK/I I_CLK_SOURCE_PCLK/I}
```

The following example queries the ZN pins of all leaf cells any number of logical levels below the BLOCK hierarchical cell.

```
prompt> get_flat_pins BLOCK/*/ZN
{BLOCK/SB/U1/ZN BLOCK/SB/U2/ZN BLOCK/SB/U3/ZN BLOCK/SB/U4/ZN
 BLOCK/U5/ZN BLOCK/U6/ZN BLOCK/U7/ZN BLOCK/U8/ZN BLOCK/U9/ZN}
```

As a comparison to the previous example, the following example finds the ZN pins of the cells that are direct children of the BLOCK hierarchical cell.

```
prompt> get_pins BLOCK/*/ZN
{BLOCK/U9/ZN BLOCK/U5/ZN BLOCK/U8/ZN BLOCK/U7/ZN BLOCK/U6/ZN}
```

The following example selects pins of leaf cells whose name begins with "O_1". You can see that these pins are selected in the GUI layout view if there is one open for the current design.

```
prompt> set csel [get_flat_cells O_1*]
{O_10_reg O_11_reg O_12_reg O_13_reg O_1_reg}
prompt> change_selection [get_flat_pins -of_objects $csel]
```

get_generated_clocks

Creates a collection of generated clocks.

SYNTAX

```
collection get_generated_clocks
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [patterns]
```

Data Types

expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each generated clock in the collection, the expression is evaluated based on

the generated clock's attributes. If the expression evaluates to true, the generated clock is included in the result.

To see the list of clock attributes that you can use in the expression, use the **list_attributes -application -class clock** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of generated clocks whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this argument, the command uses the * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of generated clocks in the current design that match the specified criteria.

To create a generated clock in the design, use the **create_generated_clock** command. To remove a generated clock from the design, use the **remove_generated_clock** command. To show information about clocks and generated clocks in the design, use the **report_clock** command.

The command returns a collection if any generated clocks match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command applies the **set_clock_latency** command on all generated clocks in the design whose names start with "GEN".

```
prompt> set_clock_latency 2.0 [get_generated_clocks "GEN*"]
```

The following command removes all the generated clocks in the design whose names start with "GEN1".

```
prompt> remove_generated_clock [get_generated_clocks "GEN1*"]
```

```

get_gui_stroke_bindings

Queries the data for stroke bindings.

SYNTAX

```
get_gui_stroke_bindings
[-dictionary dict_name]
[-builtin]
```

ARGUMENTS

-dictionary *dictionary_name*

Report only the bindings for the specified dictionary.

-builtin

Return information on the built-in commands that are available for use in bindings.

DESCRIPTION

This command queries the current state of stroke bindings for the application. If no options are specified, the application returns data for all dictionaries. The **-dictionary** option limits the data returned to only that for a given dictionary. The **-builtin** option queries for the built-in commands that are available for use with bindings.

A user does not typically use this command. The tool provides built-in reporting commands that produce human-readable reports from the information returned by this command. You can use the **report_gui_stroke_bindings** and **report_gui_stroke_builtins** commands for report generation.

This command returns its data as a Tcl list, suitable for further processing into reports or command streams by Tcl procedures.

DATA FORMAT

The command returns data differently depending on the options that are provided.

The data for a dictionary is a list of entries where each entry contains the stroke sequence and the data for the command invoked by that sequence. If the command queries more than one dictionary, another level of lists is added with dictionary name followed by dictionary data.

Built-in command data is formatted as a list of commands. Each command has the name of the built-in command followed by the data for the command.

EXAMPLES

The following example returns all binding information for all dictionaries.

```
psyn_gui-t> get_gui_stroke_bindings
```

The following example returns the bindings for the Graphics dictionary.

```
psyn_gui-t> get_gui_stroke_bindings -dictionary Graphics
```

The following example returns the built-in commands available for use in bindings.

```
psyn_gui-t> get_gui_stroke_bindings -builtin
```

SEE ALSO

get_latch_loop_groups

Returns a list of collections of pins, each collection containing the transparent latch data pins in one latch loop group.

SYNTAX

```
list get_latch_loop_groups
  [-of_objects pin_list]
  [-loop_breakers_only]
```

Data Types

pin_list list

ARGUMENTS

-of_objects *pin_list*

A collection of data pins of transparent latches. Only the pins of loop groups containing the specified pins are returned. By default, the command returns one collection for each loop group in the design.

-loop_breakers_only

Restricts the returned collection to containing only loop-breaker latch data pins. These are the pins that have their **is_latch_loop_breaker** attribute set to **true**. By default, all transparent latch data pins within the loop group are returned in the collections.

DESCRIPTION

When sequential loops of transparent latches exist in a design, a loop group containing all the latch data pins of intersecting loops is formed. The command **get_latch_loop_groups** analyzes the design and returns a collection for each loop group formed. The collection contains the latch data pins of the loop group. Combinational pins are not included in the results.

You can use the results of the **get_latch_loop_groups** command to find paths within loops that violate timing. See the example below.

This command has no effect if the variable **timing_enable_through_paths** is set to **false**.

EXAMPLES

The following example uses **get_latch_loop_groups** to report violating paths within latch loops. No paths outside the loops are reported.

```
prompt> foreach a_loop_group [get_latch_loop_groups -loop_breakers_only] {  
    report_timing -from $a_loop_group -to $a_loop_group -slack_lesser_than 0.0  
}
```

SEE ALSO

[report_latch_loop_groups\(2\)](#)
[timing_enable_through_paths\(3\)](#)

get_lib_attribute

Returns the value of an attribute on a list of library objects.

SYNTAX

```
list get_lib_attribute  
  object_list  
  attribute_name
```

Data Types

```
object_list    list  
attribute_name string
```

ARGUMENTS

object_list

Lists the library objects for which the attribute value is to be returned.

attribute_name

Specifies the name of the attribute whose value is to be returned.

DESCRIPTION

This command searches *object_list* for the specified attribute and returns a list of attribute values. If the attribute is not found on any of the specified objects, the command returns an empty list.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to find the cell named /INV and obtain its area value:

```
prompt> get_lib_attribute sample/INV area  
Performing get_lib_attribute on library object  
'sample/INV'.  
{1.0}
```

The following example shows an error issued because the command does not find a cell named *INV1*:

```
prompt> get_attribute sample/INV1 area
Error: The 'INV1' object does not exist in the 'sample' technology library.
(UIL-54)
{}
```

The following example shows the **lib_udg_attr** value returned for the user-defined group named *lib_udg1* in the library named *sample*:

```
prompt> get_lib_attribute sample/lib_udg1 lib_udg_attr
Performing get_lib_attribute on library object 'sample/lib_udg1'.
{Test}
```

The following example shows the area values returned for the gates named *G1* and *G2* in the library named *tech_lib*:

```
prompt> get_lib_attribute {sample/G1, sample/G2} area
Performing get_lib_attribute on library object 'sample/G1'.
Performing get_lib_attribute on library object 'sample/G2'.
{1.0, 2.0}
```

SEE ALSO

[set_lib_attribute\(2\)](#)

get_lib_cells

Creates a collection of library cells from the libraries loaded into memory.

SYNTAX

```
collection get_lib_cells
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-scenarios scenario_names]
  patterns | -of_objects objects
```

Data Types

<i>expression</i>	string
<i>scenario_names</i>	list
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each library cell in the collection, the expression is evaluated based on the library cell's attributes. If the expression evaluates to true, the library cell is included in the result.

To see the list of library cell attributes that you can use in the expression, use the **list_attributes -application -class lib_cell** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-scenarios scenario_names

Searches the libraries that are used in the specified scenarios.

If you do not specify this option, all libraries that are loaded into memory are searched.

patterns

Creates a collection of library cells whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The **patterns** and **-of_objects** arguments are mutually exclusive; you must specify one.

-of_objects objects

Creates a collection of library cells that are referenced by the specified cells or own the specified library pins. Each object is either a named library pin, a netlist cell, a library pin collection, or a netlist cell collection.

The **patterns** and **-of_objects** arguments are mutually exclusive; you must specify one.

DESCRIPTION

This command creates a collection of library cells from the libraries currently loaded into memory that match the specified criteria.

If no libraries have been loaded into memory, the tool loads the libraries specified in the **link_library** variable into memory the first time you run the **get_libs**, **get_lib_cells**, or **get_lib_pins** command.

If you use the **-scenarios** option, only libraries associated with the specified scenarios are included in the search.

The command returns a collection if any library cells match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example queries all library cells that are in the misc_cmos library whose names begin with AN2. Although the output looks like a list, it is just a display.

```
prompt> get_lib_cells misc_cmos/AN2*
{misc_cmos/AN2 misc_cmos/AN2P}
```

The following example shows one way to determine the library cell used by a particular cell instance:

```
prompt> get_lib_cells -of_objects [get_cells o_reg1]
{misc_cmos/FD2}
```

SEE ALSO

collections(2)
filter_collection(2)
get_cells(2)
list_attributes(2)
query_objects(2)
collection_result_display_limit(3)
wildcards(3)

get_lib_pins

Creates a collection of library cell pins from libraries loaded into memory.

SYNTAX

```
collection get_lib_pins
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  patterns | -of_objects objects
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each library cell pin in the collection, the expression is evaluated based on the library cell pin's attributes. If the expression evaluates to true, the library cell pin is included in the result.

To see the list of library cell pin attributes that you can use in the expression, use the **list_attributes -application -class lib_pin** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of library cell pins whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The **patterns** and **-of_objects** arguments are mutually exclusive; you must specify one.

-of_objects objects

Creates a collection of library cell pins referenced by the specified netlist pins or owned by the specified library cells. Each object is either a named library cell, netlist pin, library cell collection, or a netlist pin collection.

The **patterns** and **-of_objects** arguments are mutually exclusive; you must specify one.

DESCRIPTION

This command creates a collection of library cell pins from the libraries currently loaded into memory that match the specified criteria.

If no libraries have been loaded into memory, the tool loads the libraries specified in the **link_library** variable into memory the first time you run the **get_libs**, **get_lib_cells**, or **get_lib_pins** command.

The command returns a collection if any library cell pins match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example queries all pins of the AN2 library cell in the misc_cmos library. Although the output looks like a list, it is just a display.

```
prompt> get_lib_pins misc_cmos/AN2/*
{misc_cmos/AN2/A misc_cmos/AN2/B misc_cmos/AN2/Z}
```

The following example shows one way to find out how the library pin is used by a particular pin in the netlist:

```
prompt> get_lib_pins -of_objects o_reg1/Q
{misc_cmos/FD2/Q}
```

get_libs

Creates a collection of libraries loaded into memory.

SYNTAX

```
collection get_libs
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-scenarios scenario_names]
  [patterns | -of_objects objects]
```

Data Types

<i>expression</i>	string
<i>scenario_names</i>	list
<i>patterns</i>	list
<i>objects</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each library in the collection, the expression is evaluated based on the library's attributes. If the expression evaluates to true, the library is included in the result.

To see the list of library attributes that you can use in the expression, use the **list_attributes -application -class library** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-scenarios scenario_names

Searches the libraries that are used in the specified scenarios.

If you do not specify this option, all libraries that are loaded into memory are searched.

patterns

Creates a collection of libraries whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of libraries that contain the specified objects. Each object is either a named library cell or a library cell collection.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses the * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of libraries from the libraries currently loaded into memory that match the specified criteria.

If no libraries have been loaded into memory, the tool loads the libraries specified in the **link_library** variable into memory the first time you run the **get_libs**, **get_lib_cells**, or **get_lib_pins** command.

If you use the **-scenarios** option, only libraries associated with the specified scenarios are included in the search.

The command returns a collection if any libraries match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example queries all loaded libraries. Use the **list_libs** command to get a complete listing of the libraries.

```
prompt> get_libs
{misc_cmos misc_cmos_io}
```

get_license

Obtains a license for a feature.

SYNTAX

```
status get_license
  feature_list
  [-quantity num_licenses]
```

Data Types

```
feature_list    list
num_licenses   integer
```

ARGUMENTS

feature_list

Specifies a list of features to be obtained. If you specify more than one feature, the list must be enclosed in braces ({}).

By looking at your key file, you can determine all of the features licensed at your site.

-quantity num_licenses

Specifies the total number of licenses to be checked out for each feature after the command has completed. If some licenses have already been checked out, the command acquires only the additional licenses needed to bring the total to the specified quantity. If this option is not specified, only one license is checked out for each feature.

DESCRIPTION

This command obtains a license for the specified features. These features are checked out by the current user until the **remove_license** command is used or until the program exits.

If multiple licenses are required for a multicore run, you can use the **-quantity** option to specify the total number of licenses needed (which might be different than the incremental number of licenses that the command checks out). You can use this option to reserve the required number of licenses early in the session, rather than risking a failure later in the session if the licenses are not available.

The **list_licenses** command provides a list of the features that you are currently using.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example obtains the multivoltage feature:

```
prompt> get_license Galaxy-MV
```

The following example obtains two copies of the licenses required to run a multicore **compile_ultra** command in Design Compiler:

```
prompt> get_license -quantity 2 {DC-Expert DC-Ultra-Opt DC-Ultra-Features}
```

SEE ALSO

`check_license(2)`
`license_users(2)`
`list_licenses(2)`
`remove_license(2)`

get_magnet_cells

Returns a collection of magnet cells that can be pulled closer to the specified magnet objects.

SYNTAX

```
collection get_magnet_cells
  magnet_objects
  [-stop_by_sequential_cells]
  [-exclude_buffers]
  [-exclude_cells object_list]
  [-logical_level level]
  | -stop_points object_list
```

Data Types

<i>magnet_objects</i>	collection
<i>object_list</i>	collection
<i>level</i>	integer

ARGUMENTS

magnet_objects

Specifies the magnet objects, which can be fixed macro cells, a pin of a fixed macro cell, or I/O pins. Vias, blockages, and I/O pads are not allowed as magnets.

-stop_by_sequential_cells

Specifies to stop cell magnetization when the tool traverses the logical levels and encounters a sequential cell. By default, all cells in the logical levels of the specified magnet objects are magnetized by this command.

-exclude_buffers

Prevents counting buffers and inverters when calculating the level. Buffers and inverters are pulled like normal cells but are not used for level determination. By default, buffers and inverters are considered as one logic level.

-exclude_cells *object_list*

Specifies to exclude the specified cells when the command reports the target cells.

-logical_level *level*

Specifies the number of logical levels to magnetize. By default, the *level* value is 1; that is, only the first level cells are magnetized.

The **-logical_level** and **-stop_points** options are mutually exclusive.

-stop_points *object_list*

Identifies the cells that lie on the timing path between the specified magnet objects and the objects specified by this option. You can specify any pins, ports, or cell objects for this option.

The **-logical_level** and **-stop_points** options are mutually exclusive.

DESCRIPTION

The **get_magnet_cells** command returns a collection of cells that can be pulled toward the specified magnet objects. You specify magnet objects by using **get_magnet_cells magnet_objects**.

You can use the returned collection to highlight the cells affected by magnet placement in the GUI.

If there is a large number of high fanout nets, magnet placement might pull a large number of cells, which can result in long runtime. To avoid this, adjust the value of the **magnet_placement_fanout_limit** variable. The default is 1000.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns a collection of cells that are affected by magnet placement on a cell named INST_1:

```
prompt> get_magnet_cells [get_cells "INST_1"]
```

The following example returns a collection of cells that get pulled during magnet placement excluding a cell named INST_2. Two levels of cells are pulled. If any buffers exist, they are skipped.

```
prompt> get_magnet_cells \
-exclude_buffers [get_cells "INST_2"]
```

SEE ALSO

`magnet_placement(2)`
`set_cell_location(2)`
`magnet_placement_fanout_limit(3)`

get_matching_nets_for_pattern

Gets all matching nets for a defined search pattern. The time units for the **-setup_***, **-hold_***, and **-transition_*** options should always be the same as the time unit returned by the **report_units** command.

SYNTAX

```
collection get_matching_nets_for_pattern
  -pattern id
  [-setup_slack_lower_limit number]
  [-setup_slack_upper_limit number]
  [-hold_slack_lower_limit number]
  [-hold_slack_upper_limit number]
  [-transition_lower_limit number]
  [-transition_upper_limit number]
  [-optimizable]
```

Data Types

<i>id</i>	integer
<i>number</i>	float

ARGUMENTS

-pattern *id*

Specifies a net pattern ID number. Net pattern ID numbers are created by the **create_net_search_pattern** command, which utilizes combinations of physical attributes to derive collections of nets.

This is a required option.

-setup_slack_lower_limit *number*

Identifies nets in the specified pattern ID that have a setup slack that is greater than or equal to the specified value. A net's setup slack is the worst setup slack seen across all its sinks. To select all of the nets in pattern 1 that have a setup slack of more than 100, use **get_matching_nets_for_pattern -setup_slack_lower_limit 100 -pattern 1**.

-setup_slack_upper_limit *number*

Identifies nets in the specified pattern ID that have a setup slack that is less than the specified value. A net's setup slack is the worst setup slack seen across all its sinks. To select all of the nets in pattern 2 that have a setup slack of less than 0, use **get_matching_nets_for_pattern -setup_slack_upper_limit 0 -pattern 2**.

-hold_slack_lower_limit *number*

Identifies nets in the specified pattern ID that have a hold slack that is greater than or equal to the specified value. A net's hold slack is the worst hold slack seen across all its sinks. To select all of the nets in pattern 3 that have a hold slack of more than 1000, use **get_matching_nets_for_pattern -hold_slack_upper_limit 1000 -pattern 3**.

-hold_slack_upper_limit *number*

Identifies nets in the specified pattern ID that have a hold slack that is less than the specified value. A net's hold slack is the worst

hold slack seen across all its sinks. To select all of the nets in pattern 4 that have a hold slack of less than 0, use **get_matching_nets_for_pattern -hold_slack_upper_limit 0 -pattern 4**.

-transition_lower_limit number

Identifies nets in the specified pattern ID that have a net transition time that is greater than or equal to the specified value. A net's transition time is the worst transition time seen across all its sinks. To select all of the nets in pattern 5 that have a transition time of more than 100, use **get_matching_nets_for_pattern -transition_lower_limit 100 -pattern 5**.

-transition_upper_limit number

Identifies nets in the specified pattern ID that have a transition time that is less than the specified value. A net's transition time is the worst transition time seen across all its sinks. To select all of the nets in pattern 6 that have a transition time of less than 90, use **get_matching_nets_for_pattern -transition_upper_limit 90 -pattern 6**.

-optimizable

Reduces a collection of pattern-matched nets to include only nets that can be optimized. When working with patterns, it is best to ignore clock nets, ideal nets, constant nets, nets with multiple drivers, tristate nets, dont_touch nets, DRC disabled nets, and nets with no driver. For example, if you want to create buffer trees from a subset of all nets that exist in pattern 7, you can use **create_buffer_tree -from [get_matching_nets_for_pattern -optimizable -pattern 7]**.

DESCRIPTION

The **get_matching_nets_for_pattern** command returns a collection of nets that match a predefined pattern. The collection of nets it returns can be redirected to pattern-independent commands, such as **change_selection**, **create_buffer_tree**, and **set_net_routing_layer_constraints**.

Multicorner-Multimode Support

This command uses information from all active scenarios. For setup slack, hold slack, and transition time, the worst value from all active scenarios is always used.

EXAMPLES

Here are some examples of how the **get_matching_nets_for_pattern** command can be used:

```
prompt> get_matching_nets_for_pattern -pattern 3
prompt> sizeof_collection [get_matching_nets_for_pattern -pattern 3]

prompt> set_net_routing_layer_constraints \
    -min_layer_name M7 -max_layer_name M10 \
    [get_matching_nets_for_pattern -optimizable -pattern 3]
```

report_net_search_pattern_delay_estimation_options(2)
set_net_search_pattern_priority(2)

report_net_search_pattern_priority(2)

get_message_ids

Get application message ids

SYNTAX

```
string get_message_ids
    [-type severity]
    [pattern]
```

Data Types

<i>severity</i>	string
<i>pattern</i>	string

ARGUMENTS

-type *severity*

Filter ids based on type (Values: Info, Warning, Error, Severe, Fatal)

pattern

Get IDs matching pattern (default: *)

DESCRIPTION

The **get_message_ids** command retrieves the error, warning and informational messages used by the application. The result of this command is a Tcl formatted list of all message ids. Information about the id can be queried with the **get_message_info** command.

EXAMPLES

The following code finds all error messages and makes the application stop script execution when one of these messages is encountered.

```
foreach id [get_message_ids -type Error] {
    set_message_info -stop_on -id $id
}
```

SEE ALSO

`print_message_info(2)`
`set_message_info(2)`
`suppress_message(2)`

get_message_info

Returns information about diagnostic messages.

SYNTAX

```
integer get_message_info
  [-error_count
   | -warning_count
   | -info_count
   | -limit l_id
   | -occurrences o_id
   | -suppressed s_id
   | -id i_id]
```

Data Types

```
l_id    string
o_id    string
s_id    string
i_id    string
```

ARGUMENTS

-error_count

Returns the number of error messages issued so far.

-warning_count

Returns the number of warning messages issued so far.

-info_count

Returns the number of informational messages issued so far.

-limit *l_id*

Returns the current user-specified limit for a given message ID. The limit was set with the **set_message_info** command.

-occurrences *o_id*

Returns the number of occurrences of a given message ID.

-suppressed *s_id*

Returns the number of times a message was suppressed either using **suppress_message** or due to exceeding a user-specified limit.

-id *i_id*

Returns information about the specified message. The information is returned as a Tcl list compatible with the array set command.

DESCRIPTION

The **get_message_info** command retrieves information about error, warning, and informational messages. For example, if the following message is generated, information about it is recorded:

```
Error: unknown command 'wrong_command' (CMD-005)
```

It is useful to be able to retrieve recorded information about generated diagnostic messages. For example, you can stop a script after a certain number of errors have occurred, or monitor the number of messages issued by a single command.

You can also find out how many times a specific message has occurred, or how many times it has been suppressed. Also, you can find out if a limit has been set for a particular message ID.

EXAMPLES

The following example uses the **get_message_info** command to count the number of errors that occurred during execution of a specific command, and to return from the procedure if the error count exceeds a given amount:

```
prompt> proc \
  do_command {limit} {
    set current_errors [get_message_info -error_count]
    command
    set new_errors [get_message_info -error_count]
    if {[expr $new_errors - $current_errors] > $limit} {
      return -code error "Too many errors"
    }
    ...
  }
```

The following example uses the **get_message_info** command to retrieve information on the CMD-014 message:

```
prompt> get_message_info -id CMD-014
id CMD-014 severity Error limit 0 occurrences 0 suppressed 0 message
{Invalid %s value '%s' in list.}
```

SEE ALSO

```
print_message_info(2)
set_message_info(2)
suppress_message(2)
get_message_ids(2)
```

get_multibits

Creates a collection of one or more multibits loaded into dc_shell. You can assign these multibits to a variable or pass them into another command.

SYNTAX

```
string get_multibits
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [patterns]
```

Data Types

expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-filter *expression*

Filters the collection with *expression*. For any multibits that match *patterns*, the expression is evaluated based on the multibit's attributes. If the expression evaluates to true, the multibit is included in the result. This option works the same as the **filter** command in dc_shell.

patterns

Matches multibit names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, see the **wildcards** man page.

DESCRIPTION

The **get_multibits** command creates a collection of multibits from those currently loaded into dc_shell that match certain criteria. The

command returns a collection handle (identifier) if any multibits match the *patterns* and pass the filter (if specified). If no objects matched your criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_multibits** command at the command prompt, or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the **get_multibits** result to a variable.

When issued from the command prompt, **get_multibits** behaves as though **query_objects** had been called to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum using the **collection_result_display_limit** variable.

The implicit query property of **get_multibits** provides a fast, simple way to display multibits in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_multibits** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example queries the multibits that begin with *out*:

```
prompt> get_multibits out*
{out_reg}
```

The following example queries the multibits that begin with *test* in the design instance *mid1/bot1*:

```
prompt> get_multibits mid1/bot1/test*
{mid1/bot1/test_reg}
```

SEE ALSO

[filter_collection\(2\)](#)
[query_objects\(2\)](#)
[collection_result_display_limit\(3\)](#)
[wildcards\(3\)](#)

get_nets

Creates a collection of nets that match the specified criteria.

SYNTAX

```
collection get_nets
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [-top_net_of_hierarchical_group]
  [-segments]
  [-all]
  [-boundary_type upper | lower | both]
  [-rtl]
  [patterns | -of_objects objects]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	collection

ARGUMENTS

-quiet

Suppresses messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the ==, =~, and !~ filter operators.

-filter expression

Filters the collection with the value of the *expression* argument. For any nets that match the specified criteria, the expression is evaluated based on the net's attributes. If the expression evaluates to true, the net is included in the result.

-hierarchical

Searches for nets level-by-level relative to the current instance. The name of the object at a particular level must match the patterns. For example, if there is a net named block1/muxsel, a hierarchical search finds it using muxsel.

You cannot use the **-hierarchical** option with the **-of_objects** option.

-top_net_of_hierarchical_group

Keeps only the top net of a hierarchical group. When more than one hierarchical net of the same group is specified (local nets at various hierarchical levels of the same physical net), only the net closest to the top of the hierarchy is saved in the collection. In the case of multiple nets at the same level, the first net specified is kept. To get the top hierarchical net connected to a single net, need to use this option in combination with the **-segments** option.

-segments

Modifies the initial search that matches the *patterns* or **-of_object** argument to include all global segments for the matching nets. Global net segments are all the net segments that are physically connected across all hierarchical boundaries.

This option is best used with a single net.

When you use the **-segments** option with the **-top_net_of_hierarchical_group** option, you can isolate the highest net segment of a physical net.

-all

Includes power, ground, and tie nets.

-boundary_type upper | lower | both

Specifies what to do when getting nets of boundary pins.

You must specify one of the following values:

- **upper** (default)
Get the net outside of the hierarchical block.
- **lower**
Get the net inside of the hierarchical block.
- **both**
Get the net both inside and outside of the hierarchical block.

This option can be used only with the **-of_objects** option. In addition, the specified object must be a hierarchical pin or a pin on a block abstraction. This option has no meaning for pins that are not hierarchical and are not on block abstractions.

-rtl

Creates a collection of nets with the **object_rtl_name** attribute.

patterns

Creates a collection of nets whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* and **-of_objects** options arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of nets connected to the specified objects. Each object can be a pin, port, or cell.

The *patterns* and **-of_objects** options arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

You cannot use the **-hierarchical** option with the **-of_objects** option.

DESCRIPTION

This command creates a collection of nets in the current design relative to the current instance that match the specified criteria.

If the *patterns* and **-of_objects** arguments fail to match any objects and the current design is not linked, the design automatically links.

The command returns a collection if any nets match the specified criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the nets that begin with NET in a block named block1. Although the output looks like a list, it is a display.

```
prompt> get_nets block1/NET*
{block1/NET1QNX block1/NET2QNX}
```

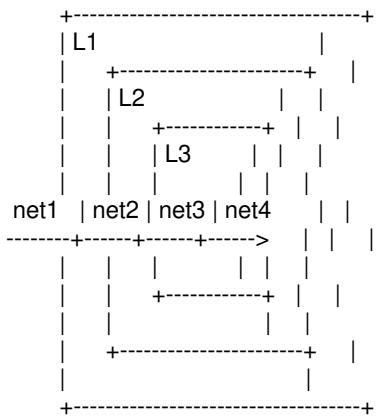

The following example queries the nets connected to a collection of pins.

```
prompt> current_instance block1
block1
prompt> set pinsel [get_pins {o_reg1/QN o_reg2/QN}]
{o_reg1/QN o_reg2/QN}
prompt> get_nets -of_objects $pinsel
{NET1QNX NET2QNX}
```

The following example queries the nets connected to a collection of cells.

```
prompt> current_instance block1
block1
prompt> set cellsel [get_cells {o_reg1 o_reg2}]
{o_reg1 o_reg2}
prompt> get_nets -of_objects $cells
{NET1QX NET1QNX NET1DX NET2QX NET2QNX NET2DX}
```

The following examples use the design shown below to show the behavior of the **get_nets** command with various options. There is a buffer instance named buffer in the L3 instance.

When you use the **-of_objects** option by itself, the command gets only the net that connects to a pin directly.

```
prompt> get_nets -of_objects L1/L2/L3/buffer/A
{L1/L2/L3/net_4}
```

When you also use the **-segments** option, the command gets all the hierarchical nets that connect together through the hierarchical pins.

```
prompt> get_nets -of_objects L1/L2/L3/buffer/A -segments
{L1/L2/L3/net_4 L1/L2/net_3 L1/net_2 net_1}
```

When you use the **-segments** and **-top_net_of_hierarchical_group** option together, the command returns only the net in the topmost hierarchical net group.

```
prompt> get_nets -of_objects L1/L2/L3/buffer/A -segments \
-top_net_of_hierarchical_group
{net_1}
```

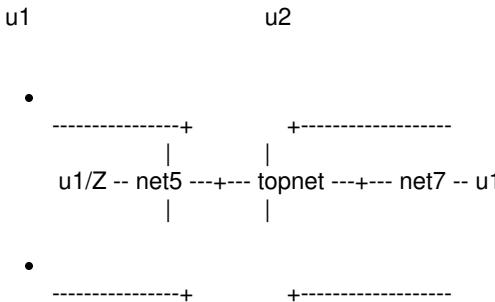

The following examples use the *patterns* argument to select the nets.

```
prompt> get_nets net*4 -hierarchical
{L1/L2/L3/net_4}
```

```
prompt> get_nets net*4 -hierarchical -segments
{L1/L2/net_3 net_1 L1/L2/L3/net_4 L1/net_2}
```

```
prompt> get_net net*4 -hierarchical -segments -filter name==net_2
{L1/net_2}
```

This example shows how to use the **-boundary_type** options. Given the following circuit:

there are hierarchical cells u1 and u2 at this level, connected by a net *topnet*. Within u1 is a pin u1/Z driving *net5*, and within u2 is a pin u1/A being driven by *net7*. These three nets are physically the same net. Assume these are the only nets in the design. Notice the difference in the results of the following two **get_nets** commands:

```
prompt> get_nets * -hierarchical
{topnet u1/net5 u2/net7}
prompt> get_nets * -hierarchical -top_net_of_hierarchical_group
{topnet}
```

Assume that at the top level, *topnet* is connected to pins u2/in and u1/out. Here are some examples of the *-boundary_type* option. Notice now in this case, the "upper" type does not add value.

```
prompt> get_nets -of_objects u2/in
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type upper
{topnet}
prompt> get_nets -of_objects u2/in -boundary_type lower
{u2/net7}
prompt> get_nets -of_objects u2/in -boundary_type both
{u2/net7 topnet}
prompt> get_nets -boundary lower -of_objects \
    [get_pins -of_objects [get_nets topnet]]
{u1/net5 u2/net7}
```

get_object_name

Returns a list of names of the objects in a collection.

SYNTAX

```
list get_object_name  
      collection
```

Data Types

collection string

ARGUMENTS

collection

Specifies the name of the collection that contains objects whose names are requested.

DESCRIPTION

This command returns a list of names of the objects in a collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns the name top as the object contained in the collection returned by the **current_design** command.

```
prompt> get_object_name [current_design]  
Current design is 'top'.  
top
```

SEE ALSO

[collections\(2\)](#)

get_path_groups

Creates a collection of path groups that match the specified criteria.

SYNTAX

```
collection get_path_groups
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  patterns
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each path group in the collection, the expression is evaluated based on the path group's attributes. If the expression evaluates to true, the path group is included in the result.

For information about the plan group attributes, see SolvNet article 008622.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

patterns

Creates a collection of path groups whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

DESCRIPTION

This command creates a collection of path groups from the current design that match certain criteria. Path groups control the optimization cost function and also affect timing reports.

The command returns a collection if any path groups match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command uses information from the current scenario only.

[wildcards\(3\)](#)

get_physical_hierarchy

Returns a list of hierarchical cells that are physical hierarchies in the current design.

SYNTAX

```
integer get_physical_hierarchy
```

ARGUMENTS

The \fbget_physical_hierarchy command has no arguments.

DESCRIPTION

The **get_physical_hierarchy** command returns a list of names of hierarchical cells in the current design that are physical hierarchies. These hierarchical cells are set as physical hierarchies through the **set_physical_hierarchy** command.

EXAMPLES

The following example first shows how to set the *U1* and *U2* hierarchical cells as physical hierarchies and then shows how they are returned by the **get_physical_hierarchy** command:

```
prompt> set_physical_hierarchy {U1 U2}  
prompt> get_physical_hierarchy  
{ U1, U2 }
```

SEE ALSO

[set_physical_hierarchy\(2\)](#)

get_pins

Creates a collection of pins that match specified criteria.

SYNTAX

```
collection get_pins
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns | -of_objects objects [-leaf]]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	collection

ARGUMENTS

-quiet

Suppresses warning and error messages when no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The **-regexp** and **-exact** options are mutually exclusive; you cannot use both.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each pin in the collection, the expression is evaluated based on the pin's

attributes. If the expression evaluates to true, the pin is included in the result.

To see the list of pin attributes that you can use in the expression, use the **list_attributes -application -class pin** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-hierarchical

Searches for pins level-by-level, relative to the current instance. The name of the object at a particular level must match the patterns. The search is similar to that of the UNIX **find** command. For example, if there is a pin named block1/adder/D[0], a hierarchical search finds it by using adder/D[0].

The **-hierarchical** option cannot be used with the **-of_objects** option.

patterns

Creates a collection of pins whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case-sensitive unless you use the **-nocase** option.

The **patterns** and **-of_objects** arguments are mutually exclusive; you can specify no more than one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of pins connected to the specified objects. Each object can be a cell or net.

By default, the command considers only pins connected to the specified nets at the same hierarchical level. To consider only pins connected to leaf cells on the specified nets, use the **-leaf** option.

You cannot use the **-hierarchical** option with the **-of_objects** option.

-leaf

Includes only those pins that are on leaf cells connected to the nets specified in the **-of_objects** option. The command crosses hierarchical boundaries to find pins on leaf cells.

You can use this option only if you also use the **-of_objects** option.

DESCRIPTION

This command creates a collection of pins in the current design relative to the current instance that match specified criteria.

If the **patterns** and **objects** arguments do not match any objects and the current design is not linked, the command automatically links the design.

The command returns a collection if any pins match the specified criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**, or assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by setting the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the CP pins of cells that begin with the letter "o". Although the output looks like a list, it is only a text report.

```
prompt> get_pins o*/CP
{o_reg1/CP o_reg2/CP o_reg3/CP o_reg4/CP}
```

The following example queries the pins connected to a collection of cells:

```
prompt> set csel [get_cells o_reg1]
{o_reg1}

prompt> get_pins -of_objects $cse1
{o_reg1/D o_reg1/CP o_reg1/CD o_reg1/Q o_reg1/QN}
```

The following example shows the difference between getting the local pins of a net and the leaf pins of net. In this example, NET1 is connected to the i2/aP and reg1/QN. Cell i2 is hierarchical. Within cell i2, port a is connected to U1/A and U2/A.

```
prompt> get_pins -of_objects [get_nets NET1]
{i2/a reg1/QN}

prompt> get_pins -leaf -of_objects [get_nets NET1]
{i2/U1/A i2/U2/A reg1/QN}
```

The following example shows how to create a clock using a collection of pins:

```
prompt> create_clock -period 8 -name CLK [get_pins o_reg*/CP]
1
```

[collection_result_display_limit\(3\)](#)
[wildcards\(3\)](#)

get_placement_area

Returns a list of coordinates for the current core placement area.

SYNTAX

```
string get_placement_area
```

ARGUMENTS

None.

DESCRIPTION

Returns a list of coordinates for the current core placement area. Returns a list of float numbers in the order of lower-left corner coordinates and upper-right corner coordinates. If the core area is not defined in the current design, the command returns an error message.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to get the core placement area coordinates in the current design.

```
prompt> get_placement_area
```

SEE ALSO

`set_placement_area(2)`

get_placement_blockages

Creates a collection of placement blockages that match the specified criteria.

SYNTAX

```
collection get_placement_blockages
  [-quiet]
  [-within region
   | -touching region
   | -intersect region]
  [-filter expression]
  [-type hard | soft | pin | hard_macro | partial]
  [patterns]
```

Data Types

region list of points
expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages.

-within *region*

Creates a collection that contains all placement blockages that are completely inside the specified region and do not overlap the boundary. The region boundary can be a rectangle or a polygon.

The format for specifying a rectangle is $\{\{llx\} \{lly\} \{urx\} \{ury\}\}$ or $\{\{lx\} \{ly\} \{urx\} \{ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\} \{y1\} \{x2\} \{y2\} \dots \{xN\} \{yN\} \{x1\} \{y1\}\}$, where each $\{x\} \{y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches the entire design.

-touching *region*

Creates a collection that contains all placement blockages that are inside the specified region, including those that overlap the boundary. The region boundary can be a rectangle or a polygon.

The format for specifying a rectangle is $\{\{llx\} \{lly\} \{urx\} \{ury\}\}$ or $\{\{lx\} \{ly\} \{urx\} \{ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\} \{y1\} \{x2\} \{y2\} \dots \{xN\} \{yN\} \{x1\} \{y1\}\}$, where each $\{x\} \{y\}$ pair specifies one point of the input

polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches the entire design.

-intersect region

Creates a collection that contains all placement blockages that intersect the boundary of the specified region and at least part of the cell is outside of the specified region. The region boundary can be a rectangle or a polygon.

The format for specifying a rectangle is `{}{lx ly} {urx ury}` or `{lx ly urx ury}`, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is `{}{x1 y1} {x2 y2} ... {xN yN} {x1 y1}`, where each `{x y}` pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches the entire design.

-filter expression

Filters the collection with the specified expression. For each placement blockage in the collection, the expression is evaluated based on the placement blockage's attributes. If the expression evaluates to true, the placement blockage is included in the result.

To see the list of placement blockage attributes that you can use in the expression, use the **list_attributes -application -class placement_blockage** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-type hard | soft | pin | hard_macro | partial

Indicates the type of placement blockage. By default, this command matches all kinds of placement blockages.

patterns

Creates a collection of placement blockages whose names match the specified patterns. Placement blockages that are named by the tool have the naming convention PB#*n*, where *n* is an integer. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive.

If you do not specify this argument, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of placement blockages by selecting placement blockages from the current design that match the specified criteria.

The command returns a collection if any ports match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show some uses of this command to create collections of placement blockages:

```
prompt> get_placement_blockages -within {{2 2} {25 25}}
{PB#5389}
```

```
prompt> get_placement_blockages -filter "area > 1000"
{PB#4683}
```

wildcards(3)
```

get_polygon_area

Calculate the area of the input polygon.

SYNTAX

```
double get_polygon_area  
    polygon
```

Data Types

polygon list

ARGUMENTS

polygon

A list of points that represents a polygon and the format is like this: {{x1 y1} {x2 y2} ... {xN yN} {x1 y1}}. The coordinate unit is specified in technology file (usually it is micron).

DESCRIPTION

This command returns the area covered by the input polygon. The input for this command is a list of points which represents a polygon; and the returned value represents the area of the input polygons. Before this command is used, the library should be opened.

EXAMPLES

The following command returns a value represents the area of the input polygons.

```
prompt> get_polygon_area {{5 5} {20 5} {20 20} {15 20} {15 10} \  
    {10 10} {10 15} {5 15} {5 5}}  
150.0
```

SEE ALSO

convert_to_polygon(2)
resize_polygon(2)

get_ports

Creates a collection of ports from the current design that match the specified criteria.

SYNTAX

```
collection get_ports
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns | -of_objects objects]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each port in the collection, the expression is evaluated based on the port's attributes. If the expression evaluates to true, the port is included in the result.

To see the list of port attributes that you can use in the expression, use the **list_attributes -application -class port** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-hierarchical

Searches for ports level-by-level, relative to the current instance. The full name of the object at a particular level must match the patterns. The search is similar to that of the UNIX **find** command. For example, if there is a port named *block1/adder/D[0]*, a hierarchical search finds it by using *adder/D[0]*.

The **-hierarchical** option is mutually exclusive with use the **-of_objects** option; you can use only one.

patterns

Creates a collection of ports whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of ports connected to the specified objects. Each object can be a net, terminal, bound, or via region.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify any of these arguments, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of ports by selecting ports from the current design that match the specified criteria.

The command returns a collection if any ports match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

In addition, see the man pages for the **all_inputs** and **all_outputs** commands, which also create collections of ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries all input ports beginning with "mode". Although the output looks like a list, it is only a display.

```
prompt> get_ports mode* -filter {@port_direction == in}
```

```
{mode[0] mode[1] mode[2]}
```

The following example sets the driving cell for ports beginning with "in" to an FD2 library cell.

```
prompt> set_driving_cell -lib_cell FD2 -library my_lib \  
[get_ports in*]
```

The following example reports ports connected to nets that match the pattern "bidir*".

```
prompt> report_port [get_ports -of_objects [get_nets bidir*]]
```

The following example get the ports connected to terminals that match the pattern "CC*".

```
prompt> get_ports -of_objects [get_terminals CC*]  
{CC CCEN}
```

The following example shows you can get bus ports by their base name. A[0], A[1], and A[2] are bus ports with the base name A; A[3] is not a bus port.

```
prompt> get_ports A  
{A[0] A[1] A[2]}
```

```
prompt> get_ports A[3]  
{A[3]}
```

wildcards(3)

get_power_derate

Returns the power derating factors for either the current design, a list of cells or library cells.

SYNTAX

```
status get_power_derate
  [-scenarios scenario_list]
  [-leakage]
  [-switching]
  [-internal]
  [-user]
  [object_list]
```

Data Types

scenario_list list
object_list list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

-leakage

Returns the leakage specific derating values only.

-switching

Returns the switching specific derating values only.

-internal

Returns the internal specific derating values only.

-user

Returns the actually stored power derating attributes if and only if they exist.

object_list

Specifies a list of cells or library cells on which the power derating factors are reported.

DESCRIPTION

This command is used to return the derate factors either on the design, specific cells or library cells contained in the design. If this

command is called without any option the current design power derating factors are returned.

If this command is called with option -user it will return the actually stored attributes if and only if they exist. Without -user, the command will return the used (inherited) derating factors. If the command is called with the object_list specified then derating factors will only be issued for the instances specified in the object list.

If none of -leakage, -internal or -switching is specified it returns all three.

Multicorner-Multimode Support

EXAMPLES

In the following example, power derating factors have been set globally on the design.

```
prompt> set_power_derate -switching 0.92
prompt> set_power_derate -internal 1.15
prompt> set_power_derate -leakage 0.75
prompt> get_power_derate

(ChipTop: {leakage: 0.750000} {internal: 1.150000} {switching: 0.920000})
```

In the following example power derating factors have been set globally on the design. More restrictive derates have been set on the hierarchical cell H1.

```
prompt> set_power_derate 0.95
prompt> set_power_derate -switching 1.06
prompt> set_power_derate -internal -leakage 0.82 [get_cell H1]
prompt> get_power_derate [get_cells H1/U1]

{H1/U1: {scenario default} {leakage: 0.82 } {internal: 0.82 } {switching: 1.06 from: TOP}}
```

In the following example only the power derating factors set specifically by the user are returned for the hierarchical cell H1.

```
prompt> get_power_derate -user [get_cells H1/U1]

{H1/U1: {scenario default} {leakage: 0.82 } {internal: 0.82 }}
```

SEE ALSO

`get_power_derate(2)`
`reset_power_derate(2)`
`report_power_derate(2)`

get_power_domains

Creates a collection of power domains that match the specified criteria.

SYNTAX

```
collection get_power_domains
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns | -of_objects objects]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>objects</i>	collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern. This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns. The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each power domain in the collection, the expression is evaluated based on the power domain's attributes. If the expression evaluates to true, the power domain is included in the result.

To see the list of power domain attributes that you can use in the expression, use the **list_attributes -application -class power_domain** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-hierarchical

Searches for power domains in the current scope and all of its descendant scopes.

If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for power domains only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical power domain names relative to the current scope.

You cannot use this option with the **-of_objects** option.

patterns

Creates a collection of power domains whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects objects

Creates a collection of power domains connected to the specified objects. The objects can be cells, supply nets, supply ports, or power switches.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of power domains by selecting power domains from the current design that match the specified criteria.

If no power domains match the criteria and the design is not linked, the tool automatically links the design.

The command returns a collection if any power domains match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all power domains in the current scope:

```
prompt> get_power_domains -hierarchical  
{PD1 SUB_INST/PD2}
```

SEE ALSO

`collections(2)`
`filter_collection(2)`

`query_objects(2)`
`create_power_domain(2)`
`remove_power_domain(2)`
`report_power_domain(2)`
`collection_result_display_limit(3)`
`wildcards(3)`

get_power_switches

Creates a collection of power switches that match the specified criteria.

SYNTAX

```
collection get_power_switches
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns]
```

Data Types

expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each power switch in the collection, the expression is evaluated based on the power switch's attributes. If the expression evaluates to true, the power switch is included in the result.

To see the list of power switch attributes that you can use in the expression, use the `list_attributes -application -class power_switch` command.

For more information about how to use the `-filter` option, see the `filter_collection` man page.

-hierarchical

Searches for power switches in the current scope and all of its descendant scopes.

If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for power switches only in the current scope and you can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical power switches relative to the current scope.

patterns

Creates a collection of power switches whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this argument, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of power switches by selecting power switches from the current design that match the specified criteria.

If no power switches match the criteria and the design is not linked, the tool automatically links the design.

The command returns a collection if any power switches match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all power switches under the current scope:

```
prompt> get_power_switches -hierarchical
{SW1 SUB_INST/SW2}
```

SEE ALSO

`create_power_switch(2)`
`report_power_switch(2)`
`collections(2)`

```
filter_collection(2)
list_attributes(2)
query_objects(2)
collection_result_display_limit(3)
wildcards(3)
```

get_references

Creates a collection of one or more references loaded into memory.

SYNTAX

```
collection get_references
  [-hierarchical]
  [-quiet]
  [-regexp]
  [-nocase]
  [-exact]
  [-filter expression]
  patterns
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list

ARGUMENTS

-hierarchical

Sets the search mode to hierarchical. Searches for hierarchical cells whose references match the pattern. The full name of the object at a particular level must match the patterns. The use of this option does not force an autolink.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Uses the *patterns* argument as real regular expressions rather than simple wildcard patterns.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * (asterisk) and ? (question mark) wildcard characters.

-filter *expression*

Filters the collection with *expression*. For any references that match *patterns*, the expression is evaluated based on the attributes of the reference. If the expression evaluates to true, the design is included in the result. This option works the same as the **filter** command in **dc_shell**.

patterns

Matches reference names against patterns. Patterns can include the wildcard characters * (asterisk) and ? (question mark). For more details about using and escaping wildcards, see the **wildcards** man page.

DESCRIPTION

The **get_references** command creates a collection of cells whose references match certain criteria. If no patterns match your criteria, the empty string is returned.

Regular expression matching is the same as in the Tcl **regexp** command. When using **-regexp**, take care in the way you quote the *patterns* and filter *expression*. Use rigid quoting with curly braces around regular expressions. Regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can expand the search by adding ".*" to the beginning or end of the expressions as needed.

You can use the **get_references** command at the command prompt, or you can nest it as an argument to another command (for example, **query_objects**). In addition, you can assign the **get_references** result to a variable.

When issued from the command prompt, **get_references** behaves as though **query_objects** has been executed to display the objects in the collection. By default, a maximum of 100 objects is displayed. You can change this maximum using the **collection_result_display_limit** variable.

The implicit query property of **get_references** provides a fast, simple way to display references in a collection. However, if you want the flexibility provided by the **query_objects** options (for example, if you want to display the object class), use **get_references** as an argument to **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the references that begin with *mpu*. Although the output looks like a list, it is just a display.

```
prompt> get_references mpu*
{mpu_0_0 mpu_0_1 mpu_1_0 mpu_1_1}
```

SEE ALSO

collections(2)
filter_collection(2)
query_objects(2)
collection_result_display_limit(3)
wildcards(3)

get_related_supply_net

Creates a collection of related supply nets of pins.

SYNTAX

```
collection get_related_supply_net
  [pins]
  [-ground]
```

Data Types

pins collection

ARGUMENTS

pins

Specifies the collection of pins to be queried.

-ground

Specifies that the ground supply net should be returned.

DESCRIPTION

The **get_related_supply_net** command creates a collection of supply nets of the specified collection of pins. Power supply net is returned by default. If the **-ground** option is specified, ground supply net is returned.

You can use the **get_related_supply_net** command either at the command prompt, or nest it as an argument to another command, such as the **report_supply_net** command. In addition, you can assign the result of the **get_related_supply_nets** command to a variable.

When you run the **get_related_supply_net** command at the prompt, it behaves as though the **query_objects** command has been called to display the objects in the collection. By default, a maximum of 100 objects are displayed. You can change this maximum limit by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the man page of the **collections** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets the supply nets of all pins of a level-shifter cell.

```
prompt> get_related_supply_net [get_pin Multiplier/mult_on_UPF_LS/*]  
{VDDL VDDL}
```

SEE ALSO

```
set_related_supply_net(2)  
connect_supply_net(2)  
report_supply_net(2)
```

get_route_zrt_common_options

Gets the value of the specified common route option.

SYNTAX

```
status get_route_zrt_common_options  
  -name name_of_option
```

Data Types

name_of_option string

ARGUMENTS

-name *name_of_option*

Specifies the option whose value is returned. This is a required option.

DESCRIPTION

This command gets the value of the specified common route option. If you want to get the values of all the common route options, use the **report_route_zrt_common_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command returns the Zroute verbose level.

```
prompt> get_route_zrt_common_options -name verbose_level
```

SEE ALSO

[set_route_zrt_common_options\(2\)](#)
[report_route_zrt_common_options\(2\)](#)

get_route_zrt_global_options

Gets the value of the specified global route option.

SYNTAX

```
status get_route_zrt_global_options  
    -name name_of_option
```

Data Types

name_of_option string

ARGUMENTS

-name *name_of_option*

Specifies the option whose value is returned. This is a required option.

DESCRIPTION

This command gets the value of the specified global route option. If you want to get the values of all the global route options, use the **report_route_zrt_global_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command tells whether crosstalk-driven global routing is enabled.

```
prompt> get_route_zrt_global_options -name crosstalk_driven
```

SEE ALSO

set_route_zrt_global_options(2)
report_route_zrt_global_options(2)

get_rp_groups

Creates a collection of relative placement groups that match the specified criteria.

SYNTAX

```
collection get_rp_groups
  [patterns | -of_objects objects]
  [-quiet]
  [-nocase]
  [-exact]
  [-regexp]
  [-ignored]
  [-top]
```

Data Types

<i>patterns</i>	list
<i>objects</i>	collection

ARGUMENTS

patterns

Creates a collection of relative placement groups whose names match the specified patterns. The format of each pattern string can be either *design_name::rp_group_name* or *rp_group_name*.

Both *design_name* and *rp_group_name* can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects *objects*

Creates a collection of relative placement groups that contain the specified objects. Each object can be a cell, an instantiated or included relative placement group or a relative placement group keepout.

The *patterns* and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-nocase

Makes matches case-insensitive.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

The regular expression matching is similar to the Tcl **regexp** command. When using the **-regexp** option, be careful how you quote the *patterns* argument. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding "*" to the beginning or end of the expressions, as needed.

The **-regexp** and **-exact** options are mutually exclusive; you can use only one.

-ignored

Includes only ignored relative placement groups.

-top

Includes only top-level relative placement groups.

DESCRIPTION

This command creates a collection of relative placement groups by selecting relative placement groups from the current design that match the specified criteria. This command is supported only for designs that do not contain multiply-instantiated designs.

The command returns a collection if any relative placement groups match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries the relative placement groups starting with "g" in a design starting with "r". Although the output looks like a list, the output is only a display.

```
prompt> get_rp_groups r*::g*
{ripple::grp_ripple}
```

The following example uses the **get_rp_groups** command to set the utilization attribute of the relative placement groups.

```
prompt> set_rp_group_options [get_rp_groups r*::g*] \
```

```
-utilization 0.95
{ripple::grp_ripple}
```

The following example queries the relative placement groups that include the U17 cell or the example3::block2 relative placement group.

```
prompt> get_rp_groups -of_objects {U17 example3::block2}
{example3::gp_2_in_example3 example3::top_group}
```

get_safety_core_groups

Returns a collection of safety core group names from the current design.

SYNTAX

```
status get_safety_core_groups
  [-of_objects of_objects]
  [-quiet]
```

Data Types

of_objects collection

ARGUMENTS

-of_objects *of_objects*

Creates a collection containing the names of safety core group of the specified safety cores.

DESCRIPTION

Finds the safety_core_group names based on the option. If no options are specified, it returns the names of all the safety core groups of the current design.

SEE ALSO

[create_safety_core_group\(2\)](#)
[report_safety_core_groups\(2\)](#)

get_safety_core_rules

return the names of safety core rules.

SYNTAX

```
status get_safety_core_rules
  [-of_objects of_object]
  [-quiet]
```

Data Types

of_object collection

ARGUMENTS

-of_objects *of_object*

Gets safety core rules associated with these cores.

DESCRIPTION

Finds the safety core rule names of specified cores. If no options are specified, it returns all the safety core rule names of the current design.

SEE ALSO

[create_safety_core_rule\(2\)](#)
[report_safety_core_rules\(2\)](#)

get_safety_error_code_groups

Returns a collection of safety error code group names from the current design.

SYNTAX

```
status get_safety_error_code_groups
  [-of_objects of_objects]
  [-quiet]
```

Data Types

of_objects collection

ARGUMENTS

-of_objects *of_objects*

Creates a collection containing the names of safety error code group of the specified safety cores.

DESCRIPTION

Finds the safety_error_code_group names based on the option. If no options are specified, it returns the names of all the safety error code groups of the current design.

SEE ALSO

[create_safety_error_code_group\(2\)](#)
[report_safety_error_code_groups\(2\)](#)

get_safety_error_code_rules

return the names of safety error code rules.

SYNTAX

```
status get_safety_error_code_rules
  [-of_objects of_object]
  [-quiet]
```

Data Types

of_object collection

ARGUMENTS

-of_objects *of_object*

Gets safety error code rules associated with these objects.

DESCRIPTION

Finds the safety error code rule names of specified error code. If no options are specified, it returns all the safety error code rule names of the current design.

SEE ALSO

[create_safety_error_code_rule\(2\)](#)
[report_safety_error_code_rules\(2\)](#)

get_safety_register_groups

Gets a collection of safety register groups.

SYNTAX

```
status get_safety_register_groups
  [-of_objects cells]
  [-quiet]
```

Data Types

cells collection

ARGUMENTS

-of_objects *cells*

Gets safety register groups associated with these registers or pins

DESCRIPTION

Finds the safety_register_group names based on the option. If no options are specified, it returns the names of all the safety register groups of the current design.

SEE ALSO

[create_safety_register_group\(2\)](#)
[report_safety_register_groups\(2\)](#)
[write_safety_register_data\(2\)](#)

get_safety_register_rules

return the names of safety register rules.

SYNTAX

```
status get_safety_register_rules
  [-of_objects registers]
  [-quiet]
```

Data Types

registers collection

ARGUMENTS

-of_objects *registers*

Gets safety register rules associated with these registers or pins

DESCRIPTION

Finds the safety register rule names of specified cells. If no options are specified, it returns all the safety register rule names of the current design.

SEE ALSO

`create_safety_register_rule(2)`
`report_safety_register_rules(2)`
`write_safety_register_data(2)`

get_scan_cell_names

Returns a list containing the names of scan cells for the specified option filters.

SYNTAX

```
list get_scan_cell_names
  [-view spec | existing_dft]
  [-chain chain_name_list | all]
  [-test_mode mode_name_list | all]
```

Data Types

<i>chain_name_list</i>	list
<i>mode_name_list</i>	list

ARGUMENTS

-view *spec* | *existing_dft*

Specifies the type of scan information to retrieve. Valid options are **spec** and **existing_dft**. Specifying the **spec** value shows only user-defined scan path information previously specified with the **set_scan_path** command. Specifying the **existing_dft** value shows only scan paths already inserted by the **insert_dft** command. The default behavior is to show both views.

-chain *chain_name_list* | **all**

When specified, retrieves and returns a list of scan cell names contained in the specified scan chains, or for all scan chains if **all** is specified. By default, the scan cells for all chains are returned.

-test_mode *mode_name_list* | **all**

Reports only on the specified test mode(s), or on all test modes if **all** is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

DESCRIPTION

This command returns a Tcl list of scan cell names (as strings), according to the specified options. The information can include scan paths defined by the **set_scan_path** command, as well as scan paths inserted by the **insert_dft** command.

By default, the command returns the scan cell names for all chains, in both the **spec** and **existing_dft** views, in the current test mode.

EXAMPLES

The following example reports all the scan cells, of every scan chain, for every defined test mode:

```
prompt> set mode_list [all_test_modes]
foreach p $mode_list {
    set chain_list [get_scan_chain_names -test_mode $p]
    foreach q $chain_list {
        set scan_cell_names_list [get_scan_cell_names -chain $q]
        foreach r $scan_cell_names_list {
            report_cell $r
        }
    }
}
```

SEE ALSO

[current_test_mode\(2\)](#)
[all_test_modes\(2\)](#)
[get_scan_chain_names\(2\)](#)
[report_dft_signal\(2\)](#)
[report_scan_configuration\(2\)](#)
[report_scan_path\(2\)](#)
[set_dft_configuration\(2\)](#)
[set_dft_signal\(2\)](#)
[set_scan_configuration\(2\)](#)
[set_scan_path\(2\)](#)

get_scan_cells_of_chain

Returns a collection containing all scan cells of the specified scan chain.

SYNTAX

```
collection get_scan_cells_of_chain
  -chain chain_name
  [-test_mode test_mode]
```

Data Types

<i>chain_name</i>	string
<i>test_mode</i>	string

ARGUMENTS

-chain *chain_name*

Specifies the name of the scan chain.

-test_mode *test_mode*

Specifies a mode name. The command returns only scan cells of this mode name in the Tcl collection. By default, this option is off.

DESCRIPTION

This command returns a Tcl collection containing all scan cells for the specified scan chain.

If CTL-modeled core scan segments exist in the scan chain,

- If the CTL-modeled core has its netlist in memory, the individual cells composing the scan segment(s) are returned. (However, remember that DFT configuration commands require CTL model scan segments to be referenced by their segment name, not by their individual scan cells.)
- If the CTL-modeled core has no netlist, the CTL-modeled cell itself is returned. This reference contains no information about the scan segment name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example gets all scan cells of the *chain1* scan chain:

```
prompt> get_scan_cells_of_chain -chain "chain1"
```

SEE ALSO

[get_scan_chains\(2\)](#)

get_scan_chain_names

Returns a list containing the names of scan chains for the specified option filters.

SYNTAX

```
list get_scan_chain_names
  [-view spec | existing_dft]
  [-test_mode mode_name_list | all]
```

Data Types

mode_name_list list

ARGUMENTS

-view spec | existing_dft

Specifies the type of scan information to retrieve. Valid options are **spec** and **existing_dft**. Specifying the **spec** value shows only user-defined scan path information previously specified with the **set_scan_path** command. Specifying the **existing_dft** value shows only scan paths already inserted by the **insert_dft** command. The default behavior is to show both views.

-test_mode mode_name_list | all

Reports only on the specified test mode(s), or on all test modes if **all** is specified. For multiple modes, the lists are concatenated together. By default, the tool reports on the current test mode. If no test modes are defined, the default is to report on the Internal_scan mode.

DESCRIPTION

This command returns a Tcl list of scan chain names (as strings), according to the specified options. The information can include scan paths defined by the **set_scan_path** command, as well as scan paths inserted by the **insert_dft** command.

By default, the command returns the scan chain names for both **spec** and **existing_dft** views, in the current test mode.

EXAMPLES

The following example reports all the scan cells, of every scan chain, for every defined test mode:

```
prompt> set mode_list [all_test_modes]
foreach p $mode_list {
  set chain_list [get_scan_chain_names -test_mode $p]
```

```
foreach q $chain_list {  
    set scan_cell_names_list [get_scan_cell_names -chain $q]  
    foreach r $scan_cell_names_list {  
        report_cell $r  
    }  
}
```

SEE ALSO

[set_dft_signal\(2\)](#)
[set_scan_configuration\(2\)](#)
[set_scan_path\(2\)](#)

get_scan_chains

Returns the number of scan chains in the current design.

SYNTAX

```
status get_scan_chains  
[-test_mode test_mode]
```

Data Types

test_mode string

ARGUMENTS

-test_mode *test_mode*

Specifies the target test mode to use to return the number of scan chains.

DESCRIPTION

This command returns the number of scan chains in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example shows how to get the number of scan chains in the design:

```
prompt> get_scan_chains
```

SEE ALSO

[get_scan_cells_of_chain\(2\)](#)

get_scenarios

Returns a list of scenarios that match all of the specified criteria.

SYNTAX

```
list get_scenarios
  [-setup true | false]
  [-hold true | false]
  [-leakage_power true | false]
  [-dynamic_power true | false]
  [-active true | false]
  [pattern]
  [-cts_mode true | false]
  [-cts_corner min | max | min_max]
```

Data Types

pattern string

ARGUMENTS

-setup true | false

Compares against the setup option for each scenario.

-hold true | false

Compares against the hold option for each scenario.

-leakage_power true | false

Compares against the leakage power option for each scenario.

-dynamic_power true | false

Compares against the dynamic power option for each scenario.

-active true | false

Controls whether the command returns active or inactive scenarios. When this option is true, returns only scenarios that are currently active. When false, returns only scenarios that are currently inactive.

pattern

Matches scenario names against the specified pattern.

DESCRIPTION

This command returns a list of scenarios that match all the specified criteria.

If you do not specify any arguments, the command returns all scenarios in the current design, similar to the **all_scenarios** command.

If you specify only the *pattern* argument, the command returns a list of all scenarios whose name matches that pattern.

All arguments other than *pattern* and **-active** are tested against the options set by the **set_scenario_options** for each scenario. For more information about the scenario options, see the man page of the **set_scenario_options** command.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example uses the **get_scenarios** command to activate a list of inactive scenarios that are configured to be used for setup and hold optimization.

```
prompt> set_active_scenarios \
[get_scenarios -setup true -hold true -active false]
Information: Scenario S4 is now active. (UID-1023)
1
```

The following example uses the **get_scenarios** command to loop through and report on all CTS scenarios for clock tree reporting.

```
prompt> set_current [current_scenario]
prompt> foreach scenario [get_scenarios -cts_mode true -active true] {
  current_scenario $scenario
  report_clock_tree
}
prompt> current_scenario $_current
```

SEE ALSO

[report_scenario_options\(2\)](#)
[set_scenario_options\(2\)](#)
[all_scenarios\(2\)](#)
[current_scenario\(2\)](#)
[set_active_scenarios\(2\)](#)

get_selection

Returns a collection that contains the objects in the current selection.

SYNTAX

```
collection get_selection
  [-slct_targets target_selection_bus
   [-slct_targets_operation operation]]
  [-create_slct_buses]
  [-name selection_bus]
  [-type object_type]
  [-design design]
  [-more_than more]
  [-fewer_than fewer]
  [-count]
  [-num max_objects]
  [-type_list]
```

Data Types

<i>target_selection_bus</i>	string
<i>operation</i>	string
<i>selection_bus</i>	string
<i>object_type</i>	string
<i>design</i>	string
<i>more</i>	integer
<i>fewer</i>	integer
<i>max_objects</i>	integer

ARGUMENTS

-slct_targets *target_selection_bus*

Specifies the name of the selection bus in which to store the result. When you use this option, the command returns the *target_selection_bus* value. By default, the command returns the result in a collection.

-slct_targets_operation *operation*

Specifies the operation used to store the result in the selection bus specified by the **-slct_targets** option. The valid values for the *operation* argument are **clear**, **add**, and **remove**.

You can use the **-slct_targets_operation** option only when you also use the **-slct_targets** option.

-create_slct_buses

Creates a new selection bus in which to store the result.

-name *selection_bus*

Specifies the selection bus from which the selection is taken.

-type *object_type*

Filters the selection by object type and returns only the objects of the specified *object_type*. The valid values for *object_type* and their descriptions are

```
design -- design object
port   -- port object
net    -- net object
cell   -- cell object
pin    -- pin object
path   -- timing path object
```

-design *design*

Returns only objects in the filter specified by *design*.

-more_than *more*

Returns 1 if the selection bus contains more than the number of objects specified by *more*; otherwise, returns 0.

This option and the **-type_list** option are mutually exclusive.

-fewer_than *fewer*

Returns 1 if the selection bus contains more than the number of objects specified by *fewer*; otherwise, returns 0.

This option and the **-type_list** option are mutually exclusive.

-count

Returns the number of elements contained in the selection bus.

This option and the **-type_list** option are mutually exclusive.

-num *max_objects*

Specifies the maximum number of objects in the collection. The tool returns *max_objects* objects or fewer depending on the number of objects in the current selection.

-type_list

Returns only the number of objects of each object type in the collection.

You cannot use this option with the **-more_than** option, the **-fewer_than** option, or the **-count** option.

DESCRIPTION

The **get_selection** command returns a collection that contains the current selection in the tool. By default, the command returns a collection handle (identifier) if any objects are selected. If no objects are selected, the command returns an empty string.

By default, the command returns a heterogeneous collection that contains all the objects that are currently selected. If you use the **-type** option, the command returns a homogeneous collection that has been filtered to contain only the objects of the type that you specify.

You can enter the **get_selection** command at the command prompt, or you can nest it as an argument to another command, such as **query_objects**, or assign the **get_selection** result to a variable.

When you enter **get_selection** at the command prompt, it behaves as if you had called **query_objects** to display the objects in the collection. By default, **get_selection** displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

The "implicit query" property of **get_selection** allows you to display cells in a collection. However, if you want the flexibility provided by the options of the **query_objects** command (for example, to display the object class), use **get_selection** as an argument to

query_objects.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example returns a collection containing the cell objects in the current selection:

```
prompt> get_selection -type cell  
{I_PRGRM_CNT_TOP I_DATA_PATH I_REG_FILE I_STACK_TOP}
```

The following example assigns the collection to a variable named "collect_a" that is passed to the **query_objects** command:

```
prompt> set collect_a [get_selection -type cell]  
{I_PRGRM_CNT_TOP I_DATA_PATH I_REG_FILE I_STACK_TOP}  
prompt> query_objects $collect_a

get_shift_register_chains

Creates a list of collections of shift-register cells in the current design, where each collection is an ordered set of shift-register chain cells.

SYNTAX

```
list of collection get_shift_register_chains
  [-quiet]
  [-power_domain ignore | skip | split]
  [patterns]
```

Data Types

patterns list or collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-power_domain ignore | skip | split

Controls how the **get_shift_register_chains** command returns shift registers that cross power domains.

Specify **ignore** to ignore power domain information and return the shift registers even if they cross power-domain boundaries. This is the default.

Specify **skip** to skip (not return) shift registers that crosspower-domain boundaries.

Specify **split** to return shift registers that crosspower-domain boundaries as if they are separate shift registers, one shift register for each power domain. Note that this option does not modify the shift register logic; it only affects the results returned by this command.

patterns

Creates collections of shift-register chains whose names match the specified patterns. Patterns can include the asterisk (*) and question mark (?) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page.

You can also provide a collection of cells as a subset so that the command only returns shift-register chains from this subset of cells.

DESCRIPTION

The **get_shift_register_chains** command queries and returns shift registers identified during test-ready compile. Shift registers are identified by the **compile_ultra -scan** command when the **compile_seqmap_identify_shift_registers** variable is set to **true**.

The **get_shift_register_chains** command creates a list of collections of shift-register chains that match the specified criteria. By default, the command creates one collection for each shift-register chain found in the current design.

The order of shift-register elements in each collection is based on netlist connectivity: the first element is the shift register that is the head of the chain, the second element is the next shift register in the chain, and so on.

Note that if you have enabled synchronous shift-register identification by setting the **compile_seqmap_identify_shift_registers_with_synchronous_logic** variable to **true**, this command does not return synchronous-logic shift registers that have discrete combinational logic cells (other than buffers and inverters) between the register cells.

The shift-register elements within a collection can span different levels of design hierarchy.

If the command cannot find a shift-register chain that matches the criteria, the command issues a UID-921 warning message unless you specify the **-quiet** option.

You can use this command to assign the resulting list to a variable, then evaluate each collection of the list using **query_objects**.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example queries shift-register chains that contains shift registers with names that begin with "sr":

```
prompt> foreach chain [get_shift_register_chains sr* ] { query_objects $chain }
{sr_reg1 sr_reg2 sr_reg3 sr_reg4}
{sr_reg5 U23/shift_reg1 U23/shift_reg2}
{U4/shr22 U4/shr23 sr_reg6}
```

The following example queries shift-registers chains that match a collection of cells:

```
prompt> foreach chain [get_shift_register_chains [get_cells shr* ] { query_objects $chain }
{U4/shr22 U4/shr23 sr_reg6}]
```

[compile_seqmap_identify_shift_registers_with_synchronous_logic\(3\)](#)

get_site_rows

Returns a collection of site rows from the current design that match the specified criteria.

SYNTAX

```
collection get_site_rows
  [-quiet]
  [-regexp | -exact]
  [-nocase]
  [-filter expression]
  [-within region
   | -touching region
   | -intersect region]
  [patterns]
```

Data Types

<i>expression</i>	string
<i>region</i>	list of points
<i>patterns</i>	list

ARGUMENTS

-quiet

Suppresses warning and error messages, if no objects match. Does not suppress syntax error messages.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-exact

Considers wildcards to be plain characters, and does not interpret their meaning as wildcards.

The `-regexp` and `-exact` options are mutually exclusive; you can use only one.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each site row in the collection, the expression is evaluated based on the site row's attributes. If the expression evaluates to true, the site row is included in the result.

To see the list of site row attributes that you can use in the expression, use the **list_attributes -application -class site_row** command.

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-within region

Creates a collection that contains all site rows that are completely inside the specified region and do not overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$ or $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\,\,y1\}\,\{x2\,\,y2\}\dots\{xN\,\,yN\}\,\{x1\,\,y1\}\}$, where each $\{x\,\,y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches for site rows in the entire design.

-touching region

Creates a collection that contains all site rows that are inside the specified region, including those that overlap the boundary. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$ or $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\,\,y1\}\,\{x2\,\,y2\}\dots\{xN\,\,yN\}\,\{x1\,\,y1\}\}$, where each $\{x\,\,y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches for site rows in the entire design.

-intersect region

Creates a collection that contains all site rows that intersect the boundary of the specified region and at least part of the cell is outside of the specified region. The region boundary can be rectangle or polygon.

The format for specifying a rectangle is $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$ or $\{\{llx\,\,lly\}\,\{urx\,\,ury\}\}$, which specifies the lower-left and upper-right corners of the rectangle.

The format for specifying a polygon is $\{\{x1\,\,y1\}\,\{x2\,\,y2\}\dots\{xN\,\,yN\}\,\{x1\,\,y1\}\}$, where each $\{x\,\,y\}$ pair specifies one point of the input polygon. A valid polygon must be rectilinear, so the startpoint and endpoint of the polygon are the same point.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, and **-intersect** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches for site rows in the entire design.

patterns

Creates a collection of site rows whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this argument, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of site rows by selecting site rows from the current design that match the specified criteria.

When using the **-within**, **-touching**, or **-intersect** option, note that the behavior differs depending on the format of the specified region. An object has both a boundary and a bounding box (bbox). In some cases, these attributes differ. When you specify a region in rectangle format, the tool searches objects by their bounding box. When you specify a region in polygon format, the tool searches objects by their boundary. Searching by bounding box is faster than searching by boundary.

The command returns a collection if any site rows match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the site rows in the current design.

```
prompt> get_site_rows
{SITE_ROW#12345 SITE_ROW#12346 SITE_ROW#12347 my_row1 my_row2}
```

The following example returns a collection that contains the site rows whose name is prefixed with my_row.

```
prompt> get_site_rows my_row*
{my_row1 my_row2}
```

The following example returns a collection that contains the site rows within the specified rectangle.

```
prompt> get_site_rows -within {{2 2} {250 150}}
{test_site_row1}
```

The following example returns a collection that contains the site rows that intersect the specified polygon.

```
prompt> get_site_rows \
    -intersect {{5 5} {200 5} {200 100} {5 100} {5 5}}
{test_site_row1 test_site_row2}
```

get_supply_nets

Creates a collection of supply nets that match the specified criteria.

SYNTAX

```
collection get_supply_nets
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns]
```

Data Types

expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each supply net in the collection, the expression is evaluated based on the supply net's attributes. If the expression evaluates to true, the supply net is included in the result.

To see the list of supply net attributes that you can use in the expression, use the `list_attributes -application -class supply_net` command.

For more information about how to use the `-filter` option, see the `filter_collection` man page.

-hierarchical

Searches for supply nets in the current scope and all of its descendant scopes.

If you specify this option, you can specify only simple names in the *patterns* argument; the name cannot contain hierarchy delimiter characters.

If you do not specify this option, the tool searches for supply nets only in the current scope. You can use hierarchy delimiter characters in the *patterns* argument to specify hierarchical supply nets relative to the current scope.

patterns

Creates a collection of supply nets whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this option, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of supply nets by selecting supply nets from the current design that match the specified criteria.

If no supply nets match the criteria and the design is not linked, the tool automatically links the design.

The command returns a collection if any supply nets match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example gets all supply nets under the current scope:

```
prompt> get_supply_nets -hierarchical  
{VDD SUB_INST/VDD}
```

get_supply_ports

Creates a collection of supply ports that match the specified criteria.

SYNTAX

```
collection get_supply_ports
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [-hierarchical]
  [patterns]
```

Data Types

expression string
patterns list

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter *expression*

Filters the collection with the specified expression. For each supply port in the collection, the expression is evaluated based on the supply port's attributes. If the expression evaluates to true, the supply port is included in the result.

To see the list of supply port attributes that you can use in the expression, use the `list_attributes -application -class supply_port` command.

For more information about how to use the `-filter` option, see the `filter_collection` man page.

-hierarchical

Searches for supply ports in the current scope and all of its descendant scopes.

When you use the **-hierarchical** option, you can specify only simple names in the *patterns* option; the name cannot contain hierarchy delimiter characters.

By default, the tool searches for supply ports only in the current scope and you can use hierarchy delimiter characters in the *patterns* option to specify hierarchical supply ports relative to the current scope.

patterns

Creates a collection of supply ports whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

If you do not specify this option, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of supply ports by selecting supply ports from the current design that match the specified criteria.

If no supply ports match the criteria and the design is not linked, the tool automatically links the design.

The command returns a collection if any supply ports match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

wildcards(3)
```

get_switching_activity

Gets switching activity information on nets, pins, ports and cells in the current design.

SYNTAX

```
string get_switching_activity
      [-state_condition state_condition]
      [-path_sources path_sources]
      [-rise]
      [-fall]
      [-related_clock]
      [-scenarios scenario_list]
      object_list
```

Data Types

<i>state_condition</i>	string
<i>path_sources</i>	list
<i>scenario_list</i>	list
<i>object_list</i>	list

ARGUMENTS

-state_condition *state_condition*

Specifies the state condition for reporting state-dependent activities. State dependent activities can be reported when the object is already annotated with state-dependent activities. The state condition specified with this argument must match to a state condition already annotated for this object. Use -state_condition default to specify the default state condition.

-path_sources *path_sources*

Specifies the path sources when reporting path-dependent activities. This can be used when the object is already annotated with path-dependent activities. The path sources specified with this argument must be the same as those annotated for this object. If -path_sources option is used to specify the path_sources value, then -state_condition option must be specified to specify the value of the path_sources.

-rise

This option is used with the **-state_condition** option. It reports rise transition.

-fall

This option is used with the **-state_condition** option. It reports fall transition.

-related_clock

This option is used to print the clock domain of the objects.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only the current scenario is considered. Output of the

command is generated separately for each scenario.

object_list

Specifies a net, pin, port or cell in the current design for which the values of static probability, the toggle rate and the type of activity are to be reported.

DESCRIPTION

This command is used to report switching activity information on nets, ports, pins and cells. Switching activity information includes toggle rate, static probability and activity type.

Note that *object_list* argument should always be provided to the command. The activity type reported by the command can only be one of 'annotated', 'simulated', 'inferred', 'propagated', or 'default'.

For more statistics on the switching activity annotation on the current design, use the **report_activity** command.

Multicorner-Multimode Support

This command uses information from the current scenario only if **-scenarios** option is not specified.

EXAMPLES

The following **get_switching_activity** command reports the toggle rate and static probability values for a list of objects for the current scenario in the design.

```
prompt> get_switching_activity {U1/A U1/B}
(U1/A: probability = 0.800000, toggle_rate = 0.900000, type = annotated)
(U1/B: probability = 0.800000, toggle_rate = 0.900000, type = annotated)
```

The following **get_switching_activity** command reports the activity information for a list of objects for the current scenario with related_clock information.

```
prompt> get_switching_activity {U1/A U1/B} -related_clock
(U1/A: probability = 0.800000, toggle_rate = 0.900000, type = annotated, related_clock = clk)
(U1/B: probability = 0.800000, toggle_rate = 0.900000, type = annotated, related_clock = clk)
```

SEE ALSO

`read_saif(2)`

`set_switching_activity(2)`

get_terminals

Creates a collection of terminals that match the specified criteria.

SYNTAX

```
collection get_terminals
  [-quiet]
  [-regexp]
  [-nocase]
  [-filter expression]
  [patterns | -of_objects port_list]
```

Data Types

<i>expression</i>	string
<i>patterns</i>	list
<i>port_list</i>	collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as a regular expression rather than a simple wildcard pattern.

This option also modifies the behavior of the `=~` and `!~` filter operators to use regular expressions rather than simple wildcard patterns.

The regular expression matching is similar to the Tcl `regexp` command. When using the `-regexp` option, be careful how you quote the *patterns* argument and filter expression. Using rigid quoting with curly braces around regular expressions is recommended. Note that regular expressions are always anchored; that is, the expression is assumed to begin matching at the beginning of an object name and end matching at the end of an object name. You can widen the search by adding `".*"` to the beginning or end of the expressions, as needed.

-nocase

Makes matches case-insensitive, both for the *patterns* argument and for the `==`, `=~`, and `!~` filter operators.

-filter expression

Filters the collection with the specified expression. For each terminal in the collection, the expression is evaluated based on the terminal's attributes. If the expression evaluates to true, the terminal is included in the result.

To see the list of terminal attributes that you can use in the expression, use the `list_attributes -application -class terminal` command.

For more information about how to use the `-filter` option, see the `filter_collection` man page.

patterns

Creates a collection of terminals whose names match the specified patterns. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case sensitive unless you use the **-nocase** option.

The **patterns** and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects port_list

Creates a collection of terminals connected to the specified ports.

The **patterns** and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

DESCRIPTION

This command creates a collection of terminals by selecting terminals from the current design that match the specified criteria.

The command returns a collection if any terminals match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a collection of terminals named reset or with a prefix of clock:

```
prompt> get_terminals [list reset clock*]
{reset clock}
```

`collection_result_display_limit(3)`
`wildcards(3)`

get_timing_paths

Creates a collection of timing paths for custom reporting and other processing.

SYNTAX

```
collection get_timing_paths
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-exclude exclude_list]
  | -rise_exclude rise_exclude_list
  | -fall_exclude fall_exclude_list]
  [-delay_type delay_type]
  [-nworst paths_per_endpoint]
  [-max_paths max_path_count]
  [-enable_preset_clear_arcs]
  [-group group_name]
  [-greater greater_limit]
  [-lesser lesser_limit]
  [-slack_greater_than greater_slack_limit]
  [-slack_lesser_than lesser_slack_limit]
  [-include_hierarchical_pins]
  [-path_type full_clock_expanded | full]
  [-unique_pins]
  [-start_end_pair]
  [-scenarios scenario_list]
```

Data Types

<i>lesser_limit</i>	float
<i>greater_slack_limit</i>	float

```
lesser_slack_limit    float
scenario_list          list
```

ARGUMENTS

-to to_list

Specifies the to pins, ports, nets, or clocks. Path endpoints are the output ports or data pins of registers. If you specify a clock, the command considers all endpoints that are constrained by the clock.

-rise_to rise_to_list

This option is similar to the **-to** option, but applies only to paths rising at the endpoint. If you specify a clock, this option selects the paths that are captured by the rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-fall_to fall_to_list

This option is similar to the **-to** option, but applies only to paths falling at the endpoint. If you specify a clock, this option selects the paths that are captured by the falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-from from_list

Specifies the from pins, ports, nets, or clocks. Path startpoints are the input ports or clock pins of registers. If you specify a clock, the command considers all startpoints clocked by the clock.

-rise_from rise_from_list

This option is similar to the **-from** option, but applies only to paths rising from the specified objects. If you specify a clock, this option selects the startpoints whose paths are launched by the rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-fall_from fall_from_list

This option is similar to the **-from** option, but applies only to paths falling from the specified objects. If you specify a clock, this option selects the startpoints whose paths are launched by the falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-through through_list

Reports only paths that pass through the named pins, ports, or clocks. If you do not use the **-through** option, the command defaults to reporting the longest path to an output port if the design has no timing constraints. If it has timing constraints, the default is to report the path with the worst slack within each path group if you do not use the **-group** option. If you use **-group**, the default is to report the path with the worst slack within the group specified by the *group_name* value.

If you specify the **-through** option only once, the tool reports only the paths that travel through one or more of the objects in the list. You can use **-through** more than once in one command invocation. For a discussion of the use of multiple **-through** options, see the *DESCRIPTION* section.

-rise_through rise_through_list

This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the *DESCRIPTION* section.

-fall_through fall_through_list

This option is similar to the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the *DESCRIPTION* section.

-exclude exclude_list

Excludes all data paths from/through/to the named pins, ports, nets, and cell instances. Any data path that starts from, contains, or ends on a listed object is excluded. If you specify a cell instance, data paths that include any pin of that cell instance are excluded. This option has higher precedence than the **-from**, **-through**, **-to**, and similar options.

The exclusion does not apply to clock paths, even when the **-path_type full** or **-path_type full_clock_expanded** option is used. It does not apply to borrowing paths from the **-trace_latch_borrow** option.

This option is not applied to clock pins.

-rise_exclude *rise_exclude_list*

Same as the **-exclude** option, but applies only to paths rising at the named pins, ports, nets, and cell instances.

-fall_exclude *fall_exclude_list*

Same as the **-exclude** option, but applies only to paths falling at the named pins, ports, nets, and cell instances.

-delay_type *delay_type*

Specifies the type of path delay. The valid values are **max**, **min**, **min_max**, **max_rise**, **max_fall**, **min_rise**, and **min_fall**. The rise or fall in the *delay_type* refers to a rising or falling transition at the path endpoint.

-nworst *paths_per_endpoint*

Specifies the maximum number of paths to get per endpoint. The default is 1, which gets only the single worst path ending at a given endpoint.

-max_paths *max_path_count*

Specifies the number of paths to get per path group by default, or the number of paths to get from the whole design if the **timing_report_fast_mode** variable is set to true. The default is 1.

-enable_preset_clear_arcs

Enables asynchronous preset and clear arcs for the timing path collection. By default, asynchronous timing arcs are disabled during timing verification.

-group *group_name*

Restricts the collection to paths in this *group_name*. Use the **group_path** or **create_clock** command to group paths.

-greater *greater_limit*

Selects only those paths that have a delay greater than the *greater_limit* value. The **-greater** and **-lesser** options can be combined to select only those paths inside or outside of a given delay range. The specified value is in main library units.

-lesser *lesser_limit*

Selects only those paths that have a delay less than the *lesser_limit* value. The **-greater** and **-lesser** options can be combined to select only those paths inside or outside of a given delay range. The specified value is in main library units.

-slack_greater_than *greater_slack_limit*

Selects only those paths with a slack greater than *greater_slack_limit*. The **-slack_greater_than** option can be combined with the **-slack_lesser_than** option to select only those paths inside or outside of a given slack range. The specified value is in main library units.

-slack_lesser_than *lesser_slack_limit*

Selects only those paths with a slack less than *lesser_slack_limit*. The **-slack_greater_than** option can be combined with the **-slack_lesser_than** option to select only those paths inside or outside of a given slack range. The specified value is in main library units.

-include_hierarchical_pins

Specifies for the returned timing paths to contain points for each hierarchical pin crossed, as well as for all leaf pins in the path. It also sets to **true** their **hierarchical** attributes. Note that clock paths are always hierarchical.

-path_type full_clock_expanded | full

Specifies whether or not to calculate launch and capture clock paths (if they exist) for the selected paths. The valid values are **full_clock_expanded** and **full**. When you specify *full_clock_expanded*, the tool calculates clock paths. When you specify **full**, it does not calculate them. You can access the clock path data of a path (if calculated) via its **launch_clock_paths** and **capture_clock_paths** attributes.

-unique_pins

Causes only the single worst timing path through any given sequence of pins to be reported. No other paths are reported for the same sequence of pins from startpoint to endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin sequence, then paths starting with a falling edge are not reported for that sequence. For non-unate logic such as XOR gates, this greatly reduces the number of paths reported because of the large number of possible rising/falling edge combinations through the sequence of pins. Using this option can require longer runtimes when used with the **-nworst n** option because many paths must be analyzed to find the worst path through each pin sequence, but only the worst path is reported and counted toward the total number of requested paths.

-start_end_pair

Limits the collection of paths returned to the single worst timing path per each combination of startpoint and endpoint found. No other paths are included that have the same startpoint and same endpoint. For example, if the worst path starts at a register output pin ff1/Q and ends at a register input pin ff5/D, the collection will omit all other less critical paths from ff1/Q to ff5/D. Using this option can require longer runtimes when used with the **-nworst n** option because many paths must be analyzed to find the worst path through each pin pair, but only the worst path in each case is selected and counted toward the total number of requested paths.

-scenarios scenario_list

Gets timing paths from the specified scenarios. Inactive scenarios are skipped.

If you do not specify this option, only the timing paths from current scenario are returned.

DESCRIPTION

This command creates a collection of paths for custom reporting or other operations. You can use the **foreach_in_collection** command to iterate among the paths in the collection. You can use the **get_attribute** and **collection** commands to obtain information about the paths. The following attributes are supported on timing paths:

```
capture_clock_paths
clock_uncertainty
clock_path
crpr_common_point
crpr_value
endpoint
endpoint_clock
endpoint_clock_close_edge_type
endpoint_clock_close_edge_value
endpoint_clock_is_inverted
endpoint_clock_is_propagated
endpoint_clock_latency
endpoint_clock_open_edge_type
endpoint_clock_open_edge_value
endpoint_clock_pin
endpoint_hold_time_value
endpoint_is_level_sensitive
endpoint_output_delay_value
endpoint_recovery_time_value
endpoint_removal_time_value
endpoint_setup_time_value
hierarchical
launch_clock_paths
object_class
```

```

path_group
path_type
points
scenario
slack
startpoint
startpoint_clock
startpoint_clock_is_inverted
startpoint_clock_is_propagated
startpoint_clock_latency
startpoint_clock_open_edge_type
startpoint_clock_open_edge_value
startpoint_input_delay_value
startpoint_is_level_sensitive
time_borrowed_from_endpoint
time_lent_to_startpoint

```

One attribute of a timing path is the **points** collection. A point corresponds to a pin or port along the path. You can iterate through these points by using the **foreach_in_collection** command and get their attributes by using the **get_attribute** command. The following attributes are available for points of a timing path:

```

arrival
object
object_class
rise_fall
slack

```

See the **collections** and **foreach_in_collection** man pages for detailed information.

By default, the **get_timing_paths** command uses a reporting engine that can run extremely fast on large designs, especially for larger values of the **nworst** and **max_paths** arguments. For designs that have multiple timing paths with identical slack, this engine might report different paths (with the same slack value) than a previous engine that was once in use.

You can use multiple iterations of the **-through**, **-rise_though**, and **-fall_through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1.

```

prompt> get_timing_paths -from A1\
           -through B1 -through C1 -to D1

```

If more than one object is specified by one **-through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1.

```

prompt> get_timing_paths -from A1 -through {B1 B2} -through {C1 C2} -to D1

```

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example prints out the startpoint name, endpoint name, and slack of the worst path in each path group.

```

proc custom_report_worst_path_per_group {} {
    echo [format "%-20s %-20s %7s" "From" "To" "Slack"]
    echo "-----"
    foreach_in_collection path [get_timing_paths] {
        set slack [get_attribute $path slack]
        set startpoint [get_attribute $path startpoint]
        set endpoint [get_attribute $path endpoint]
    }
}

```

```

        echo [format "%-20s %-20s %s" [get_attribute $startpoint full_name] \
               [get_attribute $endpoint full_name] $slack]
    }
}

```

prompt> custom_report_worst_path_per_group

From	To	Slack
ffa/CP	QA	0.1977
ffb/CP	ffd/D	3.8834

The following example shows total negative slack, total positive slack, and worst negative slack for the current design.

```

proc report_design_slack_information {} {
    set design_tns 0
    set design_wns 100000
    set design_tps 0
    foreach_in_collection group [get_path_groups *] {
        set group_tns 0
        set group_wns 100000
        set group_tps 0
        foreach_in_collection path [get_timing_paths -nworst 10000 -group [get_object_name $group]]{
            set slack [get_attribute $path slack]
            if {$slack < $group_wns} {
                set group_wns $slack
                if {$slack < $design_wns} {
                    set design_wns $slack
                }
            }
            if {$slack < 0.0} {
                set group_tns [expr $group_tns + $slack]
            } else {
                set group_tps [expr $group_tps + $slack]
            }
        }
        set design_tns [expr $design_tns + $group_tns]
        set design_tps [expr $design_tps + $group_tps]
        set group_name [get_attribute $group full_name]
        echo [format "Group '%s' Worst Negative Slack : %g" $group_name $group_wns]
        echo [format "Group '%s' Total Negative Slack : %g" $group_name $group_tns]
        echo [format "Group '%s' Total Positive Slack : %g" $group_name $group_tps]
        echo ""
    }
    echo "-----"
    echo [format "Design Worst Negative Slack : %g" $design_wns]
    echo [format "Design Total Negative Slack : %g" $design_tns]
    echo [format "Design Total Positive Slack : %g" $design_tps]
}

```

prompt> report_design_slack_information

get_tracks

Creates a collection of track objects that match the specified criteria.

SYNTAX

```
collection get_tracks
  [-quiet]
  [-filter expression]
  [-within rectangle
    | -touching rectangle
    | -intersect rectangle
    | -at at_point
  ]
  [patterns | -of_objects layers]
```

Data Types

<i>expression</i>	string
<i>rectangle</i>	list of points
<i>at_point</i>	point
<i>patterns</i>	string
<i>layers</i>	collection

ARGUMENTS

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-filter *expression*

Filters the collection with the specified expression. For each track in the collection, the expression is evaluated based on the track's attributes. If the expression evaluates to true, the track is included in the result.

You can use the following track attributes in the expression:

Attribute	Description
<i>bbox</i>	Coordinates of the bounding box of the track object
<i>name</i>	Name of the track object
<i>layer</i>	Name of the layer that the track is on
<i>direction</i>	Direction of the wire tracks, vertical or horizontal
<i>count</i>	Number of parallel wire tracks in the track object
<i>space</i>	Pitch of the wire tracks in the track object
<i>start</i>	Coordinates of the lower-left corner of the object
<i>stop</i>	Coordinates of the upper-right corner of the object

For more information about how to use the **-filter** option, see the **filter_collection** man page.

-within *rectangle*

Creates a collection that contains all tracks that are completely inside the specified rectangle and do not overlap the boundary.

The format for specifying the rectangle is $\{\{lx\ ly\} \{urx\ ury\}\}$ or $\{lx\ ly\ urx\ ury\}$, which specifies the lower-left and upper-right corners of the rectangle.

The coordinate unit is specified in the technology file; typically the unit is microns.

The **-within**, **-touching**, **-intersect**, and **-at** options are mutually exclusive; you can specify only one. If you do not specify any of these options, the command searches the entire design.

-touching rectangle

Creates a collection that contains all tracks that are inside the specified rectangle, including those that overlap the boundary.

The format for specifying the rectangle is the same as for the **-within** argument.

-intersect rectangle

Creates a collection that contains all tracks that intersect the boundary of the specified rectangle and at least part of the cell is outside of the specified rectangle.

The format for specifying the rectangle is the same as for the **-within** argument.

-at at_point

Creates a collection that contains all tracks at the specified point. The format for specifying a point is $\{x\ y\}$.

patterns

Creates a collection of tracks whose names match the specified patterns. Track names use the naming convention TRACK_n, where n is an integer. Patterns can include the * (asterisk) and ? (question mark) wildcard characters. For more information about using and escaping wildcards, see the **wildcards** man page. Pattern matching is case-sensitive.

The **patterns** and **-of_objects** arguments are mutually exclusive; you can specify only one. If you do not specify either of these arguments, the command uses * (asterisk) as the default pattern.

-of_objects layers

Creates a collection of tracks that are on the specified layers.

DESCRIPTION

This command creates a collection of track objects by selecting the track objects in the current design that match specified criteria.

When using the **-within**, **-touching**, or **-intersect** option, note that the behavior differs depending on the format of the specified region. An object has both a boundary and a bounding box (bbox). In some cases, these attributes differ. When you specify a region in rectangle format, the tool searches objects by their bounding box. When you specify a region in polygon format, the tool searches objects by their boundary. Searching by bounding box is faster than searching by boundary.

The command returns a collection if any tracks match the criteria. If no objects match the criteria, the command returns an empty string.

You can use this command at the command prompt or you can nest it as an argument to another command, such as **query_objects**. In addition, you can assign the result to a variable.

When issued from the command prompt, the command behaves as though you have called the **query_objects** command to report the objects in the collection. By default, it displays a maximum of 100 objects. You can change this maximum by using the **collection_result_display_limit** variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns the tracks within the rectangle with the lower-left corner at {2 2} and the upper-right corner at {25 25}.

```
prompt> get_tracks * -within {{2 2} {25 25}}
{TRACK_5389}
```

The following example returns the tracks that are located on the METAL2 layer.

```
prompt> get_tracks -filter "layer~=METAL2"
{TRACK_4683}
```

The following example returns all tracks.

```
prompt> get_tracks "TRACK_**"
{TRACK_4683 TRACK_5389}
```

The following example shows how to use the **get_attribute** command to query the value of a track attribute.

```
prompt> get_attribute [get_tracks TRACK_4683] layer
METAL2
prompt> get_attribute [get_tracks TRACK_4683] bbox
{{0.000 0.000} {100.000 100.000}}
prompt> get_attribute [get_tracks TRACK_4683] start
0.000 0.000
```

To get a complete report of the attribute values of all tracks, use the **report_attribute** command, as shown in the following example.

```
prompt> report_attribute -application [get_tracks TRACK_4683]
Design Object Type Attribute Name Value
-----
CORE TRACK_4683 string bbox      {0.000 0.000} {100.000 100.000}
CORE TRACK_4683 int  cell_id    3
CORE TRACK_4683 string layer     METAL2
CORE TRACK_4683 string name     TRACK_4683
CORE TRACK_4683 string object_class track
CORE TRACK_4683 int  object_id   4683
CORE TRACK_4683 string direction horizontal
CORE TRACK_4683 string start    0.000 0.0000
CORE TRACK_4683 string stop     100.000 100.000
CORE TRACK_4683 int  count     51
CORE TRACK_4683 double space   2.000
```

get_via_rules

Returns a collection of via_rules from current library.

SYNTAX

```
collection get_via_rules
  [-filter expression]
  [-quiet]
  [-regexp]
  [-nocase]
  [-exact]
  [-expect exact_count]
  [-expect_at_least minimum_count]
  [-expect_each_pattern_matches]
  [patterns]
```

Data Types

expression	string
exact_count	int
minimum_count	int
patterns	string

ARGUMENTS

-filter *expression*

Filters the collection with *expression*. For any via rule that match the patterns option, the expression is evaluated based on the via rule's attributes. If the expression evaluates to *true*, the via rule is included in the result.

-quiet

Suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

-regexp

Views the *patterns* argument as real regular expressions rather than simple wildcard patterns. Also, modifies the behavior of the =~ and !~ filter operators to compare with real regular expressions rather than simple wildcard patterns. **-regexp** and **-exact** are mutually exclusive.

-nocase

Makes matches case-insensitive.

-exact

Disables simple pattern matching. This is used when searching for objects that contain the * and ? wildcard characters. **-exact** and **-regexp** are mutually exclusive.

-expect *exact_count*

Specifies an expected number of objects to find. If the command finds a different number of objects, a Tcl error will be raised and command processing will stop.

-expect_at_least *minimum_count*

Specifies a minimum number of objects to find. If the command finds fewer objects, a Tcl error will be raised and command processing will stop.

-expect_each_pattern_matches

If this is specified, each pattern in *patterns* must match at least one object. If one or more patterns does not match, a Tcl error will be raised and command processing will stop.

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options.

patterns

Matches via rule names against the *patterns* argument. The *patterns* argument can include the wildcard character "*".

The *patterns* argument and **-of_objects** option are mutually exclusive. You can specify only one of these options. If you do not specify either option, the command uses * (asterisk) as the pattern.

DESCRIPTION

The **get_via_rules** command creates a collection of via rules from the current library that match certain criteria. The command returns a collection of via rules if any via rule matches the criteria. If no objects match the criteria, the empty string is returned.

You can use the **get_via_rules** command at the command prompt, or you can nest it as an argument to another command, such as **report_attributes**. In addition, you can assign the **get_via_rules** result to a variable.

For information about collections and the querying of objects, see the **collections** man page.

EXAMPLES

The following example returns a collection that contains all the via rules in the current library.

```
prompt> get_via_rules
{VR1 VL1}
```

get_zero_interconnect_delay_mode

Reports whether or not the timer is currently using zero interconnect delay mode.

SYNTAX

status **get_zero_interconnect_delay_mode**

ARGUMENTS

This command has no arguments.

DESCRIPTION

This command checks the timer to determine if it is currently using zero interconnect delay mode. The command returns 1 if the timer is using zero interconnect delay mode; otherwise it returns 0.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[set_zero_interconnect_delay_mode\(2\)](#)

getenv

Returns the value of a system environment variable.

SYNTAX

```
string getenv
      variable_name
```

Data Types

variable_name string

ARGUMENTS

variable_name

Specifies the name of the environment variable to be retrieved.

DESCRIPTION

The **getenv** command searches the system environment for the specified *variable_name* and sets the result of the command to the value of the environment variable. If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the **env** Tcl array variable. The **getenv**, **setenv**, and **printenv** environment commands are convenience functions to interact with this array.

The application you are running inherited the initial values for environment variables from its parent process (that is, the shell from which you invoked the application). If you set the variable to a new value using the **setenv** command, you see the new value within the application and within any new child processes you initiate from the application using the **exec** command. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the **exec** command, that value is not reflected in the current application.

See the **set**, **unset**, and **printvar** commands for information about working with non-environment variables.

EXAMPLES

In the following example, **getenv** returns you to your home directory:

```
prompt> set home [getenv "HOME"]
/users/disk1/bill
```

```
prompt> cd $home
```

```
prompt> pwd  
/users/disk1/bill
```

In the following example, **setenv** changes the value of an environment variable:

```
prompt> getenv PRINTER  
laser1
```

```
prompt> setenv PRINTER "laser3"  
laser3
```

```
prompt> getenv PRINTER  
laser3
```

In the following example, the requested environment variable is not defined. The error message shows that the Tcl variable **env** was indexed with the value UNDEFINED, which resulted in an error. In the second command, **catch** is used to suppress the message.

```
prompt> getenv "UNDEFINED"  
Error: can't read "env(UNDEFINED)": no such element in array  
    Use error_info for more info. (CMD-013)
```

```
prompt> if {[catch {getenv "UNDEFINED"} msg]} {  
    setenv UNDEFINED 1  
}
```

SEE ALSO

catch(2)
exec(2)
printenv(2)
printvar(2)
set(2)
setenv(2)
unsetenv(2)
unset(2)

group

Creates a new level of hierarchy.

SYNTAX

```
status group
  [cell_list | -logic | -pla | -fsm]
  [-soft
    | -hdl_block block_name
    | -hdl_all_blocks
    | -hdl_bussed]
  [-design_name design_name]
  [-cell_name cell_name]
  [-except exclude_list]
```

Data Types

<i>cell_list</i>	list
<i>block_name</i>	string
<i>design_name</i>	string
<i>cell_name</i>	string
<i>exclude_list</i>	list

ARGUMENTS

cell_list

Groups a list of cells in the current design into a new level of hierarchy. If more than one cell is specified, they must be enclosed in braces ({}). Cell names cannot be specified with the following options:

- logic
- pla
- fsm
- hdl_block
- hdl_all_blocks
- hdl_bussed

Note that control logic cells (those designated as type "c" in the report displayed by using the **report_cell** command) must be grouped with the cells they are controlling.

-logic

Groups combinational cells into a new level of hierarchy. A cell is combinational if it is a leaf or library cell and its output pins have Boolean functions specified. The **-logic** option cannot be used with the *cell_list* argument or with the **-pla** or **-fsm** options.

-pla

Groups programmable logic array (PLA) specifications in the design into a level of hierarchy. The **-pla** option cannot be used with the **-logic** or **-fsm** options or with the *cell_list* argument. The **-pla** option is used only when the design contains blocks read as a PLA. To group combinational gates in the PLA output, use the **group** command with the **-logic -design_name design_name**

options. After running the **compile** command, the design can be written out as a PLA.

-fsm

Groups cells that are part of a finite state machine design into a new level of hierarchy suitable for finite state machine extraction. Before using the **group** command, use the **set_fsm_state_vector** command to specify the sequential elements used to store the state of the finite state machine.

Cells in the transitive fanin or fanout of these state vector cells are grouped into the new hierarchy level. Noncombinational cells in the transitive fanin or fanout of the state vector cells are not included in the new hierarchy level. Upon completion of the group, the new design can be extracted into a state table format. This option cannot be used with the **cell_list** argument or the **-logic** or **-pla** options.

-soft

Specifies that cells be part of the same placement group. When you use this option, the **group** command sets the **group_name** attribute to the selected cells only and the design hierarchy is not modified. Use the **-soft** option with the **-logic**, **-pla**, and **-fsm** options. You cannot use the **-soft** option with the **-hdl_block**, **-hdl_all_blocks**, or **-hdl_bussed** options. You can set the value of the **group_name** attribute by using the **-cell_name** option.

-hdl_block block_name

Groups the logic cells for a labeled HDL block in the RTL file. The **-hdl_block** option requires that you specify the label name of an HDL block in the current instance. Nested HDL block labels are separated by a forward slash (/); for example, my_process/my_function.

block_name must reference a single label name. Wildcards are supported for label names, but they do not match hierarchy characters. If wildcards match multiple labels, only the first one is used.

For details on grouping HDL blocks, see the DESCRIPTION section.

-hdl_all_blocks

Groups all HDL blocks into a level of hierarchy. If you use the **-hdl_all_blocks** option alone, it recursively groups all HDL blocks in the current instance down. If you use it with the **-hdl_block** option, all HDL blocks from the *block_name* label down are recursively grouped.

For details on grouping HDL blocks, see the DESCRIPTION section.

-hdl_bussed

Places each group of bused gates created from the HDL into a level of hierarchy. If you use it with the **-hdl_block** option, the HDL blocks specified by the *block_name* argument are recursively grouped.

For details on grouping HDL blocks, see the DESCRIPTION section.

-design_name design_name

Names the design containing the new level of hierarchy. This name cannot already exist in the current design. Do not use the **-design_name** option when you use the **-hdl_all_blocks** or **-hdl_bussed** options.

-cell_name cell_name

Names the instance of the new design. By default, the command generates a unique cell name. Do not use the **-cell_name** option when you use the **-hdl_all_blocks** or **-hdl_bussed** options. Unique cell names are generated based on the **unique_cell_prefix** attribute in the current design. You can use the **get_attribute** command to obtain the value of the **unique_cell_prefix** attribute. You can set this value by using the **set_attribute** command. Note that there is no variable controlling the creation of unique cell names.

-except exclude_list

Specifies a list of cells in the current design to exclude from grouping. If more than one cell is specified, they must be enclosed in braces ({}). Do not use the **-except** option with the **-hdl_block**, **-hdl_all_blocks**, or **-hdl_bussed** options.

DESCRIPTION

This command groups any number of cells or instances in the current design into a new design, creating a new level of hierarchy. The new design name must be defined by using the **-design_name** option (unless you are using the **-hdl_all_blocks** option or the **-hdl_bussed** option). The new design is copied into the current design.

To specify the cells to group into a new design, use one of the following options:

```
cell_list
-logic
-pla
-fsm
-hdl_block
-hdl_all_blocks
-hdl_bussed
```

Specify only one of these options (except for the **-hdl_all_blocks** and **-hdl_bussed** options, which can be used together or with the **-hdl_block** option). The *cell_list* argument can contain cells from anywhere in the hierarchy, but the parent of the cells in the list must be the same.

Use the **-cell_name** option to specify the instance name of the new design. Otherwise, the following naming format is used where *integer* is an integer value that ensures a unique name:

```
cell{integer}
```

The hierarchy below a grouped block can also be grouped by issuing the **group** command specifying the new cell names.

Names for each level of hierarchy are automatically generated from the label of the grouped block. The names have the following format where *label* represents the label assigned to the block and *digits* represents an integer that makes the name unique. **HDL_BLOCK** is the default label.

```
label_digits
```

Ports in the new design are named the same as the nets to which they are connected in the current design. The direction of each port in the new design is determined for pins on the net according to the following table:

Inside pins	Outside pins	Resulting port direction
IN	OUT	IN
OUT	IN	OUT
IN & OUT	OUT	IN
IN & OUT	IN	OUT
IN	IN & OUT	IN
OUT	IN & OUT	OUT
IN & OUT	IN & OUT	INOUT (bidir)

You can use the **-soft** option to define cell grouping constraints, which can be used by the layout placement tools and can be written to a file by using the **write_constraints** command. The **group -soft** command specifies that cells be part of the same placement group. With this option, the **group** command sets only the **group_name** attribute for the cells in *cell_list* and the design hierarchy is not modified. You can set the value of the **group_name** attribute by using the **-cell_name** option. The **write_constraints** command reports cells with the **group_name** attribute as grouping constraints for placement tools. To remove the **group_name** attribute, use the **ungroup -soft** command or the **remove_attribute** command.

For the **-hdl_block**, **-hdl_all_blocks**, and **-hdl_bussed** options, only HDL blocks within the current instance can be referenced. To reference HDL blocks inside submodules, use the **current_instance** command to change the current instance to the parent block containing the HDL block. References to recursive grouping in the ARGUMENTS section refer to nested labels within the current instance, not to logical design hierarchy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information. However, in order to preserve constraints and attributes for

inactive scenarios, the tool automatically activates inactive scenarios before the hierarchy is changed and deactivates them before the command returns. Due to the overhead, if there are many **group** commands in the script, it is more runtime efficient to activate inactive scenarios once before the **group** command executions and deactivate them after all the **group** command executions finish.

EXAMPLES

The following example groups two cells into a new design:

```
prompt> group {u1 u2} -design_name NEW \
           -cell_name U
```

The following example groups cells with names beginning with *ANALOG* into a design:

```
prompt> group \
           -design_name ANALOG_CELLS [get_cells ANALOG*]
```

The following example groups all cells in the HDL function named *bar* and the process named *proc* into a design:

```
prompt> group -hdl_block proc/bar \
           -design_name my_hdl_block
```

The following example sets the current design to the new design and then uses the **group** command to group a nested function named *my_other_function* in the new design:

```
prompt> current_design my_hdl_block
prompt> group -hdl_block my_other_function
```

The following example groups all bused gates under the process named *proc* into separate levels of hierarchy (or designs):

```
prompt> group -hdl_block proc -hdl_bussed
```

The following example sets the *group_name* attribute to the name *proc* for all combinational cells. The design hierarchy is not modified.

```
prompt> group -logic -soft -cell_name proc
```

The following example creates a new hierarchy under a design named *BOT* with cells named *A*, *B*, and *C*. The *PROC/U1* is an instance of *BOT*.

```
prompt> group \
           -design_name new_design {PROC/U1/A PROC/U1/B PROC/U1/C}
```

<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list
<i>comment_string</i>	string
<i>priority_level</i>	integer

ARGUMENTS

-weight *weight_value*

Specifies a cost function weight for this group. The *weight_value* must be a number between 0.0 and 100.0. The default is 1.0. A weight of 0.0 eliminates the paths in this group from cost function calculations. Do not use very small values (for example, 0.0001); smaller values can prevent **compile** from implementing small improvements to the design. If you specify **-weight** when you add members to an existing group, the new weight for the group is used.

-critical_range *range_value*

Specifies a margin of delay for *group_name* during optimization. The *range_value* must be positive or 0.0. If you do not specify a

range_value for a group, the default is the value set with the **set_critical_range** command (the default setting is 0.0). A *range_value* of 0.0 means that only the most critical paths (the ones with the worst violation) are optimized. If you specify a nonzero *range_value*, other near-critical violating paths (one per endpoint) within that amount of the worst path are also optimized if possible. If more than one critical path to an endpoint must be optimized, use a separate **group_path** command for each distinct critical path to that endpoint. To force **compile** to optimize all violating paths, use a very large *range_value* (larger than any expected path violations).

-default

Specifies that endpoints or paths be moved to the default group and removed from the current group. You must specify **-default** unless you use **-name**; **-name** and **-default** are mutually exclusive.

-name *group_name*

Specifies a name for the group. If a group with this name already exists, the paths or endpoints are added to that group. Otherwise, a new group is created and named *group_name*. You must specify **-name** unless you use **-default**; **-name** and **-default** are mutually exclusive.

-from *from_list*

Specifies a list of names of clocks, ports, or pins that specify path startpoints. If a clock is given, all path startpoints related to that clock are implicitly included. This includes flip-flops in the transitive fanout of the clocks source pin or port, and ports that have input delay related to the clock.

-rise_from *rise_from_list*

Specifies a list the same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Specifies a list the as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of path throughpoints (port, pin, or leaf cell names) of the current design. The path grouping applies only to paths that pass through one of the points in the *through_list*. If more than one object is included, the objects must be enclosed either in quotation marks ("") or in braces ({}). If the **-through** option is specified multiple times, the group path setting applies to paths that pass through a member of each *through_list* in the order the lists were given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every specified *through_list*. If the **-through** option is used in combination with the **-from** or **-to** options, the group path applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Specifies a list the same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than one time in a single command invocation, as with the **-through** option.

-fall_through *fall_through_list*

Specifies a list the same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than one time in a single command invocation as with the **-through** option.

-to *to_list*

Specifies a list of names of clocks, ports, or pins that specify path endpoints. If a clock is given, all path endpoints related to that clock are implicitly included. This includes flip-flops in the transitive fanout of the clocks source pin or port, and ports that have output delay related to the clock.

-rise_to *rise_to_list*

Specifies a list the same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to fall_to_list

Specifies a list the same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

-priority priority_level

Assigns a priority to the command to resolve conflicting path selections between different **group_path** commands. By default, different **group_path** commands follow ordinary rules of priority to resolve conflicting path selections. For example, a command using **-from** and **-to** to select paths has priority over a conflicting command that selects a subset of those paths using **-through**, so the latter command is ignored for the paths that could be in either. By setting a higher priority in the command using the **-through** option, its path selection is honored, overriding the usual order of priority on paths in the intersection of the two groups. If unspecified, the priority is 0. You can set the priority for a **group_path** command to any integer 0 or greater.

DESCRIPTION

Groups a set of paths or endpoints for cost function calculations. The delay cost function is the sum of all groups (weight * violation), where violation is the amount for which setup was violated for all paths within the group. If there is no violation within a group, its cost is zero. Groups enable you to specify a set of paths to optimize even though there might be larger violations in another group. When endpoints are specified, all paths leading to those endpoints are grouped.

If a clock is specified in the *from_list* or *to_list*, all endpoints related to that clock are included in the group. The **create_clock** command automatically creates a group for a new clock with a weight of 1.0 and named the same as the clock name.

The weight of the default group is 1.0. If *weight_value* is not specified for a new group, the default is 1.0.

To undo **group_path**, use **reset_design** or **group_path -default**.

To list the path groups that are defined, use **report_path_group**. To show the maximum delay cost for each path group, use **report_constraint**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example groups all endpoints clocked by CLK1A or CLK1B into a new group called group1 that has a weight = 2.0:

```
prompt> group_path -name "group1" -weight 2.0 -to {CLK1A CLK1B}
```

The following example adds OUT1 and ff34/D to the existing path group named ADDR:

```
prompt> group_path -name "ADDR" -to {OUT1 ff34/D}
```

The following example removes OUT1 and CLK2 from existing groups and places them in the default group:

```
prompt> group_path -default -to {OUT1 CLK2}
```

This command adds all paths that first pass through either u1/Z or u2/Z and then pass through u5/Z or u6/Z into the group named blue:

```
prompt> group_path -name blue \
    -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

The following example groups all paths from inputs I1 and I2 to outputs O5 and O7 into a group named serious that has a weight of 10.0:

```
prompt> group_path -name serious -weight 10.0 \
    -from {I1 I2} -to {O5 O7}
```

The following example groups all endpoints clocked by CLK into a group with a critical range of 0.5:

```
prompt> group_path -name CLK -critical_range 0.5 -to CLK
```

The following example uses a large critical range value to optimize all paths. For example, assume that the worst violation is expected to be 100 units. Setting a critical range value larger than the worst violation causes optimization to speed up all paths if the transformations do not increase the worst violation (that is, make the worse path slower) for that group. In this example, the critical range value is set higher than the worst expected violation to ensure that all violating paths are considered during optimization:

```
prompt> group_path -name CLK -critical_range 1000.0 -to CLK
```

```

group_variable

Adds a variable to the specified variable group. This command is typically used only by the system administrator.

SYNTAX

```
status group_variable  
      group_name  
      variable_name
```

Data Types

```
group_name   string  
variable_name string
```

ARGUMENTS

group_name

Specifies the name of the group to which the specified variable is added. The following are the existing variable *group_names*:

```
compile_variables  
edif_variables  
hdl_variables  
insert_dft_variables  
io_variables  
multibit_variables  
plot_variables  
schematic_variables  
synlib_variables  
system_variables  
suffix_variables  
view_variables  
vhdlio_variables  
write_test_variables
```

variable_name

Specifies the name of the variable to add.

DESCRIPTION

This command adds a variable to a variable group or creates a new variable group. For descriptions of all of the current variables and variable groups, see the individual variable group man pages, which you can access online from dc_shell by entering the following command:

```
prompt> help group_name
```

To list all of the currently-defined variables, use the **print_variable_group all** command. To list all of the variables in a group, use the **print_variable_group group_name** command.

EXAMPLES

The following example adds the variable **current_design** to the system group:

```
prompt> group_variable system current_design
```

gui_add_annotation

Adds an annotation to the layout window.

SYNTAX

```
status gui_add_annotation
  [-window window_name]
  [-group group_type]
  [-type shape_type]
  [-symbol_type symbol_type]
  [-symbol_size symbol_size]
  [-text text]
  [-color color]
  [-pattern pattern]
  [-width line_width]
  [-line_style line_style]
  [-info_tip info_tip]
  [-query_text query_text]
  [-query_command query_command]
  points
```

Data Types

<i>window_name</i>	string
<i>group_type</i>	string
<i>shape_type</i>	string
<i>symbol_type</i>	string
<i>symbol_size</i>	string
<i>text</i>	string
<i>color</i>	string
<i>pattern</i>	string
<i>line_width</i>	string
<i>line_style</i>	string
<i>info_tip</i>	string
<i>query_text</i>	string
<i>query_command</i>	string
<i>points</i>	list

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window. If window name is omitted, the annotation will apply to all layout windows.

-group *group_type*

Specifies the annotation group. If group name is omitted, the **global** name is used.

-type *shape_type*

Specifies the type of annotation. The supported values for this option are

rect
line
arrow
polygon
polyline
text
symbol

The default is rect.

-symbol_type symbol_type

Specifies the type of symbol annotation. This option is only valid when annotation type is symbol. The supported values for this option are

square
x
triangle
diamond

The default is square.

-symbol_size symbol_size

Specifies the size of symbol annotation. An even symbol size will grow one automatically to find the appropriate center point. The default symbol size is 3.

-text text

Specifies the annotation text.

-color color

Specifies the annotation color. You can use a predefined color string, such as white, red, green, blue, yellow, and so forth, or a hexadecimal RGB value, such as #AA6633. The default annotation color is white.

-pattern pattern

Specifies the annotation fill pattern. The default fill pattern is none. An empty value forces the tool to use the window default value, which is usually set to solid fill.

-width line_width

Specifies the annotation line width. The default line width is 1.

-line_style line_style

Specifies the annotation line style. The default line style is none. An empty value forces the tool to use the window default value, which is usually set to solid line.

-info_tip info_tip

Specifies an info tip for this annotation. When the user starts the query tool in the layout, and puts the mouse cursor over this annotation the specified text will be displayed as the infoTip.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_text query_text

This option is only valid if an info tip was specified. Use this to specify a more detailed string that is displayed in the query palette

when the object is selected via the query tool. If query text is not specified then the query tool will just use the info tip string.

If the text starts with a '=' character the text after it will be considered to be a tcl command which, when executed, will return the query text to be displayed. The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation

-query_command *query_command*

This option is only valid if an info tip was specified. Use this to specify a tcl command to be run when the user clicks on the annotation.

The tcl command can contain special strings, which are replaced with details of the layout window and annotation, so this information can be used in the tcl procedure.

%window the layout window name
%view the layout view name
%object a collection containing the annotation
%x the x position clicked in design coordinates
%y the y position clicked in design coordinates

points

Specifies the points for the specified annotation type. The points are specified by a tool command language (Tcl) list in which each list element is one of the following:

- the {x y} location of a point
- a collection containing a single object that has a visual representation in the layout. In other words, it is not a net, for example. The location of the point is the origin of the object.

If a collection is specified the list element can optionally include a position type, one of:

- center : the annotation is placed at the center of the largest rectangle of the object. The largest rectangle is the rectangle with the most area which is completely contained inside the object shape.
- bbox_center : the annotation is placed at the center of the bounding box of the object.
- bbox_ll : the annotation is placed at the lower left of the bounding box of the object.
- bbox_lr : the annotation is placed at the lower right of the bounding box of the object.
- bbox_ul : the annotation is placed at the upper left of the bounding box of the object.
- bbox_ur : the annotation is placed at the upper right of the bounding box of the object.

If a bounding box position type is specified, i.e. one of 'bbox_center', 'bbox_ll', 'bbox_lr', 'bbox_ul' or 'bbox_ur', then the list element can also optionally include an x and y fractional offset from this bounding box point. The x and y offset is a fraction of the width and height of the object's bounding box respectively. For example, for a 'bbox_center' position type, an x offset of -0.5 is the left edge and an x offset of 0.5 is the right edge. Similarly a y offset of -0.5 is the bottom edge and a y offset of 0.5 is the top edge.

For annotations referring to a single-object collection, if the object is moved, the tool updates the point automatically as needed.

DESCRIPTION

This command defines a new annotation and returns a collection containing that annotation if it is successful.

EXAMPLES

Create a green rectangle annotation.

```
prompt> gui_add_annotation -window Layout.1 \
    -type rect -color green {{200 200} {777 777}}
```

Create a red polyline annotation in the group Test1.

```
prompt> gui_add_annotation -window Layout.2 \
    -group Test1 -type polyline -color red \
    -width 2 {{123 456} {789 12} {200 200}}
```

Create a line between two cells A and B.

```
prompt> gui_add_annotation -window Layout.1 \
    -type line [list [get_cells A] [get_cells B]]
```

Create a line between the center of largest rectangle of cell A and the center of the largest rectangle of cell B.

```
prompt> gui_add_annotation -window Layout.1 \
    -type line [list [list [get_cells A] center] [list [get_cells B] center]]
```

Create a line between the bottom left of cell A's bounding box and the middle of the top of cell B's bounding box.

```
prompt> gui_add_annotation -window Layout.1 -type line \
    [list [list [get_cells A] bbox_ll] [list [get_cells B] bbox_center 0.0 0.5]]
```

Create a blue rectangle which displays the annotation points using the annotation_query tcl procedure.

```
prompt> proc annotation_query { object window view } { \
    return [get_attribute $object points] \
}
```

```
prompt> gui_add_annotation -window Layout.1 -type rect -color blue \
    -query_text {=annotation_query %object %window %view} -info_tip {annotation points} \
    {{110 110} {160 160}}
```

SEE ALSO

ARGUMENTS

-clct *Clct*

Specifies the collection of objects that the tool partitions into bins.

-attr *Attribute*

Specifies the attribute that the tool uses to get a floating point value for each object in the collection. The tool places the objects in bins based on these attribute values.

The **-attr** and **-cmd** options are mutually exclusive.

-cmd *Command*

Specifies the tool command language (Tcl) command that the tool uses to get a floating point value for each object in the collection. The tool places the objects in bins based on these values.

The tool replaces all occurrences of %clct in the command with a collection that contains, as its only element, the object used to compute the floating point value for the object. If the tool cannot store the object in a collection, it uses the string "Error" instead.

The tool replaces all occurrences of %string in the command with the name of the object. If the tool cannot compute the name for an object, it uses the string "Error" instead.

The **-cmd** and **-attr** options are mutually exclusive.

-lower_bound *Lower_Bound*

Defines the lower bound for the range of floating point values that the tool uses to place the objects in bins.

If you specify the **-underflow** option, the tool places all the objects with a value that is less than *Lower_Bound* in a separate underflow bin. If you do not specify the **-underflow** option, the tool discards these objects.

-lower_bound_strict

Forces the tool to use the **-lower_bound** option value as the lower bound of the bin with the smallest values, not including the underflow bin.

If you do not specify the **-lower_bound_strict** option, the tool sets the lower bound of the bin with the smallest values, not including the underflow bin, to the smallest value that is greater than or equal to the value specified by the **-lower_bound** option.

-upper_bound *Upper_Bound*

Defines the upper bound for the range of floating point values that the tool uses to place the objects in the bins.

If you specify the **-overflow** option, the tool places all the objects with a value that is greater than *upper_Bound* in a separate overflow bin. If you do not specify the **-overflow** option, the tool discards these objects.

-upper_bound_strict

Forces the tool to use the **-upper_bound** option value as the upper bound of the bin with the largest values, not including the overflow bin.

If you do not specify the **-upper_bound_strict** option, the tool sets the upper bound of the bin with the largest values, not including the overflow bin, to the largest value that is less than or equal to the value specified by the **-upper_bound** option.

-boundary *Boundary*

Specifies the boundary value for one of the bins, not including the underflow and overflow bins. This value must fall within the range of values covered by the bins.

If the relevant value distribution has a specific value where the quality of the values change, such as 0 for slack, you can use this option to make sure that no bin contains values on both sides of the boundary value.

-num_bins *Number_of_Bins*

Specifies the number of bins that this command generates, not counting underflow and overflow bins. The default value is 8.

The **-num_bins** and **-bin_range** options are mutually exclusive. If you specify both of these options, the tool ignores the **-bin_range** option. If you do not specify either of these options, the default value is 8.

-bin_range Range_per_Bin

Specifies the size of the value range represented by each bin.

The **-bin_range** and **-num_bins** options are mutually exclusive. If you specify both of these options, the tool ignores the **-bin_range** option. If you do not specify either of these options, the default value is 8.

-underflow

Collects all the objects with values less than the lower bound value specified by the **-lower_bound** option, and places them in a separate underflow bin. Otherwise, these objects are discarded.

-overflow

Collects all the objects with values greater than the upper bound value specified by the **-upper_bound** option, and places them in a separate overflow bin. Otherwise, these objects are discarded.

-nice_level Nice_Level

Determines how round the boundaries of the bins are. The default value is 10. For rounder boundaries, specify a higher value. If *Nice_Level* is -1, the tool does not attempt to make the boundaries round.

-small_is_good

Sorts the values in every bin in order of decreasing values. By default, the tool sorts the objects in order of increasing values.

In addition, bins with values that are less than the value specified by the **-boundary** option are colored green, and bins with values that are greater than this value are colored red. This is opposite from the default color markings.

-exact_binning

Sets exact boundaries on the left border of the furthest left bin and the right border of the furthest right bin. By default, the tool can adjust these limits to create bins with equal widths.

-ignore_values Ignore_List

Discards the objects with values specified in *ignore_List*.

-bar_brush Brush_Pattern

Specifies the brush pattern for painting bars in a histogram based on the result of the command. The *brush_Pattern* can be one of the following values:

NoBrush	SolidPattern	Dense1Pattern
Dense2Pattern	Dense3Pattern	Dense4Pattern
Dense5Pattern	Dense6Pattern	Dense7Pattern
HorPattern	VerPattern	CrossPattern
BDiagPattern	FDiagPattern	DiagCrossPattern

-create_s1ct_buses

Creates selection buses to return the objects instead of collections.

-filter_cmd Filter_Command

Specifies a Tcl command that the **gui_bin** command uses to determine whether a collection in a bin should be filtered out.

The *filter_Command* format is

cmd %clct %attr %value

where *cmd* is a Tcl command or procedure, *%clct* is a collection, *%attr* is the name of the attribute used to create the bins, and *%value* is the maximum value for *%clct*. If the command returns a nonzero value, *%clct* is not placed in a bin.

-numBin numBins

This option is obsolete. Do not use it. Use the **-num_bins** option instead.

-return_values

Causes the **gui_bin** command to return the values of elements.

-slct_targets Selection_Tests

Specifies a list of selection containers to store the objects.

-slct_targets_operation Selection_Operation

Specifies an operation applied to the selection containers.

-value_list Element_Value_List

Specifies values for the elements in a list. The **gui_bin** command uses these values to create the bins.

DESCRIPTION

The **gui_bin** command creates a list of bins from a collection of objects that you specify with the **-clct** option. The command determines a floating point value for each of the objects by using either an attribute that you specify with the **-attr** option or a Tcl command that you specify with the **-cmd** option.

Each bin is represented by a list that contains the left boundary, the right boundary, the number of objects in the bin, a collection containing the objects in the bin, and the value green or red.

The widths of the bins are equal by default, which means that in some cases the furthest left and furthest right bins might extend the specified boundaries in order to get nice values for the boundaries. If you specify the **-exact_binning** option, the left border of the furthest left bin and the right border of the furthest right bin are set exactly to the specified boundaries.

The collections are sorted with ascending floating point values by default, and a bin is marked green only if the objects it contains have values greater than or equal to the value specified by the **-boundary** option. If you specify the **-small_is_good** option, the values in the collections are sorted with descending floating point values, and a bin is marked red only if the objects it contains have values greater than or equal to the value specified by the **-boundary** option.

The bins cover the complete range of floating point values by default. You can define the covered range by using the **-lower_bound**, **-lower_bound_strict**, **-upper_bound**, and **-upper_bound_strict** options. In this case, you can collect objects with floating point values that are too small or too big and place them into separate underflow and overflow bins by specifying the **-underflow** and **-overflow** options.

You can specify a list of objects with floating point values that can be ignored by using the **-ignore_values** option.

You can specify a bin range size that results in a very large number of bins by using the **-bin_range** option. However, this results in a histogram that is difficult to read and that might take a long time to compute and draw.

The preference variable **hist_max_num_bins** in the Histogram category allows you to set the maximum number of histogram bins. The default value is 100. If a specified range size value causes the number of bins to exceed the value set for this variable, the tool issues an error message and does not create a histogram. The error message includes information about the data range to aid you in specifying a better **-bin_range** value. This variable is used only in conjunction with the **-bin_range** option and is not used with the **-num_bins** option.

EXAMPLES

The following example creates a list of bins containing the 100 worst paths according to their slack distribution:

```
prompt> set binInfo [gui_bin -clct [get_timing_paths \
    -nworst 100 -max_paths 100] -cmd "get_attribute %clct slack"]
prompt> set bins [lindex $binInfo 0]
```

SEE ALSO

gui_change_highlight

Manipulate the set of globally highlighted objects.

SYNTAX

```
string gui_change_highlight
  [-add | -remove | -toggle]
  [-color color_id | -all_colors]
  [-collection clct]
```

Data Types

<i>color_id</i>	string
<i>clct</i>	collection

ARGUMENTS

-add

Use -add to highlight a collection of objects in a color specified with color. If -color is not specified, the current color is used. You cannot use -all_colors with -add. You must specify a collection with -collection. If -remove or -toggle are not specified, then -add is implied.

-remove

Use -remove to remove highlighting from objects. Use -collection to remove highlighting from specific objects. Use -color to remove highlighting from objects of a specific color. Use -all_colors to remove all highlighting. If you specify a collection, you cannot specify colors.

-toggle

Use -toggle to toggle the highlight state of a collection of objects. You must use -collection with -toggle, and you cannot use -color or -all_colors. Toggling an object that is highlighted will cause it to no longer be highlighted. Toggling an object that is not highlighted will cause it to be highlighted with the current color. If no operation is specified, then -add is assumed.

-color *color_id*

Specifies the color to be used for the highlight operation. This is mutually exclusive with -all_colors. The allowed colors are blue, light_blue, yellow, purple, light_purple, orange, light_orange, red, light_red, green, and light_green. If neither -color nor -all_colors is specified, then the current highlight color is assumed. You cannot use -color with -toggle.

-all_colors

This option is only valid with -remove. Use this option to clear all highlight colors.

DESCRIPTION

The `gui_change_highlight` command is used to operate on the set of highlighted objects. Objects can be added or removed from the set, or their presence can be toggled as described above. The set has a current color that can be modified with `gui_set_highlight_options(2)`. The current color is used as needed when no color is specified.

The tool provides eleven built in highlight colors with the names yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

EXAMPLES

Highlight in green all cells with names matching `foo*`.

```
prompt> gui_change_highlight -color green -collection [get_cells foo* -hier -all]
```

Remove highlights from all objects in the collection returned by the `get_cells` command.

```
prompt> gui_change_highlight -remove -collection [get_cells foo* -hier -all]
```

Clear all objects with blue highlights.

```
prompt> gui_change_highlight -remove -color blue
```

Clear objects with the current highlight color.

```
prompt> gui_change_highlight -remove
```

Clear all highlights.

```
prompt> gui_change_highlight -remove -all_colors
```

Toggle the highlight state of all objects in a collection returned by the `get_cells` command.

```
prompt> gui_change_highlight -toggle -collection [get_cells foo*]
```

SEE ALSO

`gui_get_highlight(2)`

`gui_set_highlight_options(2)`

gui_close_window

Close the specified window

SYNTAX

```
status gui_close_window
{ -window window_id | -type window_type | -all }
[ -exact_type_match ]
```

Data Types

window_id string
window_type string

ARGUMENTS

-window *window_id*

Specifies the window name id.

Any matching window of this name will be closed.

This option precludes the *-type* and *-all* options.

-type *window_type*

Specifies the window type id. Any matching window of this type will be closed.

If the *-exact_type_match* option is not specified then types derived from this window type will also be closed. Derived types are created with the **gui_create_window_type** command.

This option precludes the *-window* and *-all* options.

-all

Specifies that we want to close all the windows.

This option precludes the *-window* and *-type* options.

-exact_type_match

Specifies that types derived from the specified type are excluded when the *-type* option is specified.

Note: this option should only be used with the *-type* option.

DESCRIPTION

This command closes the specified window(s).

Windows can be specified by name, type or as all windows.

EXAMPLES

The following examples will create a toplevel window and a child layout view window, then close the command layout window.

```
shell> set top [gui_create_window -type TopLevel]  
shell> set x [gui_create_window -type Layout -parent $top]  
shell> gui_close_window -window $x
```

SEE ALSO

```

gui_create_attrgroup

Creates a group of attributes for an object type.

SYNTAX

```
status gui_create_attrgroup
      -class design_object
      -name name
      [-attr_list {{attr_1}...{attr_n}}]
```

Data Types

<i>design_object</i>	string
<i>name</i>	string
<i>attr_1</i>	string
<i>attr_n</i>	string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be created for the specified object type.

-attr_list {{*attr_1*}...{*attr_n*}}

Lists and orders the attributes to be included in the group.

DESCRIPTION

The **gui_create_attrgroup** command creates a new attribute group for a specific type of design object. The command adds the attribute group to the display in GUI tools, such as the Properties dialog box, List views, layout view InfoTips, and other graphic windows.

An attribute can be assigned to more than one attribute group at the same time.

The order of the attributes in an attribute group is important and is set by the **-attr_list** option when you create the group. Use the **gui_update_attrgroup** command if you need to change or reorder the attribute list for an attribute group.

EXAMPLES

```
prompt> gui_create_attrgroup -class Cell -name "Hierarchy" \
-attr_list { "Name" "Hierarchical" "Owning Cell"
"isPhysConstraint" "Hard Macro" "Num Children" "Num Nets"
"Num Pins" "Utilization" "Area" "Aspect Ratio" "Min Aspect"
"Max Aspect" "Min Area" "Max Area" "Area / 1M" "Hier Req Area / 1M"
"Reference" "Logical Name" "FullName" }

prompt> gui_create_attrgroup -class Cell -name "Edit" \
-attr_list { "Name" "isPhysConstraint" "Orientation"
"Location" "Bounding Box" "Fixed Location" "Is Resizable"
"Hard Macro" "Placed" "Is IO" "Off Litho Grid" "FullName" }

prompt> gui_create_attrgroup -class Pin -name "Timing" \
-attr_list { "Name" "Is Clock" "Slew" "slack_max" }

prompt> gui_create_attrgroup -class Net -name "Timing" \
-attr_list { "Name" "Lumped C" "Total Lumped C"
"Lumped Resistance" }
```

SEE ALSO

```
gui_delete_attrgroup(2)
gui_list_attrgroups(2)
gui_update_attrgroup(2)
```

gui_create_category_rule

Creates a category rule for automatic generation of one or more object categories.

SYNTAX

```
string gui_create_category_rule
  [-name rule_name]
  [-filter filter_spec]
  -category category_spec
  [-builtin]
```

Data Types

rule_name	string
filter_spec	string
category_spec	string

ARGUMENTS

-name rule_name

Specifies the name of the category rule to be created. If this option is omitted, a unique new rule name is automatically generated.

-filter filter_spec

Specifies the filter. The basic form of a filter conditional expression is a series of relations joined together with && (and), || (or), and ! (not) operators. Parentheses are used to override precedence. The basic relation is either a Boolean attribute or a comparison of one non-Boolean attribute with another or with a constant value using relational operators.

For example, a filter expression can have any of the following forms:

- **-filter {endpoint_clock_is_propagated}** (Boolean attributes)
- **-filter {slack < 0}** (Comparison with a literal number)
- **-filter {(path_group.full_name == "inputs")}** (Comparison with a literal string)
- **-filter {({startpoint_clock.full_name == endpoint_clock.full_name})}** (Comparison of attributes)

Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection. The following relational operators are supported:

- **==** (Equal)
- **!=** (Not equal)
- **=~** (Matches pattern)
- **!~** (Does not match pattern)
- **&~** (Contains all elements)

- \sim (Contains some elements)
- $>$ (Greater than)
- $<$ (Less than)
- \geq (Greater than or equal to)
- \leq (Less than or equal to)

The matching operators are used to match wildcard regular expressions. The containment operators are used to compare space-separated set or list attributes.

-category category_spec

Specifies the category. The category specification can be fixed literal text, or it can include an optional object attribute name enclosed in angle brackets; for example, **-category <path_type>**. Additional literal text is optionally allowed to the left and to the right of the angle brackets; for example **-category {Path Type: <path_type>}**. Some object attributes have values that are object collections of size one. For those attributes, "dot notation" can be used to access attributes of the object in the collection; for example, **-category <startpoint_clock.full_name>**.

When a category rule is "executed" later in the GUI, a separate category (bin of objects) is generated for each unique value of the attribute specified by the **-category** option. (The GUI "category-rule-execution engine" examines attribute values for an input set of objects.)

-builtin

Indicates that the rule being created belongs to the built-in group of category rules. If this option is omitted, the rule being created does not belong to the built-in group.

The built-in group of category rules is a group of category rules that are created before any non-built-in rules. This group of rules includes both built-in rules created by the tool (at tool startup time) and built-in rules that you create before creating any non-built-in rules.

DESCRIPTION

This command creates a category rule. If rule creation is successful, the command returns the name of the newly-created category rule; otherwise, it returns an empty string. After a category rule has been created, it can be used later (at "category-rule execution time" in the GUI) with other rules to generate one or more object categories.

EXAMPLES

This example creates a simple category rule:

```
prompt> gui_create_category_rule -name pathgroups \
    -category <path_group.full_name>
pathgroups
```

This example creates a simple filtering rule:

```
prompt> gui_create_category_rule -name {Negative Slack} \
    -category {Failing Paths} -filter {slack < 0}
Negative Slack
```

This example creates a regular expression filtering rule:

```
prompt> gui_create_category_rule -name {ATPG Sessions} \
    -category {ATPG Sessions} -filter {session_name =~ "atpg*"}  
ATPG Sessions
```

Negative Slack

This example creates a set or list containment filtering rule:

```
prompt> gui_create_category_rule -name {Through CPU and CTRL} \
    -category {Through CPU and CTRL} -filter { blocks &~ "CPU CTRL"}
```

Negative Slack

SEE ALSO

[gui_remove_category_rules\(2\)](#)

gui_create_menu

Create a menu item for the toplevel menubar or a context menu item. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item.

SYNTAX

```
string gui_create_menu -menu HierMenuName
  [-tcl_cmd TclCmd] [-separator] [-heading headingText]
  [-enable_cmd EnableCmd]
  [-get_state_cmd GetStateCmd]
  [-icon IconFilePath]
  [-hot_key HotKey]
  [-tooltip ToolTip]
  [-help_string HelpStr]
  [-anchor_item AnchorItem]
  [-anchor_offset AnchorOffset]
  [-position MenuPos]
  [-window_type WindowTypeName]
  [-root ContextMenuRoot]
  [-reference RefMenuItem]

HierMenuName      String
TclCmd           String
EnableCmd         String
GetStateCmd       String
IconFilePath       String
HotKey            String
ToolTip           String
HelpStr           String
AnchorItem         String
AnchorOffset       Integer
MenuPos           Integer
WindowTypeName    String
ContextMenuRoot   String
RefMenuItem        String
```

ARGUMENTS

-menu *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to create. If a level of the hierarchy does not exist in the menu structure it will be created automatically by this command. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '>'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so.

-tcl_cmd *TclCmd*

TclCmd specifies the tcl command to execute when the menu item is selected. This option is mutually exclusive with the -separator and -heading options.

-separator

This option creates a menu item separator. It is mutually exclusive with the -tcl_cmd and -heading options.

-heading *headingText*

This option creates a text heading in the menu with the specified **headingText**. It is visually distinct from actual menu items, and it is not selectable like an actual menu item is. This is used to provide general grouping information without requiring an additional level of sub menu. This option is mutually exclusive with the -separator and -tcl_cmd options.

-enable_cmd *EnableCmd*

EnableCmd specifies the tcl command to evaluate whether the menu item should be enabled or disabled. The tcl command should return "true" or "1" to enable, and return "false" or "0" to disable. If the enable_cmd is not specified then the menu item will always be enabled.

-get_state_cmd *GetStateCmd*

GetStateCmd specifies the tcl command that will be executed to determine whether the menu item should be in an on (checked or pushed-in) or off (unchecked or normal) state. Most menu items don't have persistent state, and for those the get_state_cmd should not be specified. This tcl command returns "true" or "1" for the "on" state, and returns "false" or "0" for the "off" state.

-icon *conFilePath*

IconFilePath specifies the absolute pathname of the icon file. The file should be in .xpm format. Typical application-supplied icons are 16x16 pixels in size and use a transparent background (color 'None' in xpm format).

-hot_key *HotKey*

HotKey specifies the hotkey (accelerator) for the menu item.

-tooltip *ToolTip*

ToolTip specifies the tooltip for the menu item.

-help_string *HelpStr*

HelpStr specifies the help string for the menu item. The help string is displayed in the status bar.

-anchor_item *AnchorItem*

AnchorItem specifies the existing menu item that will be used as the anchor position for this new menu item. This option is used together with the -anchor_offset option to determine the location of the new menu item. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

-anchor_offset *AnchorOffset*

AnchorOffset specifies the offset from the anchor item position that will be used to determine the location of the new menu item in the menu hierarchy. The offset must be a positive or negative integer, and not zero. If positive, the new menu item will be placed below the anchor item by the specified offset. If negative, it will be placed above the anchor item position by the absolute value of the specified offset. The -position option cannot be used along with the -anchor_item and -anchor_offset options.

-position *MenuPos*

MenuPos specifies the absolute menu position for the menu item within the parent popup menu. The -position option cannot be used with the -anchor_item and -anchor_offset options.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

-root *ContextMenuRoot*

ContextMenuRoot specifies the context menu root to which the menu item being defined will be added. A context menu root groups menu items that share the same context menu root. The context menu root is used for context menu. Context menu, is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a

context menu root and the menu root use by a toplevel window's menu bar .)

-reference RefMenuItem

RefMenuItem specifies the menu item under the toplevel window's menu bar, which will be used to define the behavior of the menu item being defined. Often used with the -root option to help associate a context menu item with an already defined menu entry under the menu bar. Used with the -window_type option to completely specify the reference menu item under the menu bar. If the -window_type option is not specified, the default toplevel window type as specified with the tcl variable "::gui_default_window_type" will be used.

DESCRIPTION

This command creates a menu item for the menu bar of a top level window. A menu hierarchy, based on the menu name, may be created as necessary to host the menu item. The menu hierarchy separator is denoted by "->". These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then apply the installation specific customizations, and finally the user's customizations. The installation specific setup file is specified by the variable `gui_custom_setup_file` and will have a default empty value. This can be overridden in the `.synopsys_dc.setup` file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized. The user setup file is `~/.synopsys_icc_gui.tcl` for IC Compiler.

EXAMPLES

The following simple example adds a new toplevel popup menu `&Favorite` in the menubar and add a submenu named `Preferences` then add an item named `My &Item` to that submenu. This menu item will be enabled if `enable_my_item` is set to 1 and disabled otherwise. A hotkey and tooltip are also provided.

```
set enable_my_item 1
proc enable_my_item {} {
    if { $::enable_my_item == 1 } {
        return 1
    }
    return 0
}
gui_create_menu -menu "&Favorite->Preferences->My &Item" \
    -tcl_cmd "echo {executing My Item}" \
    -enable_cmd "enable_my_item" \
    -hot_key "Ctrl+N" \
    -tooltip "short tooltip description for My Item" \
    -help_string "long status bar description for My Item" \
    -icon_file "/syn/sparc/my_item.xpm"
```

The following IC Compiler example illustrates creating a new menu item in the context menu of the layout window which will refer to the Zoom Fit Selection menu item from the Layout window main menu bar. This assumes that the tcl variable "`gui_default_window_type`" is set to the ICC window type "LayoutWindow" and thus it is not necessary to specify the `-window_type` option with the value of "LayoutWindow".

```
gui_create_menu -menu "Zoom Fit Selection" \ -root layout_view_menu_root \ -reference "View->Zoom->Zoom Fit Selection"
```

The following example create a new Tcl-based menu entry in the context menu which invokes a procedure # called `do_my_thing`.

```
gui_create_menu -menu "Do My Thing" \ -root layout_view_menu_root \ -tcl "do_my_thing"
```

The following IC Compiler example illustrates adding a context menu item to the path schematic context menu which refers to a menu item in the Main window. This example assumes that there is a context menu root called "`path_schematic_contextmenu_root`", a hierarchical menu item in the toplevel menu bar of the window type "MainWindow" with the hierarchical menu name "Schematic->Delete Selected".

```
gui_create_menu -menu "Remove Selected" \ -root path_schematic_contextmenu_root \ -reference "Schematic->Delete Selected" -  
window_type MainWindow
```

gui_create_pref_category

Create a preference category.

SYNTAX

```
string gui_create_pref_category
      -category Category
```

ARGUMENTS

-category *Category*

Category specifies the category to create.

DESCRIPTION

This command creates a preference service category with the specified name, which can be used to store and categorize key-value pairs that are created with the **gui_create_pref_key** command. If successful, the command returns the name of the category that is created.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false.

```
gui_create_pref_category -category some_category
                          gui_create_pref_key -category my_category -key some_key -value_type bool -value false
```

```
gui_update_pref_file(2)
```

gui_create_pref_key

Create a preference key.

SYNTAX

```
string gui_create_pref_key
  -key Key
  -value_type ValueType
  -value Value
  [-category Category]
  [-keep_value_if_exist]
  [-read_only]
  [-description Description]
  [-min Minimum_Value]
  [-max Maximum_Value]
  [-legal_value_list Value_ListP]
  [-string_to_int_map Value_Map]
  [-save_on_exit Boolean_Value]
```

ARGUMENTS

-key Key

Key specifies the name of the key to create.

-value_type ValueType

ValueType specifies the data type of the value of the key. It must be one of [bool | integer | double | color | string].

-value Value

Value specifies the value of the key. The value should be set appropriately in accordance with its value type. The **bool** type accepts [true, false, 0, 1, on, off]. The **color** type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

-category Category

Category specifies the category that the key belongs to. If not specified, a default category will be assigned.

-keep_value_if_exist

This Boolean option specifies to keep current value if the key already exists. The default is that the key will be assigned the value given in the **-value** option.

-read_only

If given, this flag specifies that the preference key value is read-only and its value cannot be set after the key has been created.

-description Description

If given, the given description string with the meaning of the key is assigned to the preference key.

-min *Minimum_Value*

If given, specifies the minimum value for an integer or double type preference key.

-max *Maximum_Value*

If given, specifies the maximum value for an integer or double type preference key.

-legal_value_list *Value_ListtP*

If given, this option specifies discrete valid values for an integer, double or string type preference key. Input the argument using Tcl list syntax: {{prefVal} ...}

-string_to_int_map *Value_Map*

If given, provides a map from a string key value to an integer value for preferences of integer type. Input the argument as a Tcl list of Tcl list where the internal list is a pair of the string value and the integer value: {{stringval intval} ...}

-save_on_exit *Boolean_Value*

If given, specifies whether the preference key value is saved to the user preference file upon exiting the application. Acceptable argument is either **true** or **false**.

DESCRIPTION

This command creates a preference key with the specified key name. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to the default category. Returns the value of the preference key.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create an integer key *some_key* under that category with the initial value of 200.

```
gui_create_pref_category -category some_category  
gui_create_pref_key -category my_category -key some_key -value_type integer -value 200
```

SEE ALSO

```

gui_exist_pref_category(2)  
gui_exist_pref_key(2)  
gui_update_pref_file(2)
```

gui_create_schematic

Creates a schematic or symbol view.

SYNTAX

```
string gui_create_schematic
  [-hierarchy]
  [-no_bus]
  [-symbol_view]
  [-reference]
  [-schematic_view]
```

ARGUMENTS

-hierarchy

Generates a schematic for each design in the current design.

-no_bus

Generates the schematic or symbol view without busing. Related pins and nets are not represented by a bused object in the new schematic.

-symbol_view

Generates a symbol view of the selected designs and cells. If nothing is selected, generate a symbol view of the current design.

-reference

Generates a schematic view of the reference designs of the current instance.

-schematic_view

Generates a schematic view of the currently selected designs and cells.

DESCRIPTION

The command generates a schematic or symbol view of the currently selected designs and cells.

EXAMPLES

The following example generates a bused schematic view, a bused symbol view, an unbused schematic view, and an unbused symbol view of the hierarchical cell named RAM_1.

```
prompt> change_selection [find cell RAM_1]
prompt> gui_create_schematic -schematic_view
prompt> gui_create_symbol -symbol_view
prompt> gui_create_schematic -schematic_view -no_bus
prompt> gui_create_symbol -symbol_view -no_bus
```

SEE ALSO

[change_selection\(2\)](#)

gui_create_task

Create a task.

SYNTAX

```
gui_create_task
  -item_root  ItemRootName
  [-default]
  -task string
```

ARGUMENTS

-default

This option specifies that this command will be the default task set as the current task. If another task is later created with this option, the the later setting overrides any previous settings.

-task *string*

ItemRootName specifies the name of the task root that will be associated with the task. Item root names are unique. If the same item root is associated with multiple tasks, then the tasks share the same item root.

DESCRIPTION

This command creates a task. A task defines the user task context for the whole application. Tasks may be used to configure menus and also to present a hierarchical list of task items to the user to navigate in the Task Assistant. The hierarchical list of task items is defined with the `gui_create_task_item` command.

EXAMPLES

The following simple example creates a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot
gui_create_tk_task_page -name InputFormPage -create_command create_widget_proc
gui_create_html_task_page -name AppDocument -path ./MyAppDocument.html
gui_create_task_item -name "Application->Input Form" -task MyAppTask -page InputFormPage
gui_create_task_item -name "Application->Documentation" -task MyAppTask -page AppDocument
```

SEE ALSO

`gui_create_task_item(2)`
`gui_create_tk_task_page(2)`

gui_create_task_item

Create an item in the task tree to access in the Task Assistant.

SYNTAX

```
gui_create_task_item
  -name      ItemName
  -task     TaskName | -item_root ItemRootName
  -page      PageName
  [-search_terms TermsList]
```

ARGUMENTS

-name *ItemName*

ItemName specifies the hierarchical name given to the task item being created. This is also the text displayed to the user in the Task Assistant.

-task *TaskName*

TaskName specifies the task in which this task item is created. If a task name is used to create the task item, the item is inserted into the task item root associated with the task in the create_task command. If other tasks use the same item root, they will also see the new task item created with this command. This option is mutually exclusive with the -item_root option. One must be specified but not both.

-item_root *ItemRootName*

ItemRootName specifies the task item root in which this task item is created. Item root names are associated with task names with the gui_create_task command and allows multiple tasks to share a single task item root. This option is mutually exclusive with the -item_root option. One must be specified but not both.

-page *PageName*

PageName specifies the page content factory associated with this task item. When the user selects the task item, the page specified by this option will be constructed and shown in the Task Assistant.

-search_terms *TermsList*

TermsList specifies additional terms that can be matched by the command search feature to find this task item. For example, if the task page allows the user to specify values for input parameters to a command, you may want to associate the name of that command as additional search term for the task item.

DESCRIPTION

This command creates a task item in the given task. Task items are defined in a hierarchy with hierarchy levels delimited by the separator string ">". The hierarchy of task items are shown in the task item navigation tree in the Task Assistant.

When the user selects a leaf item in the task navigation tree, the Task Assistant will show the task page associated with the item by this command. Currently, the pages can either be constructed from an HTML document or from a Tk widget factory.

EXAMPLES

The following simple example adds a new task, then defines a Tk widget task page, and an HTML task page, then creates task items referencing the task pages.

```
gui_create_task -name MyAppTask -item_root MyAppTaskRoot  
gui_create_tk_task_page -name InputFormPage -create_command create_widget_proc  
gui_create_html_task_page -name AppDocument -path ./MyAppDocument.html  
  
gui_create_task_item -name "Application->Input Form" -task MyAppTask -page InputFormPage  
gui_create_task_item -name "Application->Documentation" -task MyAppTask -page AppDocument
```

SEE ALSO

[gui_create_task\(2\)](#)
[gui_create_tk_task_page\(2\)](#)

gui_create_tk_palette_type

Creates a user configurable main window palette type.

SYNTAX

```
string gui_create_tk_palette_type
  {-type type_name}
  {-title palette_title}
  {-window_types window_type_list}
  {-create_command tcl_command}
  [-dock_edge left | right | top | bottom]
  [-icon string]
```

Data Types

<i>type_name</i>	string
<i>palette_title</i>	string
<i>window_type_list</i>	string
<i>tcl_command</i>	string

ARGUMENTS

-type *type_name*

Defines a name for the new palette type. If the specified name is not unique, an error occurs.

-title *palette_title*

Defines a title string to be used to describe palettes of this type. For example, context menus which control palette visibility use the specified title.

-window_types *window_type_list*

Specifies the types of main windows that contain the new palette type. After a palette type is defined, any new main window of the types specified are created with a palette.

-create_command *tcl_command*

Specifies a command to be called each time a main window of a type specified with *window_types* is created. The command is responsible for populating the palette with Tk control widgets. The command is called with two arguments: the name of the Tk widget to be populated and the name of the new main window.

-dock_edge left | right | top | bottom

Specifies the default dock edge to use when palettes of this type are created. If palettes are repositioned using the user interface, the new positions override the default dock position the next time the application is run.

DESCRIPTION

This command defines a type of main window palette which contains a Tk widget. An instance of each defined palette type is automatically created each time a main window of any of the specified types is instantiated. During the palette's initialization, the user's Tcl command is called to provide an opportunity for defining Tk widgets within the new palette. Creating a palette type does not create a palette. It only specifies the parameters to be used to construct palettes of that type when main windows are subsequently created.

SEE ALSO

`gui_hide_palette(2)`
`gui_show_palette(2)`

gui_create_tk_task_page

Create a Tk task page.

SYNTAX

```
gui_create_tk_task_page
  -name      PageName
  -create_command TclProcName
  [-default]
```

PageName *String*
TclProcName *String*

ARGUMENTS

-name *PageName*

PageName specifies the name of the new task page. Task page names must be unique.

-create_command *TclProcName*

TclProcName specifies the name of Tcl procedure to call to construct the Tk widget.

DESCRIPTION

This command creates a task page which can be shown in the task assistant. The name option value is the unique name of the page which can be referenced from the gui_create_task_item command. The create_command option value is the Tcl procedure name which will be called to populate the page when a task item referencing this task page is selected by the user. The procedure is called with the name of the Tk widget to populate and the name of the parent widget.

EXAMPLES

The following simple example creates a new task, then defines a Tk widget task page, then creates task items referencing the task page.

```
proc create_widget_proc {widgetName parentName} {
  #populate $widgetName with Tk
}

gui_create_task -name MyAppTask -item_root MyAppTaskRoot

gui_create_tk_task_page -name InputFormPage -create_command create_widget_proc

gui_create_tk_task_page
```

```
gui_create_task_item -name "Application->Input Form" -task MyAppTask -page InputFormPage
```

SEE ALSO

[gui_create_task\(2\)](#)
[gui_create_task_item\(2\)](#)
[gui_create_html_task_page\(2\)](#)

gui_create_toolbar

Create a toolbar with the specified name.

SYNTAX

```
string gui_create_toolbar -name ToolBarName
  [-title Title]
  [-dock_side DockSide]
  [-hidden]
  [-window_type WindowTypeName]
```

ToolBarName *String*
Title *String*
DockSide *String*
WindowTypeName *String*

ARGUMENTS

-name *ToolBarName*

ToolBarName is the toolbar identifier for the new toolbar.

-title *Title*

Title specifies the title or caption of the toolbar.

-dock_side *DockSide*

DockSide specifies the side of the window the tool docks to by default. The legal values are top, bottom, left, right.

-hidden

-hidden specifies the toolbar should be hidden by default.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

DESCRIPTION

This command creates a toolbar with the given name and title. Returns the name of the toolbar created.

EXAMPLES

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar  
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

SEE ALSO

```
gui_set_hotkey(2)  
gui_report_hotkeys(2)  
gui_create_menu(2)  
gui_delete_menu(2)  
gui_delete_toolbar(2)  
gui_create_toolbar_item(2)  
gui_delete_toolbar_item(2)  
gui_get_toolbar_names(2)  
gui_default_window_type(3)  
gui_custom_setup_files(3)
```

gui_create_toolbar_item

Create a button in the specified toolbar.

SYNTAX

```
string gui_create_toolbar_item -toolbar ToolBarName
  <-menu MenuName|-separator SeparatorNameWindowTypeName]
```

ToolBarName *String*
MenuName *String*
SeparatorName *String*
WindowTypeName *String*

ARGUMENTS

-toolbar *ToolBarName*

ToolBarName specifies the toolbar that the new toolbar item will be added to.

-menu *MenuName*

MenuName specifies the name of the menu item to be invoked from this toolbar button. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '>'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -separator option.

-separator *SeparatorName*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -menu option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

DESCRIPTION

This command adds a toolbar button to the specified toolbar using information described in the -menu option. The -menu option specifies the hierarchical menu name for some menu item. Thus, the toolbar icon becomes another interface for a menu item. Returns the item name if successful.

EXAMPLES

Create a toolbar called mytoolbar and add a button to it that invokes the File->Quit menu item.

```
gui_create_toolbar -name mytoolbar  
gui_create_toolbar_item -name mytoolbar -menu "File->Quit"
```

SEE ALSO

```
gui_set_hotkey(2)  
gui_report_hotkeys(2)  
gui_create_menu(2)  
gui_delete_menu(2)  
gui_create_toolbar(2)  
gui_delete_toolbar(2)  
gui_delete_toolbar_item(2)  
gui_get_toolbar_names(2)  
gui_default_window_type(3)  
gui_custom_setup_files(3)
```

gui_create_window

Creates a window of the specified window type.

SYNTAX

```
string gui_create_window
  -type window_type
  [-parent parent_window_id]
  [-show_state window_state]
  [-title title]
  [-rect rect | -size {width height}]
  [-icon icon]
```

Data Types

<i>window_type</i>	string
<i>parent_window_id</i>	string
<i>window_state</i>	string
<i>title</i>	string
<i>rect</i>	rectangle
<i>width</i>	integer
<i>height</i>	integer
<i>icon</i>	string

ARGUMENTS

-type *window_type*

Specifies the type of window you are creating. The tool creates an instance of this window type.

You can display a list of the supported window types by using the **gui_get_window_types** command.

-parent *parent_window_id*

Specifies the window ID of the parent top-level window for the view window you are creating.

If you do not specify a window ID and the window type is not a top-level window type, the tool uses the current top-level window. If there is no current top-level window, the tool creates a new top-level window automatically to host the window you are creating.

-show_state *create_window_state*

Specifies the window state in which to display the window you are creating. The result varies depending on whether the window is a top-level window or a view window.

For a top-level window, you can specify one of the following states:

- maximized** -- show maximized (fill whole screen)
- minimized** -- show iconified
- normal** -- show at preferred size

Note that the window manager might not fully honor the specified state. See your window manager documentation for more details.

For a view window, you can specify one of the following states:

- maximized** -- show maximized in view area and raise to top
- minimized** -- show iconified in view area
- normal** -- show at preferred size in view area and raise to top

If you display a view window in its maximized state, the tool also maximizes any existing view windows. If you display a view window in its minimized or normal state, the tool changes any maximized view windows to their normal states.

The default is -show_state normal.

-title *title*

Specifies the title for the top-level or view window you are creating.

Note that the window manager might not fully honor the specified top-level window title string. See your window manager documentation for more details.

-rect *rect*

Specifies the size and position of the window in the following format:

$\{\{x1\ y1\}\ \{x2\ y2\}\}$

The coordinates $\{x1\ y1\}$ specify the location of the top-left corner, and the coordinates $\{x2\ y2\}$ specify the location of the bottom-right corner. These coordinates are relative to the top-left corner of the screen, for a top-level window, or to the top-right corner of the view area in the parent top-level window, for a view window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The **-rect** option and the **-size** option are mutually exclusive.

-size *width height*

Specifies the width and height of the window.

Note that the window manager might not fully honor the specified top-level window geometry. See your window manager documentation for more details.

The **-size** option and the **-rect** option are mutually exclusive.

-icon *icon*

Specifies the image to be used for the top-level or view window icon.

For a view window, the icon appears in the top-left corner of the title bar when the window is in its normal or minimized state and at the left side of the menu bar when the window is maximized.

For a top-level window, the icon might not be displayed when the window is in its normal, minimized, or maximized state. See your window manager documentation for more details.

DESCRIPTION

This command creates a window of the specified type and returns the window ID. The window type that you specify controls whether the window is a top-level window or a view window.

EXAMPLES

The following example creates a top-level layout window and a minimized layout view window.

```
prompt> set top [gui_create_window -type LayoutWindow]
LayoutWindow.1
prompt> gui_create_window -type Layout -parent $top \
    -show_state minimized
layout.1
```

SEE ALSO

`gui_exist_window(2)`
`gui_show_window(2)`
`gui_get_window_types(2)`
`gui_get_window_ids(2)`
`gui_set_active_window(2)`
`gui_get_current_window(2)`

gui_delete_attrgroup

Removes a group of attributes or all attribute groups for an object type.

SYNTAX

```
status gui_delete_attrgroup
      -class design_object
      -name name
      [-all]
```

Data Types

<i>design_object</i>	string
<i>name</i>	string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be removed for the specified object type.

-all

Removes all attribute groups defined for the specified object type.

DESCRIPTION

The **gui_delete_attrgroup** command removes the specified attribute group or all attribute groups for the specified object type.

EXAMPLES

```
prompt> gui_delete_attrgroup -class Cell -name "Hierarchy"
prompt> gui_delete_attrgroup -class Cell -all
```

SEE ALSO

`gui_create_attrgroup(2)`
`gui_list_attrgroups(2)`
`gui_update_attrgroup(2)`

gui_delete_menu

Delete a menu item for the toplevel menubar or a context menu

SYNTAX

```
string gui_delete_menu
  [-menu HierMenuName | -all]
  [-window_type WindowTypeName | -root ContextMenuRoot]
```

HierMenuName *String*
WindowTypeName *String*
ContextMenuRoot *String*

ARGUMENTS

-menu *HierMenuName*

HierMenuName specifies the hierarchical menu name of the menu item to be deleted. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '->'. For example, File->Quit specifies the Quit menu item under the File menu. These names are allowed to also specify the mnemonic for the menu text which is specified with an embedded '&', but they are not required to do so. This option is mutually exclusive with the -all option.

-all

This option flag specifies all menu items in a menu root to be deleted. The option cannot be given with the -window_type option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

-root *ContextMenuRoot*

ContextMenuRoot specifies the context menu root from which the menu item will be added. A context menu root name groups menu items to be included in a pop-up context menu. A context menu is usually brought up by right clicking on a window and is used to provide context-sensitive features. (Note the difference between a context menu root and the menu root use by a toplevel window's menu bar .)

DESCRIPTION

This command deletes a menu item for the menu bar of a top level window. The menu hierarchy separator is denoted by "->". If there is a toolbar button or hotkeys defined for the menu being deleted they will also be deleted. If the path to the menu is a submenu that menu item and all its sub-items will be deleted. The option -all may be used with a menu root name to remove all menu items from a menu. This is useful if a user wishes to customize or modify an entire context menu. These settings are stored either in a user-specific setup file or one that is shared across the installation. The gui initialization sequence will load builtin system configuration, and then

apply the installation specific customizations, and finally the user's customizations. The installation specific setup file is specified by the variable `gui_custom_setup_file` and will have a default value of `$::synopsys/admin/setup/.synopsys_galileo_gui.tcl`. This can be overridden in the `.synopsys_dc.setup` file if it is desired. If the file specified by this variable exists then it will be loaded after the gui is initialized. The user setup file is `~/.synopsys_galileo_gui.tcl`.

EXAMPLES

The following example deletes the Quit item from the File menu.

```
gui_delete_menu -menu "File->Quit"
```

SEE ALSO

```
gui_set_hotkey(2)
gui_report_hotkeys(2)

gui_create_toolbar_item(2)
gui_delete_toolbar_item(2)
gui_default_window_type(3)
gui_custom_setup_files(3)
```

gui_delete_toolbar

Delete a toolbar with the specified name.

SYNTAX

```
string gui_delete_toolbar -name ToolBarName  
[-window_type WindowTypeName]
```

ToolBarName *String*
WindowTypeName *String*

ARGUMENTS

-name *ToolBarName*

ToolBarName is the toolbar identifier for the toolbar to be deleted.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

DESCRIPTION

This command deletes a toolbar and all of its toolbar items.

EXAMPLES

Delete a toolbar called mytoolbar.

```
gui_delete_toolbar -name mytoolbar
```

SEE ALSO

`gui_set_hotkey(2)`
`gui_report_hotkeys(2)`

```
gui_create_menu(2)
gui_delete_menu(2)
gui_create_toolbar(2)

gui_delete_toolbar_item(2)
gui_get_toolbar_names(2)
gui_default_window_type(3)
gui_custom_setup_files(3)
```

gui_delete_toolbar_item

Remove a toolbar button specified by the menu name from the specified toolbar.

SYNTAX

```
string gui_delete_toolbar_item -toolbar ToolBarName
  <-menu MenuName|-separator SeparatorNameWindowTypeName]
```

ToolBarName *String*
MenuName *String*
SeparatorName *String*
WindowTypeName *String*

ARGUMENTS

-toolbar *ToolBarName*

ToolBarName specifies the toolbar to be modified.

-menu *MenuName*

MenuItem specifies the hierarchical menu name for some menu item, that this toolbar item is associated with. This option is mutually exclusive with the -separator option.

-separator *SeparatorName*

SeparatorName specifies the unique separator name within the toolbar. This option is mutually exclusive with the -item option.

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window whose menu bar is to be modified. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

DESCRIPTION

This command deletes a toolbar item specified by *MenuName* or *SeparatorName* from the specified toolbar. Returns the name of the deleted toolbar item if successful.

EXAMPLES

Delete the button bound to File->Quit from the toolbar mytoolbar.

```
gui_delete_toolbar_item -name mytoolbar -menu "File->Quit"
```

SEE ALSO

```
gui_set_hotkey(2)
gui_report_hotkeys(2)
gui_create_menu(2)
gui_delete_menu(2)
gui_create_toolbar(2)
gui_delete_toolbar(2)
gui_create_toolbar_item(2)
gui_get_toolbar_names(2)
gui_default_window_type(3)
gui_custom_setup_files(3)
```

gui_eval_command

Executes and optionally logs a tool command language (Tcl) command.

SYNTAX

```
string gui_eval_command
    -command command
    [-echo]
    [-history]
    [-honor_preview | -preview]
```

Data Types

command string

ARGUMENTS

-command *command*

Specifies the Tcl command to execute and to record in the command replay log.

-echo

Echoes the command and displays the command result in the console log view. By default, the tool does not echo the command or display the result in the log view.

-history

Appends the command to the command history list in the console history view. By default, the tool does not append the command to the command history list.

-honor_preview

This option is mutually exclusive with the -preview option. Honors the Preview Command Only setting in the dialog. By default, the tool does not honor the Preview Command Only setting.

-preview

This option is mutually exclusive with the -honor_preview option. Runs the given command in preview mode, regardless of the current preview mode set from a command dialog. When -preview is given, -echo is turned on since the previewed command cannot be seen in the xterm if -echo is turned off. As with all commands issued from command dialogs when in preview mode, if a script editor is present, then the previewed command is redirected to the script editor. Using this option does not set or clear the global preview mode in the application.

DESCRIPTION

This command executes a Tcl command and records it in the command replay log. Use the **-echo** option to echo the command and its result in the console log view. Use the **-history** option to append the command to the command history list. Use the **-honor_preview** option to honor the Preview Command Only setting. Use the **-preview** option to preview the command only without executing it.

The result of a nested command is passed back as the result of **gui_eval_command**.

EXAMPLES

The following example evaluates the command "echo abc".

```
prompt> gui_eval_command -command {echo abc}
abc
```

The following example previews the command "echo abc".

```
prompt> gui_eval_command -command {echo abc} -preview
abc
```

gui_execute_menu_item

Execute a menu item in the currently active window.

SYNTAX

```
status gui_execute_menu_item
  { -menu menu_item_id }
```

Data Types

menu_item_id string

ARGUMENTS

-menu *menu_item_id*

menu_item_id specifies the hierarchical name of the menu item to execute. The "name" of a menu is a string which specifies the hierarchy of menu labels connected with '>'. For example, File->Quit specifies the Quit menu item in the File menu. These names are allowed to also specify the keyboard accelerator for the menu text which is specified with an embedded '&', but they are not required to do so.

DESCRIPTION

This command checks for the existence and enabled state of the given menu item in the currently active window. If it exists and is enabled, the menu item is executed.

The command returns and result value string from the executed menu item, if any.

EXAMPLES

The following example activates the main window named Toplevel.2, then executes the **Hierarchy Browser** menu item in the **View** menu in Toplevel.2.

```
shell> gui_set_active_window -window Toplevel.2
shell> gui_execute_menu_item -menu "View->Hierarchy Browser"
```

SEE ALSO

```
gui_create_menu(2)
gui_set_active_window(2)
```

gui_exist_pref_category

Check the existence of a preference category.

SYNTAX

```
bool gui_exist_pref_category  
    -category Category
```

ARGUMENTS

-category *Category*

Category specifies the category.

DESCRIPTION

This command checks the existence of a preference category. Return "1" if the specified category exists, otherwise return "0".

SEE ALSO

```
gui_create_pref_category(2)  
gui_create_pref_key(2)  
gui_set_pref_value(2)  
gui_get_pref_value(2)  
gui_remove_pref_key(2)  
gui_get_pref_keys(2)  
gui_exist_pref_key(2)  
gui_update_pref_file(2)
```

gui_exist_pref_key

Check the existence of a preference key.

SYNTAX

```
bool gui_exist_pref_key  
  -key Key  
  [-category Category]
```

ARGUMENTS

-key *Key*

Key specifies the preference key of interest.

-category *Category*

Category specifies the category. Default category will be used if missing.

DESCRIPTION

This command checks the existence of a preference key given the key name and the preference category. Return "1" if the specified key exists, otherwise return "0".

SEE ALSO

```
gui_create_pref_category(2)  
gui_create_pref_key(2)  
gui_set_pref_value(2)  
gui_get_pref_value(2)  
gui_remove_pref_key(2)  
gui_get_pref_keys(2)  
gui_exist_pref_category(2)  
gui_update_pref_file(2)
```

gui_exist_window

Check for the existence of specified window or window type

SYNTAX

```
status gui_exist_window
  { -window window_id | -type window_type }
  [ -parent window_id ]
```

Data Types

window_id string
window_type string

ARGUMENTS

-window *window_id*

Specifies the window id to test existence for.

This option is mutually exclusive with the *-type* option.

-type *window_type*

Specifies that the existence of a window of this window type is tested for.

If the *-parent* option is specified then the existence of a window of this window type is tested for in the specified toplevel window.

If the *-parent* option is **not** specified then the existence of a window of this window type is tested for in any toplevel window.

This option is mutually exclusive with the *-window* option.

-parent *window_id*

Specifies the toplevel window to check for existence in.

Note: This option is only relevant if the *-type* option is specified.

DESCRIPTION

This command checks the existence of the specified window, or window type across toplevel windows or within a specified toplevel window.

The command returns "1" or "0" for success or failure respectively.

EXAMPLES

The following example will create a toplevel window and a child layout view window, then check the existence of the command layout window.

```
shell> set top [gui_create_window -type TopLevel]
shell> set x [gui_create_window -type Layout -parent $top]
shell> set layout_exist [gui_exist_window $x]
shell> if { $layout_exist == 1} {echo "layout exist" }
```

gui_get_annotations

Return a collection of layout annotations

SYNTAX

string **gui_get_annotations**

[-window *window_name*]
[-group *group_id*]
[-within *region*]
[-intersect]
[-at *location*]
[-filter *filter*]
[-nocase]
[-regexp]

string *window_name*
string *group_name*
string *filter*
rectangle *region*
location *point*

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window. If not specified implies all windows.

-group *group_name*

Specifies the annotation group name. If not specified implies all groups.

-within *region*

Search for annotations contained within the specified rectangle.

-intersect

Use this option with the -within option. When -intersect is specified, all annotations that touch the search rectangle are also returned.

-at *location*

Search for annotations that are close to the specified point.

-filter *filter*

Only return annotations that satisfy the filter expression.

-nocase

Ignore case in the filter expression. Option requires -filter.

-regexp

Use regular expressions in the filter expression. Option requires -filter.

DESCRIPTION

Returns a collection of gui_annotation objects that satisfy the requirements.

EXAMPLES

The following example retrieves all the annotations in the Layout.1 window.

```
shell> gui_get_annotations -window Layout.1
```

This example shows how to use the client_data attribute to find annotations with that setting.

```
shell> gui_get_annotations -filter client_data==MyData
```

This example shows how to find annotations that are within a specified rectangle

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}}
```

To also find the annotations that touch the search rectangle:

```
shell> gui_get_annotations -within {{10.5 2.0} {23.5 14.6}} -intersect
```

SEE ALSO

gui_add_annotation **gui_remove_annotations**

gui_get_bucket_option

Returns the value of an option for a bucket in the specified visual mode or map mode.

SYNTAX

```
string gui_get_bucket_option
  -map map_name
  -bucket bucket_name
  -option option_name
  [-default]
```

Data Types

<i>map_name</i>	string
<i>bucket_name</i>	string
<i>option_name</i>	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-bucket *bucket_name*

Specifies the name of the bucket.

-option *option_name*

Specifies the name of the option whose value is to be returned.

-default

Returns the default value of the option instead of the current value.

DESCRIPTION

This command returns the current or default value of an option for a bucket in a visual mode or map mode. You must specify the visual mode or map mode name, the bucket name, and the option name. Use **-default** if you want the command to return the default option value instead of the current option value.

EXAMPLES

The following example returns the current color value for *bucket1* in the global route congestion map:

```
prompt> gui_get_bucket_option -map AREAPARTITION \
-bucket bucket1 -option color
```

SEE ALSO

[gui_get_bucket_option_list\(2\)](#)
[gui_get_map_list\(2\)](#)
[gui_get_map_option\(2\)](#)
[gui_get_map_option_list\(2\)](#)
[gui_set_bucket_option\(2\)](#)
[gui_set_map_option\(2\)](#)

gui_get_bucket_option_list

Lists the available options for buckets in the specified visual mode or map mode.

SYNTAX

```
string gui_get_bucket_option_list  
-map map_name
```

Data Types

map_name string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

DESCRIPTION

This command displays a list of all options that are available for the buckets in the specified visual mode or map mode.

EXAMPLES

The following example displays a list of the available options for buckets in the global route congestion map:

```
prompt> gui_get_bucket_option_list -map AREAPARTITION
```

SEE ALSO

gui_get_bucket_option(2)
gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_bucket_option(2)
gui_set_map_option(2)

gui_get_cell_block_marks

Gets a list of the block mark string values on one or more cells.

SYNTAX

```
list gui_get_cell_block_marks
      cells
```

Data Types

cells list

ARGUMENTS

cells

Lists one or more cell name patterns or cell collections.

DESCRIPTION

This command gets the block mark string values from one or more hierarchical or leaf-level cell instances.

EXAMPLES

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU ALU
prompt> gui_get_cell_block_marks I_TOP/I_ALU
ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the **get_cells** command, and then gets the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU] ALU
prompt> gui_get_cell_block_marks [get_cells I_TOP/I_ALU]
ALU
```

The following example shows how using the **get_attribute** command to query the **block_mark** attribute is an alternative to using the **gui_get_cell_block_marks** command:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU ALU
```

```
prompt> gui_get_cell_block_marks I_TOP/I_ALU  
ALU  
prompt> get_attribute -class cell I_TOP/I_ALU block_mark  
ALU
```

SEE ALSO

`gui_set_cell_block_marks(2)`
`gui_remove_cell_block_marks(2)`

gui_get_current_task

Get the name of the current task.

SYNTAX

string **gui_get_current_task**

DESCRIPTION

The `gui_get_current_task` command queries the name of the current task.

SEE ALSO

`gui_create_task(2)`
`gui_get_current_task_item(2)`
`gui_get_current_task_page(2)`
`gui_set_current_task(2)`
`gui_get_task_list(2)`

gui_get_current_task_item

Get the name of the current task item.

SYNTAX

string **gui_get_current_task_item**

DESCRIPTION

The `gui_get_current_task_item` command queries the name of the current task item.

SEE ALSO

`gui_get_current_task(2)`
`gui_get_current_task_page(2)`
`gui_set_current_task(2)`
`gui_get_task_list(2)`

gui_get_current_task_page

Get the name of the current task page.

SYNTAX

string **gui_get_current_task_page**

DESCRIPTION

The `gui_get_current_task_page` command queries the name of the current task page.

SEE ALSO

`gui_create_task(2)`
`gui_get_current_task(2)`
`gui_get_current_task_item(2)`
`gui_set_current_task(2)`
`gui_get_task_list(2)`

gui_get_current_window

Retrieves the window ID of the active top-level or view window.

SYNTAX

```
string gui_get_current_window
[ -toplevel | -view | -parent parent_window_id ]
[ -hier_name ]
[ -types window_type_list ]
[ -mru ]
```

Data Types

parent_window_id string
window_type_list list

ARGUMENTS

-toplevel

Retrieves the active top-level window unless you also specify the **-types** option.

If you also specify the **-types** option, the **-toplevel** option retrieves the most recently active top-level window that has one of the specified window types.

The **-toplevel**, **-view**, and **-parent** options are all mutually exclusive.

-view

Retrieves the active view window in the active top-level window unless you also specify the **-types** option, the **-mru** option, or both.

If you also specify the **-types** option but not the **-mru** option, the **-view** option retrieves the most recently active view window with one of the specified window types in the active top-level window.

If you also specify the **-mru** option but not the **-types** option, the **-view** option retrieves the most recently active view window in any of the open top-level windows.

If you also specify both the **-types** option and the **-mru** option, the **-view** option retrieves the most recently active view window that has one of the specified window types and is in an open top-level window.

The **-view**, **-toplevel**, and **-parent** options are all mutually exclusive.

-parent *parent_window_id*

Retrieves the active view window in the specified top-level window unless you also specify the **-types** option.

If you also specify the **-types** option, the **-parent** option retrieves the most recently active view window that has any of the specified window types and is in the specified top-level window.

The **-parent**, **-toplevel**, and **-view** options are all mutually exclusive.

-hier_name

Returns the window ID in Qtcl format, which is similar to a full path name for the window, for use with the `qtcl_*` commands.

Note that a value returned in this format is not usable by `gui_*` commands.

-types *window_type_list*

Forces the tool to retrieve a window with one of the specified window types.

Use this option to restrict the search to certain types of windows. If you specify multiple types, they should be consistent (all toplevel window types or all view window types), but nonconsistency is not considered an error. The first type in the list determines whether the tool retrieves a top-level window or a view window when the **-toplevel** and **-view** options are not specified.

When you use the **-types** option, you should not use the **-toplevel** option or the **-view** option because the tool can determine from the list whether the window should be a top-level window or a view window. If you specify one of these options, any types that do not correspond to the option are silently ignored. For example, if you specify **-view**, then all top-level types are ignored.

-mru

Forces the tool to retrieve the most recently active view window from among all the open top-level and view windows. This option is effective only when you specify the **-view** option or when all the window types you specify with the **-types** option are view window types.

DESCRIPTION

This command retrieves the window ID of the active top-level or view window based on the options that you specify, or returns an empty string if no match is found.

A view window is a child window of a top-level window and is created with the `gui_create_window` command.

If you do not specify the **-toplevel**, **-view**, and **-parent** options, the tool uses the **-types** option to determine the window type. If you also do not specify the **-types** option, the tool uses the **-toplevel** option by default.

EXAMPLES

The following example retrieves the active top-level window:

```
prompt> gui_get_current_window -toplevel
```

The following example retrieves the active view window:

```
prompt> gui_get_current_window -view
```

The following example retrieves the most recently active layout view:

```
prompt> gui_get_current_window -types "Layout" -mru
```

The following example return \$cons:

```
prompt> set top1 [gui_create_window -type LayoutWindow]
prompt> set top2 [gui_create_window -type LayoutWindow]
prompt> set cons [gui_create_window -type Layout -parent $top]
prompt> gui_get_current_window -parent $top
```

SEE ALSO

`gui_create_window(2)`

gui_get_highlight

Get a collection of highlighted objects.

SYNTAX

```
string gui_get_highlight
  [-color color_id | -all_colors]
  [-return_select_bus]
  [-more_than ]
```

Data Types

color_id string

ARGUMENTS

-color *color_id*

Specifies the color of objects to be returned. If neither -color nor -all_colors is used, the current color is assumed. The allowed colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

-all_colors

Specifies that all highlighted objects are to be returned.

-return_select_bus

Create a new selection bus in which to store the result instead of returning a collection of objects.

DESCRIPTION

The gui_get_highlight command returns a collection of objects highlighted with the specified colors.

EXAMPLES

Get a collection of green highlighted objects.

```
prompt> gui_get_highlight -color green
```

Get a collection of all highlighted objects.

```
prompt> gui_get_highlight -all_colors
```

SEE ALSO

`gui_change_highlight(2)`
`gui_get_highlight_options(2)`
`gui_set_highlight_options(2)`

gui_get_highlight_options

Query the options that control highlighting.

SYNTAX

```
string gui_get_highlight_options
      [-current_color | -all_colors | -auto_cycle_color]
```

ARGUMENTS

-current_color

This option returns a string which is the current highlight color, or the default color for highlighting operations.

-all_colors

This option returns Tcl list of all of the colors which are allowed to be used for highlighting.

-auto_cycle_color

This option returns the current value of the auto cycle setting ("true" or "false").

DESCRIPTION

The `gui_get_highlight_options` command queries the settings which control highlighting. Exactly one option must be provided.

EXAMPLES

Get the current highlight color.

```
prompt> gui_get_highlight_options -current_color
```

Get all highlight colors.

```
prompt> gui_get_highlight_options -all_colors
```

SEE ALSO

```
gui_change_highlight(2)
gui_get_highlight(2)
gui_set_highlight_options(2)
```

gui_get_map_list

Lists the current visual and map modes.

SYNTAX

```
string gui_get_map_list
```

ARGUMENTS

The **gui_get_map_list** command has no arguments.

DESCRIPTION

The **gui_get_map_list** command returns a list of existing visual and map modes.

EXAMPLES

The following example gets the names of all available visual and map modes:

```
prompt> gui_get_map_list
```

SEE ALSO

```
gui_get_bucket_option(2)
gui_get_bucket_option_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_bucket_option(2)
gui_set_map_option(2)
gui_show_map(2)
```

gui_get_map_option

Returns the value of an option for the specified visual mode or map mode.

SYNTAX

```
string gui_get_map_option  
  -map map_name  
  -option option_name  
  [-default]
```

Data Types

<i>map_name</i>	string
<i>option_name</i>	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-option *option_name*

Specifies the name of the option whose value is to be returned.

-default

Returns the default value of the option instead of the current value.

DESCRIPTION

This command returns the current or default value of an option for a visual mode or map mode. You must specify the visual mode or map mode name and the option name. Use **-default** if you want the command to return the default option value instead of the current option value.

EXAMPLES

The following example returns the current number of buckets for the global route congestion map:

```
prompt> gui_get_map_option -map AREAPARTITION \  
  -option num_buckets
```

SEE ALSO

`gui_get_bucket_option(2)`
`gui_get_bucket_option_list(2)`
`gui_get_map_list(2)`
`gui_get_map_option_list(2)`
`gui_set_bucket_option(2)`
`gui_set_map_option(2)`

gui_get_map_option_list

Lists the available options for the specified visual mode or map mode.

SYNTAX

```
string gui_get_map_option_list  
-map map_name
```

Data Types

map_name string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

DESCRIPTION

This command displays a list of all options that are available for the specified visual mode or map mode.

EXAMPLES

The following example displays a list of the available options for the global route congestion map:

```
prompt> gui_get_map_option_list -map AREAPARTITION
```

SEE ALSO

```
gui_get_bucket_option(2)  
gui_get_bucket_option_list(2)  
gui_get_map_list(2)  
gui_get_map_option(2)  
gui_set_bucket_option(2)  
gui_set_map_option(2)
```

gui_get_menu_roots

Return a sorted list of all menu roots used by the application.

DESCRIPTION

This command returns a list of all the menu roots used by the application. The menu roots include menu roots used by toplevel menu bars and menu roots used by context menus. A menu root is used to group menu items that share the same menu root together. All items under each toplevel window's menu bar shares the same menu root; similarly, all items in a context menu (menu brought up with right mouse click in a window) shares the same context menu root.

SEE ALSO

[gui_create_menu\(2\)](#)

gui_get_mouse_tool_option

Get the value of a mouse tool option

SYNTAX

```
string gui_get_mouse_tool_option -tool string
    -option string

string string
string string
```

ARGUMENTS

-tool *string*

Tool to get option for.

-option *string*

Option to get.

DESCRIPTION

This command returns value of a mouse tool option .

EXAMPLES

```
> gui_get_mouse_tool_option -tool SELECT -option InputMode
Smart
```

SEE ALSO

[gui_mouse_tool\(2\)](#)
[gui_set_mouse_tool_option\(2\)](#)

gui_get_pref_keys

Return a list of preference keys under the specified category.

SYNTAX

```
string gui_get_pref_keys
      -category Category
```

ARGUMENTS

-category *Category*

Category specifies the category to use.

DESCRIPTION

Return a list of preference keys under the specified category.

SEE ALSO

```
gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_remove_pref_key(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)
```

gui_get_pref_value

Get the value of a preference key.

SYNTAX

```
string gui_get_pref_value
      -key Key [-category Category]
```

ARGUMENTS

-key *Key*

Key specifies the key to retrieve the value from.

-category *Category*

Category specifies the category to search for the key. If not specified, a default category will be used.

DESCRIPTION

This command retrieves the value of a preference key from the specified key name and category.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command **gui_get_pref_value** is then used to retrieve the value of the preference key just created.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool -value false
set x [gui_get_pref_value -category my_category -key some_key]
```

SEE ALSO

```
gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
```

```
gui_remove_pref_key(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)
```

gui_get_region

Returns the coordinates of the current region rectangle or rectilinear polygon.

SYNTAX

```
list gui_get_region
```

DESCRIPTION

This command returns the coordinates of the rectangle or rectilinear polygon that defines the current region in layout region mode.

Note that the preferred command for typical extension writing is usually **gui_set_layout_user_command** instead of **gui_get_region** because **gui_set_layout_user_command** has snapping, mouse up drag, cancel, and user prompt capabilities.

EXAMPLES

```
prompt> gui_get_region
{-1743.945 18.357} {42.833 1523.657}
```

SEE ALSO

```
gui_set_region(2)
gui_set_layout_user_command(2)
```

gui_get_setting

Gets a setting on the specified window.

SYNTAX

```
string gui_get_setting
    -window WindowID
    {-setting Setting | -list}
```

ARGUMENTS

-window *WindowID*

WindowID specifies the window to get the setting

-setting *Setting*

Setting specifies the setting to get

-list

Specifies that the list of available settings needs to be returned

DESCRIPTION

Gets the list of available settings on the specified window. Windows are views or top level windows. The setting is a property of the window. The returned value is a string which has the type of the setting being read. Some windows might not have this function implemented.

EXAMPLES

```
prompt> gui_get_setting -window Layout.1 -setting showCell
1
```

```
prompt> gui_get_setting -window Layout.1 -setting viewLevel
2
```

SEE ALSO

```
gui_set_setting(2)
```

gui_get_task_list

Lists all the available task names.

SYNTAX

```
string gui_get_task_list
```

DESCRIPTION

The gui_get_task_list command queries the names of all available tasks.

DESCRIPTION

```
prompt> gui_get_task_list all {Block Implementation} {Design Planning}
```

SEE ALSO

```
gui_create_task(2)  
gui_set_task_list(2)  
gui_set_current_task(2)  
gui_get_current_task(2)
```

gui_get_task_page

Return the name of the task page for the given task item.

SYNTAX

string **gui_get_task_page**

SYNTAX

gui_get_task_page
-task *TaskName*
-item *ItemName*

TaskName *String*
ItemName *String*

ARGUMENTS

-task *TaskName*

TaskName specifies the name of the task.

-item *ItemName*

ItemName specifies the hierarchical name of the task item for which to get the page name",

DESCRIPTION

This command returns the name of the task page for the task item identified by the option values. This is useful when you want to create a new task item re-using a task page that is invoked by an existing task item.

EXAMPLES

To reuse the task page from the built-in task item "Pin Assignment->Pin Placement" in the task "Hierarchical Design" in your own task flow, you can do the following:

```
prompt> set pageName [gui_get_task_page -task "Hierarchical Design"  
           -item "Pin Assignment->Pin Placement"]  
prompt> gui_create_task_item -task myTask -name myItemName  
           -page $pageName
```

SEE ALSO

[gui_create_task_item\(2\)](#)

[gui_get_task_list\(2\)](#)

gui_get_toolbar_names

Return a Tcl list of the names of all the toolbars that have been created with the **gui_create_toolbar** command.

SYNTAX

```
void gui_get_toolbar_names  
[-window WindowId]
```

WindowId *String*

ARGUMENTS

-window *WindowId*

Return toolbars defined in this window. If omitted, return toolbars defined in the active window.

DESCRIPTION

Return a Tcl list of the names of all the toolbars that have been created with **gui_create_toolbar** command for the specified window.

SEE ALSO

gui_create_toolbar(2)
gui_create_toolbar_item(2)
gui_delete_toolbar(2)
gui_delete_toolbar_item(2)
gui_hide_toolbar(2)
gui_show_toolbar(2)

gui_get_window_ids

Get a list of window ids

SYNTAX

```
ids gui_get_window_ids
    [-parent window_id]
    [-type window_type]
```

Data Types

window_id string
window_type string

ARGUMENTS

-parent *window_id*

Specifies the toplevel window id to get child view window ids from.

-type *window_type*

Specifies that the windows id returned should be restricted to those of the specified type.

Note: as a type can be only be associated with either a toplevel window or a child view window (not both) the type implies whether toplevel or child view window ids are returned.

If this option is not specified then either all toplevel window ids are returned (-parent option not specified) or all child view window ids of a specified toplevel window id are returned (-parent option specified).

RETURNS

ids

Returned list of window ids.

DESCRIPTION

This command gets a list of the ids of all toplevel windows, all toplevel windows of a specified type, all child view windows of a specified type, or all child view windows of a specified type in a specified toplevel window.

EXAMPLES

The following example will create a toplevel window and a child layout window. Then this command will be used to retrieve the ids of the existing windows.

```
\prompt> set top [gui_create_window -type TopLevel]  
\prompt> set cons [gui_create_window -type Layout -parent $top]  
\prompt> set ids [gui_get_window_ids] # return list containing values of $top and value of $cons.  
\prompt> set child� [gui_get_window_ids -parent $top] # return value of $cons.  
\prompt> set layout_instances [gui_get_window_ids -type Layout] # return value of $cons.
```

gui_get_window_pref_categories

Get list of preference categories for object specified by window

SYNTAX

```
categories gui_get_window_pref_categories
  {-window window_id
   | -window_type window_type}
```

Data Types

```
window_id    string
window_type  string
```

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

RETURNS

categories

The returned preference categories.

DESCRIPTION

This command retrieves the list of preference categories for a window or window type.

EXAMPLES

The following example gets the preference categories for the TopLevel.1 window.

```
\prompt> ser cats [gui_get_window_pref_categories -window TopLevel.1]
```

SEE ALSO

gui_set_window_pref_key(2)
gui_get_window_pref_value(2)
gui_get_window_pref_keys(2)
gui_create_pref_category(2)
gui_set_pref_value(2)

gui_remove_pref_key(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)

gui_get_window_pref_keys

Get list of preference categories for object specified by window

SYNTAX

```
categories gui_get_window_pref_keys
  {-window window_id
   | -window_type window_type}
  [-category category]
```

Data Types

```
window_id    string
window_type  string
category    string
```

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference categories will be retrieved from. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference categories be retrieved from. This option is mutually exclusive with the -window option.

-category *category*

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

RETURNS

categories

The returned preference categories.

DESCRIPTION

This command retrieves the list of preference categories for a window or window type.

EXAMPLES

The following example gets the preference categories for the TopLevel.1 window.

```
\prompt> ser cats [gui_get_window_pref_keys -window TopLevel.1]
```

SEE ALSO

```
gui_set_window_pref_key(2)
gui_get_window_pref_value(2)
gui_get_window_pref_categories(2)
gui_create_pref_category(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_remove_pref_key(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
gui_update_pref_file(2)
```

gui_get_window_pref_value

Get preference value for object specified by window or window type

SYNTAX

```
value gui_get_window_pref_value
  {-window window_id
   | -window_type window_type}
  [-category category]
  -key key
```

Data Types

<i>window_id</i>	string
<i>window_type</i>	string
<i>category</i>	string
<i>key</i>	string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference will be retrieved from. This option is mutually exclusive with the **-window_type** option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference be retrieved from. This option is mutually exclusive with the **-window** option.

-category *category*

Specifies the category to search for the key. If not specified, a default category will be used.

-key *key*

Specifies the key to retrieve the value from.

RETURNS

value

The value of the key.

DESCRIPTION

This command retrieves the value of a preference key from the specified key name and category of the specified window or window type. If a preference is set on a window type, then all instances of that type will inherit the preference, so the value can be set on a type and retrieved from any instance of that type (or derived from that type).

EXAMPLES

The following example creates a preference for a window and then uses the **gui_get_window_pref_value** command to retrieve the value for the preference.

```
\prompt> gui_set_window_pref_key -window Console.1 -key test -value_type integer -value 201
\prompt> set x [gui_get_window_pref_value -window Console.1 -key test]
\prompt> if {$x == 201} { echo "success" }
```

gui_get_window_types

Get a list of window types

SYNTAX

```
types gui_get_window_types  
[-type token]
```

Data Types

token string

ARGUMENTS

-type *token*

Specifies whether to return toplevel windows ('toplevel') or child view windows ('child').

If toplevel window types are specified then the first type is guaranteed to be the default toplevel window type.

RETURNS

types

Returned list of window types.

DESCRIPTION

This command returns a list of existing window types. Instances of these types can be instantiated with the **gui_create_window** command. The returned list can be restricted to just toplevel windows or child view windows by specifying the **-type** option.

EXAMPLES

The following examples illustrate some usages of the command.

```
\prompt> gui_get_window_types  
\prompt> gui_get_window_types -type toplevel
```

```
\prompt> gui_get_window_types -type child
```

SEE ALSO

gui_close_window(2)
gui_exist_window(2)
gui_show_window(2)
gui_create_window(2)
gui_get_window_ids(2)
gui_set_active_window(2)
gui_get_current_window(2)

gui_hide_palette

Hides the specified palette.

SYNTAX

```
status gui_hide_palette
{ -name palette_id | -type palette_type }
[ -parent window_id ]
```

Data Types

palette_id string
palette_type string
window_id string

ARGUMENTS

-name *palette_id*

Specifies the palette name id.

Any matching palette of this name will be hidden.

This option precludes the **-type** option

-type *palette_type*

Specifies the palette type id. Any matching palette of this type will be hidden.

If the **-parent** option is specified, only palettes in the specified parent toplevel window are hidden. If the **-parent** option is not specified, all palettes of this type in all toplevel windows are hidden.

This option precludes the **-name** option

-parent *window_id*

Specifies the parent toplevel window to hide the palette type in.

Note: this option is only applicable if the **-type** option is specified.

DESCRIPTION

This command hides the specified palettes.

EXAMPLES

The following example hides all Layer palettes:

```
shell> gui_hide_palette -type Layout
```

SEE ALSO

`gui_show_palette(2)`

gui_hide_toolbar

Hides the specified toolbar or all the toolbars in the specified window.

SYNTAX

```
void gui_hide_toolbar
    -toolbar tool_bar_name | -all
    [-window window_id]
```

Data Types

<i>tool_bar_name</i>	string
<i>window_id</i>	string

ARGUMENTS

-toolbar *tool_bar_name*

Specifies the toolbar you want to hide. The **-toolbar** option and the **-all** option are mutually exclusive.

-all

Hides all the toolbars in the specified window. The **-all** option and the **-toolbar** option are mutually exclusive.

-window *window_id*

Specifies the window in which you want to hide the specified toolbar or all toolbars. By default, the tool hides the toolbar or toolbars in the active window.

DESCRIPTION

This command hides either all the toolbars or the toolbar with the specified name in the window with the specified window ID.

EXAMPLES

The following example hides the File toolbar in the active window:

```
prompt> gui_hide_toolbar -toolbar File
```

The following example hides all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_hide_toolbar -all -window LayoutWindow.1
```

SEE ALSO

`gui_create_toolbar(2)`
`gui_delete_toolbar(2)`
`gui_create_toolbar_item(2)`
`gui_delete_toolbar_item(2)`
`gui_show_toolbar(2)`
`gui_get_toolbar_names(2)`

gui_inspect_violations

Displays the specified DFT unified DRC violations in a new violation inspector window.

SYNTAX

```
status gui_inspect_violations
  [-type violation_type]
  violation_list
```

Data Types

<i>violation_type</i>	string
<i>violation_list</i>	list

ARGUMENTS

-type *violation_type*

Specifies the type of violations (for example, D1) to display when you inspect multiple violations of the same type. This option affects how the command interprets the *violation_list* argument.

violation_list

Specifies the name of the violation instance to inspect in the violation inspector window. Violation instance names have the following format, which is similar to the format used in TetraMAX:

ViolationType-ViolationId

For example, violation 1 of type D1 is named D1-1.

If you include the **-type** option, *violation_list* specifies a list of one or more violation IDs. A violation ID is the violation number shown in the first column of violation browser.

DESCRIPTION

This command displays the specified DFT unified DRC violations in a new violation inspector window or in an existing violation inspector window that has been marked for reuse.

If no violation inspector window exists, the tool opens a new violation inspector window in a new top-level window. Subsequent violation inspector windows are opened in the active top-level window. New violation inspector windows are not marked for reuse.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command displays violations 5, 9, and 13 of type D1.

```
prompt> gui_inspect_violations -type D1 {5 9 13}
```

The following two commands display violation 4 of type D2.

```
prompt> gui_inspect_violations -type D2 4
```

```
prompt> gui_inspect_violations D2-4
```

SEE ALSO

[gui_wave_add_signal\(2\)](#)

[guiViolation_schematic_add_objects\(2\)](#)

gui_list_attrgroups

Lists attribute group information for a specified object type or all object types.

SYNTAX

```
status gui_list_attrgroups
      -class design_object
      -name name
      [-all]
      [-tcl]
      [-full]
      [-attr_list]
```

Data Types

<i>design_object</i>	string
<i>name</i>	string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the name of the attribute group to be listed for the specified object type or for all object types.

-all

Lists the attribute groups for all object types. This option and the **-class** option are mutually exclusive.

-tcl

Lists the attribute group information in a tool command language (Tcl) format that is suitable for Tcl processing.

-full

Specifies the full Tcl output format, which reports all possible group information.

-attr_list

Lists attributes only.

DESCRIPTION

The **gui_list_attrgroups** command lists attribute group information for the specified object type or for all object types. Use the **-tcl** option to get the attribute group information in a tool command language (Tcl) format that is suitable for Tcl processing.

option to get results that are suitable for Tcl processing.

EXAMPLES

```
prompt> gui_list_attrgroups -class Cell -tcl
"Hierarchy" "Edit"

prompt> gui_list_attrgroups -class Cell -name "Hierarchy" -tcl -attr_list
{Name} {Hierarchical} {Owning Cell} {isPhysConstraint} {Hard Macro} ... {FullName}

prompt> gui_list_attrgroups -all -tcl
Cell { "Hierarchy" "Edit" } Net { "Timing" } Pin { "Timing" }

prompt> gui_list_attrgroups -class Cell -tcl -attr_list
{ "Hierarchy" { {Name} {Hierarchical} {Owning Cell} ...{FullName} } }
{ "Edit" { {Name} {isPhysConstraint} {Orientation} ... {FullName} } }

prompt> gui_list_attrgroups -class Cell
Cell, "Hierarchy", { {Name} {Hierarchical} {Owning Cell} {isPhysConstraint} ... } ;
Cell, "Edit", { {Name} {isPhysConstraint} {Orientation} {Location} ... } ;
The fields displayed above are in the following order:
Class, Group Name, Attributes list;
```

SEE ALSO

`gui_delete_attrgroup(2)`
`gui_list_attrgroups(2)`
`gui_update_attrgroup(2)`

gui_list_category_rules

Lists all category rules except built-in rules by default.

SYNTAX

```
list gui_list_category_rules
  [-all | -names rule_names_list]
  [-format script | tcl_list]
```

Data Types

rule_names_list list

ARGUMENTS

-all

Lists all category rules, including built-in rules.

This option and the **-names** option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

-names *rule_names_list*

Specifies the names of the category rules to be listed.

This option and the **-all** option are mutually exclusive. If you do not specify either of these options, the command lists all category rules except the built-in rules.

-format *script* | *tcl_list*

Specifies the output format in which the category rules are listed. The default output format is **script**.

When the **script** format is used, the category rules are listed as a Tool Command Language (Tcl) script of **gui_create_category_rule** commands that you can replay. In this case, the rules are streamed to the output stream. You can redirect the output by using the **redirect** command, for example, if you want to capture the script output in a file to use again later. When the **script** format is used, the command result is an empty string.

If the **tcl_list** format is specified, the category rules are listed in an "array set compatible" Tcl list format. In this case, the command result is a Tcl list.

DESCRIPTION

This command lists category rules that have already been created by the **gui_create_category_rule** command during the current run of the tool.

When you run this command without specifying either the **-all** option or the **-names** option, the command lists all category rules except built-in rules. Specify the **-all** option to list all category rules, including the built-in rules. Specify the **-names** option to list individual rules by name.

EXAMPLES

The following example lists all category rules, including the built-in rules:

```
prompt> gui_list_category_rules -all
gui_create_category_rule -name Pathgroups -builtin \
    -category <path_group.full_name>
gui_create_category_rule -name Session -builtin \
    -category <session_name>
gui_create_category_rule -name {Path Type} -builtin \
    -category <path_type>
...
...
```

The following example lists all category rules except the built-in rules:

```
prompt> gui_create_category_rule -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule -name rule2 -category <path_group.full_name>
rule2
prompt> gui_list_category_rules
gui_create_category_rule -name rule1 \
    -category <session_name>
gui_create_category_rule -name rule2 \
    -category <path_group.full_name>
```

The following example redirects the script output to a file that you can source during a subsequent run of the tool:

```
prompt> redirect -file /remote/dir1/rules.tcl {gui_list_category_rules}
prompt>
```

The following example uses the **-names** option to list only the rules named rule1 and rule3:

```
prompt> gui_create_category_rule -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule -name rule2 -category <path_group.full_name>
rule2
prompt> gui_create_category_rule -name rule3 -category <startpoint.full_name>
rule3
prompt> gui_list_category_rules -names {rule1 rule3}
gui_create_category_rule -name rule1 \
    -category <session_name>
gui_create_category_rule -name rule3 \
    -category <startpoint.full_name>
```

The following example uses the **tcl_list** output format to query the category specification of the rule named rule1:

```
prompt> gui_create_category_rule -name rule1 -category <session_name>
rule1
prompt> gui_create_category_rule -name rule2 -category <path_group.full_name>
rule2
prompt> array set rules [gui_list_category_rules -format tcl_list]
Information: Defining new variable 'rules'. (CMD-041)
prompt> array set rule1_options $rules(rule1)
Information: Defining new variable 'rule1_options'. (CMD-041)
prompt> set rule1_cat_spec $rule1_options(category)
Information: Defining new variable 'rule1_cat_spec'. (CMD-041)
```

<session_name>

SEE ALSO

`gui_create_category_rule(2)`
`gui_remove_category_rules(2)`

gui_list_cell_block_marks

Lists the cell names and block mark values for cells that are marked in the design.

SYNTAX

```
list gui_list_cell_block_marks
```

ARGUMENTS

This command has no arguments

DESCRIPTION

This command lists the cell names and block mark values for all cells that are marked in the design. The listing is sorted by the full names of the marked cells.

EXAMPLES

The following example sets block marks on two hierarchical cell instances, and then lists the names of all the marked cells and their block marks:

```
prompt> gui_remove_cell_block_marks -all
prompt> gui_set_cell_block_marks I_TOP/I_ALU ALU
prompt> gui_set_cell_block_marks I_TOP/I_REG_FILE REG_FILE
prompt> gui_list_cell_block_marks
I_TOP/I_ALU ALU
I_TOP/I_REG_FILE REG_FILE
```

SEE ALSO

gui_set_cell_block_marks(2)
gui_get_cell_block_marks(2)
gui_remove_cell_block_marks(2)

gui_load_cell_density_mm

Loads the data for cell density map mode.

SYNTAX

```
status gui_load_cell_density_mm  
[-area area]
```

Data Types

area list

ARGUMENTS

-area *area*

Analyzes area for cell density. If area is not given, the default area is whole design area.

DESCRIPTION

The command generates the map mode view of cell density in a given area. Each grid is colored based on the percentage of occupied area of cells in the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows cell density in the specified area.

```
prompt> gui_load_cell_density_mm -area \  
{284.820 390.670 1202.790 954.120}
```

SEE ALSO

gui_load_hierarchy_vm

Loads the data for hierarchy visual mode.

SYNTAX

```
status gui_load_hierarchy_vm
  -clear
  -level ncount
  -cells cell_list
```

Data Types

<i>level</i>	integer
<i>cell_list</i>	list

ARGUMENTS

-clear

Removes the coloring from all hierarchy levels.

-level *level*

Colors all the cells at a particular hierarchy level.

-cells *cell_list*

Colors specific hierarchy cells. If cells not provided, the default is cells in the entire design.

DESCRIPTION

Loads the data for hierarchy visual mode. The hierarchy visual mode provides a high-level view of the placement quality of logic blocks and hierarchical cells in your physical design. This visual mode can be used to color all the cells on a particular hierarchy level or just the specified hierarchical cells.

EXAMPLES

The following example clears the hierarchy visual mode.

```
prompt> gui_load_hierarchy_vm -clear
```

The following example colors all the cells at hierarchical level 2.

```
prompt> gui_load_hierarchy_vm -level 2
```

The following example colors all the cells in the selection.

```
prompt> gui_load_hierarchy_vm -cells [get_selection]
```

SEE ALSO

None.

gui_load_pin_density_mm

Loads the data for pin density map mode.

SYNTAX

```
status gui_load_pin_density_mm  
[-area area]
```

Data Types

area list

ARGUMENTS

-area *area*

Area to be analyzed for pin density. By default, the command uses the entire design area.

DESCRIPTION

The command generates map mode view of pin density in a given area. The grids are colored based on the number of pins within the grid.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows pin density in the specified area.

```
prompt> gui_load_pin_density_mm -area \  
{284.820 390.670 1202.790 954.120}
```

SEE ALSO

gui_load_voltage_area_vm

Loads the data for voltage area visual mode.

SYNTAX

status **gui_load_voltage_area_vm**

Data Types

ARGUMENTS

DESCRIPTION

The command generates the visual mode view of voltage areas. Each voltage area is colored based on its type.

EXAMPLES

The following example will place all the voltage areas in the design into different bins based on their type.

```
prompt> gui_load_voltage_area_vm
```

SEE ALSO

None.

gui_mouse_tool

Operate mouse tools of a given view

SYNTAX

```
gui_mouse_tool
  -window window
  [-start tool]
  -current |
  -list |
  -add_point {x y} |
  -drag {{x1 y1} {x2 y2}} |
  -delete_point |
  -apply |
  -reset |
  -abort |
  -cycle |
  -cycle_back ]
```

window *String*
tool *String*

ARGUMENTS

-window *window*

window specifies the window of which this command should operate the mouse tool.

-start *tool*

Starts the given mouse tool.

-current

Return the name of current active tool.

-list

Return the names of all available tools.

-add_point {*x* *y*}

Add an input point

-drag {{*x1* *y1*} {*x2* *y2*}}

Perform drag operation between two points.

-delete_point

Removes last input point

-apply

Performs tool action

-reset

Clears all pending input or ends the tool if no pending

-abort

Aborts mouse tool unconditionally

-cycle

Cycles through choices for a given operation

-cycle_back

Cycles back through choices for a given operation

DESCRIPTION

The **gui_mouse_tool** controls the mouse tool of a view that supports mouse actions log and replay capabilities. Not all views need to support all of the functionality provided by the interface of this command. User can use the command to script various mouse action.

EXAMPLES

The following example has the layout view start the zoom in tool and perform a zoom to particular area.

```
> gui_mouse_tool -window Layout.1 -start ZOOM_IN_TOOL  
> gui_mouse_tool -window Layout.1 -add_point {27.461 433.400}  
> gui_mouse_tool -window Layout.1 -add_point {51.261 393.123}  
> gui_mouse_tool -window Layout.1 -abort
```

SEE ALSO

gui_overlay_layout

Add/Remove/Adjust a design overlay to a layout window

SYNTAX

gui_overlay_layout

- window *windowID*
- design *design*
- add
- remove
- brightness *value*

windowID *String*

design *String*

add *Boolean flag*

remove *Boolean flag*

brightness *Integer*

ARGUMENTS

-window *windowID*

windowID specifies the layout window to add the overlay

-design *design*

design specifies the design to overlay

-add

add the design as an overlay

-remove

remove the design as an overlay

-brightness *value*

adjust the brightness of the overlay design

DESCRIPTION

Use this command to add, remove, or adjust an overlay on a layout view. The design to overlay must already be an opened design. You cannot overlay the same design twice nor can you overlay a design on itself. The -add and -remove flags are mutually exclusive. The brightness of an overlay can be varied from 0 (not visible at all) and 100 (fully bright). The -remove flag is mutually exclusive with the -brightness flags.

EXAMPLES

```
shell> gui_overlay_layout -window Layout.1 -design fill_view -add  
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness Off  
shell> gui_overlay_layout -window Layout.1 -design fill_view -brightness 33%  
shell> gui_overlay_layout -window Layout.1 -design fill_view -remove
```

gui_query_objects

Get the value of a query text for a collection of object.

SYNTAX

```
string gui_query_objects
      object_collection
```

Data Types

```
string object_collection
```

ARGUMENTS

object_collection

Specifies the collection of objects to use to get the query text.

DESCRIPTION

The **object_collection** command returns and displays the query text. Same text will be shown in Query toolbar for a particular object query.

A **object_collection** is collection of objects for which the query text will be generated. The collection of objects might be returned as the result of another command such as the **get_cells** command.

For information about collections, see the **collections** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example displays query text for the all plan groups in the design.

```
prompt> gui_query_objects [get_plan_groups]
*****
```

```
Object summary:
plan_group : 5
*****
```

```
plan_group : RES_I109
plan_group : RES_I110

gui_remove_all_annotations

Removes specified group of annotations or all annotations from the specified layout window or from all windows.

SYNTAX

```
status gui_remove_all_annotations
      [-window window_name]
      [-group group_name]
```

Data Types

window_name string
group_name string

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-group *group_name*

Specifies the annotation group name.

DESCRIPTION

This command removes specified group of annotations from the specified layout window. If group name is omitted, it will remove all annotations groups. If window name is omitted, it will remove annotations from all windows. The command returns 1 if it is successful.

EXAMPLES

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \
      -type rect -text Test1 -color green -width 2 \
      -pattern Dense5Pattern {{200 200} {777 777}}
1
prompt> gui_remove_all_annotations -window Layout.1
1
```

SEE ALSO

`gui_add_annotation(2)`
`gui_remove_annotations(2)`

gui_remove_all_rulers

Removes rulers from the specified layout window or from all windows.

SYNTAX

```
status gui_remove_all_rulers
      [-window window_name]
```

Data Types

window_name string

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

DESCRIPTION

This command removes rulers from specified layout window, or from all windows if the **-window** option is omitted, and returns 1 if it is successful.

EXAMPLES

```
prompt> gui_remove_all_rulers -window Layout.1
1
```

SEE ALSO

[gui_remove_ruler\(2\)](#)

gui_remove_annotations

Removes specified group of annotations from the specified layout window.

SYNTAX

```
status gui_remove_annotations
      [-window window_name]
      [-group group_name]
      [anno]
```

Data Types

```
window_name    string
group_name    string
anno        collection
```

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-group *group_name*

Specifies the annotation group name.

anno

Specifies a collection of annotations to remove. Get a collection of annotations with the `gui_get_annotations` command. This option cannot be specified with any other option.

DESCRIPTION

This command removes specified group of annotations from the specified layout window. If group name is omitted, global group name is used. If window name is omitted, global window name is used. The command returns 1 if it is successful.

EXAMPLES

```
prompt> gui_add_annotation -window Layout.1 -group Test1 \
      -type rect -text Test1 -color green -width 2 \
      -pattern Dense5Pattern {200 200} {777 777}
```

```
1
prompt> gui_remove_annotations -window Layout.1
1
prompt> gui_remove_annotations [gui_get_annotations -filter client_data==MyData]
1
```

SEE ALSO

[gui_add_annotation\(2\)](#)
[gui_remove_all_annotations\(2\)](#)
[gui_get_annotations\(2\)](#)

gui_remove_category_rules

Removes all category rules except built-in rules by default.

SYNTAX

```
string gui_remove_category_rules
  [-all | -names rule_names_list]
```

Data Types

rule_names_list list

ARGUMENTS

-all

Removes all category rules, including built-in rules.

This option and the **-names** option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

-names *rule_names_list*

Specifies the names of the category rules to be removed.

This option and the **-all** option are mutually exclusive. If you do not specify either of these options, the command removes all category rules except the built-in rules.

DESCRIPTION

This command removes category rules that have already been created by the **gui_create_category_rule** command during the current run of the tool.

When you use this command without specifying any options, it removes all category rules except built-in rules. Specify the **-all** option to remove all category rules, including the built-in rules. Specify the **-names** option to remove individual rules by name.

The command returns an empty string as its result.

EXAMPLES

The following example removes all category rules, including the built-in rules:

```
prompt> gui_remove_category_rules -all
```

The following example removes all category rules except the built-in rules:

```
prompt> gui_remove_category_rules
```

The following example removes the rules named Rule1 and Rule2:

```
prompt> gui_remove_category_rules -names {Rule1 Rule2}
```

The following example removes non-built-in rules at the top of a user-defined category rule creation script, which is being developed interactively. You can repeatedly change and refine this script by using a text editor, and you can source the script multiple times in a single run of the tool.

```
# first remove all existing user-defined non-built-in rules  
gui_remove_category_rules  
# now create the user-defined category rules  
gui_create_category_rule ...  
gui_create_category_rule ...  
and so forth
```

SEE ALSO

`gui_create_category_rule(2)`

gui_remove_cell_block_marks

Removes the block mark string values from one or more cells.

SYNTAX

```
status gui_remove_cell_block_marks  
-all | cells
```

Data Types

cells list

ARGUMENTS

-all

Removes all block marks on all cells that are marked.

This option and the *cells* option are mutually exclusive, and one of them must be specified.

cells

Removes block marks from one or more cells specified in a list of cell name patterns or cell collections.

This option and the **-all** option are mutually exclusive, and one of them must be specified.

DESCRIPTION

This command removes the block mark string values from one or more hierarchical or leaf-level cell instances. If the **-all** option is specified, then all the block marks are removed from all the cell instances that are marked. If the *cells* option is specified, then block marks are removed only from the specified cell instances.

EXAMPLES

The following example sets the block mark for a hierarchical cell instance identified by a cell name, and then removes the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU ALU  
prompt> gui_remove_cell_block_marks I_TOP/I_ALU
```

The following example sets the block mark for a hierarchical cell instance identified by a nested run of the **get_cells** command, and then removes the block mark from that cell instance:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU] ALU  
prompt> gui_remove_cell_block_marks [get_cells I_TOP/I_ALU]
```

The following example removes all the block marks from all the cell instances that are marked:

```
prompt> gui_remove_cell_block_marks -all
```

SEE ALSO

`gui_set_cell_block_marks(2)`
`gui_get_cell_block_marks(2)`

gui_remove_pref_key

Remove a preference key.

SYNTAX

```
string gui_remove_pref_key
      -key Key
      [-category Category]
```

ARGUMENTS

-key *Key*

Key specifies the key which will be used together with the specified category to uniquely identify the key to be removed.

-category *Category*

Category specifies the category that owns the specified key. If not specified, a default category will be used.

DESCRIPTION

This command removes the preference key specified by the key name.

SEE ALSO

`gui_create_pref_category(2)`
`gui_create_pref_key(2)`
`gui_set_pref_value(2)`
`gui_get_pref_value(2)`

`gui_update_pref_file(2)`

gui_remove_ruler

Removes the specified rulers.

SYNTAX

```
status gui_remove_ruler
      [-window window_name]
      -point point | -all
```

Data Types

window_name string
point point

ARGUMENTS

-window *window_name*

Specifies the instance name of the layout window.

-point *point*

Specifies the coordinates of the point near the ruler to be removed, in following format:

{x y}

-all

Removes all rulers.

DESCRIPTION

This command removes rulers from the specified layout window, or from all windows if the **-window** option is omitted, and returns 1 if it is successful.

EXAMPLES

```
prompt> gui_remove_ruler -window Layout.1 -point {400 400}
1
prompt> gui_remove_ruler -window Layout.1 -all
1
```

SEE ALSO

`gui_remove_all_rulers(2)`

gui_report_hotkeys

Report on the current hotkey bindings

SYNTAX

```
string gui_report_hotkeys  
  [-window_type WindowTypeName]
```

WindowTypeName *String*

ARGUMENTS

-window_type *WindowTypeName*

WindowTypeName specifies the type of top level window that the hotkey should apply to. (A top level window is a window with a menu bar.) If it is not specified then the applications default window type will be used. The read-only variable `gui_default_window_type(3)` specifies the default window type for the application.

DESCRIPTION

This command prints a report on the current key bindings. The list of bindings printed in the report are sorted by hotkey.

EXAMPLES

The following example creates a menu item and add an additional hotkey to it.

```
gui> gui_report_hotkeys  
*****  
Report : hotkeys  
Window : LayoutWindow  
Version: V-2004.06-GALILEO-BETA1-1  
Date  : Tue Aug 31 10:37:17 2004  
*****
```

Hot Key	Type	Function
Ctrl+O	Menu	File->Open Design...
Ctrl+S	Menu	File->Save Design
Ctrl+R	Menu	Edit->Properties

M Menu Edit->Move...
C Menu Edit->Copy...
Ctrl+F Menu View->Zoom->Zoom Full
F Menu View->Zoom->Zoom Full
P Tcl query_objects [get_selection]
...

SEE ALSO

gui_report_task

task.

SYNTAX

```
string gui_report_task
  -task string
  | -item_root      TaskName / ItemRootName
  [-file string]
```

ARGUMENTS

-task string

TaskName specifies the name of a task on which to report. This option is mutually exclusive with the **-item_root** option.

-item_root TaskName | ItemRootName

ItemRootName specifies the name of a task item root name on which to report. This option is mutually exclusive with the **-task** option.

-file string

FileName optionally specifies the output file into which the report is written.

DESCRIPTION

This command outputs a textual report of the given task to the xterm console. If **-file** is given, then the report is also output to the given file. The report will have the following approximate format. The strings bracketed with the angle brackets will be replaced with the actual attribute value.

Attributes are omitted if they are not defined. Item are shown one to a line with the hierarchy structure indicated by indentations and bars. The leaf-level task item names are followed by the associated task page name:

Task: <task name>
Default: <true | false>
Items: <items>

SEE ALSO

gui_create_task(2)
gui_get_task_list(2)

gui_schematic_add_logic

Adds logic to a schematic

SYNTAX

```
string gui_schematic_add_logic [-window <win>]
  [-new]
  [-schematic <schem>]
  objs

string <win>
string <schem>
string objs
```

ARGUMENTS

-window <win>

Top level window name to place new schematic (default: current window). This option is ignored unless -new is specified.

-new

Create new schematic.

-schematic <schem>

Schematic view to update (default: most recently active schematic).

objs

Objects to add to the schematic.

DESCRIPTION

This command adds logic into a Path Schematic view. The command either creates a new view containing the specified objects or updates an existing view. The command always returns the name of the schematic that was updated or created.

EXAMPLES

The following example creates a new path schematic containing all the cells in the current design:

```
gui_schematic_add_logic -new [get_cells *]
```

SEE ALSO

`gui_get_current_window(2)`
`gui_schematic_remove_logic(2)`

gui_schematic_remove_logic

Removes logic from a schematic

SYNTAX

```
string gui_schematic_remove_logic [-schematic <schem>]  
objs
```

```
string <schem>  
string objs
```

ARGUMENTS

-schematic <schem>

Schematic view to update (default: most recently active schematic).

objs

Objects to remove from the schematic.

DESCRIPTION

This command removes logic into a Path Schematic view. The command returns the name of the schematic that was updated

EXAMPLES

The following example removes the cell "U1" from the most recently active schematic view:

```
gui_schematic_remove_logic [get_cells U1]
```

SEE ALSO

```
gui_get_current_window(2)  
gui_schematic_add_logic(2)
```

gui_scroll

Scroll a window's viewport.

SYNTAX

```
gui_scroll
  -window window
  [-selection | -clct clct | [-habs absX | -hrel reIX] [-vabs absY | -vrel reIY]]
```

window *String*
absX *Float*
reIX *Float*
absY *Float*
reIY *Float*

ARGUMENTS

-window *window*

window specifies the window to be scrolled.

-selection

Determine the bounding box for all selected objects present in the view, and scroll such that the center of that box is visible.

-clct *clct*

Determine the bounding box for the collection objects present in the view, and scroll such that the center of that box is visible.

-habs *absX*

Scroll such that the specified X model position is centered in the viewport.

-hrel *reIX*

Scroll horizontally by the specified number of pages. A page is the width of the viewport. Negative values scroll left and positive values scroll right.

-vabs *absY*

Scroll such that the specified Y model position is centered in the viewport.

-vrel *reIY*

Scroll vertically by the specified number of pages. A page is the height of the viewport. Negative values scroll up and positive values scroll down.

DESCRIPTION

The **gui_scroll** command adjusts the position of views that support zooming. The viewport can be adjusted in the X and/or Y direction. Absolute values are expressed in model coordinates. Relative values allow paging. For example, *-hrel 1.0* means page to the right by the width of the viewport.

EXAMPLES

Scroll such that model coordinates (287.0, 1422.0) are centered in the viewport.

```
gui_scroll -window Layout.1 -habx 287.0 -vaby 1422.0
```

Scroll to the right by one viewport width.

```
gui_scroll -window Layout.1 -hrel 1.0
```

SEE ALSO

[gui_zoom\(2\)](#)

gui_select_vmbucket

Select the Contents of a Visual Mode Bucket

SYNTAX

```
string gui_select_vmbucket -vmname mode_identifier
  -name bucket_identifier
  [-replace | -add | -remove]

string mode_identifier
string bucket_identifier
```

ARGUMENTS

-vmname *mode_identifier*

Specifies the visual mode to which the bucket is a member. The visual mode must already exist. To see the current list of defined visual modes, use the **gui_list_vm** command.

-name *bucket_identifier*

Specifies the name of the visual mode bucket.

-replace

Optional argument that indicates that the contents of the visual mode bucket will replace the selection list.

-add

Optional string that indicates that the contents of the visual mode bucket will be added to the selection list.

-remove

Optional string that indicates the contents of the visual mode bucket will be removed from the selection list.

DESCRIPTION

The **gui_select_vmbucket** command selects the contents of a visual mode bucket. The visual mode bucket is a member of a specific visual mode. The contents of the visual mode bucket can replace, be added to, or be removed from the selection list.

EXAMPLES

Select the 2nd bucket of SNAPSHOT visual mode.

```
shell> gui_select_vmbucket -vmname SNAPSHOT -name 1 -replace
```

SEE ALSO

```

gui_set_active_window

Make the specified window the active window

SYNTAX

```
status gui_set_active_window  
    -window window_id
```

Data Types

window_id string

ARGUMENTS

-window *window_id*

Specifies the window name id.

The matching window of this id will be made the active window.

Note: both toplevel windows and child windows of a particular toplevel window have a currently active window. If the window is a toplevel window then the currently active toplevel window is changed, of the window is a child window the currently active child window in the specified window's parent is changed.

DESCRIPTION

This command makes the specified window the active window.

EXAMPLES

The following example will make the toplevel window Toplevel.2 active.

```
shell> gui_set_active_window -window Toplevel.2
```

SEE ALSO

[gui_close_window\(2\)](#)

```
gui_exist_window(2)
gui_show_window(2)
gui_get_window_types(2)
gui_get_window_ids(2)
gui_create_window(2)

```

gui_set_bucket_option

Sets the value for an option on a bucket in the specified visual mode or map mode.

SYNTAX

```
string gui_set_bucket_option
  -map map_name
  -bucket bucket_name
  -option option_name
  -value value | -default
```

Data Types

<i>map_name</i>	string
<i>bucket_name</i>	string
<i>option_name</i>	string
<i>value</i>	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-bucket *bucket_name*

Specifies the name of the bucket.

-option *option_name*

Specifies the name of the option to be set.

-value *value*

Specifies the value for the option.

The **-value** option is mutually exclusive with the **-default** option. You must use one, but not both.

-default

Sets the option to its default value.

The **-default** option is mutually exclusive with the **-value** option. You must use one, but not both.

DESCRIPTION

This command sets the value for an option on a bucket in a visual mode or map mode. You must specify the visual mode or map

mode name, the bucket name, and the option name. You must set the option to either a specific value or its default value. Use the **-value** option to set a specific value or use the **-default** option to set the option to its default value.

EXAMPLES

The following example sets the color of *bucket1* to yellow in the global route congestion map:

```
prompt> gui_set_bucket_option -map AREAPARTITION \
    -bucket bucket1 -option color -value yellow
```

SEE ALSO

```

gui_get_map_list(2)
gui_get_map_option(2)
gui_get_map_option_list(2)
gui_set_map_option(2)
```

gui_set_cell_block_marks

Sets a block mark on one or more cells.

SYNTAX

```
status gui_set_cell_block_marks
  cells
  block_mark
```

Data Types

```
cells      list
block_mark string
```

ARGUMENTS

cells

Lists one or more cells to mark with a block mark, in a list of cell name patterns or cell collections.

block_mark

Specifies the block mark string value to be set for the listed cells.

DESCRIPTION

This command sets a block mark for one or more hierarchical or leaf-level cell instances. Typically, a short symbolic string name is used as the block mark. Ultimately, a block mark can appear in the GUI as the text label for a timing path category generated from a dynamic category rule. Such block marks should be kept short to avoid using up too much screen space in the GUI.

A common application involves marking certain interesting intellectual property (IP) blocks within a design. These block marks affect the calculation of the following timing path shell attributes, which are defined only when the GUI is running:

- **blocks** - An ordered block level path; includes start, through, and end blocks
- **through_blocks** - Includes through blocks, but not the start and end blocks
- **start_block** - The start block
- **end_block** - The end block
- **start_end_blocks** - A pair consisting of the start block and the end block, in that order
- **start_end_blocks_sorted** - A pair consisting of the start block and the end block, sorted alphabetically

These block marks also affect the calculation of the following cell shell attribute, which is defined only when the GUI is running:

- **block_mark** - String value of a cell instance's (explicit) block mark, or an empty string if there is no explicit block mark

In calculating the timing path shell attributes listed previously, a block is calculated for each timing point of a timing path. If the leaf cell instance on which a timing point resides is explicitly marked with a block mark, by using the **gui_set_cell_block_marks** command, the block for the timing point is the block mark for the leaf cell. If the leaf cell instance on which a timing point resides is not explicitly marked, the block for the timing point is the block mark on the first explicitly marked hierarchical cell located by traversing up the logical hierarchy from that leaf cell instance.

If no direct or indirect hierarchical parent cell is found to be explicitly marked, the block for the timing point has a default implicit string value of "_Top_". For a timing point that is a startpoint or endpoint of a timing path, where the startpoint or endpoint is an external design port, the block has a default implicit string value of "_Port_".

Note: Each timing point of a timing path always has a defined block, which can be an explicit block mark, "_Top_", or "_Port_".

The **through_blocks** attribute value can be an empty set of blocks, which is represented by the string value "_Empty_".

EXAMPLES

The following example sets the block mark to ALU for a hierarchical cell instance identified by a cell name:

```
prompt> gui_set_cell_block_marks I_TOP/I_ALU ALU
```

The following example sets the block mark to ALU for a hierarchical cell instance identified by a nested run of the **get_cells** command:

```
prompt> gui_set_cell_block_marks [get_cells I_TOP/I_ALU] ALU
```

The following example sets the block mark for a list of cell instances where the first item is identified by a cell name and the second item is identified by a nested run of the **get_cells** command:

```
prompt> gui_set_cell_block_marks [list I_ALU [get_cells I_STACK_TOP/I1_STACK_MEM]] \
my_mark
```

SEE ALSO

```
gui_get_cell_block_marks(2)

```

gui_set_current_task

Set current task to the given task.

SYNTAX

```
string gui_set_current_task  
    -task string
```

ARGUMENTS

DESCRIPTION

The `gui_set_current_task` command sets the current application task to the given task.

SEE ALSO

`gui_create_task(2)`
`gui_get_current_task(2)`
`gui_get_task_list(2)`

gui_set_highlight_options

Change the options that control highlighting.

SYNTAX

```
string gui_set_highlight_options
  [-current_color color_id
   | -next_color
   | -auto_cycle_color enable]
```

Data Types

```
color_id    string
enable      bool
```

ARGUMENTS

-current_color *color_id*

Changes the current highlight color to the specified value. The current highlight color is used as a default when no color is specified for some operations.

-next_color

Changes the current highlight color to the next color in the set of available colors. This will wrap around so that it can be used to cycle through the color set. The provided colors are yellow, orange, red, green, blue, purple, light_orange, light_red, light_green, light_blue, and light_purple.

-auto_cycle_color *enable*

Specify if the current color should automatically be incremented after each gui_change_highlight -add operation. The color is not advanced if an explicit color is specified with the -color option of gui_change_highlight.

DESCRIPTION

The gui_set_highlight_options command can be used to modify highlighting behavior.

EXAMPLES

Set the current highlight color to blue.

```
prompt> gui_set_highlight_options -current_color blue
```

Enable auto cycling.

```
prompt> gui_set_highlight_options -auto_cycle_color true
```

Advance to the next color.

```
prompt> gui_set_highlight_options -next_color
```

SEE ALSO

[gui_change_highlight\(2\)](#)

[gui_get_highlight\(2\)](#)

[gui_get_highlight_options\(2\)](#)

gui_set_hotkey

Sets a key binding to a Tcl command or a menu command in a GUI window.

SYNTAX

```
string gui_set_hotkey
    -hot_key key_name
    -tcl_cmd command_name | -menu menu_name
    [-replace]
    [-delete]
    [-replay_log_only]
    [-window_type window_type_name | -all_window_types]
```

```
key_name      string
command_name   string
menu_name     string
window_type_name string
```

ARGUMENTS

-hot_key *key_name*

Specifies the key that you are associating with the specified command. The *key_name* is a string that contains the key name can also contain one or more modifiers. The valid modifier keys are **SHIFT**, **ALT**, and **CTRL**. You specify the modifier names by prepending them to the key name and connecting them with a plus sign (+).

If you bind an unmodified key and the shift-modified key is not bound, the binding works for both the shifted and nonshifted keys. If you set separate bindings for the shift-modified key and the unmodified key, the bindings are unique. Note that shift modifiers work only with letter keys and function keys.

Menus display the first key binding defined for a menu item. The key binding always appears in uppercase with its modifiers. For example, an unmodified accelerator for the letter "a" is shown as "A" and a shift-modified "a" (an uppercase A) is shown as "SHIFT+A."

-tcl_cmd *command_name*

Specifies the tool command language (Tcl) code that the tool executes when you press the key and its modifiers, if any.

The **-tcl_cmd** option and the **-menu** option are mutually exclusive.

-menu *menu_name*

Specifies the menu command that the tool invokes if you press the key and its modifiers, if any, when the menu command is enabled.

The *menu_name* is a string that specifies the hierarchy of the menu labels, with the labels connected by arrows formed from a hyphen and a greater than sign (>). For example, "File->Exit" specifies the Exit command on the File menu. The *menu_name* can also include the mnemonic for the menu text, which is specified with an embedded ampersand (&), but they are not required to do so.

The **-menu** option and the **-tcl_cmd** option are mutually exclusive.

-replace

Replaces an existing key binding for the specified menu command or Tcl command with the specified key.

-delete

Removes the key binding from the specified menu command or Tcl command.

-replay_log_only

Limits logging of the Tcl command associated with the key to the command replay log file. The tool suppresses the command echo and result display to the xterm and console, and the command does not appear in the output log or the Tcl history log.

The tool ignores this option if you do not specify the **-tcl_cmd** option.

-window_type window_type_name

Specifies the type of top-level window that the key should apply to. (A top-level window is a window with a menu bar.) If you do not specify this option, the tool uses the application default window type.

The read-only variable **gui_default_window_type(3)** specifies the application default window type.

-all_window_types

Sets the key binding in every type of window for which it is applicable.

For menu command key bindings, the tool searches all of the top-level windows for the specified menu command and adds the key binding in any window where it exists. If the tool does not find any applicable windows, it issues a warning.

For Tcl command key bindings, the tool adds the binding in every type of top-level window.

DESCRIPTION

This command binds a given key to a function in the graphical user interface (GUI). The function might be available on a menu or specified by Tcl code. A menu command can have multiple key bindings. Key bindings can be specified for built-in or user-defined menu commands.

Key bindings for menu commands have several additional features that Tcl command key binding do not have. The function for a menu command key binding is invoked only when the menu command is enabled. This ensures that the function is invoked only when it is valid to invoke the function. In addition, the primary key bindings for menu commands appear with the menu text to make it easier for you to remember the bindings.

EXAMPLES

The following example creates a menu item and adds an additional key binding to it.

```
prompt> gui_create_menu -menu "&Test->Sub&Menu->Echo Hi" \
    -tcl_cmd "echo hi" -hot_key "Ctrl+5"
prompt> gui_set_hotkey -menu "Test->SubMenu->Echo Hi" \
    -hot_key "Ctrl+Y"
```

The following example creates a key binding, P, that invokes a Tcl command to print a query on the currently selected objects.

```
prompt> gui_set_hotkey -tcl_cmd {query_objects [get_selection]} \
    -key P
```

SEE ALSO

gui_delete_toolbar_item(2)
gui_default_window_type(3)
gui_custom_setup_files(3)
```

gui_set_layout_user_command

Set user defined command for layout input.

SYNTAX

```
status gui_set_layout_user_command
  -apply_cmd TclCmd | -clear
  [-input_type InputType]
  [-snap_type SnapType]
  [-status_text string]
  [-cancel_cmd TclCmd]
```

Data Types

TclCmd *string*
InputType one of [rectangle / line / polygon / point]
SnapType one of [litho / site / midsite / wiretrack / midwiretrack / user]

ARGUMENTS

-apply_cmd *TclCmd*

The user procedure to be called when input completed. The coordinates will be passed as an argument to this procedure. The options is mutually exclusive with -clear.

-clear

Cancel all pending input and return layout to default mouse mode. The options is mutually exclusive with -apply_cmd.

-input_type *InputType*

The desired input type: rectangle | line | polygon | point. Default is rectangle

-snap_type *SnapType*

The desired snap type: litho | site | midsite | wiretrack | midwiretrack | user Default is litho

-status_text *string*

The help string to be shown in layout window status bar.

-cancel_cmd *TclCmd*

The user procedure to be called when input is canceled.

DESCRIPTION

This command is used to facilitate creation of user defined tools to extend the layout view standard capabilities. The command sets layout view to given input mode and executes user callback procedure on input complete. The input points are passed as an argument to user callback.

EXAMPLES

Cut the object shape with user specified rectangle

```
proc my_cut_object_shape_proc { rect } {  
    change_selection [cut_objects [get_selection] -bbox {$rect}]  
}  
  
gui_set_layout_user_command -apply_cmd {my_cut_object_shape_proc} -status_text "Drag the rectangle to cut selected objects" -in  
1
```

SEE ALSO

[change_selection\(2\)](#)
[get_selection\(2\)](#)

gui_set_map_option

Sets the value for an option in the specified visual mode or map mode.

SYNTAX

```
string gui_set_map_option
    -map map_name
    -option option_name
    -value value | -default
```

Data Types

<i>map_name</i>	string
<i>option_name</i>	string
<i>value</i>	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-option *option_name*

Specifies the name of the option to be set.

-value *value*

Specifies the value for the option.

The **-value** option is mutually exclusive with the **-default** option. You must specify one, but not both.

-default

Sets the option to its default value.

The **-default** option is mutually exclusive with the **-value** option. You must specify one, but not both.

DESCRIPTION

This command sets the value for an option in a visual mode or map mode. You must specify the visual mode or map mode name and the option name. You must set the option to a specific value or its default value. Use the **-value** option to set a specific value or the **-default** option to set the option to its default value.

EXAMPLES

The following example sets the number of bins to 9 in the global route congestion map:

```
prompt> gui_set_map_option -map AREAPARTITION \
-option num_bins -value 9
```

SEE ALSO

[gui_get_map_option_list\(2\)](#)
[gui_set_bucket_option\(2\)](#)

gui_set_mouse_tool_option

Set an option on a mouse tool

SYNTAX

```
string gui_set_mouse_tool_option -tool string
    -option string
    -value string
```

```
string string
string string
string string
```

ARGUMENTS

-tool *string*

Tool to set option for.

-option *string*

Option to set.

-value *string*

New option value.

DESCRIPTION

This command sets a mouse tool option. Mouse tool options influence the operation of the mouse tool when that tool is active

EXAMPLES

```
> gui_set_mouse_tool_option -tool SELECT -option InputMode -value Rectangle
```

SEE ALSO

```
gui_mouse_tool(2)
gui_get_mouse_tool_option(2)
```

gui_set_pref_value

Set the value of a preference key.

SYNTAX

```
string gui_set_pref_value
  -key Key -value Value
  [-category Category]
```

ARGUMENTS

-key Key

Key specifies the key to set the new value.

-value Value

Value specifies the new value of the key. The new value should be of the same data type, one of (integer,bool,double,color,string) as the data type of the value of the key.

-category Category

Category specifies the category that owns the specified key. If not specified, a default category will be used.

DESCRIPTION

This command set the value of a preference key. Returns the value of the preference key.

EXAMPLES

The following example create a user-defined category *some_category* for storing preferences and then create a boolean key *some_key* under that category with the initial value of false. The command **gui_set_pref_value** is then used to change the value of the preference key to true.

```
gui_create_pref_category -category some_category
gui_create_pref_key -category my_category -key some_key -value_type bool -value false
gui_set_pref_value -category my_category -key some_key -value true
```

SEE ALSO

`gui_get_pref_keys(2)`
`gui_exist_pref_category(2)`
`gui_exist_pref_key(2)`
`gui_update_pref_file(2)`

gui_set_region

Sets the coordinates of the current region rectangle or rectilinear polygon.

SYNTAX

status **gui_set_region**
 shape

Data Types

shape list

ARGUMENTS

shape

Specifies the region coordinates.

For a rectangle, the values should be given in the following format:

{*x1 y1* *x2 y2*}

For a rectilinear polygon, the values should be given in the following format:

{*x1 y1* *x2 y2* ... *xN yN*}

DESCRIPTION

This command sets the region shape to be used in layout region mode and returns 1 if it is successful.

EXAMPLES

```
prompt> gui_set_region {{-1743.945 18.357} {42.833 1523.657}}  
1
```

SEE ALSO

gui_get_region(2)

gui_set_setting

Sets a setting on the specified window.

SYNTAX

```
gui_set_setting
  -window WindowID
  -setting Setting
  -value Value
```

ARGUMENTS

-window *WindowID*

WindowID specifies the window to set the setting

-setting *Setting*

Setting specifies the setting to set

-value *Value*

Value specifies the value of the setting

DESCRIPTION

Sets a setting on the specified window. Windows are views or top level windows. The setting is a property of the window and the value's type is specific to the given setting.

EXAMPLES

```
prompt> gui_set_setting -window Layout.1 -setting showCell -value true
prompt> gui_set_setting -window Layout.1 -setting viewLevel -value 1
```

SEE ALSO

[gui_get_setting\(2\)](#)

gui_set_task_list

Set the list of tasks that are visible in the task assistant, and set their order.

SYNTAX

```
gui_set_task_list  
-tasks TaskList
```

DESCRIPTION

ARGUMENTS

-tasks *TaskList*

TaskList specifies the list of tasks that will be visible in the task assistant and their order. Tasks which are not included in the list will still exist but will not be shown in the selection combo box of the task assistant.

DESCRIPTION

The `gui_set_task_list` command sets the list of tasks that are visible and available in the task assistant and sets their order.

EXAMPLES

The following simple example sets the visible list of tasks to "Design Planning" followed by "Routing".

```
gui_set_task_list -tasks {{Design Planning} {Routing}}
```

SEE ALSO

`gui_get_task_list(2)`
`gui_create_task(2)`

gui_set_timing_table_paths

Set timing paths into a specified timing table.

SYNTAX

```
status gui_set_timing_table_paths
      [ -command ACmd ]
      [ -window AWindow ]
      [ -new ]
      [ -name ATable ]
```

Data Types

ACmd string
AWindow string
ATable string

ARGUMENTS

-command *ACmd*

Specifies a tcl command that returns a collection of timing paths.

If no command is specified, the "Select Paths" dialog will appear, where the desired timing paths could be specified.

-window *AWindow*

Specifies a top level window id where the timing table is open.

If this option is not specified the most recently used top level window will be used.

-new

Creates a new timing table.

This option cannot be used with option -name at the same time.

-name *ATable*

Specifies an existing timing table by its window id.

This option cannot be used with option -new at the same time.

DESCRIPTION

The **gui_set_timing_table_paths** command sets a collection of timing paths into a specified timing table. The command allows to create new timing tables in a specified top level window, or setting a table with a collection of timing paths which are generated by a

specified command.

EXAMPLES

The following example opens a new timing table in the most recently used top level window with fifteen timing paths.

```
shell> gui_set_timing_table_paths -new -command {get_timing_paths -max_paths 15}
```

This example shows how to update an existing timing table called TimingAnalysisDriver.3 with a command to show the selected timing paths.

```
shell> set my_paths [get_timing_paths -nworst 20 -delay_type max_rise]
shell> change_selection $my_paths
shell> gui_set_timing_table_paths -name TimingAnalysisDriver.3 -command { get_selection }
```

SEE ALSO

[gui_get_window_ids\(2\)](#)
[get_timing_paths\(2\)](#)

gui_set_window_pref_key

Create a preference key owned by a particular window or window type

SYNTAX

```
new_value gui_set_window_pref_key
  {-window window_id
   | -window_type window_type}
  [-category category]
  -key key
  -value_type value_type
  -value value
```

Data Types

<i>window_id</i>	string
<i>window_type</i>	string
<i>category</i>	string
<i>key</i>	string
<i>value_type</i>	string
<i>value</i>	string

ARGUMENTS

-window *window_id*

Specifies the name of the window that the preference will be applied to. This option is mutually exclusive with the -window_type option.

-window_type *window_type*

Specifies the name of the window type that instances of the type will have the preference be applied to. This option is mutually exclusive with the -window option.

-category *category*

Specifies the category that the key belongs to. If not specified, a default category will be assigned.

-key *key*

Specifies the name of the key to create.

-value_type *value_type*

Specifies the the data type of the value of the key. It must be one of [bool | integer | double | color | string].

-value *value*

Specifies the value of the key. The value should be set appropriately in accordance with its value type. The bool type accepts [true, false, 0, 1, on, off]. The color type accepts a named color, eg. "red" or a string specifying the color in this format "#RRGGBB", for example, "#0000FF".

RETURNS

`new_value`

The new value of the key.

DESCRIPTION

This command creates a preference key with the specified key name or sets the value of an existing pref key. This key will have the specified value type and value, and it will be created under the specified category. If the category is not specified, the key will belong to a default category. Returns the value of the preference key.

EXAMPLES

The following example will create a window and set a preference on that window.

```
\prompt> set wnd [gui_create_window -type Console]  
\prompt> gui_set_window_pref_key -window $wnd -category {caption} -key {title}  
-value_type string -value {Command Console}
```

SEE ALSO

`gui_get_window_pref_value(2)`
`gui_get_window_pref_categories(2)`
`gui_get_window_pref_keys(2)`
`gui_create_pref_category(2)`
`gui_set_pref_value(2)`
`gui_get_pref_value(2)`
`gui_remove_pref_key(2)`
`gui_get_pref_keys(2)`
`gui_exist_pref_category(2)`
`gui_exist_pref_key(2)`
`gui_update_pref_file(2)`

gui_show_file_in_editor

Show the contents of a file in an external text editor.

SYNTAX

gui_show_file_in_editor
-filename *Filename*

FileName *String*

ARGUMENTS

-filename *Filename*

Filename specifies the name of the file to be edited.

DESCRIPTION

The `gui_show_file_in_editor` command opens a text editor to edit the specified file. The editor is a separate task so does not block the current application.

By default the file is edited using the text editor from the `EDITOR` environment variable in a xterm. If the `EDITOR` environment variable is not set then the 'vi' text editor is used.

Both the editor and terminal (xterm) are searched for on the users path. If either the editor or terminal can no be found the command will fail.

SEE ALSO

`gui_show_url_in_browser(2)`

gui_show_man_page

Show a man page in the man browser

SYNTAX

```
string gui_show_man_page
      topic [-apropos]
```

Data Types

topic string

ARGUMENTS

topic

Man page topic to be shown.

DESCRIPTION

This command will launch or raise the man page browser, and display the topic specified in it. If no topic is specified, then the HOME page for man page indexes will be shown. If the specified topic does not exactly match a given man page, then additional searching will be done for commands. If the topic matches one or more commands, then an index page will be generated showing all of the commands which match the specified topic pattern. If the topic doesn't match any commands, then we will use the topic as the initial part of a command and add a * to it and do command matching. Any completions for the command will be shown on an index page that can then be used to select a man page for viewing. If the -apropos option is specified, then the topic will be searched via the apropos command and the topics returned will be shown with their brief help strings, and provide links to the man pages referenced.

EXAMPLES

To show the man page for the find command:

gui_show_man_page find To show the man page for all commands containing the word cell:

gui_show_man_page *cell* To show the man page for the get_attribute command using command completion:

gui_show_man_page get_attr

SEE ALSO

`man(2)`
`apropos(2)`

gui_show_map

Displays or hides the specified visual mode or map mode.

SYNTAX

```
string gui_show_map
  -map map_name
  -show true | false
  [-window window]
```

Data Types

<i>map_name</i>	string
<i>window</i>	string

ARGUMENTS

-map *map_name*

Specifies the name of the visual mode or map mode.

-show true | false

Displays the visual mode or map mode when set to **true**, or hides the visual mode or map mode when set to **false**.

-window *window*

Specifies the name of layout window in which to display or hide the visual mode or map mode.

DESCRIPTION

This command displays or hides the specified visual mode or map mode. If the **-window** option is not specified, the command uses the most recently active layout window.

EXAMPLES

The following example displays the highlight visual mode in the most recently active layout window:

```
prompt> gui_show_map -map Highlight \
  -show true
```

SEE ALSO

`gui_get_map_list(2)`

gui_show_palette

Shows the palette in the specified window state.

SYNTAX

```
status gui_show_palette
{ -name palette_id | -type palette_type }
[ -parent parent_name ]
[ -show_state window_state ]
[ -dock_edge dock_edge ]
[ -size {width height} ]
```

Data Types

```
palette_id    string
palette_type   string
parent_name   string
window_state  string
dock_edge     string
width         float
height        float
```

ARGUMENTS

-name *palette_id*

Specifies the palette name id.

Any matching palette of this name will be shown.

This option precludes the **-type** option

-type *palette_type*

Specifies the palette type id. Any matching palette of this type will be shown.

If the **-parent** option is specified only palettes in the specified parent toplevel window are shown. If the **-parent** option is not specified all palettes of this type in all toplevel windows are shown.

This option precludes the **-name** option

-parent *parent_name*

Specifies the parent toplevel window name.

-show_state *window_state*

Specifies the window state to show the palette.

Legal states are **maximized**, **minimized**, **normal**, or **docked**.

The default is **normal**.

-dock_edge dock_edge

Specifies the edge to dock the palette.

Legal dock edges are **left**, **top**, **right**, or **bottom**.

Note: this option is only valid if the state is set to **docked**.

The default is **right**.

-size {width height}

Specifies the width and height of the palette.

Note: this option is only valid if the state is set to **normal**.

DESCRIPTION

This command shows the specified palette in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

EXAMPLES

The following example shows the Layer palette docked on the left of the workspace.

```
shell> set top [gui_create_window -type TopLevel]  
shell> set layout [gui_create_palette -type Layout -parent $top]  
shell> gui_show_palette -name $layout -show_state docked -dock_edge left
```

SEE ALSO

`gui_hide_palette(2)`

gui_show_toolbar

Displays the specified toolbar or all the toolbars in the specified window.

SYNTAX

```
void gui_show_toolbar
    -toolbar tool_bar_name | -all
    [-window window_id]
```

Data Types

<i>tool_bar_name</i>	string
<i>window_id</i>	string

ARGUMENTS

-toolbar *tool_bar_name*

Specifies the toolbar you want to display. The **-toolbar** option and the **-all** option are mutually exclusive.

-all

Displays all the toolbars in the specified window. The **-all** option and the **-toolbar** option are mutually exclusive.

-window *window_id*

Specifies the window in which you want to display the specified toolbar or all toolbars. By default, the tool displays the toolbar or toolbars in the active window.

DESCRIPTION

This command displays either all the toolbars or the toolbar with the specified name in the window with the specified window ID.

EXAMPLES

The following example displays the File toolbar in the active window:

```
prompt> gui_show_toolbar -toolbar File
```

The following example displays all the toolbars in the layout window named LayoutWindow.1:

```
prompt> gui_show_toolbar -all -window LayoutWindow.1
```

SEE ALSO

`gui_create_toolbar(2)`
`gui_delete_toolbar(2)`
`gui_create_toolbar_item(2)`
`gui_delete_toolbar_item(2)`
`gui_hide_toolbar(2)`
`gui_get_toolbar_names(2)`

gui_show_url_in_browser

Show the contents of a URL in an external web browser.

SYNTAX

gui_show_url_in_browser
-url *URL*

URL String

ARGUMENTS

-url *Url*

Url specifies the url to be displayed.

DESCRIPTION

The `gui_show_url_in_browser` command an external web browser to display the specified web page. The default web browser is defined by the application but is usually 'firefox' on UNIX platforms.

If the web browser supports external communication (which 'firefox' does) then if no web browser is running the web browser is started. If the web browser is running then the URL is loaded in the browser usually as a new tab.

The default browser can be set using the '`gui_online_browser`' variable but the set of valid browsers is usually restricted by the application so not all browsers may be supported. If an unsupported browser is specified the command will fail.

SEE ALSO

`gui_online_browser(3)`
`gui_show_file_in_editor(2)`

gui_show_window

Show the window in the specified window state

SYNTAX

```
status gui_show_window
  -window window_id
  [ -show_state window_state ]
  [ { -rect rect | -size  isize } ]
```

Data Types

```
window_id    string
window_state  string
rect        {{x1 y1} {x2 y2}}
 isize      {width height}
```

ARGUMENTS

-window *window_id*

Specifies the toplevel window or view id to show.

-show_state *window_state*

Specifies the window state to show the toplevel window or view.

For a toplevel window we have one of:

normal - show at preferred size
 maximized - show maximized (fill whole screen)
 minimized - show iconized
 hidden - hide but do not destroy

Note: The window manager may or may not fully honor the specified state. See your window manager documentation for more details.

For a view window we have one of:

normal - show at preferred size in view area and raise to top
 maximized - show maximized in view area and raise to top
 minimized - show iconized in view area
 hidden - hide but do not destroy

Note: If displaying maximized then any existing view windows are also maximized. If displaying minimized or normal then any maximized windows are shown as normal.

The default is **SHOW_WINDOW_STATE_NORMAL**.

-rect *rect*

Specifies the size and position of the window.

It is of this format "`{x1 y1} {x2 y2}`", where `{x1 y1}` specifies the top left location and `{x2 y2}` specifies the bottom right location of the window.

Note: This option precludes the use of the `-size` option.

-size *isize*

Specifies the width and height of the window.

It is of this format "`{width height}`"

Note: This option precludes the use of the `-rect` option.

DESCRIPTION

This command shows the specified toplevel window or view in the specified state and optionally sets the geometry.

If no state is specified then it defaults to normal.

EXAMPLES

The following examples will create a layout window then use this command to illustrate the various options

```
shell> set top [gui_create_window -type TopLevel]
shell> set layout [gui_create_window -type Layout -parent $top]
shell> gui_show_window -window $layout -show_state {maximized}
shell> gui_show_window -window $layout -show_state {normal}
```

SEE ALSO

`gui_close_window(2)`
`gui_exist_window(2)`

gui_start

Starts the application GUI.

SYNTAX

```
string gui_start
  [-file script]
  [-no_windows]
  [-offscreen sbool]
```

Data Types

script string

ARGUMENTS

-file *script*

The given script file is sourced before the GUI starts.

-no_windows

The GUI starts without showing the default window.

DESCRIPTION

This command starts the application GUI from the shell prompt. It is ignored if the application GUI has already been started. start_gui is an alias for gui_start.

Note the application can only ever connect to one X server during program execution, so changing the value of the DISPLAY environment variable after the first successful gui_start command has no effect.

EXAMPLES

The following example starts the application GUI.

```
prompt> gui_start
```

SEE ALSO

`gui_stop(2)`
`start_gui(2)`
`stop_gui(2)`

gui_stop

Stops the application GUI.

SYNTAX

string **gui_stop**

ARGUMENTS

None.

DESCRIPTION

This command stops the application GUI and returns to the shell prompt. It is ignored if the application GUI has not been started or has been stopped. stop_gui is an alias for gui_stop.

EXAMPLES

The following example stops the application GUI and returns to the shell prompt.

```
prompt> gui_stop
```

SEE ALSO

`gui_start(2)`
`start_gui(2)`
`stop_gui(2)`

gui_update_attrgroup

Updates a group of attributes for an object type.

SYNTAX

```
status gui_update_attrgroup
  -class design_object
  -name name
  [-attr_list {{attr_1}...{attr_n}}]
  [-add]
  [-delete]
  [-move up | down | top | bottom | after | before]
  [-attr attribute]
  [-anchor attribute]
```

Data Types

<i>design_object</i>	string
<i>name</i>	string
<i>attr_1</i>	string
<i>attribute</i>	string

ARGUMENTS

-class *design_object*

Specifies the type of design object.

-name *name*

Specifies the non-editable name of the attribute group to update for the specified object type.

-attr_list {{*attr_1*}...{*attr_n*}}

Lists and orders the attributes to be included in the group.

-add

Adds the attribute specified by the **-attr** option to the end of attributes list, by default, or after the attribute specified by the **-anchor** option.

-delete

Removes the attributes specified by the **-attr** option from the attribute list. Note that the attribute still exists.

-move up | down | top | bottom | after | before

Moves the attribute specified by the **-attr** option in the specified direction. If you specify **before** or **after** to move the attribute relative to the position of a reference attribute, use the **-anchor** option to specify the reference attribute.

-attr *attribute*

Specifies the attribute to be added, removed, or moved with the **-add**, **-delete**, or **-move** option.

-anchor *attribute*

Specifies the reference attribute to be used with the **-add** or **-move** option.

DESCRIPTION

The **gui_update_attrgroup** command updates an attribute group for the specified object type. You can reset the entire attribute list by using the **-attr_list** option, or you can change the list by adding, removing, or moving with a single attribute.

The order of the attributes in an attribute group is important and is set by the **-attr_list** option when you create or update the group.

EXAMPLES

```
prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
    -attr_list { "TestAttr1" "TestAttr2" "TestAttr3" }

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
    -add -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
    -add -attr "TestAttr5" -anchor "TestAttr2"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
    -delete -attr "TestAttr5"

prompt> gui_update_attrgroup -class Cell -name "TestGroup2" \
    -move down -attr "TestAttr2"
```

SEE ALSO

`gui_create_attrgroup(2)`
`gui_delete_attrgroup(2)`
`gui_list_attrgroups(2)`

gui_update_pref_file

Save current application preferences to the user preference file.

SYNTAX

```
string gui_update_pref_file
      [-file FilePathName]
```

ARGUMENTS

-file *FilePathName*

FilePathName specifies the full pathname of the user preference file to write the current preferences to. If this option is missing, the file to write to is controlled by the gui variables : pref_file_name and pref_file_path. These two variables are set with the **gui_set_var** command and their values retrieved with the **gui_get_var** command.

DESCRIPTION

This command updates the user preference file. Normally, application will automatically save user preferences to a default system preference file on exit, and retrieve the preferences from the default user preference file on application start. So, this command is rarely used, except internally.

SEE ALSO

```
gui_create_pref_category(2)
gui_create_pref_key(2)
gui_set_pref_value(2)
gui_get_pref_value(2)
gui_remove_pref_key(2)
gui_get_pref_keys(2)
gui_exist_pref_category(2)
gui_exist_pref_key(2)
```

gui_view_port_history

Does the gui_view_port_history operations.

SYNTAX

```
gui_view_port_history
  [-window fwindow_name]
  [-next]
  [-previous]
  [-add name]
  [-to name]
  [-list_names]
  [-rect bounding box]
  [-delete_name]
  [-isprevious]
  [-isnext]
  [-dialog]
  [-tcl_list]
  [-help_cmd]
```

ARGUMENTS

-window *fwindow_name*

Give the name of a window. this is required option except if you use *-dialog* option.

-next

Specify if you want to go to previous stored view port history. If you use *-next* option you can not use any other option except *-window* option: they are mutually exclusive.

-previous

Specify if you want to go to previous stored view port history. If you use *-previous* option you can not use any other option except *-window* option: they are mutually exclusive.

-add *name*

Current view port will be stored by this name. *-add* option can be combined with *-rect* option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name.

If you use *-add* option you can not use any other option except *-window* and *-rect* option : they are mutually exclusive.

-to *name*

Give the name of a view port history already stored. If you use *-to* option you can not use any other option except *-window* option: they are mutually exclusive.

-list_names

Specify if you want to see list of names of all the named view port history. If you use **-list_names** option you can not use any other option except **-window** option: they are mutually exclusive.

-delete_name name

The already stored view port history with this name will be deleted. If you use **-delete_name** option you can not use any other option except **-window** option: they are mutually exclusive.

-rect boundingbox

Adds give the bounding box (in design units) to unnamed view port history. The values should be given in following format. format: $\{\{x1\ y1\}\ \{x2\ y2\}\}$ **-rect** option can be combined with **-add** option. In that case the view port history with the given rect instead of current view port will be saved in to view port history with the given name. If you use **-add** option you can not use any other option except **-window** and **-add** option : they are mutually exclusive.

-isnext

return true returns true if there previous zoom history. If you use **-isnext** option you can not use any other option except **-window** option: they are mutually exclusive.

-isprevious

returns true if there next zoom history. If you use **-isprevious** option you can not use any other option except **-window** option: they are mutually exclusive.

-dialog

specify to invoke dialog for named view port history. If you use **-dialog** option you can not use any other option except **-help_cmd** option: they are mutually exclusive.

-tcl_list

return a **tcl_list** of named view port history If you use **-tcl_list** option you can not use any other option except **-window** option: they are mutually exclusive.

help_cmd help_command

Give a command which will be executed when help buttonis clicked in the dialog.

DESCRIPTION

This command store view port for the application. At least one option needs to be specified.

last 100 View ports will be stored in view port history, which can be accessed by specifying **-previous** and **-next** options.

When you use **-add** then the current view port will be stored by the given name in the to view port history.

when you use **-to** then the view port stored by this name will be shown and added to the view port history.

EXAMPLES

The following example zooms in to the given rectangle.

```
fpc_shell> gui_view_port_history -rect {{-2232.321 -536.887} {141.286 2175.807}}
```

The following example zooms to next .

```
fpc_shell> gui_view_port_history -next
```

The following example zooms to previous.

```
fpc_shell> gui_view_port_history -previous
```

The following example gives list of all the named zooms.

```
fpc_shell> gui_view_port_history -list_names
```

The following example puts the current zoom in to zoom history by given name.

```
fpc_shell> gui_view_port_history -add xyz
```

The following example zooms to already stored to zoom .

```
fpc_shell> gui_view_port_history -to xyz
```

The following example deletes an already stored to zoom.

```
fpc_shell> gui_view_port_history -delete xyz
```

guiViolationSchematicAddObjects

Adds the specified objects to the violation schematic in a violation inspector window.

SYNTAX

```
status guiViolationSchematicAddObjects
  [-window window_name]
  [-clct]
  object_list
```

Data Types

window_name string
object_list list

ARGUMENTS

-window *window_name*

Specifies the violation inspector window in which you want to add the specified objects. If *window_name* does not exist, the command exits with an error message.

By default, the command adds the objects to the most recently active violation inspector window.

-clct

Causes the command to treat *object_list* as a collection of object handles. By default, the command treats *object_list* as a list of object names.

object_list

Specifies the objects that you want to add to the schematic in the violation inspector window. By default, *object_list* is a list of object names. If you use the **-clct** option, *object_list* specifies a collection of object handles. In both cases, *object_list* can consist of heterogeneous names.

DESCRIPTION

This command adds the specified objects (leaf cells, pins, or nets) to the violation schematic in the specified or active violation inspector view window.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example adds a cell named gate_clock to the violation schematic in the active violation inspector window:

```
prompt> guiViolationSchematicAddObjects gate_clock
```

The following example adds a cell named gate_clk and a port named i_rd to the violation schematic in the violation inspector window named violationInspector.2:

```
prompt> guiViolationSchematicAddObjects \  
      -window violationInspector.2 {gate_clk i_rd}
```

The following example adds the selected objects to the violation inspector window named ViolationInspector.3:

```
prompt> guiViolationSchematicAddObjects \  
      -window ViolationInspector.3 -clct [get_selection]
```

SEE ALSO

[guiInspectViolations\(2\)](#)

gui_wave_add_signal

Adds the specified signals to the waveform view in a violation inspector window.

SYNTAX

```
status gui_wave_add_signal
      [-window window_name]
      [-clct]
      object_list
```

Data Types

window_name string
object_list list

ARGUMENTS

-window *window_name*

Specifies the violation inspector window with the waveform view in which you want to add the specified signals. If *window_name* does not exist, the command exits with an error message.

By default, the command adds the signals to the first open violation inspector window with a waveform view.

-clct

Causes the command to treat *object_list* as a collection of object handles. By default, the command treats *object_list* as a list of object names.

object_list

Specifies the signals that you want to add to the waveform view in the violation inspector window. You can specify leaf cells, pins, ports, nets, or buses.

By default, *object_list* is a list of object names. If you use the **-clct** option, *object_list* specifies a collection of object handles. In both cases, *object_list* can consist of heterogeneous names.

DESCRIPTION

This command adds the specified signals to the waveform view in a violation inspector window. The command creates a new group that contains a list of the specified signals. If you specify a cell, the group contains all the pins on the cell. If you specify a bus, the group contains all the nets in the bus.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example adds the port named i_rd to the waveform view in the first open violation inspector window:

```
prompt> gui_wave_add_signal i_rd
```

The following example adds the selected objects to the waveform view in the window named ViolationInspector.3:

```
prompt> gui_wave_add_signal -window ViolationInspector.3 \  
  -clct [get_selection]
```

SEE ALSO

[gui_inspect_violations\(2\)](#)

gui_write_layout_image

Save a layout image in a file

SYNTAX

```
status gui_write_layout_image
      -output file_name
      [-window window_title]
      [-view_only]
```

Data Types

file_name string
window_title string

ARGUMENTS

-output *file_name*

Specifies the output file name, including a suffix (.jpg, .png, .xpm, or .bmp) that identifies format.

-window *window_title*

Identifies the layout window. The defaults is the most recently used Layout window.

-view_only

Writes only the layout view contents. The default is to write all of the layout window contents.

DESCRIPTION

The command `gui_write_layout_image` command writes the layout image, as seen on the screen, into a file. The image content can be the complete layout window (including layout window title, menus, menu bars and other visible toolbars docked in the layout window) or simply that of the view. The output file name must include one of supported formats as file suffix.

The supported formats are JPEG, PNG, XPM, and BMP.

This command works only in a GUI session.

EXAMPLES

The following example writes the latest layout image, excluding the layout window title, menus, and toolbars, in JPEG format to a file named risc_core.jpg that resides in the current directory.

```
prompt> gui_write_layout_image -view_only -output risc_core.jpg
```

SEE ALSO

`gui_start(2)`
`gui_stop(2)`

gui_write_window_image

Saves an image of a view window or top-level window in the specified image file.

SYNTAX

```
status gui_write_window_image
      -file file_name
      [ -format png | xpm | jpg | bmp ]
      [ -window window_id ]
```

Data Types

file_name string
window_id string

ARGUMENTS

-file *file_name*

Specifies the name of the file in which the tool saves the window image.

If you include a file name extension, it determines the image format unless you also specify the **-format** option.

-format png | xpm | jpg | bmp

Specifies the image format to be used in the file. The default value is png.

Note that if the format that you specify with the **-format** option is different from the format specified by the file name extension, the **-format** value takes precedence and the tool appends an additional extension to the file name.

-window *window_id*

Specifies the name of the window for which you want to save an image in the specified image file.

You can view a list of the window names for all the open top-level and view windows by using the **gui_get_window_ids** command.

By default, the tool saves an image of the most recently active view window.

DESCRIPTION

The **gui_write_window_image** command saves an image of a view window or atop-level window in the specified image file.

EXAMPLES

In the following example, the tool creates a new schematic view window and saves an XPM image of the window in a file named my_image.xpm:

```
prompt> set schm [gui_create_schematic]
prompt> gui_write_window_image -file my_image.xpm -window $schm
```

SEE ALSO

`gui_create_schematic(2)`
`gui_create_window(2)`
`gui_get_window_ids(2)`
`gui_set_active_window(2)`
`gui_get_current_window(2)`

gui_zoom

Change the viewport of a view

SYNTAX

```
gui_zoom
  -window window
  [-fit | -exact]
  [-full]
  [-selection]
  [-rect {{lx ly} {ux uy}}]
  [-factor factor]
  [-at_point {x y}]
  [-clct clct]
  [-zoom_in_mode]
  [-zoom_out_mode]
  [-select_mode]
```

<i>window</i>	<i>String</i>
<i>rect</i>	<i>String</i>
<i>factor</i>	<i>Float</i>

ARGUMENTS

-window *window*

window specifies the window of which this command should change the viewport.

-full

Zoom such that all objects are visible.

-factor *factor*

Keep the center of the viewport and zoom by factor *factor*. A *factor* > 1 causes a zoom-in, a *factor* < 1 causes a zoom-out. The argument must be greater than zero.

-at_point {*x y*}

Can only be specified with -factor argument. If supplied, zoom is performed at specified point instead of viewport center. The option is not supported by all window types.

-fit

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to not over zoom. Will zoom a reasonable distance away from the rectangle or objects being zoomed. The definition of "reasonable" is window dependent. This argument is mutually exclusive with -exact.

-exact

Effects the -rect, -selection and -clct arguments. If supplied, will cause the zoom to zoom exactly to the arguments. This argument is mutually exclusive with -fit.

-selection

Zoom such that all selected objects that are represented in the window are visible and if possible are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

-rect {{lx ly} {ux uy}}

Zoom such that the window shows the rectangle *rect* in its viewport. What coordinates are assumed for *rect* are dependent on the window. If neither -fit or -exact is supplied, -exact is assumed.

-clct *clct*

Zoom such that all objects in *clct* that are represented in the window are visible and if possible, are easy to see and are shown in a reasonable context. If neither -fit or -exact is supplied, -fit is assumed.

-zoom_in_mode

Put the window in zoom-in mode.

-zoom_out_mode

Put the window in zoom-out mode.

-select_mode

Put the window in selection mode.

DESCRIPTION

The **gui_zoom** controls the viewport of a view that supports zooming. Not all views need to support all of the functionality provided by the interface of this command.

EXAMPLES

The following example has the layout view show the entire design and then zooms in by a factor of 2, i.e. only a quarter of the area of the design is still visible:

```
gui_zoom -window Layout.1 -full  
gui_zoom -window Layout.1 -factor 2  
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}}  
gui_zoom -window Layout.1 -rect {{0.0 0.0} {123.456 500.123}} -fit  
gui_zoom -window Layout.1 -selection -exact
```

SEE ALSO

gui_zoom_all_layouts_to_current_view

Rescales all layout views to the current view.

SYNTAX

`gui_zoom_all_layouts_to_current_view`

ARGUMENTS

None.

DESCRIPTION

The command sets the zoom factor of all layout views to the zoom factor of current layout view.

EXAMPLES

prompt> `gui_zoom_all_layouts_to_current_view`

SEE ALSO

`gui_zoom(2)`

help

Displays quick help for one or more commands.

SYNTAX

```
string help
  [-verbose]
  [-groups]
  [pattern]
```

Data Types

pattern string

ARGUMENTS

-verbose

Displays the command options; for example *command_name -help*.

-groups

Displays a list of command groups only.

pattern

Displays commands matching the specified pattern.

DESCRIPTION

The **help** command is used to get quick help for one or more commands or procedures. This is not the same as the **man** command that displays reference manual pages for a command. There are many levels of help.

By typing the **help** command, a brief informational message is printed followed by the available command groups.

List all of the commands in a group by typing the group name as the argument to **help**. Each command is followed by a one-line description of the command.

To get a one-line help description for a single command, type **help** followed by the command name. You can specify a wildcard pattern for the name; for example, all commands containing the string "alias". Use the **-verbose** option to get syntax help for one or more commands. Use the **-groups** option to show only the command groups in the application. This option cannot be combined with any other option.

EXAMPLES

The following example lists the commands by command group:

```
prompt> help
Specify a command name or wild card pattern to get help on individual
commands. Use the '-verbose' option to get detailed option help for a
command. Commands also provide help when the '-help' option is passed to
the command.'
```

You can also specify a command group to get the commands available in that group. Available groups are:

Procedures:	Miscellaneous procedures
Help:	Help commands
Builtins:	Generic Tcl commands
...	

The following example displays the list of procedures in the Procedures group:

```
prompt> help procedures
ls          # List files
sh          # Execute a shell command
```

The following example uses a wildcard character to display a one-line description of all commands beginning with *a*:

```
prompt> help a*
alias      # Create a command which expands to words.
append     # Builtin
array      # Builtin
```

This example displays option information for the **source** command:

```
prompt> help -verbose source
source      # Read a file and execute it as a script
[-echo]     (Echo all commands)
[-verbose]  (Display intermediate results)
file_name   (Script file to read)
```

SEE ALSO

[man\(2\)](#)
[sh_help_shows_group_overview\(3\)](#)

history

Displays or modifies the commands recorded in the history list.

SYNTAX

```
string history
  [-h]
  [-r]
  [argument_list]
```

Data Types

argument_list list

ARGUMENTS

-h

Displays the history list without the leading numbers. You can use this for creating scripts from existing history. You can then source the script with the **source** command. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

-r

Reverses the order of output so that most recent history entries display first rather than the oldest entries first. You can combine this option with only a single numeric argument. Note that this option is a nonstandard extension to Tcl.

argument_list

Additional arguments to **history** (see DESCRIPTION).

DESCRIPTION

The **history** command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." The most commonly used forms of the command are described below. You can combine each with either the **-h** or **-r** option, but not both.

- With no arguments, the **history** command returns a formatted string (intended for you to read) giving the event number and contents for each of the events in the history list.
- If a single, integer argument *count* is specified, only the most recent *count* events are returned. Note that this option is a nonstandard extension to Tcl.
- Initially, 20 events are retained in the history list. You can change the length of the history list using the following:

history keep *count*

Tcl supports many additional forms of the **history** command. See the "Advanced Tcl History" section below.

EXAMPLES

The following examples show the basic forms of the **history** command. The first is an example of how to limit the number of events shown using a single numeric argument:

```
prompt> history 3
7 set base_name "my_file"
8 set fname [format "%s.db" $base_name]
9 history 3
```

Using the **-r** option creates the history listing in reverse order:

```
prompt> history -r 3
9 history -r 3
8 set fname [format "%s.db" $base_name]
7 set base_name "my_file"
```

Using the **-h** option removes the leading numbers from each history line:

```
prompt> history -h 3
set base_name "my_file"
set fname [format "%s.db" $base_name]
history -h 3
```

Advanced Tcl History

The **history** command performs one of several operations related to recently-executed commands recorded in a history list. Each of these recorded commands is referred to as an "event." When specifying an event to the **history** command, the following forms may be used:

- A number, which if positive, refers to the event with that number (all events are numbered starting at 1). If the number is negative, it selects an event relative to the current event; for example, **-1** refers to the previous event, **-2** to the one before that, and so on. Event **0** refers to the current event.
- A string selects the most recent event that matches the string. An event is considered to match the string either if the string is the same as the first characters of the event, or if the string matches the event in the sense of the **string match** command.

The **history** command can take any of the following forms:

history

Same as **history info**, described below.

history add command [exec]

Adds the *command* argument to the history list as a new event. If **exec** is specified (or abbreviated), the command is also executed and its result is returned. If **exec** is not specified, an empty string is returned.

history change newValue [event_number]

Replaces the value recorded for an event with *newValue*. The *event_number* specifies the event to replace, and defaults to the *current* event (not event-1). This command is intended for use in commands that implement new forms of history substitution and want to replace the current event (that invokes the substitution) with the command created through substitution. The return value is an empty string.

history clear

Erases the history list. The current keep limit is retained. The history event numbers are reset.

history event [event_number]

Returns the value of the event given by *event_number*. The default value of *event_number* is **-1**.

history info [count]

Returns a formatted string, giving the event number and contents for each of the events in the history list except the current event. If *count* is specified, then only the most recent *count* events are returned.

history keep [count]

Changes the size of the history list to *count* events. Initially, 20 events are retained in the history list. If *count* is not specified, the current keep limit is returned.

history nextid

Returns the number of the next event to be recorded in the history list. Use this for printing the event number in command-line prompts.

history redo [event_number]

Reruns the command indicated by *event* and returns its result. The default value of *event_number* is **-1**. This command results in history revision. See the following section for details.

History Revision

Pre-8.0 Tcl had a complex history revision mechanism. The current mechanism is more limited, and the **substitute** and **words** history operations have been removed. The **clear** operation was added.

The **redo** history option results in much simpler "history revision." When this option is invoked, the most recent event is modified to eliminate the history command and replace it with the result of the history command. If you want to redo an event without modifying the history, use the **event** operation to retrieve an event, and use the **add** operation to add it to history and execute it.

identify_clock_gating

Identifies Power Compiler-inserted clock-gating circuitry in a structural netlist.

SYNTAX

```
status identify_clock_gating  
    [-gating_elements cell_collection]
```

Data Types

cell_collection collection

ARGUMENTS

-gating_elements *cell_collection*

Marks the specified cell as a gating element. By default, this option is off. Performs specific recognition of the listed cells as gating elements. Each element must meet the following minimum conditions to be accepted as a gating element:

- Minimum 2 input pins
- Minimum 1 output pin
- One of the inputs pins must be connected to a clock source

OBSOLETE ARGUMENTS

The following arguments are no longer supported and are ignored if used:

-reset_only *cells_or_pins*

-gated_element *gated_cells_or_pins*

-ungated_element *ungated_cells*

DESCRIPTION

This command identifies the Power Compiler-inserted clock-gating circuitry in the structural netlist. Identification refers to the process of detecting clock gates and the corresponding gated element association and setting different attributes on these objects. These attributes enable the later steps in the tool to work efficiently.

There is no need to invoke this command if the netlist was in .ddc or Milkyway format and the clock-gating structure was not changed

outside the tool.

Set the correct clock-gating style by using the **set_clock_gating_style** command before invoking the **identify_clock_gating** command.

The most common usage is to invoke the command without any options. The **identify_clock_gating** command searches all of the clocks in the design for clock gates and gated cells. The tool then marks the clock-gating properties with attributes that are used by subsequent clock gating commands. Because only clocks are traversed in this case, it is important to run the **create_clock** command before running the **identify_clock_gating** command in this mode.

If test control pins are present on the clock gates, the **identify_clock_gating** command tries to reinstate the necessary attributes for the **insert_dft** command to work. The control signal is assumed to be of **scan_enable** type, unless otherwise marked as **test_mode**, by using the **set_clock_gating_style** command with the **-control_signal test_mode** option, before running the **identify_clock_gating** command. These attributes are applied to all the clock gates of the design that have been identified.

If you specify the **-gating_elements** option, the command automatically detects the gated elements through netlist traversal. Each successfully identified element is automatically constrained with the **pwr_cg_preservation_type** attribute to prevent it from being removed from the design and from being merged with other gating elements. If the specified gating cell has the characteristics of a type of clock gate that can be inserted by the tool, then the value for **pwr_cg_preservation_type** is **preserve**. If the gating cell is different from one originally inserted by Power Compiler, then the value for the attribute is **unmodifiable_read_only**. After the manual identification process is done, the command also performs the design-scoped identification process to search for additional clock gates, if any.

The **identify_clock_gating** command assumes the only nonsequential cells in the clock network are single output cells (netlinks, inverters, or buffers). If it finds a combinational cell with multiple outputs, it stops the traversal, with the exception of pad cells.

The **identify_clock_gating** command reports identified elements by printing two (2) informational messages: PWR-875 and PWR-877. The former reports the number of manually identified elements (only if **-gating_element** option is used) for cells that do not have the characteristics of a type of clock gate that can be inserted by the tool. The latter reports the number of elements identified by the design-scoped identification process.

In addition, you can use the **report_clock_gating** command to verify the results accuracy of the identification step. If there are any problems, rerun the **identify_clock_gating** command with the **-gating_elements** option to make repairs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the typical flow for using the **identify_clock_gating** command to identify the clock-gating circuitry:

```
prompt> read_verilog mapped_design.v
prompt> current_design top
prompt> link
prompt> create_clock clk

prompt> identify_clock_gating
prompt> report_clock_gating
```

The following example shows how to apply clock-gating attributes to the user-inserted *user_cg1* clock gate as the corresponding clock gate of the *reg1_reg* register bank:

```
prompt> read_verilog mapped_design.v
prompt> current_design top
prompt> link

prompt> identify_clock_gating -gating_elements user_cg1
prompt> report_clock_gating
```

The following example shows how to apply clock-gating attributes to the user-inserted *user_cg1* clock gate and allow the tool identify the corresponding registers:

```
prompt> read_verilog mapped_design.v
prompt> current_design top
prompt> link

prompt> identify_clock_gating -gating_elements user_cg1

prompt> report_clock_gating
```

The following example shows how to use the **identify_clock_gating** command with the **report_clock_gating** command to fix problems:

```
prompt> read_verilog mapped_design.v
prompt> current_design top
prompt> link

prompt> create_clock -period 3 clk
prompt> identify_clock_gating

# Inspect if all clock gates are identified
prompt> report_clock_gating -gated

# Assume cg1 is not identified as a clock gate
prompt> identify_clock_gating -gating_elements cg1

prompt> report_clock_gating -gated
```

```

identify_register_banks

Identifies register banking opportunities and writes out a register banking script. This command is supported only in Design Compiler topographical mode.

SYNTAX

```
status identify_register_banks
  -output_file file_name
  [-input_map_file file_name]
  [-register_group_file file_name]
  [-maximum_flop_count flop_count]
  [-minimum_flop_count flop_count]
  [-exclude_instances exclude_cells]
  [-wns_threshold percentage]
  [-common_net_pins names]
  [-name_prefix prefix]
  [-wns_threshold_file file_name]
  [-exclude_library_cells library_cells]
  [-exclude_size_only_flops]
  [-exclude_start_stop_scan_flops]
  [-multibit_components_only]
```

Data Types

<i>file_name</i>	string
<i>flop_count</i>	integer
<i>exclude_cells</i>	list or collection
<i>percentage</i>	float
<i>names</i>	list of string
<i>prefix</i>	string
<i>library_cells</i>	list or collection

ARGUMENTS

-output_file *file_name*

Specifies the name of the output file that contains the generated register banking guidance commands. The output file contains a series of **create_register_bank** commands. The output file can be sourced back into the tool to replace single-bit registers with multibit registers.

-input_map_file *file_name*

Specifies the name of the input map file that contains the mapping information about which multibit register bank replaces which single-bit registers. The tool reads in the input map file during placement.

The format for the input map file is described in the FILE FORMATS section of this man page.

If the **-input_map_file** option is not specified, the **-register_group_file** option is ignored. If you do not specify the input map file and register group file, the **identify_register_banks** command identifies the single-bit registers that can be replaced by available multibit registers in the target and link libraries based on the functional information of the library cells; the tool then uses that

information to control mapping.

-register_group_file *file_name*

Specifies the file from which functional grouping information for the library cells are to be read. If this option is not provided, the tool treats all library cells as part of one functional group.

The format for the register group file is described in the FILE FORMATS section of this man page.

If the **-register_group_file** option is not specified, the **-input_map_file** option is ignored. If you do not specify the input map file and register group file, the **identify_register_banks** command identifies the single-bit registers that can be replaced by available multibit registers in the target and link libraries based on the functional information of the library cells; the tool then uses that information to control mapping.

-maximum_flop_count *flop_count*

Specifies the maximum number of registers that can be grouped together. If this option is not provided, the tool automatically determines the value as the maximum bit-width for which mapping is provided in the input map file.

-minimum_flop_count *flop_count*

Specifies the minimum number of registers that can be grouped together. If this option is not provided, the tool automatically determines the value as the minimum bit-width for which mapping is provided in the input map file.

-exclude_instances *exclude_cells*

Specifies the list of instances to be ignored for grouping.

-wns_threshold *percentage*

Specifies the percentage of the total number of registers in the design that can be ignored during grouping if registers have negative setup slack.

For example, if there are 1000 registers in the design and the **-wns_threshold** option is specified as 10, the tool ignores 100 (10% of 1000) registers that have the most negative setup slack. If the design has fewer registers with negative setup slack, for example 60, the tool ignores all 60 registers.

The default is zero (no register is ignored). This option is ignored by the tool if the **-wns_threshold_file** option is specified.

-common_net_pins *names*

Specifies a list of pin names that need to be connected to the same net for all the registers in a group.

For example, if you specify the **-common_net_pins {CP RN}** option setting, the tool ensures that the CP pins of the registers in a group are connected to a common net, and that the RN pins of the registers are connected to a common net. In other words, the tool does not form a group with registers with CP pins that are connected to different nets or RN pins that are connected to different nets.

-name_prefix *prefix*

Specifies a prefix for the register bank name that the **create_register_bank** command uses in the output file. By default, the tool derives the name of the register bank by concatenating the names of the registers it is grouping.

For example, if you do not specify the **-name_prefix** option, the tool groups a_reg[0] and a_reg[1] registers to one multibit cell and generates the following in the output file:

```
create_register_bank -name a_reg[0]_a_reg[1]
```

If you specify the **-name_prefix** option with an MBIT prefix, the output file generated during grouping uses MBIT as the prefix, as shown:

```
create_register_bank -name MBIT_a_reg[0]_a_reg[1]
```

To revert to the previous naming style, before version J-2014.09-SP3, use the following variable setting:

```
set_app_var banking_enable_concatenate_name false
```

-wns_threshold_file *file_name*

Specifies the file from which the worst negative slack (WNS) threshold information (based on the timing group) is read. This overrides the **-wns_threshold** option.

If this option is not specified, the **-wns_threshold** option is used to determine the timing-critical registers that are ignored.

The format for the WNS threshold file is described in the FILE FORMATS section of this man page.

-exclude_library_cells *library_cells*

Specifies the list of library cells whose instances are ignored for grouping.

-exclude_size_only_flops

Specifies that flip-flops having size_only attribute should be excluded from grouping.

-exclude_start_stop_scan_flops

Specifies that flip-flops containing start or stop pins of scan chains should be excluded from grouping.

-multibit_components_only

Optional switch to make the clustering process work only on pre-existing multibit components of the design. This allows the user to avoid banking cells that don't belong to multibit components, as well as to avoid banking cells of different multibit components together in the same multibit cell.

DESCRIPTION

The **identify_register_banks** command sets the strategy used to identify groups of registers that can be replaced by multibit registers and generates a register banking script file. This script can then be sourced back into the tool to replace single-bit registers with multibit registers.

FILE FORMATS

Format for specifying **-input_map_file**

You can specify the input map file sequence as shown:

```
bits { number_of_instances ref_multibit_flop } { ... }
```

Where **bits** specifies the number of single-bit registers in a group to be replaced, *number_of_instance* specifies the number of multibit registers to be used, and *ref_multibit_flop* specifies the reference multibit library cell to be used.

For example:

```
4 {1 MREG4}  
10 {2 MREG4} {1 MREG2}
```

4 {1 MREG4} specifies that a group of four single-bit registers can be replaced by one cell whose reference is MREG4.

Similarly, **10 {2 MREG4} {1 MREG2}** means a group of ten single-bit registers can be replaced using two instances of MREG4 and one instance of MREG2.

You can include a comment using the # character in the input map file. Lines beginning with the # character to the end of the line is treated as a comment.

Format for specifying **-register_group_file**

You can specify the register group file sequence as shown:

```
reg_group_name number{list_of_reference_of_single_bit_flops} {list_of_reference_of_multi_bit_flops}
```

Where *reg_group_name* specifies the name of the register group, *number* specifies the number of reference of single-bit registers

used for this register group, *list_of_reference_of_single_bit_flops* specifies the list of references of single-bit registers, and *list_of_reference_of_multibit_flops* specifies the list of references of multibit registers.

For example:

```
reg_group_1 3 {REGX1 REGX2 REGX4} {MREG2 MREG4}
reg_group_2 3 {REGNX1 REGNX2 REGNX4} {MREG2N MREG4N}
```

reg_group_1 3 {REGX1 REGX2 REGX4} {MREG2 MREG4} means that single-bit registers whose reference is either REGX1, REGX2, or REGX4 can be grouped together and replaced with a multibit bank whose reference is either MREG2 or MREG4.

Format for specifying -wns_threshold_file

You can specify the WNS threshold file sequence as shown:

name : *threshold_number*

Where *name* is either the name of a timing path group or the keyword **others**, and *threshold_number* is a floating-point number.

For example:

```
to_memory : 23.3
rsg_aclk : 15
others   : 10.0
```

In this example, 23.3% of the registers having the most negative setup slack in the timing path group **to_memory** are ignored for grouping. Similarly, 15% of registers in the timing path group **rsg_aclk** are ignored for grouping, and 10% of the registers for the rest of the timing path groups in the design are ignored for grouping.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **identify_register_banks** command to generate the register banking script:

```
prompt> identify_register_banks -input_map_file ./input.map -output_file ./create_bank.out
1
```

SEE ALSO

[create_register_bank\(2\)](#)
[split_register_bank\(2\)](#)

if

Conditional execution control structure.

SYNTAX

```
return_val if
```

ARGUMENTS

The **if** command has no arguments.

DESCRIPTION

The command conditionally executes commands based on the value of an evaluated expression. The format of the **if** command is similar to that in the C programming language.

The expression is evaluated upon execution. If the expression evaluates to a nonzero value, the **then** part of the command is executed. If the expression evaluates to zero, the optional **else** part of the command is executed. If **else** is not present, no commands execute.

The **if** command allows an **else-if** form. In this form, the condition expressions are evaluated in sequence, until one having a nonzero value is encountered. The *statement_block* corresponding to the nonzero condition executes; if none of the conditions evaluate to a nonzero value, the *else_statement_block* executes as expected.

The return value of the **if** command is the return value of the last statement executed. If no statements execute, the return value is 0.

The entire output of the **if** command can be redirected to a file. This file contains the output of any of the statements executed in the body of the **if** command. See the Tcl documentation for more information on file redirection.

If you use **else** in the **if** command, **else** must appear on the same line as the closing brace. If **else** is not on the same line as the closing brace, it is flagged as a syntax error.

EXAMPLES

The following example shows a simple use of the **if** command.

```
if {$x == 0} {  
    echo "Equal"  
} elseif {$x > 0} {  
    echo "Greater"  
} else {
```

```
    echo "Less"  
}
```

SEE ALSO

[continue\(2\)](#)
[while\(2\)](#)

import_ndm_block

Imports one or more IC Compiler II block abstracts as DCNXT block abstractions

SYNTAX

```
status import_ndm_block
  -blocks block_names
  [-output_dir ddc_cache_dir]
  [-setup_script library_setup_script]
```

ARGUMENTS

-blocks *block_names*

Specifies the block names with NDM library and label, for which the DCNXT block abstractions are to be generated. The input NDM libraries can be absolute path, relative path or from search_path. The format to specify block is:

NDM_library:block_name/label_name. label_name is optional. If specifying multiple blocks, they should be separated by " ".

-output_dir *ddc_cache_dir*

Specifies cache directory where the DCNXT block abstraction DDCs are saved.

-setup_script *library_setup_script*

Specifies the library setup script to be sourced for DCNXT block generation

DESCRIPTION

This command imports DCNXT **.ddc** format block abstractions for all the IC Compiler II abstracts specified in the **-blocks** argument. The command helps enable the hierarchical top-level synthesis using IC Compiler II NDMs.

At the top level, **set_top_implementation_options** command is used to specify the blocks that are integrated with the top-level design as block abstractions. Thus, it is required for each IC Compiler II blocks to be present in top level **set_top_implementation_options** command. Else, the command errors out.

When the command is executed, it imports the DCNXT block abstraction in **.ddc** format and loads them into the current DCNXT session.

In case of nested abstracts, only the top-level abstract needs to be imported via **import_ndm_block** command. There is no need to specify all the nested abstracts underneath using **-blocks**.

The command provides a caching mechanism so that the earlier imported DCNXT block abstractions can be re-used. The **import_ndm_block** command creates the DCNXT block abstraction for each IC Compiler II abstract and places them in the cache. The tool generates a unique checksum for the IC Compiler II block and corresponding DCNXT **.ddc** format abstraction, and creates a one-to-one mapping between them. If the IC Compiler II abstract NDM is not changed, tool can generate the block level **.ddc** format abstract name and pick them up from the cache directory.

The user cache directory can be specified using option **-output_dir**. If specified, the DCNXT .ddc format block abstractions will be created in that directory. If the option is not specified, the command will create a default cache directory **fc_to_dcnxt_abs** in the current working directory and generate the .ddc format DCNXT abstracts corresponding to each IC Compiler II block abstracts in the default cache directory. If the cache directory doesn't have write permission, the command will fail. The directories in **search_path** can also be specified as cache directories to pick up the DCNXT .ddc format block abstractions.

When the command is triggered, it first checks if the DCNXT .ddc format block abstractions corresponding to IC Compiler II abstracts are already present in the cache directory or not. If a .ddc format abstraction is found for a block, no DCNXT block abstraction is imported for the same and the cached abstractions are used to load abstraction design. This helps avoiding the block abstraction import every-time the command is run and saves runtime.

The tool builds the cache internally when the command is run. Thus, it's required to run the command even if the DCNXT .ddc format abstractions are already present in specified cache directory or default cache directory **fc_to_dcnxt_abs**.

The block level library setup can be specified using **-setup_script** option. If not specified, the top level **link_library** will be used at the block to link the DCNXT .ddc format abstraction. User needs to provide a complete set of **link_library** via **-setup_script** option or the top level **link_library app_var**. If the specified **link_library** set is incomplete, user needs to provide the complete set to resolve any linking issues.

The command does not support block abstractions with transparent interface optimization.

In Milkyway mode, the command fails if **set_icc2_options** command is not run before invoking it.

The command is available only in DCNXT topographical mode.

Multicorner-Multimode Support

This command uses information from all scenarios.

EXAMPLES

The following example shows how to import DCNXT .ddc format block abstraction:

```
prompt> create_lib -technology tech.tf -ref_libs std_ref.nlib design_nlib
prompt> set_top_implementation_options -block_references "mid"
prompt> set_icc2_options -ref $ref_ndm_files -tech $mw_tech_file
prompt> import_ndm_block -block "mid.nlib:mid" -output_dir ddc_cache
prompt> read_ddc top.ddc
prompt> link
```

The following example shows how to import DCNXT .ddc format block abstraction with the **-setup_script** option:

```
prompt> create_lib -technology tech.tf -ref_libs std_ref.nlib design_nlib
prompt> set_top_implementation_options -block_references "mid"
prompt> set_icc2_options -ref $ref_ndm_files -tech $mw_tech_file
prompt> import_ndm_block -block "mid.nlib:mid" -output_dir ddc_cache -setup_script library_setup.tcl
prompt> read_ddc top.ddc
prompt> link
```

SEE ALSO

[check_block_abstraction\(2\)](#)
[set_top_implementation_options\(2\)](#)

index_collection

Given a collection and an index into it, if the index is in range, create a new collection containing only the single object at the index in the base collection. The base collection remains unchanged.

Optionally, a second index can be passed which creates a new collection with the objects between the two indices in the base collection. Makes an implicit assumption that `index<=index2`

SYNTAX

```
collection index_collection
  collection1
  index
  index2
  [step]
```

Data Types

<i>collection1</i>	collection
<i>index</i>	index2
<i>index2</i>	index
<i>step</i>	int

ARGUMENTS

collection1

Specifies the collection to be searched.

index

Specifies the index into the collection.

The index is either a simple integer to specify the offset from the start of the collection or the string "end" optionally followed by a negative integer to specify the offset from the end of the collection.

For the start offset case the value must range from 0 to `sizeof_collection` - 1. For the end offset case the negative integer (if specified) must range from 0 to -(`sizeof_collection` - 1).

index2

Specifies an optional second index into the collection.

Specifies a second index to create a collection of a range of objects from the base collection, defined by the two indices [index, index2] (boundaries inclusive)

step

Specifies the step increment from index to index2. By default 1 is used.

DESCRIPTION

You can use the **index_collection** command to extract a single object from a collection. The result is a new collection containing only that object. The index operation is done in constant time - it is independent of the number of elements in the collection, or the specific index.

The range of indices is from 0 to one less than the size of the collection. If the specified index is outside that range, an error message is generated.

Commands that create a collection of objects do not impose a specific order on the collection, but they do generate the objects in the same, predictable order each time. Applications that support the sorting of collections allow you to impose a specific order on a collection.

You can use the empty string for the *collection1* argument. However, by definition, any index into the empty collection is invalid. Therefore, using the **index_collection** command with the empty collection always generates the empty collection as a result and generates an error message.

Note that not all collections can be indexed.

EXAMPLES

The following examples from PrimeTime use the **index_collection** command to extract the first, second, last and penultimate object of a collection.

```
prompt> set c1 [get_cells {u1 u2 u3}]
{u1 u2 u3}
prompt> query_objects [index_collection $c1 0]
{u1}
prompt> query_objects [index_collection $c1 1]
{u2}
prompt> query_objects [index_collection $c1 0 1]
{u1 u2}
prompt> query_objects [index_collection $c1 end]
{u3}
prompt> query_objects [index_collection $c1 end-1]
{u2}
prompt> query_objects [index_collection $c1 end-1 end]
{u2 u3}
```

SEE ALSO

[collections\(2\)](#)
[query_objects\(2\)](#)
[sizeof_collection\(2\)](#)

infer_switching_activity

Infers and sets the switching activity annotation on drivers of special pins of the current design.

SYNTAX

```
int infer_switching_activity
  [-apply]
  [-output file_name]
  [-nosplit]
  [-verbose]
  [-scenarios scenario_list]
  [-sci_based type]
```

Data Types

<i>file_name</i>	string
<i>scenario_list</i>	list

ARGUMENTS

-apply

Applies the proposed switching activity annotation on the drivers of special pins.

-output *file_name*

Writes the script to the specified file.

-nosplit

Prevents lines from being split when column fields overflow. Most of the information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the correct column.

-verbose

Displays the detailed special pin information.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only the current scenario is considered. Output of the command is generated separately for each scenario.

-sci_based *type*

Specifies whether to report or apply activity on any essential point based on the number of special control inputs it influences. The **type** specified can take one of the following three values: **sci**, **non_sci**, and **all**. If type is **sci**, the activity for any essential point is reported and applied based on the number of SCIs (Special Control Inputs) in its fanout. If there is no SCI in the fanout of an essential point, the tool does not report for the point. For the **non_sci** type, the default activity value is reported and applied on all essential points that do not have any SCIs in their fanout. If the type is **all**, the tool reports and applies all the essential points. If this option is not specified, the default behavior corresponds to **all**.

DESCRIPTION

This command is used to infer the switching activity for the drivers of special pins. These special pins include asynchronous set, asynchronous clear, synchronous set, and synchronous clear. The switching activity include simple toggle rate and static probability on the drivers of these pins.

For statistics on the switching activity annotation on the current design, use the **report_saif** or **report_activity** command.

Multicorner-Multimode Support

This command uses information from the current scenario only if **-scenarios** option is not specified.

EXAMPLES

The following **infer_switching_activity** command, issued after **compile_ultra**, displays the current and proposed switching activity annotation for the driver of a special pin.

```
prompt> infer_switching_activity
infer_switching_activity
Created by infer_switching_activity on Sun Mar 20 12:32:16 2011
```

Objects	Type	Current	Current	Proposed	Proposed
		Static	Toggle	Static	Toggle
rst	driver	None	None	1.0	0.0

1

The following **infer_switching_activity** command, issued after **compile_ultra**, displays the current and proposed switching activity annotation for the driver of a special pin. It also displays the special pin information.

```
prompt> infer_switching_activity -verbose
infer_switching_activity
Created by infer_switching_activity on Fri Jul 15 14:40:28 2011
```

report_power(2)
```

insert_buffer

Inserts buffer cells on specified nets or nets connected to specified ports or pins.

SYNTAX

```
collection insert_buffer
  [-new_net_names new_net_names]
  [-new_cell_names new_cell_names]
  [-no_of_cells number]
  [-inverter_pair]
  object_list
  buffer_lib_cell
```

Data Types

<i>new_net_names</i>	list
<i>new_cell_names</i>	list
<i>number</i>	integer
<i>object_list</i>	list
<i>buffer_lib_cell</i>	collection

ARGUMENTS

-new_net_names *new_net_names*

Specifies the names of the new nets created by buffer insertion. You should specify one net name per buffer, or two net names per inverter pair when inserting inverter pairs. You can optionally specify only a single common base name; the tool generates new net names by adding unique numeric suffixes to this base name.

The specified names can be any valid net names, but must be leaf (not hierarchical) names and cannot contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance. If the specified net name already exists, the command adds a suffix of "_%d" or "%d_%d" to the net name.

By default, the command uses the base name eco_net.

-new_cell_names *new_cell_names*

Specifies the names of the new buffer cells inserted. You should specify one cell name per buffer, or two cell names per inverter pair when inserting inverter pairs. You can optionally specify only a single common base name; the tool generates new cell names by adding unique numeric suffixes to this base name.

The specified names can be any valid cell names, but must be leaf (not hierarchical) names and cannot contain embedded hierarchical separators. They must be unique in the current context, as specified by the current instance. If the specified cell name already exists, the command adds a suffix of "_%d" or "%d_%d" to the cell name.

By default, the command uses the common base name eco_cell.

-no_of_cells *number*

Specifies the number of buffer cells or inverter pairs to be inserted per net. The inserted repeaters are connected back-to-back in series. By default, the command inserts a single buffer cell or inverter pair per net.

-inverter_pair

Inserts inverter pairs instead of buffer cells. If you use this option, you need to also specify a library cell that has an inverting output, using the *buffer_lib_cell* option.

object_list

Specifies a list of nets, pins, or ports to be buffered. The new buffers or inverter pairs are placed in the specified net or in the net connected to the specified pins or ports, close to pin or port.

If you specify a net, the inserted buffer is the new load of the specified existing net.

If you specify pins, the tool groups all of the specified pins based on the nets to which they are connected. When the grouped pins are load pins, the tool inserts the buffers so that the new buffer cells can drive them. When the grouped pins are driver pins, the tool connects the new buffer cells so that they become the load of the specified driver pin.

buffer_lib_cell

Specifies the library cell object to be used as a buffer or inverter. Specify the object as either a named library cell or a library cell collection. If the library cell is a buffer cell, the number of instances inserted is equal to the number specified by the **-no_of_cells** option. If the library cell is an inverter, the cells are inserted as pairs, so the number of instances inserted is twice the number specified by the **-no_of_cells** option.

If the library cell has both inverting and noninverting outputs (that is, it can act as both a buffer and inverter), the **-inverter_pair** option controls which output is used. If the library cell has multiple outputs of the same type, the command uses the first noninverting or inverting output found.

DESCRIPTION

This command adds buffers or inverter pairs at one or more specified nets, pins, or ports. A library cell with a single input and one or more outputs can be used as the buffer or inverter, as long as each output has the same or inverted logic function of the input.

Like all other netlist editing commands, all of the **insert_buffer** command's arguments must be valid to have a successful command run. If any specified argument is invalid, the netlist remains unchanged. If the command succeeds, the result is a collection of the newly inserted cells. If the command fails, the result is an empty collection or an empty string.

By default, each newly created cell has a name beginning with the *eco_cell* string and ending with a unique numeric suffix. Each newly created net has a name beginning with the *eco_net* string and ending with a unique numeric suffix. To override the default name strings, use the **-new_net_names** and **-new_cell_names** options.

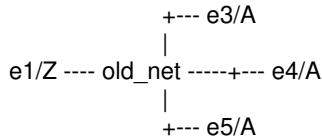

You can mimic buffer insertion by using other commands such as **create_cell**, **create_net**, **disconnect_net**, and **connect_net**. The **insert_buffer** command provides a more efficient and reliable way to insert buffers.

The **insert_buffer** command uses the following basic rules to check its arguments for validity:

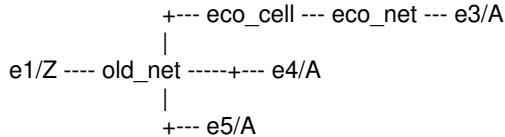

- The pin or port must be in the current scope (at or below the current instance).
For a description of special scoping rules, see the "Buffering Inside Boundary Pins" section.
- The pin or port must be connected to a net.
- Bidirectional pins cannot be buffered.
- The net cannot be a PG net or a tie net.
- The specified library cell cannot be a sequential device.
- The specified library cell must be a buffer or inverter, as previously defined.
- The library cell must have an inverting output when you use the **-inverter_pair** option.
The command uses the first inverting output and inserts two cells so that it preserves the logic sense of the path.
- The *number* argument of the **-no_of_cells** option must be a positive, nonzero integer.

Inserting and Connecting the New Buffer

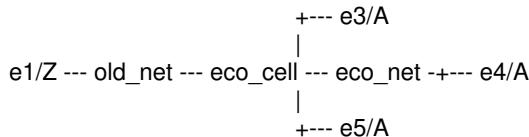

The following figure shows a network example that is used to describe the rules used by the **insert_buffer** command to connect the new buffer or inverter pair.

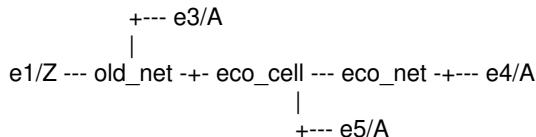

If the specified pin is a load, the load first is disconnected from its old net and then connected to the new net, as shown in the following figure:

If the specified pin is a driver, all loads on that net are disconnected from the old net and are connected to the new net, as shown in the following figure:

If you specify a list of load pins on the same net, these load pins are grouped and the new net drives them, as shown in the following figure:

The command cannot buffer a multidriver net.

Buffering Inside Boundary Pins

When you specify the insertion of a buffer at a pin on the boundary of a hierarchical block, the **insert_buffer** command inserts the buffer either inside or outside the hierarchical block, depending on the current hierarchical scope. To insert the buffer inside the hierarchical block, set the scope to that block by using the **current_instance** command, and then run the **insert_buffer** command. The tool inserts the buffer within the block to which the **current_instance** is set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies a library cell that is not a buffer. The command fails and generates an error message.

```

prompt> insert_buffer e1/Z class/AN2P
Information: Buffering net old_net. (HFS-701)
Error: library cell 'AN2P' is not a buffer or an inverter. (NLE-010)

```

The following example specifies a buffer for the library cell:

```

prompt> insert_buffer e1/Z class/B1I
Information: Buffering net old_net. (HFS-701)
Creating net 'eco_net' in design 'top'.
Creating cell 'eco_cell' in design 'top'.
Disconnecting net 'old_net' from pin 'e3/A'.
Disconnecting net 'old_net' from pin 'e4/A'.
Disconnecting net 'old_net' from pin 'e5/A'.
Connecting net 'eco_net' to pin 'e3/A'.
Connecting net 'eco_net' to pin 'e4/A'.
Connecting net 'eco_net' to pin 'e5/A'.
Connecting net 'eco_net' to pin 'eco_cell/Z'.
Connecting net 'old_net' to pin 'eco_cell/I'.
{eco_cell}

```

The following example specifies an inverter for the library cell. The command succeeds and creates the new cells named *eco_cell* and *eco_cell_1*. The new nets are named *eco_net* and *eco_net_1*.

```

prompt> insert_buffer e3/A class/IV
Information: Buffering net old_net. (HFS-701)
Creating net 'eco_net' in design 'top'.
Creating net 'eco_net_1' in design 'top'.
Creating cell 'eco_cell' in design 'top'.
Creating cell 'eco_cell_1' in design 'top'.
Disconnecting net 'old_net' from pin 'e3/A'.
Connecting net 'eco_net' to pin 'e3/A'.
Connecting net 'eco_net' to pin 'eco_cell/Z'.
Connecting net 'eco_net_1' to pin 'eco_cell/A'.
Connecting net 'eco_net_1' to pin 'eco_cell_1/Z'.
Connecting net 'old_net' to pin 'eco_cell_1/A'.
{eco_cell eco_cell_1}

```

```

prompt> report_cell -connections e3
*****
Report : cell
         -connections
*****

```

Connections for cell 'e3':

Reference:	B1I
Library:	class

Input Pins	Net
A	eco_net

Output Pins	Net
Z	out2

insert_clock_gating

Performs clock gating on an appropriately-prepared GTECH netlist.

SYNTAX

```
status insert_clock_gating
  [-regular_only]
  [-global]
  [-no_hier]
```

ARGUMENTS

-regular_only

Disables enhanced clock gating during register-based clock gate insertion.

-global

Performs hierarchical clock gating on all subdesigns as one global step.

-no_hier

Limits clock gating to the top level of the current design.

DESCRIPTION

This command performs clock gating on an appropriately-prepared GTECH netlist. To insert or optimize clock gating on a mapped netlist, use the **compile** or **compile_ultra** command with the **-gate_clock** option. You can optionally use the **set_clock_gating_style** command beforehand to specify the structure of the clock-gating circuitry to be inserted. If no style is explicitly set, a default clock-gating style is applied. See the **set_clock_gating_style** command man page for more details on the default clock-gating style.

To control the names of modules, cells and gated clock nets created by this command, you can set different naming style variables listed at the end.

In addition to standard bank clock gating, the **insert_clock_gating** command searches for more clock gating opportunities by combining different register banks that share common enable conditions. This type of enhanced clock gating can result in extra clock-gating cells and/or gated registers.

The **insert_clock_gating** command performs clock gating at all levels of hierarchy in the design. By using the **-no_hier** option, the clock gating is limited to only the top level. If you want to perform clock gating on some, but not all, levels of hierarchy, the other levels can be excluded by setting **dont_touch** attributes on those designs or instances.

When the **-no_hier** option is omitted, clock gating is performed on all subdesigns. Every subdesign is processed independently. With the **-global** option, the design and its subdesigns are processed in one single global step. The advantage of the one-step hierarchical clock gating is twofold. First, the subdesigns are analyzed in their context, which is similar to boundary optimization during **compile** command. Second, the clock gates can be inserted at higher levels in the design, allowing for sharing of registers among different subdesigns. When a clock gate is inserted in a different hierarchical level than the registers that are being gated, new ports will be

added to connect the gated clock and enable nets.

Important: when using the **-global** option, the operation is no longer context independent. The functionality of the subdesigns instantiated in the design can be modified in context of the current design. The functionality of the top level (current_design) is preserved. However, when certain subdesigns are also instantiated elsewhere (in a design different from the current design), the functionality of those designs can change. Therefore, it is not recommended to change the current design to that of a lower level and then run **insert_clock_gating -global**. If you choose to do so, you must uniquify the original design before changing the current design and running the **insert_clock_gating -global** command on a subdesign to guarantee that the functionality of the original design is not altered.

During test (scan shifting), the clock gate has to be surpassed so that each clock pulse is passed onto the register. This is facilitated with a control-point insertion. See the **set_clock_gating_style** man page for details. If the clock gates have control points, all of them must be hooked up correctly to the top level test_mode or scan_enable pins using the **insert_dft** command.

EXAMPLES

The commands in the following example show the typical flow for using the **insert_clock_gating** command. After reading or elaborating the design and defining the clock ports, you set the clock-gating style to specify how to perform clock gating. The **insert_clock_gating** command inserts clock gating for the registers.

```
prompt> read_verilog design.v
prompt> current_design top
prompt> link
prompt> set_clock_gating_style -sequential latch
prompt> create_clock clk
prompt> insert_clock_gating
prompt> propagate_constraints -gate_clock
prompt> compile
```

The following example specifies using an integrated cell for the clock-gating circuitry. The **target_library** environment variable also contains the name of the library that contains the integrated cell. This example results in a mapped netlist that has integrated clock-gating cells.

```
prompt> set_clock_gating_style -sequential latch \
          -pos integrated -neg integrated -control_point before
prompt> set target_library {$target_library integrated_cell_library.db}
prompt> read_verilog design.v
prompt> current_design top
prompt> link
prompt> insert_clock_gating
prompt> uniquify
prompt> propagate_constraints -gate_clock
prompt> compile
```

insert_dft

Inserts DFT logic in the current design.

SYNTAX

status **insert_dft**

ARGUMENTS

The **insert_dft** command has no arguments.

DESCRIPTION

This command inserts DFT logic in the current design. The following types of DFT logic are supported:

- Standard scan chains
- Compressed scan chains with scan compression codec logic
- Clock-gating cell test pin connections
- AutoFix logic
- Test points
- On-chip clock (OCC) controller blocks
- Core wrappers
- ANSI/IEEE Std 1149.1/1149.6-compliant boundary-scan logic

By default, **insert_dft** performs standard scan chain insertion and routing. To insert compressed scan, boundary scan, or other types of DFT logic, use the applicable DFT configuration commands for that DFT logic type before running **insert_dft**.

The **insert_dft** command is supported with multicorner-multimode (MCMM) technology, which is available with Design Compiler Graphical.

Use the **set_dft_location** command to specify an alternate user-defined location for one or more types of DFT logic. For more information, see the man page.

Scan Synthesis Description

Scan cells and DFT logic cells are chosen from the technology library specified in the **target_library** variable. You must define a target library before issuing the **insert_dft** command.

The **insert_dft** command supports top-down, bottom-up, and middle-out scan insertion methodologies. In the process of adding

DFT logic, testable versions of the subdesigns and top-level design are created. For testable subdesigns, new designs are created in the database that are distinct from the original subdesigns. The new subdesigns are named according to the value of the **insert_test_design_naming_style** variable. Note that the name of the current design is not changed during the **insert_dft** execution.

If existing test ports have been identified with the **set_dft_signal**, **insert_dft** will make connections to these ports.

If test ports have not been identified, new ports are added to the design as needed. The new ports are named according to the following variables:

```
test_mode_port_naming_style  
test_mode_port_inverted_naming_style  
test_clock_port_naming_style  
test_scan_clock_a_port_naming_style  
test_scan_clock_b_port_naming_style  
test_scan_clock_port_naming_style  
test_scan_enable_inverted_port_naming_style  
test_scan_enable_port_naming_style  
test_scan_in_port_naming_style  
test_scan_out_port_naming_style
```

These variables are described in their respective man pages.

The DFT insertion process performed by the **insert_dft** command works as described below.

First, existing logic is marked so scan insertion can detect whether a particular piece of logic has been added.

If test DRC results from a previous **dft_drc** command are not available, **insert_dft** invokes test DRC for the specified scan style. DRC generates the clock information that scan insertion retrieves. DRC also marks violating cells that cannot belong to scan chains.

Next, **insert_dft** architects scan chains into the design. The **insert_dft** command applies a scan-equivalence process to nonscan cells that passed DRC. Scan equivalents are initially selected based on library function identifiers. If no scan equivalent for a sequential cell is found using this behavior, **insert_dft** uses constraint-based sequential mapping techniques. These techniques consider the logic function implemented by each flip-flop instance to be scan replaced, along with immediately surrounding logic. This consideration generates a set of possible alternatives, from which the best replacement is selected based on **scan_style**, design rule considerations (for example, **connection_class** and **max_fanout**), and design area.

Use the **preview_dft** command to view the proposed architecture without inserting it. By default, **insert_dft** constructs as many scan chains as there are clocks and edges. By setting the **-clock_mixing** option of **set_scan_configuration**, the number of scan chains created based on clocks can be controlled. Set the **-clock_mixing** option to **no_mix**, **mix_edges**, or **mix_clocks**. If you want **insert_dft** to build more than the minimal scan chain count, set the **-chain_count** option of **set_scan_configuration** command. Multiple scan chains are also constructed to reflect the assignment of scan cells to scan chains by using the **set_scan_path** command.

When **insert_dft** constructs multiple scan chains, scan cells are allocated to scan chains based on the following criteria:

- The **set_scan_path** command
- Clock signals in the design
- Subdesign scan chains
- Design hierarchy
- Names of individual scan cells.

Scan cells are ordered on scan chains based on the following criteria:

- The **set_scan_path** command position
- Scan
- Clock trigger times
- Scan clock domains

- Scan cell names

The **insert_dft** command overrides the **set_scan_path** command positions to ensure functional chains if **set_scan_path** is not inserting lock-up latches.

Next, the **insert_dft** command makes any needed clock-gating cell test pin connections. These test pin connections place the clock-gating cells into a bypass mode when the test pin is asserted. For information on the available controls for these test pin connections, see the man pages for the **set_dft_clock_gating_configuration** and **set_dft_clock_gating_pin** commands.

insert_dft ensures that the internal three-state buses, which are on-chip buses not driven by pad cells, are disabled during scan shift. It also ensures that bidirectional ports are properly configured during scan shift. You can force the **insert_dft** command to disregard these steps by using the **-fix_bus_disable** or **-fix_bidirectional_disable** options of the **set_dft_configuration** command.

The **insert_dft** command avoids adding unnecessary logic by ignoring buses that already have exactly one active driver during scan shift, and bidirectional ports that are properly configured for scan shift. It takes into account any constant signals that have been applied with the **set_dft_signal -view existing_dft -type Constant** command.

Having identified candidate buses, **insert_dft** identifies the disabling logic required. The command iterates through all three-state bus drivers and computes the logic values that must be applied to input pins to disable the bus. It does not succeed in the following situations, when:

- A bus driver belongs to a design that has a **dont_touch** attribute.
- Any of the three-state drivers cannot be disabled.
- Conflicting logic values are required to disable three-state drivers.
- Disabling values conflict with those of previous buses.

The **insert_dft** command then adds generic disabling logic where necessary. It finds and gates all pins that do not hold the values they require during scan shift.

The command processes all bidirectional ports. It discards the following:

- Ports used to apply scan enable signals to the design
- Degenerated bidirectional ports that are configured as inputs or outputs by constant logic values
- Ports that do not have exactly 1 three-state driver that is not in a **dont_touch** design

The **insert_dft** command establishes the direction to which bidirectional ports must be configured during scan shift. Scan outputs are turned outwards, and other scan signals are turned inwards. By default, all other bidirectional ports are turned inwards. To turn bidirectional ports outwards, use the **set_ autofix_element** command with the **-type external_bus** and **-method output** options.

The **insert_dft** command computes the logic values that must be applied to the driver input pins to configure each port. It fails if required logic values conflict with previous logic values. The command then adds generic configuration logic where necessary. It finds all pins that do not hold the required values during scan shift, and inserts appropriate test mode logic.

Having disabled three-state buses and configured bidirectional ports, **insert_dft** builds the scan chains if the **set_scan_configuration** command has not been previously specified with the **-route false** option. For each chain, **insert_dft** determines the scan-in pin. It first looks for **ScanDataIn** signals specified by using the **set_dft_signal** commands. It then looks for design ports with **ScanDataIn signal_type** attributes. If it finds no such ports, it creates a dedicated scan-in port for the chain.

Having identified the scan-in pin, **insert_dft** jumps over the connected pad if it is not in a **dont_touch** design. It first tries finding a true or inverting path through the pad that is sensitized by test hold, scan enable, and bidirectional control signals, and does not need any additional disabling. If not successful, it gets the vector required to enable a path through the pad and the resulting hookup pin. It finds all pins that do not hold the necessary values during scan shift and inserts appropriate test mode logic. Note that **insert_dft** does not have to add three-state disabling logic to ensure that the pad is in input mode because this was performed during a previous step.

The **insert_dft** command then jumps through input buffers. Starting at the load pin, it jumps over single-fanout inverters and buffers to find a better hookup pin. The scan sense is toggled as this process jumps over inverters.

Given the best hookup pin, scan insertion builds the rest of the chain. The preferred routing order, specified by using the **set_scan_path** command, is used to route between serial signals and scan cells. If no preferred order is specified, it uses a default ordering scheme.

If the **set_scan_configuration** command has not been previously executed with the **-add_lockup false** option, the **insert_dft** command inserts lock-up latches at clock-domain boundaries. This compensates for clock skew and ensures a glitch-free scan shift. You can specify to **insert_dft** to add lock-up latches at the end of chain by using the **set_scan_configuration** command with **-insert_terminal_lockup**.

The **insert_dft** command can reuse functionally-connected **ScanDataIn** ports or pins for scan chain routing. It does not recognize a pin as functionally connected if the following conditions are true:

- The pin is not connected to a net.
- The pin has been created by **insert_dft**.
- The pin is a driver and does not have a load, or the pin is connected to a subdesign output port that **insert_dft** created.
- The pin is a load and does not have a driver, or the pin is connected to a subdesign input port that **insert_dft** created.

The **insert_dft** command does not touch optional methodology signal pins that are functionally connected. It reconnects mandatory methodology signal pins that are functionally connected. A warning message appears in this case.

The **insert_dft** command selects the scan-out driver for each cell by using the following criteria:

- It identifies the scan-out signal by looking at **signal_type** attributes. If pins with both **ScanDataIn** and **ScanDataIn** with inverted attributes are present, it chooses the noninverted pin, unless the other has a routing position.
- It considers all of the equal and opposite output pins (such as Q and QN) on the final scan cell in the chain, and chooses the output pin with the most slack. If equal, it chooses the driver with greatest drive strength.

You can set the **test_disable_find_best_scan_out** environment variable to **true** to disable this behavior.

To finish construction, **insert_dft** locates the scan-out port for the chain. If a scan-out port has not been previously specified with the **set_dft_signal** command, **insert_dft** creates a new one. If an existing scan-out port is found, **insert_dft** analyzes it to avoid inserting redundant multiplexing logic. It first establishes whether there is already a signal path between the last scan-out pin and the scan-out port when scan enable, test hold, and bidirectional control conditions are asserted. If the scan out port is connected to a three-state driver or a pad, it uses the reverse of the method described earlier for input ports to jump back through three-state drivers, pads, buffers, or inverters to a hookup pin. If the this pin is already functionally connected, **insert_dft** adds multiplexing logic and connects the selected output pin of the chain's last scan cell to the multiplexer input. If the scan-out net connects to some other existing port, **insert_dft** isolates the scan-out port connection by making the connection with a buffer. The reason for this port isolation is because some downstream tools cannot handle nets that fanout to multiple ports.

Finally, **insert_dft** routes global signals (including any scan enable and test clock signals) and performs a default technology mapping for all new generic logic (including disabling logic and multiplexers). It introduces dedicated test clock signals for the **clocked_scan**, **lssd**, and **scan_enabled_lssd** scan styles.

When **set_dft_configuration -scan disable -clock_gating enable** has been previously specified, **insert_dft** performs only clock-gating cell routing. In this case, the **create_test_protocol** command should be run after **insert_dft** to update the CTL model with the correct ScanEnable or TestMode signal assertions.

Typically, at this point, the **insert_dft** command has violated compile design rules and constraints. If the **set_dft_insertion_configuration -synthesis_optimization none** command has been previously issued, or if Design Compiler topographical mode is used, optimization is skipped and the initial mapping is retained. Otherwise, **insert_dft** optimizes the design according to the setting of the **-map_effort** option of the **set_dft_insertion_configuration** command. For more information, see the **set_dft_insertion_configuration** man page. Note that **insert_dft** does not optimize the ScanEnable net to meet timing constraints.

In Design Compiler topographical mode, you should follow DFT insertion with an incremental topographical compile.

At this point, some cleanup is necessary. The **insert_dft** command resolves connection class violations, replaces and merges logic constants, then unifies the design. This is because you might want to write out subdesigns that **insert_dft** has modified as instances of new designs. In some cases, where test modifies instances of the same design differently, **insert_dft** produces more than one new design. It uses a technique called selective unification to produce new designs only when necessary. This technique generates a canonical netlist ID that does not depend on net-names or cell-names. The canonical netlist ID works only on gate-type, net connections, and port-names.

In the case of a non-unified hierarchical design, forced unification is performed to record the changes to the design. This is because you might want to write out subdesigns that **insert_dft** has modified as instances of new designs. In some cases, where test modifies instances of the same design differently, **insert_dft** produces more than one new design. You might want **insert_dft** to do this only when necessary.

The **insert_dft** command only considers **dont_touch** attributes for basic initial scan replacement of nonscan cells, such as those that would occur if a test-ready compile was not used. They are ignored for scan stitching, test signal routing, logic insertion, and identified shift register splitting (which scan-replaces the new head flip-flop). To control the scope of DFT insertion, use test-specific directives such as **set_scan_element false** or **set_scan_configuration -exclude_elements**.

BSD Synthesis Description

The **insert_dft** command synthesizes ANSI/IEEE Std 1149.1/1149.6-compliant boundary-scan logic using DesignWare macro cells when you specify the **-bsd enable** option of the **set_dft_configuration** command.

Synthesis is done at the gate level. The newly-synthesized BSD logic is mapped to the target library. The BSR cells added during BSD insertion are not unqualified. You must run the **uniquify** command after BSD insertion if you need a unqualified design. The **insert_dft** command can use a design with or without core logic, but pad cells must be present on the top-level design ports.

All JTAG test access ports (TAPs) must be specified. If you omit the JTRST signal using the **set_bsd_configuration -asynchronous_reset false** command, you must specify the remaining four mandatory ports. otherwise, you must specify all five ports.

Depending on the instructions you selected to implement with the **set_bsd_instruction** command, by default the instruction register (IR) is synthesized with the minimum number of bits to accommodate the set of instructions. However, you can enforce one-hot encoding of the instruction register by using **set_bsd_configuration -instruction_encoding one_hot**. The **insert_dft** command synthesizes BSR cells using DesignWare BC_1 on all the design output ports except on bidirectional ports, where a BC_7 is synthesized. On all input ports and for all control points, BC_2 BSR cells are synthesized. If you set system clocks, a BC_4 is synthesized on these design ports. If you used some design ports other than the actual controlling ports to control the pads' controlling logic (for example, an extra controlling port to disable all three-state outputs together), logic is synthesized to allow the actual controlling signal to do the controlling during the boundary-scan testing. This removes the need for subsequently setting the extra controlling ports as compliance-enable ports.

It is not possible to synthesize boundary scan logic without pads. If the design does not have pads, the command terminates.

Error messages can result from missing TAP ports, missing pad cells or missing pad cell functionality in the library. A message is printed indicating an inability to proceed, and the command exits.

By default, synthesis of boundary scan logic is done in compliance with the IEEE1149.1-2001 standard. You can switch back to the IEEE1149.1-1993 standard by setting the **-std {ieee1149.1_1993}** option of the **set_bsd_configuration** command. To implement the IEEE1149.6-2003 standard, specify the **-std {ieee1149.6_2003}** option of the **set_bsd_configuration** command.

By default, synthesis of boundary scan logic is done using the new DesignWare tap, DW_tap_uc. To use the old DesignWare tap, DW_tap, instead, set the **bsd_use_old_tap** variable to true.

To use user-defined BSR/TAP designs in BSD synthesis, use the **define_dft_design** command to specify the user-defined designs.

For more details on the IEEE Std 1149.1/1149.6 rules, see the *IEEE Std Test Access Port and Boundary-Scan Architecture*.

EXAMPLES

The following example shows the usage syntax for the **insert_dft** command on the design **WC66** without fixing constraint violations and compile design rules:

```
prompt> current_design WC66
prompt> insert_dft
```

The following command performs synthesis of boundary-scan logic in compliance with ANSI/IEEE Std 1149.1 on the current design, and illustrates the types of messages that are output:

```
prompt> current_design M1
prompt> set_dft_configuration -scan disable -bsd enable
prompt> set_dft_signal -type tdi -port my_tdi
prompt> set_dft_signal -type tck -port my_tck
```

```
prompt> set_dft_signal -type tms -port my_tms
prompt> set_dft_signal -type trst -port my_trst
prompt> set_dft_signal -type tdo -port my_tdo
prompt> create_clock -p 10 my_system_clock
prompt> insert_dft
```

set_scan_configuration(2)
```

insert_isolation_cell

Inserts isolation cells on the specified nets, pins or ports. Isolation cell is a general term that applies to isolation cells and enabled level-shifter cells.

SYNTAX

```
status insert_isolation_cell
  [-force]
  [-verbose]
  -enable enable_signal
  -object_list objects
  -reference lib_cell_name
```

Data Types

<i>enable_signal</i>	collection
<i>objects</i>	collection
<i>lib_cell_name</i>	string

ARGUMENTS

-force

Forces insertion of isolation cells on nets with the **dont_touch** or **always_on** attributes.

-verbose

Provides a detailed report on the isolation cells inserted in the design.

-enable *enable_signal*

Specifies the signal in the design to be connected to the enable pin of the inserted isolation cells. You can specify this signal as either a net, a pin, or a port.

This option is required.

-object_list *objects*

Specifies a list of pins, ports, or nets on which to insert the isolation cells. If you specify object names, the tool resolves conflicts in the order of ports, pins and nets.

This option is required.

-reference *lib_cell_name*

Specifies the name of the library cell of the isolation cell. This can be either an isolation cell or an enabled level-shifter cell.

This option is required.

DESCRIPTION

The **insert_isolation_cell** command inserts isolation cells on the netlist objects specified in the **-object_list** option. It connects the enable pin of each inserted cell to the enable signal specified in the **-enable** option. The tool determines the set of possible reference cells for the isolation or enabled level-shifter cells by searching the link libraries for cells matching the name specified in the **-reference** option.

The tool selects the reference cell for each netlist object by using the following strategy:

- If the driver and all loads of the associated net operate at the same voltage, the tool selects an isolation cell that matches the operating condition of the subdesign in which the net resides. If such an isolation cell is not found, but an appropriate enabled level-shifter cell is found, the tool selects the enabled level-shifter cell.
- If the driver and loads of the associated net operate at different voltages (a multivoltage net), the tool selects the first enabled level-shifter cell that implements voltage-level shifting. Isolation cells are not used for multivoltage nets.

The tool determines where to put each isolation or enabled level-shifter cell based on the type of the netlist object:

- If you specify a subdesign port, the tool inserts the isolation or enabled level-shifter cell on the net connection inside the subdesign, next to the specified port. When you specify a driver port, the isolation or enabled level-shifter cell connects to all paths driven by the port. When you specify a load port, the isolation or enabled level-shifter cell connects only to the path ending at the load port.

To specify subdesign ports, use the **get_ports** command.

- If you specify a subdesign pin, the tool inserts the isolation or enabled level-shifter cell on the net connection outside the subdesign, next to the specified pin. When you specify a driver pin, the isolation or enabled level-shifter cell connects to all paths driven by the pin. When you specify a load pin, the isolation or enabled level_shifter cell connects only to the path ending at the load pin.

To specify subdesign pins, use the **get_pins** command.

- If you specify a net, the tool inserts the isolation or enabled level-shifter cell in net's parent subdesign.

To specify a net, use the **get_nets** command.

By default, the tool uses the <power_domain_name>_ISO_<count> naming rule to generate names for isolation cells. Each isolation cell inside its own domain gets a unique count. You can add a prefix string to the automatically-generated name by specifying a value for the **isolation_cell_naming_prefix** variable.

In the following situations, the command does not insert an isolation or enabled level-shifter cell on the associated net and flags the net as a violating net:

- The tool cannot find an appropriate library cell for the net.
- The net has multiple drivers.
- The net is connected to a bidirectional pin.
- The net has a **dont_touch** or **always_on** attribute. You can use the **-force** option to force the insertion of isolation cells on such nets. However, do not use this option when the operating conditions of the isolation cell and the subdesign do not match.

Note that this command is supported only on unqualified designs and designs with power domains.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example inserts a GTECH isolation cell on the *IN* net inside the *I1* hierarchical instance. The enable pin of the isolation cell is wired to the *ENABLE* port of the design.

```
prompt> insert_isolation_cell -reference GTECH_ISO1_EN0 \
    -object [get_nets {I1/IN}] \
    -enable [get_ports ENABLE]
```

The following example inserts a GTECH isolation cell on the net connected to port *A* of instance *I1*. Because a port is specified, the isolation cell is inserted inside the *I1* block.

```
prompt> insert_isolation_cell -reference GTECH_ISO1_EN0 \
    -object [get_ports {I1/A}] \
    -enable [get_ports ENABLE]
```

The following example inserts a GTECH isolation cell on the net connected to pin *A* of instance *I1*. Because a pin is specified, the isolation cell is inserted outside the *I1* block.

```
prompt> insert_isolation_cell -reference GTECH_ISO1_EN0 \
    -object [get_pins {I1/A}] \
    -enable [get_ports ENABLE]
```

The following example inserts an enabled level shifter on the RET net. The enable pin of the enabled level shifter is wired to the *en* net inside the *PWRCTRL* hierarchical instance.

```
prompt> insert_isolation_cell -reference LVLHLEHX2 \
    -object [get_nets RET] \
    -enable [get_nets PWRCTRL/en]
```

insert_mv_cells

Inserts isolation and level-shifter cells to the design.

SYNTAX

```
status insert_mv_cells
  [-isolation]
  [-level_shifter]
  [-all]
  [-verbose]
```

ARGUMENTS

-isolation

Inserts isolation cells.

-level_shifter

Inserts level-shifter cells.

-all

Inserts both isolation and level-shifter cells. This is the default behavior.

-verbose

Inserts the isolation cells in verbose mode. It does not affect the actual insertion but this option might give additional information if level-shifters were not inserted. It does not provide any additional information regarding isolation-cell insertion.

DESCRIPTION

This command inserts isolation cells and level-shifter cells as specified by the UPF specification. It allows these cells to be inserted without having to run a full optimization on the design using the **compile_ultra** command. The result might not be identical to that of automatic insertion of these cells during the **compile_ultra** activity. This difference is due to additional optimizations done to the design during **compile_ultra** activity, before the insertion of isolation and level-shifter cells. All UPF strategies are applied for isolation and level-shifter cells. It is not possible to select specific strategies. If there are repeater supply attributes on the domain boundaries, repeaters are inserted before the insertion of other power management cells.

EXAMPLES

The following example uses the **insert_mv_cells** command:

prompt> **insert_mv_cells**

SEE ALSO

set_isolation(2)
set_isolation_control(2)
set_level_shifter(2)
set_port_attributes(2)

is_false

Tests the value of a specified variable, and returns 1 if the value is 0 or the case-insensitive string **false**; returns 0 if the value is 1 or the case-insensitive string **true**.

SYNTAX

status **is_false**
 value

Data Types

value string

ARGUMENTS

value

Specifies the name of the variable whose value is to be tested.

DESCRIPTION

This command tests the value of a specified variable, and returns 1 if the value is either 0 or the case-insensitive string **false**. The command returns 0 if the value is either 1 or the case-insensitive string **true**. Any value other than 1, 0, **true**, or **false** generates a Tcl error message.

The **is_false** command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings **true** or **false**. When such variables are set to **true** or **false**, they cannot be tested in the negative in an **if** statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x FALSE
if { !$x } {
    set y TRUE
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!=". So, although you can test the positive condition, **is_false** allows you to test both conditions safely.

EXAMPLES

The following example shows the use of the **is_false** command:

```
prompt> set x TRUE
TRUE

prompt> if { ![is_false $x] } {
?     set y TRUE
?
}
TRUE

prompt>
```

SEE ALSO

[expr\(2\)](#)
[if\(2\)](#)
[is_true\(2\)](#)

is_true

Tests the value of a specified variable, and returns 1 if the value is 1 or the case-insensitive string **true**; returns 0 if the value is 0 or the case-insensitive string **false**.

SYNTAX

```
status is_true  
      value
```

Data Types

value string

ARGUMENTS

value

Specifies the name of the variable whose value is to be tested.

DESCRIPTION

This command tests the value of a specified variable, and returns 1 if the value is either 1 or the case-insensitive string **true**. The command returns 0 if the value is either 0 or the case-insensitive string **false**. Any value other than 1, 0, **true**, or **false** generates a Tcl error message.

The **is_true** command is used in writing scripts that test Boolean variables that can be set to 1, 0, or the case-insensitive strings **true** or **false**. When such variables are set to **true** or **false**, they cannot be tested in the negative in an **if** statement by simple variable substitution, because they do not constitute a true or false condition. The following example is not legal Tcl:

```
set x TRUE  
if { !$x } {  
    set y FALSE  
}
```

This results in a Tcl error message, indicating that you cannot use a non-numeric string as the operand of "!=". So, although you can test the positive condition, **is_true** allows you to test both conditions safely.

EXAMPLES

The following example shows the use of the **is_true** command:

```
prompt> set x FALSE
FALSE

prompt> if { ![is_true $x] } {
?     set y FALSE
? }

FALSE

prompt>
```

lib2saif

Creates a forward-annotation SAIF file for a specified technology library.

SYNTAX

```
status lib2saif
  [-output file_name]
  library
  [-lib_pathname lib_path_name]
```

Data Types

<i>file_name</i>	string
<i>library</i>	list
<i>lib_path_name</i>	list

ARGUMENTS

-output *file_name*

Specifies the name of the library forward-annotation SAIF file created by **lib2saif**. The default file name is the value of the **power_sdpd_saif_file** variable. By default, the value of the **power_sdpd_saif_file** variable is *power_sdpd.saif*.

library

Specifies the library name, or library file name for which the forward SAIF file is generated. If a library file name is specified then the library must be in .db format. The library must have state-dependent leakage power characterization and/or pin-level state-dependent and/or path-dependent internal power characterization for a library forward SAIF file to be generated.

-lib_pathname *lib_path_name*

Specifies the path name to the simulation library information. This is optional, and is only required if the library is not in the simulation tool's current path during simulation.

DESCRIPTION

This command creates a forward-annotation SAIF file that contains the state-dependent and path-dependent information for library cells. The library forward-annotation SAIF file is used in flows where a gate-level back-annotation SAIF file with state-dependent and/or path-dependent switching activity is generated.

For details on the SAIF format, see the SAIF specification.

For details on state-dependent and path-dependent power characterization, see the Library Compiler and Power Compiler documentation.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples illustrate the use of this command:

```
prompt> lib2saif -out a130.saif asic130_typical
```

```
prompt> lib2saif -out a130.saif ..libs/asic130.db
```

SEE ALSO

[report_power\(2\)](#)
[set_switching_activity\(2\)](#)

license_users

Lists the current users of the Synopsys licensed features.

SYNTAX

```
status license_users  
    [feature_list]
```

Data Types

feature_list list

ARGUMENTS

feature_list

Lists the licensed features for which to obtain the information. If more than one feature is specified, they must be enclosed in braces ({}). See the Synopsys *Installation Guide: UNIX-Based Platforms* for a list of features supported by the current release, or determine from the key file all of the features that are licensed at your site.

DESCRIPTION

This command displays information about all of the licenses, related users, and host names currently in use. If a feature list is specified, only information about those features is displayed.

The **license_users** command is valid only when Network Licensing is enabled.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In this example, all of the users of the Synopsys features are displayed:

```
prompt> license_users  
krig@node1 DC-Expert, Design-Compiler, Design-Vision,  
          Milkyway-Interface  
doris@node2 Design-Compiler, HDL-Compiler, Power-Optimization  
schen@node3 DC-Expert, DC-Ultra-Features, DC-Ultra-Opt,
```

```
Design-Compiler,  
wru@node4 DC-Expert, DC-Ultra-Features, DC-Ultra-Opt,  
Design-Compiler, DesignWare,  
Milkyway-Interface, Test-Compiler,  
VHDL-Compiler
```

4 users listed.

This example shows the users of the "HDL-Compiler" or "VHDL-Compiler" features.

```
prompt> license_users {HDL-Compiler VHDL-Compiler}
```

```
doris@node2 Design-Compiler, HDL-Compiler, Power-Optimization  
wru@node4 DC-Expert, DC-Ultra-Features, DC-Ultra-Opt,  
Design-Compiler, DesignWare,  
Milkyway-Interface, Test-Compiler,  
VHDL-Compiler
```

2 users listed.

SEE ALSO

```
get_license(2)  
remove_license(2)
```

link

Resolves design references.

SYNTAX

status **link**

ARGUMENTS

The **link** command has no arguments.

DESCRIPTION

Performs a name-based resolution of design references for the current design. For a design to be complete, it needs to be connected to all of the library components and designs it references. The references must be located and linked to the current design in order for the design to be functional. The purpose of this command is to locate all of the designs and library components referenced in the current design and connect (link) them to the current design.

The **link** command uses the **link_library** and **search_path** variables along with the **local_link_library** design attribute to resolve design references. The **local_link_library** attribute and **link_library** variable specify a list of design and library files. A "*" entry in the value of the **link_library** variable indicates that **link** should search all the designs already loaded in memory. If the **link_library** variable has no "*" entry, the already-loaded designs are not searched. The default value for the **link_library** variable is "* your_library.db". The **search_path** variable specifies a list of directory names that the **link** command uses to search for **link_library** or **local_link_library** files.

If the reference is to a parameterized design (and the design is not already in memory), **link** automatically builds the template with the specified parameters. Parameterized designs can only be specified using HDL code.

The **link** command searches for referenced designs by looking in each file specified by the **local_link_library** attribute and the **link_library** variable. If the **local_link_library** attribute is set on the current design, those files are searched ahead of those specified by the **link_library** variable. For simple file names (names that contain no '/' character), the **link** command looks for the files in the directories specified by the **search_path** variable. For absolute or relative path names, the **search_path** variable is not used. If the referenced designs are not found in any of the specified files, the **link** command looks in the search path directories for any .ddc or .db files that have the same name as the referenced design (for example, adder.ddc or adder.db). In this case, the .ddc files are searched first.

The order of directories in the search path and of the files in the link libraries is important. Search order during a link is

1. Local link library files
2. Link library files
3. Search path directories

The first occurrence of a design reference is used.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

In all modes, if a design named TOP refers to design named test in its implementation, the **link** command must find and connect the test design to this reference. The **link** command first searches the files specified in the link libraries for TOP. If it does not find the test design in the link libraries, it searches the directories specified in the **search_path** variable for a file named test.ddc or test.db. If it does not find it there, a warning is issued stating that the reference cannot be resolved.

Assume that the **local_link_library** attribute, **search_path** variable, and **link_library** variable for the previous example are set as follows:

```
prompt> set_app_var search_path "$synopsys_root/libraries /usr/bill/project"  
/usr/synopsys/libraries /usr/bill/project  
  
prompt> set_local_link_library tech1_lib.db  
1  
  
prompt> set_app_var link_library ** tech2_lib.db ./project.db"  
* tech2_lib.db ./project.db
```

To find the test design, the **link** command performs the following sequence:

Step 1.

Read the tech1_lib.db file. Because this is a simple filename, the search path is used to find the file's location.

Step 2.

Search all the designs already loaded in memory for a design called test.

Step 3.

Read the tech2_lib.db file. Because this is a simple filename, the search path is used to find the file's location.

Step 4.

Read the project.db file from the current directory. Because this is a complex filename (the current directory is specified), the search path is not used to find the file.

Step 5.

Look for the test design in the list of designs contained in tech1_lib.db, tech2_lib.db, and project.db.

Step 6.

If the test design is not found in Step 5, search for a file named either test.ddc or test.db using the search path. In the unlikely event that test.ddc and test.db both exist, the .ddc file is used.

The following examples demonstrate the different ways the **link** command can search for referenced designs.

Example 1

The **search_path** variable is set to a list of directories where designs and technology libraries reside. In the following example, the top, counter, and controller designs are built using components from the tech_lib library. You need to read in only the top-level design. The **link** command automatically loads designs from both the link library files and, as needed, files in the search path.

```
prompt> set_app_var search_path "$synopsys_root/libraries /usr/bill"  
/usr/synopsys/libraries /usr/bill  
  
prompt> read_file top.ddc
```

```

Loading db file '/usr/synopsys/libraries/syn/gtech.db'
Loading db file '/usr/synopsys/libraries/syn/standard.sldb'
  Loading link library 'gtech'
Reading ddc file '/usr/bill/top.ddc'.
Loaded 1 design.
Current design is 'top'.
{top}

```

```

prompt> set_app_var link_library "tech_lib.db"
* tech_lib.db

```

```

prompt> link

```

```

Linking design 'top'
Using the following designs and libraries:
-----
top          /usr/bill/top.ddc
tech_lib (library)  /usr/synopsys/libraries/tech_lib.db

```

```

Reading ddc file '/usr/bill/controller.ddc'.
Reading ddc file '/usr/bill/counter.ddc'.
1

```

Example 2

The following example shows that reading a design into memory has no effect on the **link** command if the "*" is missing from the **link_library** variable. The adder design is read into memory explicitly, but cannot be found on the search path or in the link libraries. Therefore, it is unresolved during linking.

This command sets the **search_path** variable without including the directory that contains the adder.ddc file:

```

prompt> set_app_var search_path "$synopsys_root/libraries /usr/bill"
/usr/synopsys/libraries /usr/bill

```

The next two commands read the adder design into memory and set the current design to top:

```

prompt> read_file /usr/bill/dc/adder.ddc
Loading db file '/usr/synopsys/libraries/syn/gtech.db'
Loading db file '/usr/synopsys/libraries/syn/standard.sldb'
  Loading link library 'gtech'
Reading ddc file '/usr/bill/dc/adder.ddc'.
Loaded 3 designs.
Current design is 'adder'.
adder mux81 top

```

```

prompt> current_design top
Current design is 'top'.
{top}

```

The next command sets the **link_library** variable without including the adder.ddc file or "*":

```

prompt> set_app_var link_library "tech_lib.db"
tech_lib.db

```

The following command shows that the **link** command fails for the designs in adder.ddc:

```

prompt> link
Linking design 'top'
Using the following designs and libraries:
-----
tech_lib (library)  /usr/synopsys/libraries/tech_lib.db

```

Warning: Unable to resolve reference 'adder' in 'top'. (LINK-5)
 Warning: Unable to resolve reference 'mux81' in 'top'. (LINK-5)

Adding "*" to the **link_library** variable allows the design to link successfully:

```
prompt> set_app_var link_library "* $link_library"
* tech_lib.db

prompt> link

Linking design 'top'
Using the following designs and libraries:
-----
* (3 designs)      /usr/bill/dc/adder.ddc, etc
tech_lib (library) /usr/synopsys/libraries/tech_lib.db

1
```

An alternate solution for the link failure is to add the adder.ddc file to the **link_library** variable:

```
prompt> set_app_var link_library "tech_lib.db /usr/bill/dc/adder.ddc"
tech_lib.db /usr/bill/dc/adder.ddc

prompt> link

Linking design 'top'
Using the following designs and libraries:
-----
* (3 designs)      /usr/bill/dc/adder.ddc, etc
tech_lib (library) /usr/synopsys/libraries/tech_lib.db

1
```

Example 3

This example shows how to handle files with multiple designs. If you need to link with a file of multiple designs, put that file in your **link_library**.

If a design is not found in the **link_library** files, **link** searches the **search_path** directories for a file of the same name as the referenced design, with a .db or .ddc suffix. If your multiple-design file has a different file name then it will not be found, even if it is located on the **search_path**.

```
prompt> set_app_var search_path "$synopsys_root/libraries /usr/project"
/usr/synopsys/libraries /usr/project
```

The following command sets **link_library** without including "mylib.ddc":

```
prompt> set_app_var link_library "tech_lib.db"
tech_lib.db
```

The link fails for designs in "mylib" that are not found in any **link_library** files or in files in **search_path** directories that are named with the design names:

```
prompt> read_file top.ddc
Loading db file '/usr/synopsys/libraries/syn/gtech.db'
Loading db file '/usr/synopsys/libraries/syn/standard.sldb'
  Loading link library 'gtech'
Reading ddc file '/usr/project/top.ddc'.
Loaded design.
Current design is 'top'.
top
```

```
prompt> link
```

```
Linking design 'top'
Using the following designs and libraries:
-----
tech_lib (library)      /usr/synopsys/libraries/tech_lib.db
```

Warning: Unable to resolve reference 'adder' in 'top'. (LINK-5)
Warning: Unable to resolve reference 'mux81' in 'top'. (LINK-5)

Because the adder and mux81 designs are in the mylib.ddc file, adding this file to the **link_library** variable enables a successful link:

```
prompt> lappend link_library mylib.ddc
tech_lib.db mylib.ddc

prompt> link
Reading ddc file '/usr/project/mylib.ddc'.

Linking design 'top'
Using the following designs and libraries:
-----
tech_lib (library)      /usr/synopsys/libraries/tech_lib.db
* (2 designs)          /usr/project/mylib.ddc, etc

1
```

list

Creates a list.

SYNTAX

int **list** *arg1 arg2 ... argn*

ARGUMENTS

arg1 arg2 ... argn

Items to be included in the returned list.

DESCRIPTION

This command returns a list comprised of all the specified arguments or an empty string if no arguments are specified. Braces and backslashes are added as necessary, so that the **index** command can be used on the result to re-extract the original arguments, and also so that the **eval** command can be used to execute the resulting list, with *arg1* comprising the command's name and the other arguments comprising its arguments. Unlike the **concat** command, which removes one level of grouping before forming the list, the **list** command works directly from the original arguments. For example, the following command

list a b {c d e} {f {g h}}

returns

a b {c d e} {f {g h}}

while the **concat** command, issued with the same arguments, returns the following:

a b c d e f {g h}

SEE ALSO

help(2)

list_attributes

Lists the currently-defined attributes.

SYNTAX

```
status list_attributes
  [-application]
  [-class class_name]
  [-nosplit]
```

Data Types

class_name string

ARGUMENTS

-application

Lists application attributes and user-defined attributes.

-class *class_name*

Limits the listing to attributes of a single class. Valid classes are **all**, **bound**, **cell**, **clock**, **design**, **ilms**, **lib**, **lib_cell**, **lib_pin**, **net**, **phys_cluster**, **phys_design**, **phys_layer**, **physcell**, **physnet**, **physport**, **pin**, **placement_bound**, **port**, **power_domain**, **power_switch**, **region**, **supply_net**, and **supply_port**.

-nosplit

Prevents lines from being split when column fields overflow. Most of the attribute information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the correct column.

DESCRIPTION

The **list_attributes** command displays an alphabetically-sorted list of currently-defined attributes. The attributes are divided into two categories: application-defined and user-defined. By default, **list_attributes** lists all user-defined attributes.

Using the **-application** option adds all application attributes to the listing. Since there are many application attributes, you can limit the listing to a specific object class by using the **-class** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example listing of some attributes defined with the **define_user_attribute** command:

```
prompt> list_attributes
*****
Report : attribute definition
Design :
*****
Attributes:
  r - read-only
  u - user-defined

Attribute name          Class   Type   Attributes
-----
DDB_EXTRACT_HIGH_FAN_OUT_THRES_ATTR lib_cell integer u
DDB_HIER_TOTAL_UNGROUP_AREA_ATTR    lib_cell integer u
DDB_REAL_METALFILL_EXTR_ATTR      lib_cell integer u
DDB_VIR_SHIELD_EXTR_ATTR         lib_cell boolean u
...
worst_slack              port    float   u
write_port_name           cell    string   u
write_sched_step           cell    integer   u
-----
1
```

The following example adds application-defined attributes, but limits the listing to net attributes only:

```
prompt> list_attributes -application -class net
*****
Report : attribute definition
  -application
Design :
*****
Attributes:
  a - application-defined
  r - read-only
  u - user-defined

list_commands

Displays quick help for one or more commands.

SYNTAX

```
string list_commands
  [-verbose]
  [-groups]
  [-bg]
  [pattern]
```

Data Types

pattern string

ARGUMENTS

-verbose

Displays the command options; for example *command_name -help*.

-groups

Displays a list of command groups only.

-bg

Displays the list of commands supported within redirect -bg.

pattern

Displays commands matching the specified pattern.

DESCRIPTION

The **list_commands** command is used to get quick help for one or more commands or procedures. This is not the same as the **man** command that displays reference manual pages for a command. There are many levels of help.

By typing the **list_commands** command, a brief informational message is printed followed by the available command groups.

List all of the commands in a group by typing the group name as the argument to **list_commands**. Each command is followed by a one-line description of the command.

To get a one-line help description for a single command, type **list_commands** followed by the command name. You can specify a wildcard pattern for the name; for example, all commands containing the string "alias". Use the **-verbose** option to get syntax help for one or more commands. Use the **-groups** option to show only the command groups in the application. This option cannot be combined

with any other option.

EXAMPLES

The following example lists the commands by command group:

```
prompt> list_commands
```

Specify a command name or wild card pattern to get help on individual commands. Use the '-verbose' option to get detailed option help for a command. Commands also provide help when the '-help' option is passed to the command.'

You can also specify a command group to get the commands available in that group. Available groups are:

Procedures:	Miscellaneous procedures
Help:	Help commands
Builtins:	Generic Tcl commands
...	

The following example displays the list of procedures in the Procedures group:

```
prompt> list_commands procedures  
ls      # List files  
sh      # Execute a shell command
```

The following example uses a wildcard character to display a one-line description of all commands beginning with *a*:

```
prompt> list_commands a*  
alias      # Create a command which expands to words.  
append     # Builtin  
array      # Builtin
```

This example displays option information for the **source** command:

```
prompt> list_commands -verbose source  
source      # Read a file and execute it as a script  
[-echo]     (Echo all commands)  
[-verbose]   (Display intermediate results)  
file_name   (Script file to read)
```

SEE ALSO

[man\(2\)](#)
[sh_help_shows_group_overview\(3\)](#)

list_designs

Lists the designs available in memory.

SYNTAX

```
status list_designs
  [design_list]
  [-show_file]
```

Data Types

design_list list

ARGUMENTS

design_list

Specifies the designs to list. If this option is not specified, all designs are listed. When specifying designs, the wildcard characters * (asterisk) and ? (question mark) are supported. For details about using and escaping wildcard characters, see the **wildcards** man page.

-show_file

Specifies that designs are shown according to the file in which they reside. The **-show_file** option is typically used when 2 or more designs share the same name.

DESCRIPTION

The **list_designs** command displays the designs currently read in dc_shell. In the design listing, the current design is designated by an asterisk (*).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **list_designs**:

```
prompt> list_designs
ADDER      FULL_SUBTRACTOR  HALF_SUBTRACTOR  TOP
```

```
FULL_ADDER  HALF_ADDER      SUBTRACTOR
```

```
prompt> current_design TOP
```

```
Current design is 'TOP'.
```

The following example shows that the current design is denoted with an asterisk:

```
prompt> list_designs
ADDER      FULL_SUBTRACTOR  HALF_SUBTRACTOR  TOP (*)
FULL_ADDER  HALF_ADDER      SUBTRACTOR
```

The following example lists all designs that end with *_ADDER*:

```
prompt> list_designs "*_ADDER"
HALF_ADDER  FULL_ADDER
```

The following example uses the **-show_file** option to differentiate between designs having the same name:

```
prompt> list_designs
ADDER      FULL_SUBTRACTOR  HALF_SUBTRACTOR  TOP
FULL_ADDER  HALF_ADDER      SUBTRACTOR
```

```
prompt> copy_design TOP example.db:TOP
```

```
Copying design 'TOP' to 'example.db:TOP'
```

```
prompt> list_designs
ADDER      FULL_SUBTRACTOR  HALF_SUBTRACTOR  TOP
FULL_ADDER  HALF_ADDER      SUBTRACTOR      TOP (*)
```

```
prompt> list_designs -show_file
```

```
/usr/users/bill/test/designs/top.db
ADDER      FULL_SUBTRACTOR  HALF_SUBTRACTOR  TOP (*)
FULL_ADDER  HALF_ADDER      SUBTRACTOR
```

```
example.db
TOP
```

list_dont_touch_types

Lists the currently defined dont_touch types.

SYNTAX

```
status list_dont_touch_types  
[-class class_name]
```

Data Types

class_name string

ARGUMENTS

-class *class_name*

Limits the list of dont_touch types to either the cell or net object class. The value for **-class** is a class name. The supported class names are **cell** and **net**.

If you do not use this option, the command lists the dont_touch types for both the cell and net object classes.

DESCRIPTION

The **list_dont_touch_types** command displays an alphabetically sorted list of currently defined cell and net dont_touch types and their descriptions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following command generates the list of dont_touch types for both cells and nets.

```
prompt> list_dont_touch_types  
*****  
Report : Types of dont_touch  
Version: E-2010.12-SP2  
Date : Thu Mar 3 12:06:02 2011  
*****
```

Class	Type	Description
<hr/>		
net	cts_synthesized	Net is synthesized with clock tree synthesis
net	dft_scanbuf	Net connected to input pin of scan compression buffer cell
net	dtn	Net in dont_touch network set by set_dont_touch_network command
net	dtn_charz	Net in dont_touch network through characterization
net	fp_abutted	Net is floorplan abutted net
net	fp_border	Net is dangling on floorplan border
net	idn	Net in ideal network set by set_ideal_network command
net	ilm	Net is part of an interface logic model
net	inh_parent	Net inherits dont_touch from parent
net	mv_ao	Net has derived dont_touch from always-on synthesis
...		
cell	cg_mo	Clock-gating cell has dont_touch derived from map_only setting
cell	charz	Cell has dont_touch derived from characterization
cell	dft_scan	Cell is a DFT scan cell
cell	dft_scandef	Cell is SCANDEF generation cell
cell	dft_scg	DFT scan cell has dont_touch because it is replaced by clock-gating cell
cell	dt_conn	Cell connected to dont_touch net
cell	dtn	Cell in dont_touch network set by set_dont_touch_network command
...

list_duplicate_designs

Lists designs that have the same design name in dc_shell.

SYNTAX

status **list_duplicate_designs**

ARGUMENTS

The **list_duplicate_designs** command has no arguments.

DESCRIPTION

This command displays a list of designs currently in dc_shell that have the same name as other designs also currently in dc_shell.

The command returns 1 if multiple designs with the same name are detected. The command returns 0 if no designs in dc_shell memory share the same design name.

EXAMPLES

In the following example, **list_duplicate_designs** lists 2 designs that have the same name in dc_shell memory:

```
prompt> list_duplicate_designs
Warning: Multiple designs in memory with the same design name.

Design      File          Path
-----
seq2       A.db        /usr/joe/design
seq2       B.db        /usr/joe/design
1
```

In the following example, **list_duplicate_designs** reports that there are no designs with the same name in dc_shell memory:

```
prompt> list_duplicate_designs
No duplicate designs found.
0
```

SEE ALSO

`current_design(2)`
`get_designs(2)`
`list_designs(2)`

list_files

Lists the files that are loaded into memory.

SYNTAX

status **list_files**

ARGUMENTS

The **list_files** command has no arguments.

DESCRIPTION

The **list_files** command lists the files loaded in memory.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the output from the **list_files** command:

```
prompt> list_files
  File          Path
  ----        -----
adder.db      /remote/usr4/joeuser/designs
clock.db      /remote/usr4/joeuser/designs
gtech.db      /remote/usr4/joeuser/libraries
lsi_10k.db    /remote/usr4/joeuser/libraries
1
```

SEE ALSO

[list_designs\(2\)](#)

list_hdl_blocks

Lists the HDL blocks available in memory.

SYNTAX

```
int list_hdl_blocks
  [-nosplit]
  [-all_objects]
  [instance_list]
```

Data Types

instance_list list

ARGUMENTS

-nosplit

Prevents line-splitting and facilitates writing software to extract information from the report. Most of the information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the correct column.

-all_objects

Displays all objects in each HDL block when this option is specified. By default, only up to 10 objects in each HDL block is displayed.

instance_list

Specifies the instances to display HDL blocks. If this option is not specified, the HDL blocks in the top-level instance are listed. This option supports the wildcard characters "*" and "?". For information about using and escaping wildcard characters, see the **wildcards** man page.

DESCRIPTION

The **list_hdl_blocks** command displays the HDL blocks in the current design.

The **list_hdl_blocks** command is not affected by the **current_instance** command. To report HDL blocks in lower-level blocks, you must use the *instance_list* argument.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **list_hdl_blocks** command:

```
prompt> list_hdl_blocks
list_hdl_blocks: hdl_block_2
Group          Objects
-----
block_47      NIL
block_47/z_reg z_reg[4] z_reg[5] z_reg[6] z_reg[7]
block_03      NIL
block_03/z_reg z_reg[0] z_reg[1] z_reg[2] z_reg[3]
```

SEE ALSO

[wildcards\(3\)](#)

list_instances

Lists the instances in the current design or current instance.

SYNTAX

```
status list_instances
  [instance_list]
  [-hierarchy]
  [-max_levels num_levels]
  [-full]
  [-config]
```

Data Types

<i>instance_list</i>	list
<i>num_levels</i>	integer

ARGUMENTS

instance_list

Specifies the instances to list. By default, all instances in the current design or current instance are listed.

-hierarchy

Lists all levels of instance hierarchy. By default, only the current level of hierarchy is listed.

-max_levels *num_levels*

Modifies the **-hierarchy** option by specifying a limit to the number of levels of hierarchy that are listed. You must use the **-hierarchy** option if you use the **-max_levels** option.

-full

Displays the full hierarchy. By default, if there is a submodule in multiple locations in a hierarchy, its components are listed only once with ellipses (...) indicating the contents of a previously displayed module.

-config

Reports the RTL design library, template name, and specializing parameters rather than the generated name of the design cell.

DESCRIPTION

The **list_instances** command lists the instances in memory. The command displays cells at the current level of hierarchy, as specified by the **current_design** and **current_instance** commands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **list_instances** to display the available instances. The design that each instance references is shown in parentheses following the instance name.

```
prompt> current_design TOP
Current design is 'TOP'.

prompt> list_instances
U1 (ADDER)    U2 (SUBTRACTOR)

prompt> current_instance U1
Current instance is 'TOP/U1'.

prompt> list_instances
U1 (FULL_ADDER)    U2 (FULL_ADDER)
U3 (FULL_ADDER)    U4 (FULL_ADDER)

prompt> list_instances {U1, U2}
U1 (FULL_ADDER)    U2 (FULL_ADDER)

prompt> current_instance U2
"TOP/U1/U2"

prompt> list_instances "*"
U1 (HALF_ADDER)    U2 (HALF_ADDER)    U3 (OR2)
```

The following examples use the **-hierarchy** option to display multiple levels of the instance hierarchy. All instances at each level of hierarchy are listed as a group.

```
prompt> current_instance
Current instance is the top level of design 'TOP'.

prompt> list_instances -hierarchy
U1 (ADDER)
U1 (FULL_ADDER)
U1 (HALF_ADDER)
U1 (EO)      U2 (AN2)
U2 (HALF_ADDER)...
U3 (OR2)
U2 (FULL_ADDER)...
U3 (FULL_ADDER)...
U4 (FULL_ADDER)...
U2 (SUBTRACTOR)
U1 (FULL_SUBTRACTOR)
U1 (HALF_SUBTRACTOR)
U1 (EO)      U2 (IV)      U3 (AN2)
U2 (HALF_SUBTRACTOR)...
U3 (OR2)...
U2 (FULL_SUBTRACTOR)...
U3 (FULL_SUBTRACTOR)...
U4 (FULL_SUBTRACTOR)...

prompt> list_instances -hierarchy -max_levels 2
U1 (ADDER)
U1 (FULL_ADDER)...
```

```
U2 (FULL_ADDER)...
U3 (FULL_ADDER)...
U4 (FULL_ADDER)...
U2 (SUBTRACTOR)
U1 (FULL_SUBTRACTOR)...
U2 (FULL_SUBTRACTOR)...
U3 (FULL_SUBTRACTOR)...
U4 (FULL_SUBTRACTOR)...
```

```
prompt> current_instance U1/U1
Current instance is 'TOP/U1/U1'.
```

```
prompt> list_instances -hierarchy
U1 (HALF_ADDER)
  U1 (EO)      U2 (AN2)
U2 (HALF_ADDER)...
U3 (OR2)
```

```
prompt> list_instances -hierarchy -full
U1 (HALF_ADDER)
  U1 (EO)      U2 (AN2)
U2 (HALF_ADDER)
  U1 (EO)      U2 (AN2)
U3 (OR2)
```

list_libs

Lists the libraries available in memory.

SYNTAX

```
status list_libs  
[lib_list]
```

Data Types

lib_list list

ARGUMENTS

lib_list

Specifies the libraries to list. You can use the * (asterisk) and ? (question mark) wildcard characters when specifying the libraries to list. For information about using and escaping wildcards, see the **wildcards** man page. By default, the tool lists all libraries.

DESCRIPTION

This command displays all libraries that are currently available in memory.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This example shows a simple use of the **list_libs** command. The library flagged with *M* is the maximum library used for maximum delay analysis. It corresponds to the library flagged with *m* used for minimum delay analysis.

```
prompt> set_min_library sc_max.db -min sc_min.db  
prompt> set_min_library tt_max.db -min tt_min.db  
prompt> list_libs  
Logical Libraries:  
-----  
Library      File          Path  
-----      ---          ----
```

```
cell      cells.db          /remote/usr4/joeuser/designs
gtech     gtech.db          /remote/usr4/joeuser/libraries
standard.sldb standard.sldb /remote/usr4/joeuser/libraries
M fs120_max   sc_max.db    /remote/usr4/joeuser/libraries
m fs120_min   sc_min.db    /remote/usr4/joeuser/libraries
M cb_max      tt_max.db     /remote/usr4/joeuser/libraries
m cb_min      tt_min.db     /remote/usr4/joeuser/libraries
```

list_licenses

Displays a list of licenses currently checked out by the user.

SYNTAX

status **list_licenses**

ARGUMENTS

The **list_licenses** command has no arguments.

DESCRIPTION

The **list_licenses** command lists the licenses you currently have checked out. If more than one copy of a license key is checked out, the number of keys checked out is shown in parentheses following the license name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the output from **list_licenses**:

```
prompt> list_licenses
```

Licenses in use:

DC-Expert (3)
DC-Ultra-Features (3)
DC-Ultra-Opt (3)
Design-Compiler
DesignWare

1

SEE ALSO

```
check_license(2)

list_size_only_types

Lists the currently defined size_only types.

SYNTAX

status **list_size_only_types**

DESCRIPTION

The **list_size_only_types** command displays an alphabetically sorted list of currently defined cell size_only types and their descriptions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following command generates the list of size_only types.

```
prompt> list_size_only_types
```

```
*****
Report : Types of size_only
Version: H-2013.03
Date  : Mon Aug 20 14:39:42 2012
*****
```

Type	Description
abs	Block abstraction cell in sizing-only optimization mode
cg_mo	Clock-gating cell has size_only derived from map_only setting
cg_obs	Clock-gating observation cell
charz	Cell has size_only derived from characterization
cts_sg	Cell is a self-gating cell created by clock tree synthesis
dft_so	Cell has size_only because it has a test_dft_cell_is_size_only attribute
dtn_conn	Cell connected to dont_touch net
dtn_noprop_load	Load cell whose driver is dont_touch_network source with dont_touch_network_no_propagate attribute
dtn_src	Output pin of the cell is dont_touch_network source
dw_so	Cell with dw_size_only attribute
dw_struct	Cell in DesignWare structure to be preserved
footprint	Cell has size_only to only perform footprint-preserving sizing
fp_ft_buffer	Floorplan feed-through buffer cell
fp_group	Leaf cell connected to port in floorplan group

hdl_rp Cell with hdl_rp_cell attribute
icg Integrated clock gate cell
inh_parent Cell inherits size_only from hierarchical parent cell
inh_ref Cell inherits size_only from reference design or library cell
inplace Cell in a placed cluster
other Cell has size_only due to other internal reason
pdft_scan PDEF scan cell has size_only
power_roi Isolation operand cell
reg_bank Register cell in user-created register bank
scan_chain_element Cell is a scan chain element
scan_comp_pg Power gating cell for scan compressor
scan_exact_reg Scan register that needs an exact match
...
upf_retention_net Driver of retention save-net or restore-net
upf_supply_conn Cell connected to a supply net has size_only to prevent the supply net from being removed
user Cell has specific user-set size_only attribute

list_test_models

Lists the designs in memory that have CTL test models attached to them.

SYNTAX

```
status list_test_models  
[-compressors]
```

ARGUMENTS

-compressors

Lists the compressors and decompressors that are contained in each CTL-modeled design.

DESCRIPTION

This command displays the designs in memory that have CTL test models attached to them. Designs that do not have CTL test model information are not listed. All designs in memory are analyzed, even if they are not a part of the current design or its hierarchy.

EXAMPLES

The following example lists the designs that have CTL test model information:

```
prompt> list_test_models  
des_unit      /remote/my_dir/des_unit_xtol/db/des_unit.db  
des_unit_SCCOMP_COMPRESSOR  /remote/my_dir/des_unit_xtol/ \  
                           des_unit_SCCOMP_COMPRESSOR.db  
des_unit_SCCOMP_DECOMPRESSOR /remote/my_dir/des_unit_xtol/ \  
                           des_unit_SCCOMP_DECOMPRESSOR.db
```

The following example lists the compressors and decompressors for each design:

```
prompt> list_test_models -compressors  
TOP          /path/my_dir/TOP.db  
Codecs:  
  
C_CORE1      /path/my_dir/TOP.db  
Codecs:  
  C_CORE1_U_decompressor_ScanCompression_mode  
  C_CORE1_U_compressor_ScanCompression_mode  
  
C_CORE2      /path/my_dir/TOP.db
```

Codecs:

C_CORE2_U_decompressor_ScanCompression_mode
C_CORE2_U_compressor_ScanCompression_mode

list_test_modes

Displays all of the test modes that are defined for the current design.

SYNTAX

status **list_test_modes**

ARGUMENTS

The **list_test_modes** command has no arguments.

DESCRIPTION

The **list_test_modes** command displays all of the modes defined for the current design. The **define_test_mode** command is used to define a mode of operation for a design.

If a design does not have any test modes defined, it displays the message "Design has no test modes."

EXAMPLES

The following is an example of the test modes report:

```
prompt> list_test_modes
Test Modes
=====
Name: ScanCompression_mode
Type: InternalTest
Focus:
Core des_unit_U_decompressor in decompress mode
Core des_unit_U_compressor in compress mode

Name: Internal_scan
Type: InternalTest
Focus:

Name: Mission_mode
Type: Normal
```

SEE ALSO

`insert_dft(2)`

Iminus

Removes one or more named elements from a list and returns a new list.

SYNTAX

```
list Iminus
  [-exact]
  original_list
  elements
```

Data Types

<i>original_list</i>	list
<i>elements</i>	list

ARGUMENTS

-exact

Specifies that the exact pattern is to be matched. By default, **Iminus** uses the default match mode of **Isearch**, the **-glob** mode.

original_list

Specifies the list to copy and modify.

elements

Specifies a list of elements to remove from *original_list*.

DESCRIPTION

The **Iminus** command removes elements from a list by using the element itself, rather than the index of the element in the list (as in **Ireplace**). The **Iminus** command uses the **Isearch** and **Ireplace** commands to find the elements and replace them with nothing.

If none of the elements are found, a copy of *original_list* is returned.

The **Iminus** command is often used in the translation of Design Compiler scripts that use the subtraction operator (-) to remove elements from a list.

EXAMPLES

The following example shows the use of the **Iminus** command. Notice that no error message is issued if a specified element is not in

the list.

```
prompt> set l1 {a b c}
a b c

prompt> set l2 [lminus $l1 {a b d}]
c

prompt> set l3 [lminus $l1 d]
a b c
```

The following example illustrates the use of **lminus** with the **-exact** option:

```
prompt> set l1 {a a[1] a* b[1] b c}
a a[1] a* b[1] b c

prompt> set l2 [lminus $l1 a*]
{b[1]} b c

prompt> set l3 [lminus -exact $l1 a*]
a {a[1]} {b[1]} b c

prompt> set l4 [lminus -exact $l1 {a[1] b[1]} ]
a a* b c
```

SEE ALSO

[lreplace\(2\)](#)
[lsearch\(2\)](#)

load_of

Returns the capacitance of the specified library cell pin.

SYNTAX

```
float load_of  
    library_cell_pin
```

Data Types

library_cell_pin string

ARGUMENTS

library_cell_pin

Specifies the name of the library cell pin whose capacitance is to be returned. The format for *library_cell_pin* is *library_name/lib_cell_name/pin_name*. The specified library must be already loaded into memory.

DESCRIPTION

This command returns the load of the specified library cell pin. It is primarily used as an argument to the **set_load** command. If the specified *library_cell_pin* cannot be found, a warning message is issued and 0.0 is returned.

EXAMPLES

The following command returns the load of the pin named A on the AND2 cell in the tech_lib library:

```
prompt> load_of tech_lib/AND2/A
```

The following example uses the **load_of** command with the **set_load** command. It sets the load on all output ports of the design to the value of the load on the A input pin of the INV cell in the tech_lib library:

```
prompt> set_load [load_of tech_lib/INV/A] [all_outputs]
```

SEE ALSO

set_load(2)

load_upf

Executes a script file containing UPF commands.

SYNTAX

```
status load_upf
  [gupf_file_name]
  [-scope instance_name]
  [-noecho]
  [-simulation_only]
  [-strict_check true | false]
  [-supplemental supf_file_name]
```

Data Types

<i>gupf_file_name</i>	string
<i>instance_name</i>	string
<i>supf_file_name</i>	string

ARGUMENTS

gupf_file_name

Specifies the name of the file containing UPF commands to be executed.

In UPF-prime (non-golden) mode, this argument is required.

In golden UPF mode, this argument is optional; it specifies the name of the golden UPF script file to execute, if any. To execute a supplemental UPF script file, use the **-supplemental** option.

-scope *instance_name*

Specifies the scope where the UPF commands are executed. By default, the commands are executed in the current scope.

In the golden UPF mode, this option specifies the scope where both the golden UPF file and supplemental UPF file are executed.

-noecho

Prevents the UPF commands from being displayed as they are executed. By default, the UPF commands are echoed on the screen as they are executed.

-simulation_only

Indicates that the commands in the UPF file are for simulation only. A tool that does not perform simulation reads the commands and preserves them for output with the **save_upf** command, but does not execute them.

-strict_check true | false

Specifies whether to perform strict name matching during execution of the UPF commands. Use this option only in the golden UPF mode.

Set this option to **true** when you load the golden UPF file into the synthesis tool for the very first time, when object names in the UPF commands are expected to match object names in the design exactly.

Set this option to **false** when you reapply the golden UPF file any time after the synthesis tool has operated on the design, when object names in the file are not expected to match object names in the design due to optimization, grouping, and wildcard name expansion. In this case, the tool identifies objects using rule-based matching and name map file, if any.

The default setting is **true**; if you do not use the-**strict_check** option in the golden UPF mode, the tool uses strict name checking.

-supplemental *supf_file_name*

Specifies the name of the supplemental UPF file to be read. This option is supported only in the golden UPF mode.

DESCRIPTION

The **load_upf** command executes the set of UPF commands in the specified UPF file. It works like the **source** command, but performs additional checking specifically for UPF power intent. In the golden UPF mode, using the **load_upf** command is the only way to execute UPF commands (other than query commands).

If you use the **-scope** option, the command first sets the scope to the specified instance, executes the UPF command script to apply the commands at that scope, and then restores the scope to its previous state. Similarly, specifying the **-scope** option, also sets the design top instance to specified scope, and restores it to previous state at the end of the command.

The **load_upf** command executes the constraints as they are being read. If it encounters errors while the UPF file is being read, execution might stop, so that only some of the UPF constraints are applied.

The **load_upf** command supports the following UPF commands. Usage of some of these commands is restricted when reading the UPF file. In certain cases, some command options are not supported.

```
add_port_state
add_pst_state
bind_checker
connect_supply_net
create_upf2hdl_vct
create_hdl2upf_vct
create_power_domain
create_power_switch
create_pst
create_supply_net
create_supply_port
create_supply_set
load_upf
map_isolation_cell
map_level_shifter_cell
map_power_switch
map_retention_cell
name_format
save_upf
set_scope
set_isolation
set_isolation_control
set_retention
set_retention_control
set_domain_supply_net
set_design_top
set_level_shifter
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example loads the UPF script file named top.upf:

```
prompt> load_upf top.upf  
Loading UPF file top.upf with version 1.0...  
End loading UPF file top.upf  
1
```

The following example shows the usage of the **-scope** option:

```
prompt> load_upf top.upf -scope A  
Loading UPF file top.upf with version 1.0...  
End loading UPF file top.upf  
1
```

The following example reads the UPF script file named top2.upf, which contains commands that are not supported by UPF. CMD-005 error messages are generated for the unsupported commands.

```
prompt> load_upf top2.upf  
Loading UPF file top2.upf with version 1.0...  
link_design  
Error: Unknown command `link_design` (CMD-005)  
End loading UPF file top2.upf  
0
```

The following example shows the behavior of the **load_upf** command when the UPF file contains commands not supported by the tool. One UPF message is generated for every unsupported command. When the execution of the **load_upf** command is complete, the tool also reports a summary of all unsupported commands encountered in the UPF file.

```
prompt> load_upf t2.upf  
Loading UPF file t2.upf with version 1.0...  
set_logic_zero portA  
Warning: Constraint 'set_logic_zero' is not supported by dc_shell. (UPF-042)  
set_logic_zero portB  
Warning: Constraint 'set_logic_zero' is not supported by dc_shell. (UPF-042)  
set_logic_one portC  
Warning: Constraint 'set_logic_zero' is not supported by dc_shell. (UPF-042)  
  
Summary of unsupported constraints:  
Information: Ignored 1 unsupported 'set_logic_one' constraint. (UPF-043)  
Information: Ignored 2 unsupported 'set_logic_zero' constraints. (UPF-043)
```

```
End loading UPF file t2.upf  
1
```

The following example illustrates the use of the **-noecho** option:

```
prompt> load_upf 5.upf -noecho  
Loading UPF file 5.upf with version 1.0...  
End loading UPF file 5.upf  
1
```

The following example illustrates how to load the golden UPF file for the first time, with **-strict_check** set to **true**:

```
prompt> load_upf g.upf -strict_check true
```

Loading Golden UPF file g.upf ...

End loading UPF file g.upf
1

The following example illustrates how to reapply the golden UPF file:

```
prompt> load_upf g.upf -strict_check false
```

Loading Golden UPF file g.upf ...

End loading UPF file g.upf
1

The following example shows how to load a supplemental UPF file in the golden UPF mode:

```
prompt> load_upf -supplemental s.upf
```

Loading Supplemental UPF file s.upf ...

End loading UPF file s.upf
1

ls

Lists the contents of a directory.

SYNTAX

string **ls**

ARGUMENTS

The **ls** command has no arguments.

DESCRIPTION

If no argument is specified, the contents of the current directory are listed. For each *filename* matching a directory, **ls** lists the contents of that directory. If *filename* matches a file name, the file name is listed.

EXAMPLES

```
prompt> ls *.db *.pt  
  
test1.pt      c1.db      c3.db      c5.db  
  
test2.pt      c2.db      c4.db      c6.db
```

SEE ALSO

[cd\(2\)](#)

magnet_placement

Performs magnet placement.

SYNTAX

```
status magnet_placement
      [-move_fixed]
      [-mark_fixed]
      [-exclude_cells object_list]
      [-avoid_soft_blockages]
      [-stop_by_sequential_cells]
      [-exclude_buffers]
      [-logical_level level]
      [-stop_points object_list]
      [-cells object_list]
      [-align]
      magnet_objects
```

Data Types

<i>object_list</i>	collection
<i>level</i>	integer
<i>magnet_objects</i>	collection

ARGUMENTS

-move_fixed

Specifies that a cell marked fixed can be moved. A warning occurs when a fixed cell is being moved. By default, fixed cells cannot be moved.

-mark_fixed

Specifies that the cells are to be marked fixed after placement. By default, no cells are marked fixed.

-exclude_cells *object_list*

Instructs the command to skip the specified cells when pulling cells toward the magnet object.

-avoid_soft_blockages

Specifies that cells should not be placed over soft blockages. By default, soft blockages are ignored.

-stop_by_sequential_cells

Specifies to stop pulling cells closer to the magnet objects when a sequential cell is encountered during level traversal. This option should be used together with -logical_level

-exclude_buffers

Specifies not to consider buffers and inverters when calculating the level. They are pulled like normal cells but are skipped over for

level determination. By default, buffers and inverters are considered as one level of logic. This option should only be used together with **-logical_level**.

-logical_level *level*

Specifies the number of logical levels to pull. By default, *level* is 1 (only the first-level cells are pulled).

This option is mutually exclusive with **-stop_points**.

-stop_points *object_list*

Specifies to pull only the cells that are on the timing paths between the magnet objects and the stop-points objects. The objects can be lists of any pin, port, or cell objects.

This option is mutually exclusive with **-logical_level** and **-exclude_buffers**.

-cells *object_list*

Specifies to pull only the cells in the specified object list. You specify only cell objects in the object list.

This option is mutually exclusive with **-logical_level**, **-exclude_buffers**, **-stop_by_sequential_cells**, and **-stop_points**.

-align

Specifies to place the cells in a horizontal or vertical alignment with respect to the pin of the macro.

magnet_objects

Specifies the objects to become magnets. The objects can be a fixed macro cell, a fixed standard cell, a pin of a fixed macro cell, or an I/O pin. Objects like vias and blockages are not allowed to be magnets.

DESCRIPTION

The **magnet_placement** command allows you to define a set of objects as magnets and pull the neighboring cells up to a specified logical level closer to the magnet. Specify a large macro with many placeable standard cell neighbors. Magnet placement can be used on this type of macro to ensure that the standard cells are placed close to the macro, resulting in better timing and congestion.

If there are a large number of high fanout nets, the **magnet_placement** command might pull a large number of cells resulting in long runtime. To avoid this situation, set the **magnet_placement_fanout_limit** variable to a reasonable value. The default is 1000.

The effect of magnet placement is not preserved from one invocation to another; for example, if cells A and B are made magnets and there are cells that are connected to both of them through possibly multiple levels. Running **magnet_placement A** and then **magnet_placement B** could result in a different result from running **magnet_placement [get_cells "A B"]** together. Doing the two cells together gives the correct result.

By default, only the logic before sequential elements is pulled by magnet placement.

If the **magnet_placement** command finds a fixed cell and the **-move_fixed** option is not specified, the fixed cell and all cells behind it are not pulled.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example performs magnet placement on the *INST_1* cell:

```
prompt> magnet_placement [get_cells "INST_1"]
```

The following example performs magnet placement and marks the moved cells as dont_touch placement:

```
prompt> magnet_placement -mark_fixed [get_cells "INST_2"]
```

The following example pulls two levels of cells to *INST_2*. Buffers (if any) are pulled but skipped over when calculating levels.

```
prompt> magnet_placement -exclude_buffers -logical_level 2 \
[get_cells "INST_2"]
```

The following example works in default hierarchy mode:

```
prompt> magnet_placement INST1 -cells [get_cells module*] \
-hierarchy_mode default
```

man

Displays reference manual pages.

SYNTAX

string **man**
 topic

Data Types

topic string

ARGUMENTS

topic

Specifies the subject to display. Available topics include commands, variables, and error messages

DESCRIPTION

The **man** command displays the online manual page for a command, variable, or error message. You can write man pages for your own Tcl procedures and access them with the **man** command by setting the **sh_user_man_path** variable to an appropriate value. See the man page for the **sh_user_man_path** variable for details.

EXAMPLES

The following command displays the man page for the **echo** command:

```
prompt> man echo
```

The following command displays the man page for the error message CMD-025:

```
prompt> man CMD-025
```

SEE ALSO

[help\(2\)](#)

sh_user_man_path(3)

map_isolation_cell

Specifies how to map or remap the isolation and enable level-shifter cells belonging to the specified isolation strategy.

SYNTAX

```
status map_isolation_cell
  isolation_strategy
  -domain power_domain
  -lib_cells lib_cells
```

Data Types

<i>isolation_strategy</i>	string
<i>power_domain</i>	string
<i>lib_cells</i>	list

ARGUMENTS

isolation_strategy

Specifies the UPF isolation strategy name. The name of the isolation strategy must be unique within the specified power domain.

-domain *power_domain*

Specifies the name of the power domain name to which this isolation strategy belongs.

-lib_cells *lib_cells*

Specifies a list of the target library cells to be used for the isolation mapping.

DESCRIPTION

This command defines how the **compile** command performs the mapping of an isolation cell. All isolation cells that match the strategy are mapped or remapped to one of the cells specified with the **-lib_cells** option. Resizing is done if required, but the choice is limited only to the library cells specified with the **-lib_cells** option.

You can also specify enable level-shifter cells using the **-lib_cell** option. If the isolation cells are later changed to enable level-shifter cells in the technology library, the cells can only be mapped to the one of the enable level-shifter cells specified with this command.

If you specify cells that invert the data pin, they will only be considered for remapping pre-instantiated isolation cells that also invert the data pin. Pre-instantiated isolation cells that invert the data pin are only remapped to isolation cells that also invert the data pin.

EXAMPLES

In the following example, the isolation cells belonging to the strategy named *isolation_1* can only be mapped to the *LIB_HICLAMP0X2* or *LIB_HICLAMP0X4* library cells:

```
prompt> map_isolation_cell isolation_1 -domain PD1 \
           -lib_cells {LIB_HICLAMP0X2, LIB_HICLAMP0X4}
```

SEE ALSO

`set_isolation(2)`
`set_isolation_control(2)`

map_level_shifter_cell

Specifies that the level-shifter cells belonging to the specified strategy can only be mapped to a subset of the library cells.

SYNTAX

```
status map_level_shifter_cell
  level_shifter_strategy
  -domain power_domain
  -lib_cells lib_cells
```

Data Types

<i>level_shifter_strategy</i>	string
<i>power_domain</i>	string
<i>lib_cells</i>	list

ARGUMENTS

level_shifter_strategy

Specifies the UPF level-shifter strategy name. The level-shifter strategy name must be unique within the specified power domain.

-domain *power_domain*

Specifies the power domain name to which this level-shifter strategy belongs.

-lib_cells *lib_cells*

Specifies a list of library cells that can be used to map to the level-shifter cells.

DESCRIPTION

This command defines how the **compile** command maps the level-shifter cells. All level-shifter cells belonging to the specified strategy are mapped to one of the library cells specified in the **-lib_cells** list. This subset is honored during resizing. If a valid solution cannot be reached using only the specified library cells, no level-shifter cells are inserted. For example, if the level shifters specified in the **-lib_cells** option cannot be used to shift between the required voltage levels, the tool does not insert any level-shifter cell.

For mapping the enable level-shifter cells, use the **map_isolation_cell** command.

EXAMPLES

In the following example the level-shifter cells belonging to the strategy named *VL_1* can only be mapped to the *LIB_LSHIX2* or *map_level_shifter_cell*

LIB_LSHIX4 library cells:

```
prompt> map_level_shifter_cell LVL_1 -domain PD1 \
           -lib_cells {LIB_LSHIX2, LIB_LSHIX4}
```

SEE ALSO

`map_isolation_cell(2)`
`set_level_shifter(2)`

map_power_switch

Defines which power switch library cells to use for the mapping of the given UPF power switch.

SYNTAX

```
status map_power_switch
  switch_name
  -domain domain_name
  -lib_cells list
```

Data Types

<i>switch_name</i>	string
<i>domain_name</i>	string
<i>list</i>	list

ARGUMENTS

switch_name

Specifies the name of the power switch to be mapped using the specified library cells. The specified name must be a simple name and follow the name specified in the **create_power_switch**. This option is required.

-domain *domain_name*

Specifies the power domain where this power switch was created. This option is required.

-lib_cells *list*

Specifies a list of target library cells to use for the power switch cell mapping. This option is required.

DESCRIPTION

This command is used to explicitly specify which library power switch cells are mapped for the corresponding UPF power switch.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the *switch_1A* power switch in the power domain named *myPowerDomain* with the *lib2A/switch2A* library cell:

```
prompt> map_power_switch switch_1A \
           -domain myPowerDomain -lib_cells lib2A/switch2A
1
```

SEE ALSO

[create_power_switch\(2\)](#)

map_retention_cell

Defines how to map the unmapped sequential cells to retention cells for the specified UPF retention strategy of the power domain.

SYNTAX

```
status map_retention_cell
  retention_strategy
  -domain power_domain
  [-lib_cells lib_cells]
  [-lib_cell_type lib_cell_type]
  [-elements objects]
  [-lib_model_name name {-port port_name net_ref}*]
```

Data Types

retention_strategy	string
power_domain	string
lib_cells	list
lib_cell_type	string
objects	list
name	string
port_name	string
net_ref	string

ARGUMENTS

retention_strategy

Specifies the UPF retention strategy name. The retention strategy name must be unique within the specified power domain.

-domain power_domain

Specifies the power domain name to which this UPF retention strategy is applied.

-lib_cells lib_cells

Specifies a list of target library *lib_cells* to be used for the retention mapping.

-lib_cell_type lib_cell_type

Specifies the retention type to be used for the retention mapping.

-elements objects

Specifies that retention mapping only applies to the sequential cells within the specified objects. The objects can be a list of hierarchical cells, leaf cells, HDL blocks, or register signals of a Verilog always block.

-lib_model_name name {-port port_name net_ref}*^{*}

Specifies the retention library cell or behavioral model and associated port connectivity for verification tools.

DESCRIPTION

This command specifies how the **compile** command performs retention mapping. If **-elements** is not specified, then the mapping applies to all sequential cells to which the specified retention strategy applies.

The retention cell specified using the **-lib_model_name** option is used only by the verification tools. It is not used by the implementation tools. The **-lib_model_name** option is not written out in the UPF' file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the sequential cells under the retention_1 retention strategy to the CLK_LOW retention type:

```
prompt> map_retention_cell retention_1 \
           -domain PD1 -lib_cell_type CLK_LOW
```

The following example maps the sequential cells under the retention_2 retention strategy to the RSDFCD1HVT and RSDFCD2HVT retention library cells. The **-lib_model_name** option specifies the retention library cell, port name, and net reference used by the verification tools.

```
prompt> map_retention_cell retention_2 \
           -domain PDM -lib_cells { RSDFCD1HVT RSDFCD2HVT } \
           -lib_model_name RSDFCDHVT { -port CP UPF_GENERIC_CLOCK \
           -port D ~UPF_GENERIC_DATA \
           -port VDD sn1 \
           -port TVDD retention_ref.power }
```

SEE ALSO

```
set_retention(2)
set_retention_control(2)
```

map_retention_clamp_cell

Defines how to map the zeropin retention clamp cells for the specified UPF retention strategy of the power domain.

SYNTAX

```
status map_retention_clamp_cell
  retention_strategies
  -domain power_domain
  -lib_cells {lib_cells}
```

Data Types

<i>retention_strategies</i>	list
<i>power_domain</i>	string
<i>lib_cells</i>	string

ARGUMENTS

retention_strategies

Specifies a list of UPF retention strategies defined on the given power domain.

-domain *power_domain*

Specifies the power domain name on which this UPF retention strategy is defined.

-lib_cells {*lib_cells*}

Specifies a list of target library *lib_cells* to be used for the zeropin retention clamp cell mapping. Only isolation or enable level-shifter library cells will be allowed to be specified. This option can be used exactly once or twice in a single command. This option should be of the following syntax:

{*path_keyword*{*list_of_library_cells*}}

The *path_keyword* should be UPF_GENERIC_CLOCK or UPF_GENERIC_ASYNC_LOAD. UPF_GENERIC_CLOCK indicates that these library cells must be used for mapping zeropin clamp cells on clock path. UPF_GENERIC_ASYNC_LOAD indicates that these library cells must be used for mapping zeropin clamp cells on async set/reset paths.

DESCRIPTION

This command specifies how the tool performs mapping of zeropin clamp cells. All clamp cells inserted for the specified retention strategy are mapped or remapped to one of the cells specified with the **-lib_cells** option. Resizing is done if required, but the choice is limited only to the library cells specified with the **-lib_cells** option.

This is an override command. It is a TCL command and not a UPF command and so will not be written out in UPF'.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example maps the zeropin retention clamp cell belonging to RET1 strategy inserted on clock path to LC1. Zeropin retention clamp cell belonging to RET1 strategy inserted on async set/reset path will be mapped to LC2.

```
prompt> map_retention_clamp_cell RET1 \
    -domain PD1 \
    -lib_cells {UPF_GENERIC_CLOCK {LC1}} \
    -lib_cells {UPF_GENERIC_ASYNC_LOAD {LC2}}
```

The following example, RET2 retention strategy is specified in two map_retention_clamp_cell commands.

ZPR clamp cells belonging to RET1 strategy of domain PD1 that are

- Inserted on clock path will use LC1
- Inserted on async set/rest path will use LC2

ZPR clamp cells belonging to RET2 strategy of domain PD1 that are

- Inserted on clock path will use LC3 and LC4
- Inserted on async set/rest path will use LC2: This is because, the second command overrides the previously specified clock path clamp cells for RET2 (LC1) with new library cells LC3 and LC4

ZPR clamp cells belonging to RET3 strategy of domain PD1 that are

- Inserted on clock path will use LC3 and LC4
- Inserted on async set/rest path will not have any mapping constraint

```
prompt> map_retention_clamp_cell {RET1 RET2} \
    -domain PD1 \
    -lib_cells {UPF_GENERIC_CLOCK {LC1}} \
    -lib_cells {UPF_GENERIC_ASYNC_LOAD {LC2}}
prompt> map_retention_clamp_cell {RET2 RET3} \
    -domain PD1 \
    -lib_cells {UPF_GENERIC_CLOCK {LC3 LC4}} \
```

mem

Reports memory usage information.

SYNTAX

```
status mem
[-all]
[-verbose]
[-debug]
```

ARGUMENTS

-all

Reports the maximum of the peak memory usage among the main process and its child processes during the compile phase.

-verbose

Reports in detail the peak memory usage of the main process and each child process, including placement, extraction, and routing during the compile phase.

DESCRIPTION

This command reports the peak memory usage of processes. By default, it reports the peak memory usage of the main process in kilobytes. If you specify the **-all** option, it reports the maximum of the peak memory usage among the main process and its child processes for compile. If you specify both the **-all** and **-verbose** options, it also prints out the peak memory usage in megabytes for the main process and each child process.

Memory peak is defined as the memory high-water mark of processes. When the tool reports a memory peak, it means the maximum memory allocated from the operating system. When child processes exist, the tool reports the maximum number among the main process and its child processes.

Note that the **mem** command reports the peak memory usage, not the swap space usage of the process. It actually reports how much memory was allocated from the operating system at the peak point. Some of the memory can be swapped out by the operating system based on the system status.

IMPORTANT: Peak memory use of child processes is only tracked for the "compile" and "optimize_netlist" commands.

EXAMPLES

The following example shows the default command output:

```
prompt> mem  
102400
```

The following example shows the output when using the **-all** and **-verbose** options:

```
prompt> mem -all  
Multicore compile mem-peak: 110 Mb  
102400  
  
prompt> mem -all -verbose  
Multicore compile mem-peak: 110 Mb  
Main process mem-peak: 100 Mb  
Child "placement" called 3 times, mem-peak: 60 Mb  
Child "extraction" called 3 times, mem-peak: 50 Mb  
102400
```

merge_saif

Reads a list of SAIF files with their corresponding weights, computes the merged toggle rate and static probability, and annotates the switching activity for the nets, pins, and ports in the current design. The command then generates a merged output SAIF file.

SYNTAX

```
status merge_saif
  -input_list saif_file_and_weight_list
  [-instance_name inst_name]
  [-output merged_saif_name]
  [-simple_merge]
  [-ignore ignore_name]
  [-ignore_absolute ig_absolute_name]
  [-exclude exclude_file_name]
  [-exclude_absolute ex_absolute_file_name]
  [-unit_base unit_value]
  [-scale scale_value]
  [-khrate khrate_value]
  [-map_names]
```

Data Types

<i>saif_file_and_weight_list</i>	list
<i>inst_name</i>	string
<i>merged_saif_name</i>	string
<i>ignore_name</i>	string
<i>ig_absolute_name</i>	string
<i>exclude_file_name</i>	string
<i>ex_absolute_file_name</i>	string
<i>unit_value</i>	string
<i>scale_value</i>	integer
<i>khrate_value</i>	float

ARGUMENTS

-input_list *saif_file_and_weight_list*

Specifies the name and the corresponding weight of the Switching Activity Interchange Format (SAIF) file list. The *saif_file_and_weight_list* argument is a list of items in the following format:

{-input *name.saif* -weight *number*}

The **-input** and **-weight** are keywords, use the **-input** option to specify the .saif file and use the **-weight** option to specify a number between 0 and 100. For example, in the following statement, the gate_back_1.saif and gate_back_2.saif files are weighted by 20% and 80%, respectively and the sum of all weights is equal to 100.

```
prompt> {-input gate_back_1.saif -weight 20 \
           -input gate_back_2.saif -weight 80}
```

-instance_name *inst_name*

Specifies the instance name as it appears in each SAIF file of the current design instance to annotate. The command annotates the instance itself and all subinstances in the hierarchy of the specified instance.

-output *merged_saif_name*

Specifies the name of the output file. The output file is the merged SAIF file.

-simple_merge

Specifies that all nets, ports, and pins of the current design must be annotated by the specified SAIF file. It also specifies that a simple SAIF file data merge must be performed. You can use the **report_saif** command to verify that each SAIF file annotates 100% of the current design.

-ignore *ignore_name*

Specifies the name of an instance for which the switching activity should be ignored. Use this option to ignore switching activity within the hierarchy of that instance in each SAIF file. The ignored names are recognized by the **-instance_name** option.

-ignore_absolute *ig_absolute_name*

Specifies the name of an instance for which the switching activity should be ignored, but is not affected by the use of the **-instance_name** option. The command determines whether a net name is within the ignored hierarchy before applying the **-instance_name** option.

-exclude *exclude_file_name*

Specifies the name of a file that contains a list of names that should be ignored. Use this option to ignore switching activity for instances specified by the **exclude_file_name** argument. In the file specified with the **exclude_file_name** argument, each ignored name should be on a separate line. Do not mention the **-exclude** option in the file. The ignored names are recognized after the **-instance_name** option is applied.

-exclude_absolute *ex_absolute_file_name*

Specifies the name of a file that contains a list of absolute names to be ignored but which are not affected by the use of the **-instance_name** option.

-unit_base *unit_value*

Specifies the base synthesis timing unit for all SAIF files. The synthesis timing unit is obtained from the value specified with the **-scale** option. This value is used to scale the base unit. The valid values for **unit_value** are **ns**, **us**, or **ps**. The default is **ns**.

-scale *scale_value*

Specifies the value of the scaling factor for the base synthesis timing unit for all SAIF files. The synthesis timing unit is obtained by using **scale_value** to scale the base unit. The valid values for **scale_value** are **1**, **10**, or **100**. The default is **1**.

-khrate *khrate_value*

Specifies a default derating factor value to be used for internal problems for all SAIF files. If you do not use the **-khrate** option, the command uses a default derating factor of **0.5**.

-map_names

Specifies that the SAIF name mapping mechanism should be used to match objects in the SAIF file, with design objects. Since **saif_map** command is not supported in **icc_shell**, this option is not valid in **icc_shell**.

OBSOLETE ARGUMENTS

-rtl_direct

The flows involving forward RTL SAIF files, and flows involving the \Bmerge_saif -rtl_direct is obsolete.

-strip_module *annotated_instance_name*

Specifies the instance name to be annotated in the current design. This option is obsolete. Use the **-instance** option instead.

DESCRIPTION

The **merge_saif** command reads a list of SAIF files with their corresponding weights, computes the merged toggle rate and static probability, and annotates the switching activity, **toggle_rate**, and **static_probability** attributes for the nets, ports, and pins of the current design. The **merge_saif** command also generates a merged output SAIF file.

To identify the instance (and corresponding subinstances) to annotate, use the **-instance_name** option. To set the synthesis timing unit, use the **-unit_base** and **-scale** options, unless you are certain that the synthesis timing unit is 1ns. To specify a derating factor use the **-khrate** option. If you do not specify a derating factor, the tool uses a default value of 0.5.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reads and merges weighted SAIF files, annotates switching activity for the current design, and generates an output SAIF file:

```
prompt> merge_saif -input_list \
  {-input gate_back1.saif -weight 10 \
  -input gate_back2.saif -weight 20 \
  -input gate_back3.saif -weight 30 \
  -input gate_back4.saif -weight 40} \
  -instance E/UUT -output merged_saif.saif
```

move_lib

Moves a library and its contents from one place to another.

SYNTAX

```
status move_lib
  [-force]
  [-from_lib source_name]
  -to_lib destination_name
```

Data Types

<i>source_name</i>	string
<i>destination_name</i>	string

ARGUMENTS

-force

Overwrites the destination library when the library is open, modified, but not yet saved.

-from_lib *source_name*

Specifies the source library. If not given, the current_lib is used. This can be a (full-path, relative-path, or simple) name.

-to_lib *destination_name*

Specifies the destination library name. This can be a simple, relative, or absolute path. If it is a relative or absolute path, the trailing portion of the path after the last '/' becomes the name of the library. It will be an error if the a library, file, or directory of the same name already exists on disk.

DESCRIPTION

This command moves a library from one place to another in the file system. It is largely unnecessary as the LINUX mv(1) command will work also, but it is in our system for completeness. For both **copy_lib** and **move_lib**, care is taken to not read into memory any of the designs that are already in memory, so copying a large library is as efficient as it can be.

The command returns 1 if successful, or 0 otherwise. If an illegal name is given, a TCL error is raised.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

This example moves RefLib1, calling it RefLibA.

```
prompt> move_lib -from_lib RefLib1 -to_lib RefLibA  
1
```

mw_cel_collection

Describes the methodology for using mw_cel collection.

DESCRIPTION

How to specify mw_cel by name

A unique mw_cel can be specified by the following:

A[B;C]

Where:

A is the base name of the mw_cel, and the maximum length of A is 1023.

B is the view name of the mw_cel, and the maximum length of B is 31.

C is the version number. The version number starts at 1.

The following characters . (period) and ; (semicolon) are invalid in the base name, view name, or version of an mw_cel name.

The version of an mw_cel name is usually omitted. If the version is not specified, the latest version is assumed unless an individual command has a special interpretation. The latest version is the version with highest version number.

Because ; is a keyword in Tcl language, if the version is to be specified for an mw_cel, you must use proper quoting, such as double quotation marks, for example:

"top.CEL;1".

If you do not use double quotation marks, the command might appear to succeed, but might produce unexpected results. For example, in the following command:

```
prompt> open_mw_cel test1.CEL;1
Info: Opened "test1.CEL;2" from "/root/data/design" library
[1]
```

1 is considered as a separate command, and the **open_mw_cel** command actually opens the latest version, not version 1.

You can omit the view name. When you do this, you must also omit the version. If you do not specify the view name, the command will assume the CEL view and the latest version unless the individual command has a special interpretation.

Currently supported views

Currently, 5 kind of views are supported: CEL, FRAM, err, FILL and ILM. You can not specify the mw_cel of other views through the command line. However, some commands may have the ability to operate on other views internally.

Display of the mw_cel collection

The display of an mw_cel collection does not contain view and version. For example:

```
prompt> open_mw_cel test1
Info: Opened "test1.CEL;2" from "/root/data/design" library
{test1}
```

To get the view and version information, use the attribute `version` and `view_name`.

```
prompt> get_attribute [current_mw_cel] view_name  
CEL  
prompt> get_attribute [current_mw_cel] version  
2
```

name_format

Specifies the prefix and suffix used for naming isolation cells and level shifters created by the tool.

SYNTAX

```
status name_format
  [-isolation_prefix name]
  [-isolation_suffix name]
  [-level_shift_prefix name]
  [-level_shift_suffix name]
```

Data Types

name string

ARGUMENTS

-isolation_prefix

Specifies the prefix to use for naming isolation cells. The default is "".

-isolation_suffix

Specifies the suffix to use for naming isolation cells. The default is "_UPF_ISO".

-level_shift_prefix

Specifies the prefix to use for naming level-shifter cells. The default is "".

-level_shift_suffix

Specifies the suffix to use for naming level-shifter cells. The default is "_UPF_LS".

DESCRIPTION

This command specifies the suffix and prefix used for naming new isolation cells and level shifters created by the tool. The name of the element that is being isolated or level-shifted is used as the base for the name. The prefix is added to the front and the suffix is added to the back to create the new name.

For example, an isolation cell that isolates a port named *p1* is named *snps_PDName_ISOName_snps_p1_UPF_ISO* by default, where "PDName", "ISOName", and "_UPF_ISO" represent the power domain name, isolation strategy name, and default suffix, respectively.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the prefixes for naming new isolation cells and level shifters:

```
prompt> name_format -isolation_prefix "MY_ISO" -level_shift_prefix "MY_LS"
```

SEE ALSO

`set_isolation(2)`
`set_level_shifter(2)`

open_lib

Open an already-existing library for edit or read access.

SYNTAX

```
open_return open_lib
  [-edit | -read]
  [-ref_libs_for_edit]
  library_name
```

Data Types

library_name Library name in simple, relative, or absolute path.

ARGUMENTS

-edit

Opens the library in edit mode.

This is the default for design libraries if you do not specify any options with this command.

In an implementation tool, cell libraries can be opened only in read mode. If you try to explicitly open a cell library in edit mode, the command issues a warning message and the library is opened in read mode.

This option is mutually exclusive with the **-read** option and is not available in the library manager.

-read

Opens the library in read-only mode.

This is the default open mode for cell libraries in an implementation tool.

This option is mutually exclusive with the **-edit** option and is not available in the library manager.

-ref_libs_for_edit

Open reference module libraries in edit mode so that lower-level designs can be modified. Lib-cell libraries will still be open in read mode even if this option is used. This option can only be used when opening a design library in edit mode, either by using the default open mode or explicitly with **-edit**.

To edit cell libraries, use the edit flow in the library manager (icc2_lm_shell).

This option is not available in the library manager.

library_name

Specifies library to open.

Because library names become directory or file names, they cannot contain the slash ("/") or colon (":") character.

RETURN VALUE

Returns the library if successful, or 0 if not. If an illegal name is given, a Tcl error is raised.

DESCRIPTION

This command opens a pre-existing library. The library can be in is distributed (file-system hierarchical) form or a single-file form. The library name can be given as a full path name, a relative path name, or a single name. In the last two cases, the search_path is used to determine the full path for the library. When the library is opened, its design catalog is read in, but no designs are read in. As a library is being opened through this command, all of the libraries on its ref-lib list are also opened in read-only mode. These reference libraries have their design catalogs read in, but their reference libs are not read in until and unless the reference lib is also explicitly opened. The technology section in the design library, or the technology section of the dedicated technology library in the reference libraries, or the first technology section found in its reference libraries if no technology library is specified, becomes the technology data for the design library. In the library manager, if an aggregate flow is created, this command adds the cell library to an aggregate library. To edit the cell library, use the edit flow in the library manager (icc2_lm_shell).

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following command opens the design library MyDesigns.

```
prompt> open_lib MyDesigns
INFO: loading technology data from "MyLibCells"
1
prompt> get_libs
{MyDesigns RefLib1 RefLib2 MyLibCells}
```

open_mw_lib

Opens a Milkyway library.

SYNTAX

```
collection open_mw_lib
  [-readonly | -write_ref]
  mw_lib
```

Data Types

mw_lib string

ARGUMENTS

-readonly

Opens the Milkyway library only for reading. You cannot modify and save the library in this mode.

The **-readonly** and **-write_ref** options are mutually exclusive. The default is to open the main library as read/write and all reference libraries as read only.

-write_ref

Opens the reference library for writing. This option implies that the main library is opened for writing.

The **-readonly** and **-write-ref** options are mutually exclusive. The default is to open the main library as read/write and all reference libraries as read only.

mw_lib

Opens the Milkyway library.

DESCRIPTION

This command opens a Milkyway library. The two access permissions for an opened library are read only or read/write. Specifying the write permission implies that read permission is granted. If you specify the **-readonly** option, the command opens the main library and all reference libraries as read only. If you specify the **-write_ref** option, it opens the main library and all reference libraries as read/write.

If you open the library as read only, you can read from the library but you cannot write to the library.

Specifically, opening the Milkyway CEL view to write in it is not permitted. If you open the library as read/write, you can modify it.

The opened Milkyway library is automatically set to be the current Milkyway library.

You cannot open more than one main library at the same time. To open another main library, you must first close the previous main

library.

This command returns a collection of Milkyway libraries if it succeeds.

See the man pages for the **set_mw_lib_reference** and **set_mw_technology_file** commands for information on setting or changing reference libraries and technology files.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example opens a Milkyway library named *access05* for writing in the current session:

```
prompt> open_mw_lib access05
{access05}
```

optimize_netlist

Performs a high-effort optimization on the current design for better quality of results (QoR).

SYNTAX

```
status optimize_netlist
  [-area]
  [-no_boundary_optimization]
  [-no_seq_output_inversion]
  [-force]
```

ARGUMENTS

-area

Performs monotonic gate-to-gate optimization to improve area without degrading timing or leakage. To maximize area benefits, run the **optimize_netlist -area** command as the final area recovery step at the end of the synthesis flow. You can also use the command on legacy netlists.

-no_boundary_optimization

Disables hierarchical boundary optimization. This option is superseded by **set_boundary_optimization** settings.

-no_seq_output_inversion

Disables sequential output inversion. This option is superseded by **set_register_output_inversion** settings.

-force

If **compile_optimize_netlist_area** or **compile_high_effort_area** is set to **true** for compile, then the subsequent **optimize_netlist -area** will be NO-OP by default. This option is used to run **optimize_netlist -area** even in that case. This option is applicable for DC NXT only.

SEE ALSO

[compile_ultra\(2\)](#)
[compile_optimize_netlist_area\(3\)](#)
[compile_high_effort_area\(3\)](#)

optimize_registers

Performs retiming of sequential cells (edge-triggered registers or level-sensitive latches) on a mapped gate-level netlist; determines the placement of sequential cells in a design to achieve a target clock period; and minimizes the number of sequential cells while maintaining that clock period.

SYNTAX

```
status optimize_registers
  [-minimum_period_only]
  [-no_compile]
  [-sync_transform multiclass | decompose | dont_retime]
  [-async_transform multiclass | decompose | dont_retime]
  [-check_design [-verbose]]
  [-print_critical_loop]
  [-clock clock_name [-edge rise | fall]]
  [-latch]
  [-justification_effort low | medium | high]
  [-only_attributed_designs]
  [-delay_threshold target_clock_period]
```

Data Types

<i>clock_name</i>	string
<i>target_clock_period</i>	float

ARGUMENTS

-minimum_period_only

Indicates that only the minimum period step of the retiming algorithm (minimum clock-period retiming) and not the minimum area (sequential cell-count optimization) step is to be executed. By default, both the minimum period and minimum area optimization steps are executed. This option is useful if you want a fast turnaround when trying to optimize the design's timing. The runtime is reduced, but the area results will not be optimal.

After you are satisfied with the timing, you can attempt to reduce the area by running the retiming command without this option.

-no_compile

Indicates that the default incremental logic synthesis step, normally performed after computation of the optimal sequential cell locations, is to be omitted. If you specify this option, no design rule fixing is performed. Generic sequential cells may remain in the design if the **-no_compile** option is specified. Using the **-no_compile** option, you can choose a logic compilation script that is adapted to your design instead of relying on the default used internally by **optimize_registers**. It is important to perform a logic synthesis step after sequential cell retiming to obtain the best possible timing results.

-sync_transform multiclass | decompose | dont_retime

Specifies which transformation method is used for synchronous sequential cells in the design. An edge-triggered register is synchronous if none of its input pins change the outputs asynchronously. A level-sensitive latch is considered synchronous if none of its input pins can change the outputs during the clock phase where the latch is not transparent.

Specifying **multiclass** transformation indicates that the identifiable synchronous clear, set, and enable functionality is moved with the synchronous sequential cells if they are moved during retiming. Sequential cells are classified according to their set, clear, and enable connections. The class of the sequential cells at the fanin or fanout of a combinational cell determines whether retiming across this cell can be performed.

Specifying **decompose** transformation indicates that synchronous sequential cells in the design are transformed into an instance of a D-flip-flop or D-latch and additional combinational logic to create the necessary synchronous functionality. Only the D-flip-flop/D-latch instance can be moved during retiming.

Specifying **dont_retime** indicates that synchronous sequential cells are not moved during retiming. Their mapping might still be changed to a different flip-flop from the technology library.

The **dont_touch** attributes and retiming transformation attributes set on individual sequential cells override the value set in this option. To set retiming transform attributes, use the **set_transform_for_retimming** command.

The default argument for this option is **multiclass**.

-async_transform multiclass | decompose | dont_retime

Specifies which transformation method is used for asynchronous sequential cells in the design. An edge-triggered register is asynchronous if at least one of its input pins changes the outputs asynchronously. A level-sensitive latch is asynchronous if at least one of its inputs can change the outputs during the clock phase where the latch is not transparent.

Specifying the **multiclass** transformation indicates that the identifiable asynchronous clear and set functionality, as well as any synchronous set, clear, and enable functionality, is moved with the asynchronous sequential cells, if they are moved during retiming. Sequential cells are classified according to their set, clear, and enable connections. The class of the sequential cells at the fanin or fanout of a combinational cell determines whether retiming can be performed across this cell.

Specifying the **decompose** transformation indicates that asynchronous sequential cells in the design are transformed into an instance of a flip-flop or latch with asynchronous set and clear inputs, as necessary, and additional combinational logic to create the necessary synchronous functionality. Only the flip-flop/latch instances can be moved during retiming. They will be classified according to their synchronous set, clear, and enable functionality.

Specifying the **dont_retime** value indicates that asynchronous sequential cells are not moved during retiming. Their mapping might still be changed to a different flip-flop from the technology library.

The **dont_touch** attributes and retiming transformation attributes set on individual sequential cells override the value set in this option. To set retiming transform attributes, use the **set_transform_for_retimming** command.

The default value for this option is **multiclass**.

-check_design

Displays additional information about the design before and after retiming. This information includes the number of cells in different categories (for example, hierarchy cells with **dont_touch** attributes or non-movable sequential cells) and more detailed information about the selection of the preferred flip-flop or latch. You use this information to help in troubleshooting if retiming does not show the expected results.

-verbose

Displays the explicit names of the cells along with the number of cells in each category for most categories of the **-check_design** option. This option can be used only with the **-check_design** option. The explicit naming of cells can help to locate a problem; however, the lists of output names might be long.

-print_critical_loop

Displays the critical loop of the design, as seen during retiming. The critical loop is defined as the sequence of directly-connected combinational and sequential cells whose total combinational delay divided by the number of registers in the loop has a higher value than any other loop in the design. The critical loop limits the minimum clock period that can be achieved by retiming. Use this option to help with troubleshooting problem areas of the design if the intended clock period cannot be achieved with the given number of sequential cells in the design. If you are pipelining a data path, you might need to add pipeline stages in the HDL code.

-clock clock_name

Specifies the name of the clock whose sequential cells are to be retimed. The clock must not be a virtual clock, that is, it must have a clock port associated with it. The name of the clock is either the name specified in the **create_clock** command or the name of the clock port, if the **create_clock** command had no name specified. The registers of the clock are all sequential cells which are

triggered by this clock. The connection from the clock port to the sequential cell can be through clock-gating cells, buffer cells, and inverter cells. If the **-clock** option is specified and edge-triggered registers are retimed, registers of other clocks are not retimed. If level-sensitive latches are retimed and the **-clock** is specified, the latches driven by this clock as well as those driven by other clocks needed to complete a two-phase clock system are retimed. If edge-triggered registers are retimed, only registers triggered by one specific edge of the clock are retimed. By default the registers triggered by the rising edge are retimed. A different edge can be specified using the **-edge** option.

-edge rise | fall

Specifies whether the registers triggered by the rising or the falling edge of the clock are to be retimed. This option can be used only with the **-clock** option. When level-sensitive latches are retimed, this option has no effect.

-latch

Specifies that level-sensitive latches are to be retimed instead of edge-triggered sequential cells (flip-flops). If this option is used, the edge-triggered sequential cells in the design are not moved. In order to be able to retime latches they must be driven by a symmetrical two-phase clocks system. Latches that are used to prevent glitches in gated clocks are not moved, even if the **-latch** option is used. These latches are in the fanin of clock-gating cells.

-justification_effort low | medium | high

Specifies the justification effort level to be used during backward justification of registers. You can specify either **low**, **medium** or **high** as a value for this option. Specifying **low** ensures that justification terminates very quickly, but the QoR may be bad. Specifying **medium** might give good QoR with a larger runtime. Specifying **high** might give the best QoR without any regard for runtime. The default value for this option is **medium**.

-only_attributed_designs

Specifies that instead of the top-level design, only instances of those designs in the hierarchy below the current designs that have the **optimize_registers** attribute set are retimed. The **optimize_registers** attribute can be set by using the **set_optimize_registers** command. The instances with attributes are retimed using the constraints derived from their environment.

-delay_threshold target_clock_period

Instructs *Design Compiler* to improve paths with delays less than worst delay as given in critical loop report. *Design Compiler* makes additional retiming passes until all such paths are optimized to operate at given target clock period.

DESCRIPTION

The **optimize_registers** command operates by default on the current design. If the **-only_attributed_designs** option is used, it will work only inside those hierarchical cells of the current design that are instances of designs having the **optimize_registers** attribute. The command operates in two phases. During the first phase, it performs retiming by moving the sequential cells in the design to meet a target clock period and minimize the number of sequential cells while maintaining that clock period. The second phase consists of an incremental compile, which adjusts the design to the changed fanout structure. By default, **optimize_registers** uses the clock period of the clocks being retimed, if available. Otherwise, **optimize_registers** returns without moving registers. The final incremental compile targets the clock period defined by the **create_clock** command.

If the design has multiple clocks that are not virtual clocks and the **-clock** option has not been used, sequential cells for all clocks are retimed during the first phase of retiming. When retiming edge-triggered registers, the retiming is performed one clock at a time. When retiming level-sensitive latches the retiming is performed for sets of clocks which together with their latches form a symmetric two-phase clock system. Clocks with a larger clock period are retimed before clocks with a smaller clock period. If two clocks have the same clock period, the clock with the larger number of movable sequential cells is retimed first. When retiming edge-triggered registers for each single clock, the registers triggered by the rising edge are retimed before those triggered by the falling edge. Note that this default order may not yield the best possible results. Also, retiming all clocks in phase one means that there will be no incremental optimization of the combinational logic when retiming different clocks. Therefore, it is recommended that you determine the best order for retiming clocks and apply it using multiple runs of **optimize_registers** using the **-clock** option.

The **optimize_registers** command has the following requirements:

- A gated clock must be derived from one of the design's clock ports or another gated clock through a unate clock-gating cell (usually an logic AND or logic OR gate). The clock gating control logic may contain latches. The clock network between the base clock port and gated clocks may contain buffer and inverter cells.

- Flip-flops and master-slave elements cannot be present in the same design. Master and slave clock waveforms cannot overlap.
- All clock pins of all flip-flops in the design must be connected to their base clock or a gated clock derived from the base clock in the following way: The connection from the clock origin (that is, the clock port or the clock-gating cell) to the clock pins can contain buffer and inverter cells with one input and one output pin. All clock pins must be connected either by an even number (including zero) or odd number of inverters to the clock origin. Buffer and inverter cells on the clock network may be removed during retiming. Therefore, any existing clock tree must be resynthesized.
- All sequential cells must be single bit, or it must be possible to decompose them into single-bit registers.
- Only certain FPGA technologies are supported.
- Designs cannot contain a combinational loop.
- Set the timing constraints for the design in the following way: The external clock ports of the design must have a clock constraint created by the **create_clock** command. These are called the base clocks. All primary inputs of the design must have a non-negative input delay relative to one or more of the base clocks. All primary outputs of the design must have a non-negative output delay relative to one of the base clocks. Negative input and output delays are tolerated, but the quality of the final retiming result may be worse than expected. Point-to-point timing exceptions as created by the **set_false_path**, **set_multicycle_path**, **set_max_delay**, and **set_min_delay** commands are respected but their presence may reduce the quality of results. In the presence of such point-to-point exceptions, timing constraint violations may be worsened by retiming. Therefore, it is best not to apply retiming to designs with these exceptions. Case analysis constraints are also ignored when moving the sequential cells. The incremental compilation after moving the sequential cells takes all types of constraints into account.
- Designs cannot contain unmapped synthetic library components.

The movement of sequential cells and the handling of hierarchical subdesigns can be controlled as follows (in addition to the **-async_transform** and **-sync_transform** options):

- If a sequential cell has the **dont_touch** attribute set, **optimize_registers** does not move the sequential cell itself, nor does it move any other sequential cell across that cell.
- If instances contain the **dont_touch** attribute, they are not ungrouped. The **optimize_registers** command does not ungroup and does not place any registers inside an instance that has the **dont_touch** attribute set. If a hierarchical cell does not contain sequential cells and has the **dont_touch** attribute set, sequential cells can move across the cell. If the cell does contain sequential cells and has the **dont_touch** attribute set, sequential cells cannot move across the cell.
- The **optimize_registers** command can move sequential cells into a level of hierarchy. In this case, a clock pin is inserted into the interface of the instance if there was no clock pin previously. The new clock pin is named after the clock pin of the enclosing hierarchical instance.

The **optimize_registers** command supports handling of black-box cells (that is, cells for which no timing is specified; for example, placeholders for RAMs). The **optimize_registers** command models a black-box cell as if the cell were external to the current design, without actually changing the interface of the design itself.

The **optimize_registers** command includes a delay modeling capability. For predictability, the algorithm selects from the target library a flip-flop or latch that has a small setup time, good drive at the outputs, and low input loading as compared with other flip-flops or latches in the library. This flip-flop or latch is designated as the preferred flip-flop or preferred latch. The preferred flip-flop/latch helps to provide tighter bounds on the performance variation after the **optimize_registers** sequence. To select a particular preferred flip-flop, use the **set_register_type** command. To exclude certain flip-flops, use the **set_dont_use** command.

The retiming process produces some delay report information. For details, see the *Design Compiler User Guide*. After retiming, implementation selection is no longer performed on synthetic library components in the design by subsequent executions of the **compile** command.

The **optimize_registers** command can also be used to optimizesub-critical paths using *delay threshold optimization*. Sub critical paths are those paths which operate at delays less than the final worst critical delay provided by retiming. Threshold optimization technique can be used to balance delays on paths with positive slacks. Optimize register uses target clock period specified using **delay_threshold** and performs multiple passes of min-period retiming on paths that operate at delays less than worst delay but greater than target clock period.

The **optimize_registers** command is also supported in multicorner-multimode (MCMM) technology, which is available with Design Compiler Graphical.

EXAMPLES

The following example shows **optimize_registers** being applied to a netlist:

```
prompt> read pre_retimimg.db
```

```
/*
 * Delete dont_touch'es used for
 * hierarchical compile strategy.
 */
```

```
prompt> optimize_registers
```

SEE ALSO

```
current_design(2)

set_dont_use(2)
set_transform_for_retiming(2)
set_register_type(2)
set_optimize_registers(2)
attributes(3)
```

parallel_execute

Runs reporting or checking commands in parallel.

SYNTAX

```
status parallel_execute
  [-out file_name]
  [-list_all]
  [report_command_list]
```

Data Types

<i>file_name</i>	string
<i>report_command_list</i>	list

ARGUMENTS

-out *file_name*

Specifies the file name for the generated output file.

-list_all

Lists all supported commands that can run in parallel using this command.

report_command_list

Specifies a list of checking or reporting commands to execute in parallel.

DESCRIPTION

This command runs various supported reporting and checking commands in parallel. You must specify a list of commands to run. New jobs are launched to run the listed commands. The **parallel_execute** command completes after the longest running command has finished. Use the **set_host_options** command to specify the number of cores that the **parallel_execute** command can use to run the listed commands in parallel. The command can use only up to eight cores by default. When you specify more than eight cores, the tool overrides it with the default. You should run the **update_timing** command before issuing **parallel_execute** command.

You must enclose the complete command string with double quotation marks, for example, "**report_timing -input_pins -nets -path_type only**".

EXAMPLES

The following example shows a **parallel_execute** run.

```
prompt> update_timing  
prompt> set_host_options -max_cores 4  
prompt> parallel_execute [list "report_qor" \  
    "report_timing -from a-to z2 -path_type short" \  
    "report_cell -connections -verbose {t_bar}" \  
    "report_design"]
```

The following example redirects the output of the command to a file. The tool handles write and append modes properly. Each command output can be redirected to a separate file or append mode can be used to append the output to an existing file.

```
prompt> set LOG "qor_report.log"  
prompt> update_timing  
prompt> set_host_options -max_cores 2  
prompt> parallel_execute [list \  
    "report_timing -input_pins -nets -path_type only > $LOG" \  
    "report_qor -summary >> $LOG"]
```

The following example redirects the output of all commands to a file. Output of all the listed commands are written to the report.log file.

```
prompt> set LOG "report.log"  
prompt> update_timing  
prompt> set_host_options -max_cores 2  
prompt> parallel_execute -out $LOG [list "report_timing" "report_qor" "report_cell"]
```

SEE ALSO

[set_host_options\(2\)](#)

parse_proc_arguments

Parses the arguments passed into a Tcl procedure.

SYNTAX

```
string parse_proc_arguments
```

ARGUMENTS

The **parse_proc_arguments** command has no arguments.

DESCRIPTION

The **parse_proc_arguments** command is used within a Tcl procedure to enable use of the -help option, and to support argument validation. It should typically be the first command called within a procedure. Procedures that use **parse_proc_arguments** will validate the semantics of the procedure arguments and generate the same syntax and semantic error messages as any application command (see the examples that follow).

When a procedure that uses **parse_proc_arguments** is invoked with the -help option, **parse_proc_arguments** will print help information (in the same style as using **help -verbose**) and will then cause the calling procedure to return. Similarly, if there was any type of error with the arguments (missing required arguments, invalid value, and so on), **parse_proc_arguments** will return a Tcl error and the calling procedure will terminate and return.

If you didn't specify -help, and the specified arguments were valid, the array variable *result_array* will contain each of the argument values, subscripted with the argument name. Note that the argument name here is NOT the names of the arguments in the procedure definition, but rather the names of the arguments as defined using the **define_proc_attributes** command.

The **parse_proc_arguments** command cannot be used outside of a procedure.

EXAMPLES

The following procedure shows how **parse_proc_arguments** is typically used. The argHandler procedure parses the arguments it receives. If the parse is successful, argHandler prints the options or values actually received.

```
proc argHandler args {  
    parse_proc_arguments -args $args results  
    foreach argname [array names results] {  
        echo " $argname = $results($argname)"  
    }  
}  
define_proc_attributes argHandler -info "argument processor" \
```

```
-define_args \
{{-Oos "oos help" AnOos one_of_string {required value_help {values {a b}}}}
 {-Int "int help" AnInt int optional}
 {-Float "float help" AFloat float optional}
 {-Bool "bool help" "" boolean optional}
 {-String "string help" AString string optional}
 {-List "list help" AList list optional}}
{-IDup int dup AIDup int {optional merge_duplicates}}
```

Invoking argHandler with the -help option generates the following:

```
prompt> argHandler -help
Usage: argHandler # argument processor
-Oos AnOos      (oos help:
                  Values: a, b)
[-Int AnInt]     (int help)
[-Float AFloat]  (float help)
[-Bool]          (bool help)
[-String AString] (string help)
[-List AList]    (list help)
```

Invoking argHandler with an invalid option causes the following output (and a Tcl error):

```
prompt> argHandler -Int z
Error: value 'z' for option '-Int' not of type 'integer' (CMD-009)
Error: Required argument '-Oos' was not found (CMD-007)
```

Invoking argHandler with valid arguments generates the following:

```
prompt> argHandler -Int 6 -Oos a
-Oos = a
-Int = 6
```

proc(2)

preview_dft

Previews, but does not implement, the test points, scan chains, and on-chip clocking control logic to be added to the current design.

SYNTAX

```
status preview_dft
[-show object_types]
[-test_points all]
[-test_wrappers all]
[-bsd cells | data_registers | instructions | tap | all]
[-script]
[-verbose]
```

Data Types

object_types list

ARGUMENTS

-show *object_types*

Reports information for the objects specified as values, in addition to the summary report the command produces by default. You must specify one or more of the following values for the *object_types* argument:

- The **bidirectionals** argument displays bidirectional port conditioning in scan shift. Reports the specified and resolved conditioning for each bidirectional port.
- The **cells** argument displays scan cells. Scan segments are distinguished by using keys that default to **s**. Scan link locations are marked by keys placed on the cells that precede them. Wire keys default to **w**; scan-out lockup keys default to **l**. You can change key defaults by using the **test_scan_segment_key**, **test_scan_link_so_lockup_key**, and **test_scan_link_wire_key** variables.
- The **qgates** argument is similar to the **cells** argument, except that the report also displays "(g)" annotations beside scan cells whose functional outputs have been gated to reduce power during scan shift. This functional gating feature is enabled by the **set_scan_suppress_toggling** command. For more information, see the man page.
- The **scan** argument displays hierarchical **set_scan_element** command attribute values. Although **set_scan_element** commands can be applied to hierarchical cells, leaf cells, library cells, and designs, the **preview_dft** command reports scan attribute values only for hierarchical cells and leaf cells. These reflect the impact of every **set_scan_element** command you apply to the design. Scan cells with true scan attributes are distinguished by using keys that default to **t**. You can change the default by using the **test_scan_true_key** environment variable.
- The **scan_clocks** argument displays scan clock domains. For multiplexed flip-flop scan styles, it displays the first cell or segment clocked by a new clock in each chain, and it shows the last cell or segment in the chain. An ordered triplet shows the scan clock name, trigger time, and whether the clock edge is rising or falling.

The **preview_dft** command does not distinguish capture time and launch time because these are the same for edge-triggered elements. Additional entries are generated when either the scan clock or trigger time changes. It displays exit and entry points. Lines containing three dots (...) show that there are intervening scan cells. Only entry points have ordered triplets, which are aligned for readability. If internal clocks have been created in the design by using the **set_scan_configuration**

command with the **-internal_clocks** option or the **create_test_clock** command with the **-internal_clocks** option, the **preview_dft** command displays internal clock pin names instead of the external clock names. The triplet is replaced by "(No clock)" if the cell or segment does not have scan clock information.

For other scan styles, using the **preview_dft** command with the **-show scan_clocks** option prints the scan clocks for every scan chain.

- The **scan_signals** argument displays scan signals, including hookup pins and sense values between them. If scan ports are not shared with mission mode ports, the **preview_dft** command generates interim port names by using the strings specified following environment variables, as appropriate, with %s characters deleted. The following names can change when the ports are created to avoid naming conflicts:

```
test_clock_port_naming_style
test_scan_clock_a_port_naming_style
test_scan_clock_b_port_naming_style
test_scan_clock_port_naming_style
```

- The **segments** argument displays scan segments. It also displays segment scan inputs, scan outputs, scan enables, and scan clocks.
- The **tristates** argument displays the disabling in scan shift for all tristate nets in a design. It reports the specified and resolved disabling for each tristate net.
- The **voltages** argument displays the voltage value for a scan cell or scan segment. It displays the operating voltages of the cell or segment in a scan chain. The voltage is displayed only for the first cell or segment and any other cell or segment at voltage boundaries.
- The **power_domains** argument displays the power domain ID for a scan cell or scan segment. It displays the power domain ID of the cell or segment in a scan chain. The power domain ID is displayed only for the first cell or segment, and any other cell or segment at power domain boundaries.
- The **scan_summary** argument displays scan chain information in short format.
- The **all** argument displays all information about a scan configuration.

The **-show** and **-script** options are mutually exclusive; do not use them together. If you attempt to use them together, the command generates a warning message, and the **-show** option is ignored.

-test_points all

Reports all test points information, in addition to the summary report the **preview_dft** command produces by default. The information displayed includes names assigned to the test points, locations of violations being fixed, names of test mode tags, logic states that enable the test mode, and names of data sources or sinks for the test points.

The **-test_points** and **-script** options are mutually exclusive; do not use them together. If you attempt to use them together, the command generates a warning message, and the **-test_points** option is ignored.

-test_wrappers all

Reports all information about core wrappers, in addition to the summary report the command produces by default. This option displays the number of interface ports, ports wrapped, type of wrapper cells inserted, and ports excluded from wrapping. You cannot use this option with the **-script** option.

-bsd cells | data_registers | instructions | tap | all

Specifies that **preview_dft** reports detailed information about one or more sections of the boundary-scan architecture. The valid values are as follows:

- **cells** shows the boundary-scan register cells.
- **data_registers** shows the name and length of each boundary-scan test data register.
- **instructions** shows the boundary-scan instructions and their optimization codes.
- **tap** shows the TAP ports.
- **all** shows all details of the boundary-scan architecture.

-script

Produces a shell script, written to standard output, that specifies the required scan configuration. You cannot use this option with the **-show**, **-test_points**, or **-test_wrappers** option. If you attempt to use **-script** with these options, the command generates a warning message, and ignores the **-show**, **-test_points**, and **-test_wrappers** options.

-verbose

Generates multiple warning messages for a set of similar cells or pins with the same design rule violation. By default, a warning message is generated for only the first cell or pin found for a rule violation.

DESCRIPTION

This command previews, but does not implement, the test points, scan chains, and clock controllers to be added to the current design. The preview is based on the current set of scan, test point, and clock controller specifications. The command generates a report without actually performing any synthesis tasks. The report shows the effects of the current specifications, which you can modify, and then rerun the command as many times as needed until you are satisfied with the previewed results.

Process

The **preview_dft** command first generates information on the scan architecture that will be implemented. In the case of a DFTMAX insertion, **preview_dft** provides information about the compressor being created, and for basic scan, the specific chain information for the design.

Next, the command generates and displays a scan chain design that satisfies scan specifications on the current design. This design is exactly the scan chain design that is presented to the **insert_dft** command for synthesis, so you can preview your test point and scan chain designs without synthesizing the design; you can change your specifications to explore the design space, as necessary.

Executing the command without options generates a summary report that includes the number of test points, test_modes, test point enables, sources and sinks, number of scan chains, test methodology, and scan style. Applicable clock domain constraints, scan enable (or scan enable inverted), and hookup pins are included if the scan style is **multiplexed_flip_flop**. For each scan chain, the command displays the chain name, scan-in port, scan-out port, and length.

If scan ports are not shared with mission mode ports and new ports are created, the command generates interim port names. This is performed by appending an internal integer chain index to the strings specified in the following environment variables, as appropriate, with %s characters deleted. These names can change when the ports are created to avoid cell-naming conflicts.

```
test_scan_in_port_naming_style
test_scan_out_port_naming_style
test_scan_enable_port_naming_style
test_scan_enable_inverted_port_naming_style
```

EXAMPLES

The following example displays scan clocks:

```

print_message_info

Prints information about diagnostic messages that have occurred or have been limited.

SYNTAX

```
string print_message_info
  [-ids id_list]
  [-summary]
```

Data Types

id_list list

ARGUMENTS

-ids *id_list*

Specifies a list of message identifiers to report. Each entry can be a specific message or a glob-style pattern that matches one or more messages. If this option is omitted and no other options are given, then all messages that have occurred or have been limited are reported.

-summary

Generates a summary of error, warning, and informational messages that have occurred so far.

DESCRIPTION

The **print_message_info** command enables you to print summary information about error, warning, and informational messages that have occurred or have been limited with the **set_message_info** command. For example, if the following message is generated, information about it is recorded:

```
Error: unknown command 'wrong_command' (CMD-005)
```

It is useful to be able to summarize all recorded information about generated diagnostic messages. Much of this can be done using the **get_message_info** command, but you need to know a specific message ID. By default, **print_message_info** summarizes all of the information. It provides a single line for each message that has occurred or has been limited, and one summary line that shows the total number of errors, warnings, and informational messages that have occurred so far. If an *id_list* is given, then only messages matching those patterns are displayed. If **-summary** is given, then a summary is displayed.

Using a pattern in the *id_list* is intended to show a specific message prefix, for example, "CMD*". Note that this does not show all messages with that prefix. It shows only the messages that have occurred or have been limited.

EXAMPLES

The following example uses **print_message_info** to show a few specific messages:

```
prompt> print_message_info -ids [list "CMD*" APP-99]
```

Id	Limit	Occurrences	Suppressed
CMD-005	0	7	2
APP-99	1	0	0

At the end of the session, you might want to generate some information about a set of interesting messages, such as how many times each occurred (which includes suppressions), how many times each was suppressed, and whether a limit was set for any of them. The following example uses **print_message_info** to get this information:

```
prompt> print_message_info
```

Id	Limit	Occurrences	Suppressed
CMD-005	0	12	0
APP-027	100	150	50
APP-99	0	1	0

Diagnostics summary: 12 errors, 150 warnings, 1 informational

Note that the suppressed count is not necessarily the difference between the limit and the occurrences, since the limit can be dynamically changed with the **set_message_info** command.

SEE ALSO

[get_message_info\(2\)](#)
[set_message_info\(2\)](#)
[suppress_message\(2\)](#)

print_suppressed_messages

Displays an alphabetical list of message IDs that are currently suppressed.

SYNTAX

string **print_suppressed_messages**

ARGUMENTS

The **print_suppressed_messages** command has no arguments.

DESCRIPTION

The **print_suppressed_messages** command displays all messages that you suppressed using the **suppress_message** command. The messages are listed in alphabetical order. You only can suppress informational and warning messages. The result of **print_suppressed_messages** is always the empty string.

EXAMPLES

The following example shows the output from the **print_suppressed_messages** command:

```
prompt> print_suppressed_messages
No messages are suppressed

prompt> suppress_message {XYZ-001 CMD-029 UI-1}

prompt> print_suppressed_messages
The following 3 messages are suppressed:
CMD-029, UI-1, XYZ-001
```

[suppress_message\(2\)](#)
[unsuppress_message\(2\)](#)

print_variable_group

Lists the variables defined in a specified variable group, along with their current values.

SYNTAX

```
status print_variable_group  
      group
```

Data Types

group string

ARGUMENTS

group

Specifies the name of the group of variables for which you want to see the definitions and current values.

DESCRIPTION

The **print_variable_group** command lists the variables and related values defined in *group*. The current values for *group* are as follows:

all	All variables
acs	Variables that affect Automated Chip Synthesis
bsd	Variables that affect the insert_dft , optimize_bsd , check_bsd , and write_bsdl commands
compile	compile command variables
dpcm	Variables that affect DPCM
hdl	Variables that affect reading, writing, and optimizing HDL
insert_dft	insert_dft command variables
io	read_file , read_lib , and write command variables
links_to_layout	links_to_layout variables
multibit	Variables that affect compile multibit mapping
power	Variables that affect Power Compiler commands
preview_scan	Variables that affect the preview_scan command
suffix	Variables that define file suffixes
synlib	cache_ls command variables
system	Global system variables
test	DFT Compiler variables
testmanager	Variables that affect fault list handling
timing	Variables that affect timing
vhdlio	Variables that affect writing VHDL files and libraries
write_test	write_test command variables

The available variable groups are configurable. Change variable groups or create new ones with the **group_variable** command.

EXAMPLES

The following example displays the variables in the *timing* variables group, along with their current values:

```
prompt> print_variable_group timing
case_analysis_log_file = ""
case_analysis_sequential_propagate = "false"
case_analysis_with_logic_constants = "false"
create_clock_no_input_delay = "false"
disable_auto_time_borrow = "false"
disable_case_analysis = "false"
disable_conditional_mode_analysis = "false"
disable_library_transition_degradation = "false"
.
.
.
timing_self_loops_no_skew = "false"
when_analysis_permitted = "true"
when_analysis_without_case_analysis = "false"
1
```

SEE ALSO

[dc_shell\(1\)](#)
[group_variable\(2\)](#)

printenv

Prints the value of environment variables.

SYNTAX

```
string printenv
      [variable_name]
```

Data Types

variable_name string

ARGUMENTS

variable_name

Specifies the name of a single environment variable to print.

DESCRIPTION

The **printenv** command prints the values of the environment variables inherited from the parent process or set from within the application with the **setenv** command. When no arguments are specified, all environment variables are listed. When a single *variable_name* is specified, if that variable exists, its value is printed. There is no useful return value from **printenv**.

To retrieve the value of a single environment variable, use the **getenv** command.

EXAMPLES

The following examples show the output from the **printenv** command:

```
prompt> printenv SHELL
/bin/csh
```

```
prompt> printenv EDITOR
emacs
```

SEE ALSO

getenv(2)
setenv(2)

printvar

Prints the values of one or more variables.

SYNTAX

```
string printvar  
  [pattern]  
  [-user_defined | -application]
```

Data Types

pattern string

ARGUMENTS

pattern

Prints variable names that match *pattern*. The optional *pattern* argument can include the wildcard characters * (asterisk) and ? (question mark). If not specified, all variables are printed.

-user_defined

Shows only user-defined variables. This option is mutually exclusive with the **-application** option.

-application

Shows only application variables. This option is mutually exclusive with the **-user_defined** option.

DESCRIPTION

The **printvar** command prints the values of one or more variables. If the *pattern* argument is not specified, the command prints out the values of application and user-defined variables. The **-user_defined** option limits the variables to those that you have defined. The **-application** option limits the variables to those created by the application. The two options are mutually exclusive and cannot be used together.

Some variables are suppressed from the output of **printvar**. For example, the Tcl environment variable array **env** is not shown. To see the environment variables, use the **printenv** command. Also, the Tcl variable **errorInfo** is not shown. To see the error stack, use the **error_info** command.

EXAMPLES

The following command prints the values of all of the variables:

```
prompt> printvar
```

The following command prints the values of all application variables that match the pattern *sh*a**:

```
prompt> printvar -application sh*a*
sh_arch      = "sparcOS5"
sh_command_abbrev_mode = "Anywhere"
sh_enable_page_mode   = "false"
sh_new_variable_message = "false"
sh_new_variable_message_in_proc = "false"
sh_source_uses_search_path = "false"
```

The following command prints the value of the **search_path** variable:

```
prompt> printvar search_path
search_path    = ". /designs/newcpu/v1.6 /lib/cmos"
```

The following command prints the values of the user-defined variables:

```
prompt> printvar -user_defined
a           = "6"
designDir    = "/u/designs"
```

SEE ALSO

`error_info(2)`
`printenv(2)`
`setenv(2)`

proc_args

Displays the formal parameters of a procedure.

SYNTAX

```
string proc_args  
    proc_name
```

Data Types

proc_name string

ARGUMENTS

proc_name

Specifies the name of the procedure.

DESCRIPTION

The **proc_args** command is used to display the names of the formal parameters of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command **info** with the *args* argument.

EXAMPLES

This example shows the output of **proc_args** for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }  
prompt> proc_args plus  
a b  
prompt> info args plus  
a b  
prompt>
```

SEE ALSO

`info(2)`
`proc(2)`
`proc_body(2)`

proc_body

Displays the body of a procedure.

SYNTAX

```
string proc_body  
    proc_name
```

Data Types

proc_name string

ARGUMENTS

proc_name

Specifies the name of the procedure.

DESCRIPTION

The **proc_body** command is used to display the body (contents) of a user-defined procedure. This command is essentially a synonym for the Tcl builtin command **info** with the *body* argument.

EXAMPLES

This example shows the output of **proc_body** for a simple procedure:

```
prompt> proc plus {a b} { return [expr $a + $b] }  
  
prompt> proc_body plus  
return [expr $a + $b]  
  
prompt> info body plus  
return [expr $a + $b]  
  
prompt>
```

`proc(2)`
`proc_args(2)`

propagate_constraints

Propagates timing constraints from lower levels of the design hierarchy to the current design.

SYNTAX

```
status propagate_constraints
  [-design design_list]
  [-all]
  [-clocks]
  [-disable_timing]
  [-dont_apply]
  [-false_path]
  [-gate_clock]
  [-ideal_network]
  [-ignore_from_or_to_port_exceptions]
  [-ignore_through_port_exceptions]
  [-max_delay]
  [-min_delay]
  [-multicycle_path]
  [-operating_conditions]
  [-power_supply_data]
  [-output file_name]
  [-port_isolation]
  [-verbose]
  [-case_analysis]
  [-target_library_subset]
  [-opcond_inference]
```

Data Types

<i>design_list</i>	list
<i>file_name</i>	string

ARGUMENTS

-design *design_list*

Specifies a list of names of lower-level designs from which constraints are to be propagated. The constraints are propagated from every instance of the designs in this list. By default, constraints are propagated from every lower-level design in the hierarchy.

-all

Propagates clocks, **gate_clock** checks, **false_path** exceptions, **multicycle_path** exceptions, **max_delay** and **min_delay** exceptions, instance-specific operating conditions, power supply data, and **disable_timing** attributes. This is the default. Issuing the command without options has the same effect as specifying the **-all** option.

-clocks

Propagates only clocks previously created by using the **create_clock** command. Virtual clocks are not propagated.

-disable_timing

Propagates only **disable_timing** attributes previously set by using the **set_disable_timing** command.

-dont_apply

Prevents the propagated constraints from being applied to the current design. Warnings are still reported. You can use this option with the **-verbose** option to see the effects of propagating the constraints without actually propagating them. If you do not use the **-verbose** option, the command only reports warnings about conflicting exceptions.

-false_path

Propagates only **false_path** exceptions previously specified by using the **set_false_path** command.

-gate_clock

Note: This option will be obsolete in a future release. Clock-gating insertion with **compile_ultra -gate_clock** automatically propagates clock gate setup and hold time.

Propagates only setup and hold clock gating checks previously specified by using the **set_clock_gating_check** command. RTL clock gating automatically imposes setup and hold time constraints during elaboration.

-ideal_network

Propagates ideal networks previously created by using the **set_ideal_network** command.

-ignore_from_or_to_port_exceptions

Propagates exceptions for ports on *from_lists* and/or *to_lists* of commands that set timing constraints. By default, the command converts "from port" and "to port" exceptions into "through" exceptions and propagates them to the current design.

-ignore_through_port_exceptions

Prevents propagation of exceptions for ports on *through_lists* of commands that set timing constraints. By default, these exceptions are propagated.

-max_delay

Propagates only **max_delay** exceptions previously specified by using the **set_max_delay** command.

-min_delay

Propagates only **min_delay** exceptions previously specified by using the **set_min_delay** command.

-multicycle_path

Propagates only **multicycle_path** exceptions previously specified by using the **set_multicycle_path** command.

-operating_conditions

Propagates only **operating_conditions** previously specified by using the **set_operating_condition** command. It propagates the operating conditions specified on instances as well as those specified on lower-level subdesigns.

-power_supply_data

Propagates only power intent data, including UPF (supply network, power state table, and various power intent strategies) and operating voltages on the supply nets.

-output file_name

Writes the command output to the file specified by *file_name*.

-port_isolation

Propagates exceptions previously set by the **set_isolate_ports** command.

-verbose

Reports equivalent constraint-setting commands that are applied to the current design as a result of using the **propagate_constraints** command. Following each propagated constraint, the name enclosed in /* */ is the name of the lower-level design from which the constraint is propagated.

-case_analysis

Propagates case values previously set by using the **set_case_analysis** command.

-target_library_subset

Propagates target library subsets that have been specified by using the **set_target_library_subset** command. It propagates the target library subset specified on instances as well as those specified on subdesigns.

-opcond_inference

Propagates only the strategies of operating condition inference that have been specified by using the **set_opcond_inference** command. It propagates the strategies specified on instances as well as those specified on subdesigns.

DESCRIPTION

This command collects constraints from instances of lower-level designs and applies those constraints to the current design for use during timing analysis and compilation. After the constraints are propagated, you can remove, override, or report them like any other constraints that are set on the current design. Issuing the command without options is the same as issuing it with the **-all** option.

The command produces a warning in some cases where it does not propagate constraints because of one of the following conditions:

- Clock name conflict: multiple clocks from different designs have the same name.
- Clock source conflict: an object is specified as a clock source of more than one clock.
- Clock exception from/to unpropagated clock: if a clock is not propagated, exceptions from or to the clock are not propagated. The command does not propagate a clock if you do not use the **-clock** option, if the clock is a virtual clock, or if propagating the clock creates a conflict.

The command does not propagate a constraint that creates a conflict; the constraint is echoed in comments using the object names in the current design.

You must propagate timing **gated_clock** checks before compilation if automatic clock gating has been performed during elaboration.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example propagates only false path constraints, from all lower-level designs to the current design:

```
prompt> propagate_constraints -false_path
```

The following example propagates only **multicycle_path** exceptions from the SUB1 subdesign to the current design:

```
prompt> propagate_constraints -design SUB1 -multicycle_path
```

The following example propagates clocks, exceptions, **gated_clock** checks, and **disable_timing** arcs to the current design from all instances of lower-level designs. The output is shown in non-verbose mode. Clock warnings are issued in this mode.

```
prompt> propagate_constraints -all
```

```

propagate_switching_activity

Forces the propagation of power-switching activity information.

SYNTAX

```
status propagate_switching_activity
  [-verbose]
  [-infer_related_clocks]
```

ARGUMENTS

-verbose

Specifies that the switching activity mechanism is run in verbose mode, which displays detailed information and warning messages.

-infer_related_clocks

Specifies that only related clock information is to be inferred. When this option is used, static probability and toggle rate information is not propagated; but the related clock information is inferred for design objects that request a related clock.

DESCRIPTION

Use of the **propagate_switching_activity** command is not recommended. This feature will be obsolete in a future release. The **propagate_switching_activity** command forces a propagation of the power switching activity information.

During the propagation of the switching activity, the information annotated using the **read_saif**, **set_switching_activity**, **merge_saif** commands is used to estimate the activity on unannotated nets. All commands that need switching activity information on all design objects use the switching activity propagation mechanism automatically. In most cases, you do not need to explicitly run the **propagate_switching_activity** command. The **propagate_switching_activity** command allows you to access propagated switching activity values directly without using a command such as the **report_power** command, which propagates the switching activity as a side effect.

The mechanism to propagate switching activity uses the static probability and toggle rate information you annotate to estimate the static probability and toggle rate information on unannotated design objects.

The mechanism used by the tool is based on a stochastic simulation method, which is that random activity based on the annotated switching activity is generated on the annotated design objects, and this activity is propagated across the design using a zero-delay simulator. This is repeated a few thousand times, depending on the effort level.

The **-infer_related_clocks** option is used to restrict the action of the **propagate_switching_activity** command to inferring only the related clock information on design objects on which it was requested. Use the **-clock ***** option of the **set_switching_activity** command to specify that the related clock on the specified design object is inferred automatically by the tool. Related clock information is inferred when commands that need switching activity information (such as **report_power**) are used. Use the command with the **-infer_related_clocks** option to infer only the related clock information. The related clock is placed in the **related_clock** attribute on the design objects.

The method in which the related clock information is inferred is described in the following steps:

First, the tool determines a starting set of inferred related clocks using the following rules:

- The inferred related clock on an object with a user-set related clock, is the user-set related clock.
- The inferred related clock on a clock source port or pin is the clock.
- If the **power_rclock_inputs_use_clocks_fanout** variable is set to **true**, primary input nets that do not have an inferred related clock according to the rules already mentioned, the following rule is applied. If the transitive fanout of the input contains a clock network object, then the inferred related clock on the input is the clock driving the network. A clock network is the transitive fanout of a clock port or pin, stopping and including sequential cells. If more than one of this type of a clock object exists, then the fastest clock of this type is chosen as the related clock.

The related clocks are then inferred on design objects by the following rules:

- For flip-flops, if the **power_rclock_use_asynch_inputs** variable is set to **false**, then the inferred related clock on the cell's outputs is the inferred related clock on the cell's clock pin. If **power_rclock_use_asynch_inputs** is set to **true**, then the inferred related clock on the cell's outputs is the fastest inferred related clock on the cell's clock pin and the cell's asynchronous input pins.
- The inferred related clock on clock-gating cell outputs is the inferred related clock on the cell's clock input pin.
- For non-flip-flop and non-clock-gating cells, the inferred related clock on the cell's outputs is the fastest related clock on the cell's inputs.

The inferred related clocks are then made to be the design object's related clock for objects that requested a related clock. The inferred related clock information on design objects that did not request a related clock is discarded. For design objects that requested a related clock, but no clock was inferred by the above rules, the fastest design clock is set as the related clock if the **power_rclock_unrelated_use_fastest** variable is set to **true**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example propagates the power-switching activity information:

```
prompt> propagate_switching_activity
```

SEE ALSO

```
merge_saif(2)
read_saif(2)
report_saif(2)

power_rclock_unrelated_use_fastest(3)
power_rclock_use_asynch_inputs(3)
```

propagate_user_attributes

Propagates user attributes from lower levels of the design hierarchy to the current design.

SYNTAX

```
status propagate_user_attributes
  [-design design_list]
  [-verbose]
  attribute_list
```

Data Types

<i>design_list</i>	list
<i>attribute_list</i>	list

ARGUMENTS

-design *design_list*

Specifies a list of names of lower-level designs from which the specified attributes are to be propagated. The specified attributes are propagated from every instance of the designs in this list. By default, the specified attributes are propagated from all lower-level designs in the hierarchy.

-verbose

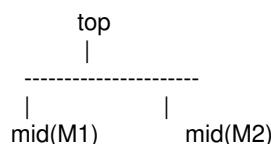

Reports the lower-level designs that attributes are propagated from.

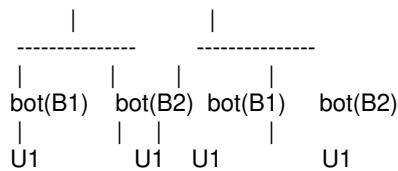

DESCRIPTION

This command propagates the specified user attributes from instances of lower-level designs and sets them on instances in the current design.

EXAMPLES

The following is an example of the **propagate_user_attributes** command. Assume you have the following design:

If you set the current design to mid and set the **set_user_attribute** value to XYZ on all cells in the mid design, when the current design is changed to top, the attributes set on the B1/U1 and B2/U1 instance cells inside mid are not propagated or visible from the top design. When you use the **propagate_user_attributes** command, the specified attributes are propagated to the instances in the current design, as shown in the following example.

```
prompt> current_design mid
Current design is 'mid'.
{mid}
prompt> define_user_attribute -type boolean -classes cell XYZ
XYZ
prompt> set_user_attribute [get_cells -hierarchy *] XYZ false
Information: Attribute 'XYZ' is set on 4 objects. (UID-186)
B1/U1 B2/U1 B1 B2
prompt> current_design top
Current design is 'top'.
{top}
prompt> get_cells -hierarchical -filter "XYZ==false"
{M1/B1 M1/B2 M2/B1 M2/B2}
prompt> propagate_user_attributes {XYZ}
1
prompt> get_cells -hierarchical -filter "XYZ==false"
{M1/B1/U1 M1/B2/U1 M1/B1 M1/B2 M2/B1 M2/B2}
```

SEE ALSO

[set_user_attribute\(2\)](#)

push_down_model

Creates a new hierarchy around the current design for use with wrapping models flow in SoCTest.

SYNTAX

```
status push_down_model
      new_design_name
```

Data Types

new_design_name string

ARGUMENTS

new_design_name

Specifies the name of the new design to be created.

DESCRIPTION

The **push_down_model** command creates a new level of hierarchy around the current design. It creates a new design with the specified design name, instantiates the current design as an instance in the new design, creates ports in the new design for all corresponding pins of the instantiated cell, and connects all pins of the instantiated cell to the corresponding ports of the new design. The current design is set to the new design created by this command.

EXAMPLES

The following example creates a new design named *sub1_pushed* around the current design named *sub1*:

```
prompt> current_design sub1
{sub1}

prompt> push_down_model sub1_pushed
Current design is 'sub1_pushed'.
```

SEE ALSO

insert_dft(2)
preview_dft(2)

pwd

Displays the path name of the present working directory (pwd), also called the current directory.

SYNTAX

string **pwd**

ARGUMENTS

The **pwd** command has no arguments.

DESCRIPTION

The **pwd** command displays the path name of the current directory. The directory from which you invoke the shell is the initial current directory.

A file specification of dot (.) is shorthand for the current directory. Dot is commonly included in the **search_path** variable.

Use the **cd** command to change the current directory.

EXAMPLES

The following is an example of **pwd** showing the current working directory:

```
prompt> pwd
/usr/designer/joe
```

SEE ALSO

[cd\(2\)](#)
[sh\(2\)](#)
[search_path\(3\)](#)

query_cell_instances

Finds all instances of a given library cell or module within the active scope. This is a UPF query command.

SYNTAX

```
list query_cell_instances
  cell_name
  [-domain domain_name]
```

Data Types

<i>cell_name</i>	string
<i>domain_name</i>	string

ARGUMENTS

cell_name

Specifies the name of the library cell or module to find in the active scope. The command reports all instances of the specified cell or module.

-domain *domain_name*

Limits the search to the instances in the specified power domain.

DESCRIPTION

The **query_cell_instances** command finds all instances of a mapped cell within the active scope. It returns a list of the found instances.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports all instances of the AND2 library cell in the I_REG_FILE/PD_ALU power domain.

```
prompt> query_cell_instances -domain I_REG_FILE/PD_ALU AND2  
I_ALU/C132 I_ALU/C133 I_ALU/C134 I_ALU/C135 I_ALU/C136
```

SEE ALSO

`get_cells(2)`
`query_cell_mapped(2)`

query_cell_mapped

Identifies the library cell or module mapped to a given instance. This is a UPF query command.

SYNTAX

```
string query_cell_mapped
      instance_name
```

Data Types

instance_name string

ARGUMENTS

instance_name

Specifies the name of the instance to query.

DESCRIPTION

The **query_cell_mapped** command identifies the library cell or module that is mapped to a given instance. It returns the cell name.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the library cell mapped to instance I_ALU/C132.

```
prompt> query_cell_mapped I_ALU/C132
AND2
```

SEE ALSO

```
get_cells(2)
query_cell_instances(2)
```

query_map_power_switch

Returns information about the previous mapping of a library cell to a power switch in the active scope. This is a UPF query command.

SYNTAX

```
list query_map_power_switch
      switch_name
      [-detailed]
```

Data Types

switch_name string

ARGUMENTS

switch_name

Specifies the name of the power switch. The command returns the full **map_power_switch** command previously used to map a library cell to the power switch.

-detailed

Returns the **map_power_switch** command information in the form of a Tcl list of keyword and value pairs.

DESCRIPTION

The **query_map_power_switch** command returns the full **map_power_switch** command previously used to map library cells to a specified power switch. The **-detailed** option returns the same information in the form of a Tcl list of keyword and value pairs. If you specify an asterisk for the switch name, the command returns the mapping information for all power switches. It returns a warning message for each switch that is not yet mapped.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show how to report the **map_power_switch** command previously used to map a library cell to power switch

SW1.

```
prompt> query_power_switch *
{SW1 SW2 }

prompt> query_map_power_switch SW1
map_power_switch SW1 -domain TOP -lib_cells {STN_SWITCH_Y2_PM }

prompt> query_map_power_switch SW1 -detailed
{switch_name SW1} {domain TOP} {lib_cells {STN_SWITCH_Y2_PM }}

prompt> query_map_power_switch SW2
Warning: Can't find map_power_switch constraint for power switch SW2. (UPF-299)
```

SEE ALSO

[query_power_switch\(2\)](#)

query_net_ports

Finds all the ports that are logically connected to a given net. This is a UPF query command.

SYNTAX

```
list query_net_ports
      net_name
      [-transitive true | false]
      [-leaf]
```

Data Types

net_name string

ARGUMENTS

net_name

Specifies the net. The command finds all ports connected to that net.

-transitive true | false

Specifies whether to search the only the current level of hierarchy (**false**, the default behavior) or both the current level and hierarchical descendants below the current level (**true**).

-leaf

Returns only the leaf-cell ports connected to the specified net. By default, both hierarchical and leaf-level cell ports are reported.

DESCRIPTION

The **query_net_ports** command returns the ports that are logically connected to the specified net. It returns a list of the port names. If no ports are connected to the specified net, it returns the null string.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the ports connected to net I[30] at the current level of hierarchy.

```
prompt> query_net_ports I[30]
I[30] I_LAT/Inst_1[30]
```

The following example reports the ports connected to net I[30] at the current level of hierarchy and in descendants below the current level.

```
prompt> query_net_ports I[30] -transitive true
I_LAT/Inst_1_reg[30]/Q I[30] I_LAT/Inst_1[30]
```

The following example reports the ports of leaf-level cells connected to net I[30] at the current level of hierarchy and in descendants below the current level.

```
prompt> query_net_ports I[30] -transitive true -leaf
I_LAT/Inst_1_reg[30]/Q
```

SEE ALSO

get_ports(2)
query_port_net(2)
```

query_objects

Searches for and displays objects in the database.

SYNTAX

```
string query_objects
  [-verbose]
  [-truncate elem_count]
  [-class class_name]
  object_spec
```

Data Types

<i>elem_count</i>	int
<i>class_name</i>	string
<i>object_spec</i>	list

ARGUMENTS

-verbose

Displays the class of each object found.

By default, the command lists only the name of each object. When you use this option, the command lists prefixes the name of each object with its class, as shown in the EXAMPLES section.

-truncate *elem_count*

Truncates the display to *elem_count* elements.

By default, the command displays up to 100 elements. To change the number of elements displayed by the command, use this option. To see all elements, set the *elem_count* value to 0.

-class *class_name*

Specifies the class used to search for objects when an element in the *object_spec* argument is not a collection. Valid classes are application-specific.

If you do not specify this option, the command displays only those elements in the *object_spec* argument that are collections and displays an error message for any other elements, as shown in the EXAMPLES section.

object_spec

Specifies the objects to find and display. Each element in the list is either a collection or a pattern.

- When you specify a collection, the command displays the contents of the collection.
- When you specify a pattern, the command searches the database for objects of the class specified in the **-class** option. If you do not specify the **-class** option, the command issues an error message for the pattern.

DESCRIPTION

The **query_objects** command finds and displays objects in the application's runtime database. The command does not have a meaningful return value; it displays the objects found and returns an empty string.

To control the number of elements displayed, use the **-truncate** option. If the display is truncated, the command prints an ellipsis (...) as the last element. If the default truncation occurs, the command displays a message that shows the total number of elements that would have displayed, as shown in the EXAMPLES section.

Although the output from the **query_objects** command looks similar to the output from any command that creates a collection, the **query_objects** command always returns an empty string.

The **query_objects** command displays the output in either a Legacy format or in a Tcl compatible format. The default output format varies by tool but you can control the format yourself by setting the **query_objects_format** variable. For example, to force Tcl-compatible output use this command:

```
prompt> set_app_var query_objects_format Tcl  
Tcl
```

The EXAMPLES section shows output in both the Legacy and Tcl formats.

EXAMPLES

These following examples show the basic usage of the **query_objects** command in both Legacy and Tcl format.

```
prompt> set_app_var query_objects_format Legacy  
Legacy  
prompt> query_objects [get_cells o*]  
{or1 or2 or3}  
prompt> query_objects -class cell U*  
{U1 U2}  
prompt> query_objects -verbose -class cell \  
? [list U* [get_nets n1]]  
{cell:U1 cell:U2 net:n1}  
prompt> set_app_var query_objects_format Tcl  
Tcl  
prompt> query_objects [get_cells o*]  
{or1 or2 or3}  
prompt> query_objects -class cell U*  
{U1 U2}  
prompt> query_objects -verbose -class cell \  
? [list U* [get_nets n1]]  
{cell U1} {cell U2} {net n1}
```

When you omit the **-class** option, only those elements of the *object_spec* argument that are collections generate output. The other elements generate error messages.

```
prompt> query_objects [list U* [get_nets n1] n*]  
Error: No such collection 'U*' (SEL-001)  
Error: No such collection 'n*' (SEL-001)  
{n1}
```

When the output is truncated, the command prints an ellipsis at the end of the display. For the following example, assume the default truncation is 5 (it is actually 100).

```
prompt> query_objects [get_cells o*] -truncate 2  
{"or1", "or2", ...}  
prompt> query_objects [get_cells *]
```

```
{"or1", "or2", "or3", "U1", "U2", ...}  
Output truncated (total objects 126)
```

query_port_net

Finds the net that is logically connected to a specified port. This is a UPF query command.

SYNTAX

```
string query_port_net
      port_name
      [-conn low | high]
```

Data Types

port_name string

ARGUMENTS

port_name

Specifies the name of the port to query for its connected net.

-conn low | high

Specifies whether to return the higher-level net (**high**, the default behavior), or lower-level net (**low**) connected to the port. For a top-level port, you must use **-conn low**, or else nothing is returned. For a port of a leaf-level cell, using this option is not allowed.

DESCRIPTION

The **query_port_net** command returns the net that is logically connected to the specified port. For a hierarchical port, the command returns the higher-level net by default. To return the lower-level net instead, use the **-conn low** option.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the higher-level net connected to port I_LAT/Inst_1[30].

```
prompt> query_port_net I_LAT/Inst_1[30]
```

I[30]

The following example reports the lower-level net connected to port I_LAT/Inst_1[30].

```
prompt> query_port_net I_LAT/Inst_1[30] -conn low  
I_LAT/Inst_1[30]
```

The following example demonstrates the reporting of a net connected to a top-level port, A_IN. Because the command reports the higher-level net by default, you must use the **-conn low** option to get the lower-level net name.

```
prompt> query_port_net A_IN  
prompt>  
prompt> query_port_net A_IN -conn low  
netA_IN
```

query_port_state

Returns information about the port states that have been previously defined for a specified supply port in the active scope. This is a UPF query command.

SYNTAX

```
list query_port_state
  port_name
  [-state state_name]
  [-detailed]
```

Data Types

<i>port_name</i>	string
<i>state_name</i>	string

ARGUMENTS

port_name

Specifies the supply port. The command reports the port states previously defined for this port.

-state *state_name*

Returns the **add_port_state** command that was used to create the specified state. If you omit this option, the command returns a list of all the defined states for the port.

-detailed

Causes the **-state** option to return the **add_port_state** command information in the form of a Tcl list of keyword and value pairs.

DESCRIPTION

The **query_port_state** command returns information about the port states that have been previously defined for a specified supply port. If you specify only the port name without any other options, the command returns a list of the defined port states. If you use the **-state** *state_name* option, the command returns the full **add_port_state** command previously used to create that state for the port. The **-detailed** option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show how to report the port states defined for the supply port named "I_REG/I_REG_sw/out".

```
prompt> query_port_state I_REG/I_REG_sw/out  
{BLOCK BLOCK_off }  
  
prompt> query_port_state I_REG/I_REG_sw/out -state BLOCK  
add_port_state I_REG/I_REG_sw/out -state {BLOCK {1.080000 }}  
  
prompt> query_port_state I_REG/I_REG_sw/out -state BLOCK -detailed  
{port_name I_REG/I_REG_sw/out} {state_name BLOCK } {state {1.080000 }}  
  
prompt> query_port_state I_REG/I_REG_sw/out -state *  
add_port_state I_REG/I_REG_sw/out -state {BLOCK {1.080000 }}  
add_port_state I_REG/I_REG_sw/out -state {BLOCK_off {off }}
```

SEE ALSO

`add_port_state(2)`

query_power_switch

Returns information about a power switch that was previously created in the active scope. This is a UPF query command.

SYNTAX

```
list query_power_switch  
      switch_name  
      [-detailed]
```

Data Types

switch_name string

ARGUMENTS

switch_name

Specifies the name of the power switch. The command returns the full **create_power_switch** command previously used to create the power switch. Use an asterisk (*) to get a list of all the power switch names.

-detailed

Returns the **create_power_switch** command information in the form of a Tcl list of keyword and value pairs.

DESCRIPTION

The **query_power_switch** command returns information about previously defined power switches. The command "query_power_switch **" returns a list of the power switch names. If you specify the name of the particular power switch, the command returns the full **create_power_switch** command previously used to create that power switch. The **-detailed** option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show how to report the **add_pst_state** command previously used to create power state s2 in power state

table PST1.

```
prompt> query_power_switch *
{SW1 SW2 }

prompt> query_power_switch SW1
create_power_switch SW1 -domain TOP -output_supply_port {out SN2}
-input_supply_port {in SN1} -control_port {ctrl on} -on_state
{state1 in {ctrl} }

prompt> query_power_switch SW1 -detailed
{switch_name sw1} {domain TOP} {output_supply_port {out SN2}}
{input_supply_port {in SN1}} {control_port {ctrl on}} {on_state
{state1 in {ctrl}}}
```

SEE ALSO

`create_power_switch(2)`
`query_map_power_switch(2)`

query_pst

Returns information about the power state tables that have been previously created in the active scope. This is a UPF query command.

SYNTAX

```
list query_pst
      table_name
      [-detailed]
```

Data Types

table_name string

ARGUMENTS

table_name

Specifies the name of the power state table. The command returns the full **create_pst** command previously used to create the power state table. Use an asterisk (*) to get a list of all power state table names.

-detailed

Returns the **create_pst** command information in the form of a Tcl list of keyword and value pairs.

DESCRIPTION

The **query_pst** command returns information about previously defined power state tables in the active scope. The command "**query_pst** *" returns a list of the power state table names. If you specify the name of the particular power state table, the command returns the full **create_pst** command previously used to create that power state table. The **-detailed** option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show how to report the **create_pst** command previously used to create power state table PST1.

```
prompt> query_pst *
{PST1 PST2 }

prompt> query_pst PST1
create_pst PST1 -supplies {SP1 SP2 SP3 }

prompt> query_pst PST1 -detailed
{table_name PST1} {supplies {SP1 SP2 SP3 }}
```

SEE ALSO

[create_pst\(2\)](#)
[query_pst_state\(2\)](#)

query_pst_state

Returns information about a state in a power state table that was previously created in the active scope. This is a UPF query command.

SYNTAX

```
list query_pst_state  
    state_name  
    -pst table_name  
    [-detailed]
```

Data Types

<i>state_name</i>	string
<i>table_name</i>	string

ARGUMENTS

state_name

Specifies the name of the power state. The command returns the full **add_pst_state** command previously used to create the power state. Use an asterisk (*) to get a list of all the power states for the specified power state table.

-pst table_name

Specifies the name of the power state table. To get a list of the power state tables in the current scope, use the "**query_pst ***" command.

-detailed

Returns the **add_pst_state** command information in the form of a Tcl list of keyword and value pairs.

DESCRIPTION

The **query_pst_state** command returns information about the states that have been previously defined for a specified power state table. The command "**query_pst_state * -pst table_name**" returns a list of the power states defined for the specified table. If you specify the name of the particular power state, the command returns the full **add_pst_state** command previously used to create that power state. The **-detailed** option returns the same information in the form of a Tcl list of keyword and value pairs.

You can use this command at the tool shell prompt or in a script run by the **source** command, but not in a script run by the **load_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples show how to report the **add_pst_state** command previously used to create power state s2 in power state table PST1.

```
prompt> query_pst *
{PST1 PST2}

prompt> query_pst_state * -pst PST1
{s1 s2 s3 }

prompt> query_pst_state s2 -pst PST1
add_pst_state s2 -pst PST1 -state {s12 s11 s12 }

prompt> query_pst_state s2 PST1 -detailed
{state_name s2} {pst PST1} {state {s12 s11 s12 }}
```

SEE ALSO

[add_pst_state\(2\)](#)
[query_pst\(2\)](#)

query_qor_snapshot

Analyzes timing report files from existing QoR snapshots, applies any specified filters, and displays the results in an appropriate format.

This command operates in two distinct modes: CTR (general timing) mode and CTS (clock tree synthesis) mode.

SYNTAX for CTR Mode

```
status query_qor_snapshot
  [-name snapshot_name]
  [-directory directory_name]
  [-display]
  [-type min | max]
  [-incremental]
  [-output_file file_name]
  [-output_false_paths file_name]
  [-sort_by column_list]
  [-group_by column_list]
  [-columns column_list]
  [-and column_list]
  [-filters filter_list]
  [-hierarchy]
  [-from module_list]
  [-to module_list]
  [-through module_list]
  [-output_group_paths file_name]
  [-group_path_prefix prefix]
  [-group_path_append appendix]
  [-case_sensitive]
  [-subgroup {[subgroup_name] [subgroup_options]}}
  [-infeasible_paths]
```

Data Types

<i>snapshot_name</i>	string
<i>directory_name</i>	string
<i>file_name</i>	string
<i>column_list</i>	list of strings
<i>filter_list</i>	string
<i>module_list</i>	list of strings
<i>prefix</i>	string
<i>appendix</i>	string
<i>subgroup_options</i>	string

SYNTAX for CTS Mode

```
status query_qor_snapshot
  [-clock_tree_only]
  [-name snapshot_name]
```

```
[-directory directory_name]  
[-display]  
[-cts_output_file file_name]  
[-cts_sort_by column_list]  
[-cts_columns column_list]  
[-cts_and column_list]  
[-cts_filters filter_list]  
[-cts_set_exceptions_file file_name]  
[-cts_clear_exceptions_file file_name]  
[-case_sensitive]
```

ARGUMENTS

-name *snapshot_name*

Specifies the name of the QoR snapshot to be analyzed.

This is a required option when you run this command the first time in the current session. In subsequent runs, if you do not specify this option, the report used in the last query is reused.

-directory *directory_name*

Specifies the name of the directory to search for the QoR snapshot specified by the **-name** option.

If you do not specify this option, the tool searches for the QoR snapshot in the directory specified by the **icc_snapshot_storage_location** variable.

-display

Displays the output using a built-in HTML viewer to allow for interactive viewing of selected paths in the layout window (Not supported for DCT). This option starts the GUI; do not use this option in batch mode. The **-display** option takes priority over (disables) the **-output_file** and **-cts_output_file** options.

-type **min** | **max**

Loads the appropriate snapshot setup report if you specify **max** and hold report if you specify **min**.

The default is **max** for loading setup.

-incremental

Queries the previous queried result instead of querying from scratch. This option is only valid when it is used with the **-hierarchy** option.

-output_file *file_name*

Specifies the name of the generated output files.

If you specify a file name that ends in .html, only an HTML output is created. If you specify a file name that ends in .txt, only a text output is created. Otherwise, both text and HTML outputs are created and saved into files with appropriate names. If the destination directory is read-only, an error message is displayed and you must specify a different file name.

-output_false_paths *file_name*

Generates a Tcl command file that contains the **set_false_path** commands. One **set_false_path** command is generated for each timing path that matches one or more filters. Only those attributes of the timing path that violate a filter are used to create each individual **set_false_path** command.

The set of **set_false_path** commands created is the same as the set that is created by selecting all paths and all columns in the HTML report or interactive report and then clicking the Create False Paths button.

After all **set_false_path** commands have been created, the tool creates a minimum set of commands to eliminate duplicates. The duplicate elimination process often causes the order of the **set_false_path** commands in the output file to be different than the

order of the timing paths in the output file or input report.

The `_fp.tcl` suffix is appended to the specified file name.

-sort_by column_list

Specifies the column used to sort the results. The default is `wns`.

To sort a column in descending order, specify "`column_name`" or "`+column_name`". To sort a column in ascending order, specify "`-column_name`". Two exceptions: `wns` and `zero_path` columns have their default sorting order reversed (`+wns` results in an ascending sort). This is so that the default sort order for a column produces the most meaningful sorting order (descending for most numeric columns).

Valid sort columns are: `path_group`, `startpoint`, `endpoint`, `scenario`, `wns`, `transition_degradation`, `slew_degradation`, `zero_path`, `logic_levels`, `path_delay`, `input_delay`, `output_delay`, `clock_uncertainty`, `incremental`, `transition_time`, `capacitance`, `fanout`, `clock_skew`, `launch_clock`, `launch_clock_latency`, `capture_clock`, `capture_clock_latency`, `bufinvcount`, `io_path`, and `cross_clock`.

-group_by column_list

Specifies the column used to group the results. This option groups the results based on the unique values found for this column to create a summary that links to details for that value of the column. Each detail page is sorted by the sort column.

Valid group columns are: `path_group`, `startpoint`, `endpoint`, `scenario`, `launch_clock`, `capture_clock`, `bufinvcount`, `logic_levels`, and `cross_clock`.

-columns column_list

Specifies the list of columns to include in the output. The columns are displayed in the specified order. If you specify a column multiple times, its location is determined by the last instance. Use of the `instance` or `file_instance` filters as an output column is not recommended because the results are not meaningful.

The column names are specified in the following format:

`column_name[.width]`

where `column_name` is the same as the corresponding filter name (see the description for the **-filters** option for information about the filter names) and `width` is an optional integer value that defines the column width. Width is somewhat flexible in HTML output and the column will not expand past the width of the widest value. All available columns are printed by default.

Note: Not all the columns available in the IC Compiler tool are available in the Design Compiler product family tools. For example, if you specify the `bufinvcount` column in Design Compiler, the tool does not recognize it and issues the following message:

No columns matched specification bufinvcount

You can specify the column names as minimally-distinct strings. That is, instead of using `capacitance`, you can use `"capa"` or even `"pac"` because no other column name contains that sequence of letters.

If you do not specify this option, the default columns are:

- `Path_group`, `startpoint`, `endpoint`, `wns`, `zero_path`, `path_delay`, `input_delay`, `output_delay`, `clock_uncertainty`, `incremental`, `fanout`, `logic_levels`, `launch_clock`, `capture_clock`.

-and column_list

Specifies a list of filters to apply with AND logic. These filters are applied to the paths that pass the filters specified in the **-filters** option. Paths that match one or more OR filters and all AND filters are included in the result.

For example, if you specify `-filters "-wns -3.0 -cross_clock 1"`, the command reports the paths with timing violations where WNS is worse than -3.0 OR `-cross_clock` is true. If you specify `-filters "-wns -3.0 -cross_clock 1" -and wns`, the command reports the paths with timing violations where WNS is worse than -3.0 and `-cross_clock` is true. If all specified filters are also specified as using **-and**, one will automatically be treated as OR.

-filters filter_list

Specifies a list of filters to apply to the paths analyzed from the timing report. The list must be enclosed in double quotes. The specified filters are applied with OR logic; all paths matching any specified filter are selected.

Each filter consists of a filter option and its argument. Most filters accept a range of either floating point or integer numbers as an

argument. The argument range consists of two numbers separated by a comma. The first number is the lower bound and the second number is the upper bound. You can also specify just one number. In this case, it is interpreted as the lower bound, unless it is preceded by a comma. If the number is preceded by a comma, it is interpreted as the upper bound.

Filters can be grouped into two areas: default filters and other general filters. Default filters are used to indicate violations with respect to important matrices in the timing report, such as output pin transition degradation, bad net slew degradation, and long logic levels, that can be quantified. Other general filters exist to allow you to further narrow down the query searches.

You can specify one or more of the following filters:

- **-wns *lower_bound,upper_bound***
Includes all paths that have a worst negative slack (WNS) within the specified floating point range.
- **-transition_degradation *lower_bound,upper_bound***
Includes all paths that have their transition degradation ratio (output pin transition time / input pin transition time) within the specified floating point range.
- **-slew_degradation *lower_bound,upper_bound***
Includes all paths that have a slew degradation (input pin transition / last stage output pin transition) within the specified floating point range.
- **-logic_level *lower_bound,upper_bound***
Includes all paths that have their number of logic levels within the specified integer range.
- **-fanout *lower_bound,upper_bound***
Includes all paths that have their worst fanout within the specified integer range.
- **-input_delay *lower_bound,upper_bound***
Includes all paths that have an external input delay within the specified floating point range.
- **-output_delay *lower_bound,upper_bound***
Includes all paths that have an external output delay within the specified floating point range.
- **-clock_uncertainty *lower_bound,upper_bound***
Includes all paths that have clock uncertainty within the specified floating point range.
- **-zero_path *lower_bound,upper_bound***
Includes all paths with a zero-path margin within the specified floating point range.
- **-clock_skew *lower_bound,upper_bound***
Includes all paths that have clock skew within the specified floating point range.
- **-path_delay *lower_bound,upper_bound***
Includes all paths that have a path delay within the specified floating point range.
- **-infeasible_paths *value***
Includes all paths that have the specified value, YES or NO, under the Infeasible Paths column.
- **-transition_time *lower_bound,upper_bound***
Includes all paths that have a transition time within the specified floating point range.
- **-capacitance *lower_bound,upper_bound***
Includes all paths that have their worst capacitance within the specified floating point range.
- **-derate *lower_bound,upper_bound***
Includes all paths that have their timing derate within the specified floating point range.
- **-incremental *lower_bound,upper_bound***
Includes all paths that have an incremental value within the specified floating point range.
- **-bufinvcount *lower_bound,upper_bound***
Includes all paths that have their buffer+inverter count within the specified integer range.
- **-io_path *lower_bound,upper_bound***
Include all paths that contain an input or output element in their path. Input/Output elements are: (in), (inout) or (out).
- **-cross_clock *lower_bound,upper_bound***

Includes all paths that have different values for the launch and capture clocks. Paths with the same launch and capture clocks will have a value of 0 for this attribute, and paths with different launch and capture clocks will have an attribute of 1.

- **-launch_clock pattern**

Includes all paths whose launch clock name matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-capture_clock pattern**

Includes all paths whose capture clock name matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-path_group pattern**

Includes all paths whose path group matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-startpoint pattern**

Includes all paths whose startpoint matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-endpoint pattern**

Includes all paths whose endpoint matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-scenario pattern**

Includes all paths whose scenario matches the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern at the beginning or end.

- **-instance pattern**

Includes all paths that contain an instance matching the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern.

- **-file_instance file_name**

Includes all paths that contain an instance that matches any of the patterns listed in the specified file (patterns can be separated by space or a newline). Patterns take the same form as those for -instance.

- **-libcell pattern**

Includes all paths that contain a library cell matching the pattern. You can specify multiple patterns by using the OR operator, "|". Wildcards are supported in the pattern.

- **-instance_mcnt lower_bound,upper_bound**

Includes all paths for which the total count of matches of any of -instance or -file_instance patterns is within the specified range.

- **-libcell_mcnt lower_bound,upper_bound**

Includes all paths for which the total count of matches of any -libcell pattern is within the specified range.

- **-tns lower_bound,upper_bound**

Includes all potential path groups with total negative slack (TNS) values within the specified floating point range.

You must use the **-hierarchy** option when you use this filter.

- **-nvp lower_bound,upper_bound**

Includes all potential path groups whose number of violating paths is within the specified integer range.

You must use the **-hierarchy** option when you use this filter.

Note: You can specify the filters as minimally-distinct strings. That is, instead of using capacitance, you can use "capa" or even "pac1", since no other column name contains that sequence of letters.

If you do not specify this option, the following filters are applied:

```
-filters "-wns ,0 -zero_path ,0 -fanout 40 -transition_degradation 2.0
-slew_degradation 2.0 -logic_levels 50"
```

-hierarchy

Checks if timing violations are related to blocks, hard macros, or user-specified hierarchical modules (using the **-from**, **-through**,

and **-to** options).

-from module_list

Specifies the instances to use as the from instance list. Each instance in this list is used as a startpoint for one or more potential path groups. Paths that start at one of these points might also pass through instances specified in the **-through** option and might end at instances specified in the **-to** option. Each combination is considered as a potential path group.

This option is valid only when you also use the **-hierarchy** option.

-to module_list

Specifies the instances to use as the to instance list. Each instance in this list is used as an endpoint for one or more potential path groups. Paths that end at one of these points might also start at instances specified in the **-from** option and might pass through instances specified in the **-through** option. Each combination is considered as a potential path group.

This option is valid only when you also use the **-hierarchy** option.

-through module_list

Specifies the instances to use as the through instance list. Each instance in this list is used as a through point for one or more potential path groups. Paths that pass through one of these points might also start at instances specified in the **-from** option and might end at instances specified in the **-to** option. Each combination is considered as a potential path group.

This option is valid only when you also use the **-hierarchy** option.

-output_group_paths file_name

Generates an SDC file containing the list of path groups identified by the **-hierarchy** option and other related options, such as **-filter**).

If you do not specify the **-output_group_paths** option, you must use the HTML browser to manually select the path groups to create from the HTML report. The `_gp.tcl` suffix is appended to the file name.

This option is valid only when you also use the **-hierarchy** option.

-group_path_prefix prefix

Specifies a string that is inserted at the beginning of any group names created by the Create Groups button in the top-level summary page displayed with the **-hierarchy** option of the **query_qor_snapshot** command. This option can be used only with the **-hierarchy** option. For example, **-group_path_prefix "CUSTOM"** will create path groups named CUSTOM_... .

-group_path_append appendix

Specifies a string that is appended to the end of any **group_paths** commands created by the Create Groups button in the top-level summary page displayed with the **-hierarchy** option of the **query_qor_snapshot** command. This option can be used only with the **-hierarchy** option. For example, **-group_path_append "-critical_range 0.5"** will cause any **group_path** commands created by the Create Groups button in the following format:

```
group_path ... -critical_range 0.5
```

-case_sensitive

Makes the option argument values and filters case sensitive.

-subgroup {subgroup_name subgroup_options}

Allows multiple queries with some restrictions in CTR mode. You can specify multiple **-subgroup** options in a single run of the **query_qor_snapshot** command.

The key difference between using the **-subgroup** option and running multiple queries on the same data set is that the set of timing paths in each subgroup is unique when using the **-subgroup** option. That is, the second subgroup uses those paths that do not meet the requirements of the first subgroup, the third subgroup uses those paths that do not meet the requirements of the first two subgroups, and so forth. After processing each specified subgroup, the tool creates a default subgroup named Others, which consists of all the remaining paths that are not included in the subgroups created by this option.

The results are summarized in a format similar to that used by the **-group_by** option; that is, one line per subgroup to show the paths found, worst negative slack (WNS) for the set of paths, and total negative slack (TNS) for the set of paths. You can click a

subgroup name to see details about that subgroup.

If you do not specify the subgroup name, the tool assigns a name to the subgroup.

For each subgroup, you can specify zero or more of the following options to define the subgroup: **-columns**, **-case_sensitive**, **-filters**, **-and**, **-sort_by**, and **-group_by**. Any unspecified subgroup options have the same default values as a regular categorized timing report query.

To control the settings for the Others group, use the following command options (outside of the subgroup specification): **-columns**, **-sort_by**, and **-group_by**.

You can define a subgroup query with only **-subgroup { }**.

You cannot use this option with the **-hierarchy**, **-incremental**, and **-clock_tree_only** options or with clock tree reports.

-infeasible_paths

Enables the displaying of feasibility information of each path under the Infeasible Paths column. This information is collected during compile exploration. If the snapshot query is created without the **-infeasible_paths** option, the column is filled with N/A instead of YES or NO.

-clock_tree_only

Indicates the command should run in CTS (clock tree synthesis) mode instead of the default CTR (general timing) mode. All CTR arguments are ignored and CTS arguments become active.

-cts_output_file file_name

Specifies the name of the generated output files.

If you specify a file name that ends in .html, only an HTML output is created. If you specify a file name that ends in .txt, only a text output is created. Otherwise, both text and HTML outputs are created and saved into files with appropriate names. If the destination directory is read-only, an error message is displayed and you must specify a different file name.

-cts_sort_by column_list

Specifies the column used to sort the results in CTS mode. The default is skew.

To sort a column in descending order, specify "*column_name*" or "+*column_name*". To sort a column in ascending order, specify "-*column_name*". This is so that the default sort order for a column produces the most meaningful sorting order (descending for most numeric columns).

Valid CTS sort columns are: clock, scenario, master_clock, master_source, sinks skew, path_delay, transitionViolation, fanoutViolation, capacitanceViolation, skew_bottleneck_pins, skew_bottleneck_skew, skew_bottleneck_delay, explicit_ignore, dont_touch_subtree, dont_buffer_nets, dont_size_cells, hierarchy_preservation, size_only_cells, explicit_sync, explicit_nonstop, implicit_ignore, implicit_nonstop, etm_impossible_pins, etm_internal_pins, multi_output_skew_cells, multi_output_skew_diff, multi_timing_arc_cells, multi_timing_arc_diff, transition_degradation, slew_degradation, logic_levels and worst_incremental.

-cts_columns column_list

Specifies the list of columns to include in the output in CTS mode. The columns are displayed in the specified order. If you specify a column multiple times, its location is determined by the last instance.

The column names are specified in the following format:

column_name[.*width*]

where *column_name* is the same as the corresponding filter name (see the description for the **-cts_filters** option for information about the filter names) and *width* is an optional integer value that defines the column width. Width is somewhat flexible in HTML output and the column will not expand past the width of the widest value. To show all available columns in a predetermined order, specify **-cts_columns ALL**. The only column available for use with **-cts_columns** that is not described under the **-cts_filters** option is the "name" column, which shows the Pathname column (values are All, Longest, Shortest, Skew Bottleneck Pins).

Note: You can specify the column names as minimally distinct strings. That is, instead of using "capacitanceViolation", you can use "capa" or even "e_viol", since no other column name contains that sequence of letters.

If you do not specify this option, the default is to display all available CTS columns.

-cts_and column_list

Specifies a list of filters to apply with AND logic. These filters are applied to the clocks that pass the filters specified in the **-cts_filters** option. Clocks that match one or more OR filters and all AND filters are included in the result.

For example, if you specify **-cts_filters {-skew,-3.0 -etm_internal 1}**, the command reports the clocks which have a skew worse than -3.0 OR clocks which have one or more ETM internal pins. If you specify **-cts_filters {-skew,-3.0 -etm_internal 1}-cts_and skew**, the command reports the paths with timing violations where skew is worse than -3.0 AND the clock has one or more ETM internal pins. If all specified filters are also specified with the **-cts_and** option, one of the filter is automatically treated as an OR filter.

-cts_filters filter_list

Specifies a list of filters to apply to the clocks analyzed from the clock tree report files. The list must be enclosed in double quotes. The specified filters are applied with OR logic; all clocks matching any specified filter are selected.

Each filter consists of a filter option and its argument. Most filters accept a range of either floating-point or integer numbers as the argument. The range argument consists of two numbers separated by a comma. The first number is the lower bound and the second number is the upper bound. You can also specify just one number. In this case, it is interpreted as the lower bound, unless it is preceded by a comma. If the number is preceded by a comma, it is interpreted as the upper bound.

Filters can be grouped into two areas: default filters and other general filters. Default filters are used to indicate violations with respect to important matrices in the clock tree report, such as output pin transition degradation, bad net slew degradation, and long logic levels, that can be quantified. Other general filters exist to allow you to further narrow down the query searches.

You can specify one or more of the following filters:

- **-skew lower_bound,upper_bound**
Include all clocks that have a skew within the specified floating point range.
- **-transition_degradation lower_bound,upper_bound**
Include all clocks that have their transition degradation ratio (output pin transition time divided by input pin transition time) within the specified floating-point range.
- **-slew_degradation lower_bound,upper_bound**
Include all clocks that have slew degradation (input pin transition divided by last stage output pin transition) within the specified floating-point range.
- **-logic_levels lower_bound,upper_bound**
Include all clocks that have their number of logic levels within the specified integer range.
- **-path_delay lower_bound,upper_bound**
Include all clocks that have the longest path delay within the specified floating-point range.
- **-sinks lower_bound,upper_bound**
Include all clocks having their number of sinks within the specified integer range.
- **-transitionViolation lower_bound,upper_bound**
Include all clocks having their number of transition violations within the specified integer range.
- **-capacitanceViolation lower_bound,upper_bound**
Include all clocks having their number of capacitance violations within the specified integer range.
- **-fanoutViolation lower_bound,upper_bound**
Include all clocks having their number of fanout violations within the specified integer range.
- **-explicitIgnore lower_bound,upper_bound**
Include all clocks having their number of explicit ignore pins clock tree exceptions within the specified integer range.
- **-implicitIgnore lower_bound,upper_bound**
Include all clocks having their number of implicit ignore pins clock tree exceptions within the specified integer range.
- **-explicitSync lower_bound,upper_bound**
Include all clocks having their number of explicit sync pins clock tree exceptions within the specified integer range.
- **-explicitNonstop lower_bound,upper_bound**
Include all clocks having their number of explicit nonstop pins clock tree exceptions within the specified integer range.

- **-implicit_nonstop *lower_bound,upper_bound***
Include all clocks having their number of implicit nonstop pins clock tree exceptions within the specified integer range.
- **-dont_touch_subtree *lower_bound,upper_bound***
Include all clocks having their number of dont touch subtree pins clock tree exceptions within the specified integer range.
- **-dont_buffer_nets *lower_bound,upper_bound***
Include all clocks having their number of dont buffer nets clock tree exceptions within the specified integer range.
- **-dont_size_cells *lower_bound,upper_bound***
Include all clocks having their number of dont size cells clock tree exceptions within the specified integer range.
- **-hierarchy_preservation *lower_bound,upper_bound***
Include all clocks having their number of hierarchy preservation objects clock tree exceptions within the specified integer range.
- **-size_only_cells *lower_bound,upper_bound***
Include all clocks having their number of size only cells clock tree exceptions within the specified integer range.
- **-skew_bottleneck_pins *lower_bound,upper_bound***
Include all clocks having their number of skew bottleneck pins within the specified integer range.

Skew bottleneck pins are driver pins in the clock tree having an increase in skew at the driver compared to the load pins. Skew at a driver is calculated, and then, skew at each load pin of the driver is calculated. The largest increase in skew from any load pin to the driver is then compared to the **-skew_bottleneck_threshold** value. If skew increase is greater than the threshold, the driver pin is marked as a skew bottleneck pin.

- **-skew_bottleneck_threshold *lower_bound,upper_bound***
When calculating skew bottleneck pins, use this range to determine whether a pin is considered a skew bottleneck pin. The default value (even if not specified) is 0.05 (that is, lower bound of 0.05 or no upper bound).

Note: this filter has no corresponding column that can be shown with the **-cts_columns** option.

- **-skew_bottleneck_skew *lower_bound,upper_bound***
Include all clocks having their worst skew bottleneck pin skew within the specified floating-point range.
- **-etm_impossible_pins *lower_bound,upper_bound***
Include all clocks having their number of ETM impossible pins within the specified integer range.
- **-etm_impossible_threshold *lower_bound,upper_bound***
When marking ETM impossible pins, use this range to determine whether a pin is considered an ETM impossible pin. The default value (even if not specified) is 0.01 (that is, lower bound of 0.01 and no upper bound).

Note: this filter has no corresponding column that can be shown with the **-cts_columns** option.

- **-etm_internal *lower_bound,upper_bound***
Include all clocks having their number of ETM internal pins within the specified integer range.
- **-multi_output_skew_cells *lower_bound,upper_bound***
Include all clocks having cells with multiple outputs and skew at these outputs within the specified integer range.
- **-multi_output_skew_threshold *lower_bound,upper_bound***
When marking multiple output skew pins, use this range to determine whether a pin is considered a multiple output skew pin. The default value (even if not specified) is 0.05 (that is, lower bound of 0.05 and no upper bound).

Note: this filter has no corresponding column that can be shown with the **-cts_columns** option.

- **-multi_output_skew_diff *lower_bound,upper_bound***
Include all clocks having cells with multiple outputs and the worst skew at the outputs within the specified floating-point range.
- **-multi_timing_arc_cells *lower_bound,upper_bound***
Include all clocks having cells with multiple timing arcs and the number of arcs within the specified integer range.
- **-multi_timing_arc_threshold *lower_bound,upper_bound***
When marking multiple timing arc pins, use this range to determine whether a pin is considered a multiple timing arc pin. The default value (even if not specified) is 0.05 (that is, lower bound of 0.05 and no upper bound).

Note: this filter has no corresponding column that can be shown with the **-cts_columns** option.

- **-multi_timing_arc_diff lower_bound,upper_bound**
Include all clocks having cells with multiple timing arcs and the worst difference of the timing arcs within the specified floating-point range.
- **-worst_incremental lower_bound,upper_bound**
Include all clocks that have a cell with incremental cell value within the specified floating-point range.
- **-scenario pattern**
Include all clocks whose scenario name matches any of the specified patterns. You can specify multiple patterns as a space-separated list. The specified patterns are applied with OR logic; all scenarios matching any specified pattern are selected. Wildcards are supported in patterns at the beginning or at the end.
- **-clock pattern**
Include all clocks whose clock name matches any of the specified patterns. You can specify multiple patterns as a space-separated list. The specified patterns are applied with OR logic; all clock names matching any specified pattern are selected. Wildcards are supported in patterns at the beginning or at the end.
- **-master_clock pattern**
Include all clocks whose master clock name matches any of the specified patterns. You can specify multiple patterns as a space-separated list. The specified patterns are applied with OR logic; all master clock names matching any specified pattern are selected. Wildcards are supported in patterns at the beginning or at the end.
- **-master_source pattern**
Include all clocks whose master source name matches any of the specified patterns. You can specify multiple patterns as a space-separated list. The specified patterns are applied with OR logic; all master source names matching any specified pattern are selected. Wildcards are supported in patterns at the beginning or at the end.

If you do not specify this option, the following filters are applied:

```
-cts_filters {-transitionViolation 1 -fanoutViolation 1  
-capacitanceViolation 1 -dontTouch 1 -dontBuffer 1 -dontSize 1  
-sizeOnly 1 -explicitIgnore 1 -skew 0 -transitionDeg 2.0 -slewDeg 2.0}
```

-cts_set_exceptions_file file_name

Generates a Tcl command file containing **set_clock_tree_exceptions** commands. One or more **set_clock_tree_exceptions** commands are generated for each clock path matching one or more filters that can create exceptions. The filters that can create clock tree exceptions are extracted timing model (ETM) internal pins, ETM impossible pins, multiple timing arc cells, and multiple output skew cells. If none of these filters are specified, this output file will be empty.

The set of **set_clock_tree_exceptions** commands created is the same as selecting all paths and all columns that can create clock tree exceptions in the HTML report or interactive report and then selecting the **Remove/Create Exceptions** button.

After creating all **set_clock_tree_exceptions** commands, a minimum set of commands is created by eliminating duplicates. The duplicate elimination process often causes the order of the **set_clock_tree_exceptions** commands in the output file to be different than the order of the clock paths in the output file or input report.

The _se.tcl suffix is appended to the specified file name.

-cts_clear_exceptions_file file_name

Generates a Tcl command file that contains **remove_clock_tree_exceptions** commands. One or more **set_clock_tree_exceptions** commands are generated for each clock path that matches one or more filters that can remove exceptions. The filters that can generate remove clock tree exception commands are don't touch subtree, don't buffer nets, don't size cells, size-only cells, explicit sink pins, explicit nonstop pins, and hierarchy preservation. If none of these filters are specified, this output file will be empty.

The set of **remove_clock_tree_exceptions** commands created is the same as selecting all paths and all columns that can generate remove clock tree exception commands in the HTML report or interactive report, and then selecting the **Remove/Create Exceptions** button.

After creating all **remove_clock_tree_exceptions** commands, a minimum set of commands is created by eliminating duplicates. The duplicate elimination process often causes the order of the **remove_clock_tree_exceptions** commands in the output file to be different than the order of the clock paths in the output file or input report.

The _ce.tcl suffix is appended to the specified file name.

DESCRIPTION

The **query_qor_snapshot** command analyzes timing report files from existing QoR snapshots, applies any specified filters, and displays the results in an appropriate format.

The **query_qor_snapshot** command operates in two distinct modes: CTR (general timing) mode and CTS (clock tree synthesis) mode. When you use the **-clock_tree_only** option, the command operates in CTS mode and all CTR options are ignored. Similarly, in the default CTR mode, all CTS options are ignored. General options are applicable to both modes.

CTR Mode

In CTR mode, this command reads in a timing report file created by the **create_qor_snapshot** command and analyzes it. It shows a summary of the timing report, subject to one or more filters specified. All values that match a filter are highlighted with a * for text or red text for HTML. You can specify which columns to output with the **-columns** option, sorting with the **-sort_by** option, and which filters to apply as AND filters with the **-and** option.

The **query_qor_snapshot -hierarchy** command reads in the same timing report file and attempts to group violated paths across hierarchical modules, based on criteria you provide. The potential path groups are then listed based on the combinations of modules specified by the **-from**, **-to**, and **-through** options. If you do not specify hierarchical modules by using the **-from**, **-through**, and **-to** options, the **query_qor_snapshot -hierarchy** command automatically finds all the blocks and hard macros and looks for timing violation paths that cross all blocks and hard macros.

CTS Mode

In CTS mode, this command reads in a group of clock report files created by the **create_qor_snapshot -clock_tree_only** command and analyzes them.

The command reports a summary of the clock tree, subject to one or more specified filters. All values that match a filter are highlighted (with a * for text or red text for HTML). You can specify columns to display with the **-cts_columns** option, column value sorting order with the **-cts_sort_by** option, and filters to apply as AND filters with the **-cts_and** option.

Strings and Collections

Many commands, such as the **get_cells** command, return collections of objects. The **query_qor_snapshot** command is intended to run in a very minimalist environment without requiring a lot of design information to be loaded. As a result, collections are not supported as inputs to the **query_qor_snapshot** command. All input must be in the form of text strings. You can use the **join** and **collection_to_list** commands to turn a collection into a list of strings. See the CTR EXAMPLES section for an example.

CTR EXAMPLES

Before running the **query_qor_snapshot** command, you must run the **create_qor_snapshot** command to generate the snapshot data, as shown in the following example:

```
prompt> create_qor_snapshot -name place_opt
prompt> create_qor_snapshot -name place_opt_zwl -zero_wire_load
```

In the following example, the **query_qor_snapshot** command analyzes a QoR snapshot named preroute, which is saved under the snapshot directory and reports the values with WNS between -2.0 and -1.0.

```
prompt> query_qor_snapshot -name preroute -filters "-wns -2.0,-1.0"
```

In the following example, the **query_qor_snapshot** command analyzes QoR snapshot named placeopt, which is saved under the snapshot directory and reports the values with WNS less than -1.0 or fanout over 40.

```
prompt> query_qor_snapshot -name placeopt -filters "-wns ,-1.0 -fanout 40"
```

In following example, the **query_qor_snapshot** command reports the groups with violated timing paths through all blocks and hard macros.

```
prompt> query_qor_snapshot -hierarchy
```

In the following example, the **query_qor_snapshot** command reports the groups with violated timing path (WMS < 0) between the modules specified in the **-from** and **-to** options.

```
prompt> set user_list [join [collection_to_list \
[get_cells {A/B C/D E F}]]]
prompt> query_qor_snapshot -hierarchy -from $user_list -to $user_list
```

In the following example, the **query_qor_snapshot** command reports the groups with TNS more than -100 ns or timing violations with WNS worse than -3 ns. If the worst violation is -3.1ns, this group is reported. If the worst slack is -2.9ns, the command checks the TNS of these violations. If the TNS is more than 100 ns, these groups are reported; otherwise, these groups are not reported.

```
prompt> set user_list [collection_to_list [get_cells {A/B C/D E F}]]
prompt> query_qor_snapshot -hierarchy -from $user_list -to $user_list \
-filter "-wns ,-3.0 -tns ,-100"
```

The following example shows all paths that have WNS less than zero.

```
prompt> query_qor_snapshot -name timing_report -filters "-wns ,0"
```

The following example shows all paths that have cells with output or input transition time over 2 ns.

```
prompt> query_qor_snapshot -name timing_report \
-filters "-transition_degradation 2"
```

The following example shows all paths that have path stages with slew degradation over 3 ns.

```
prompt> query_qor_snapshot -name timing_report \
-filters "-slew_degradation 3"
```

The following example shows all paths that have over 50 logic levels:

```
prompt> query_qor_snapshot -name timing_report \
-filters "-logic_level 50"
```

The following example shows all paths that have cells with a fanout over 40.

```
prompt> query_qor_snapshot -name timing_report -filters "-fanout 40"
```

The following example looks at all timing paths that match the worst negative slack (WNS) filter or zero-path filter. If the WNS violation is more than -10 ns or the path violates zero-path delay, the command automatically generates appropriate **set_false_path** commands for those timing paths.

```
prompt> query_qor_snapshot -name timing_report \
-filter "-wns ,-10.0 -zero_path ,0" \
-output_false_paths "my_"
```

The following example looks at all timing paths that match the WNS or zero_path filters. If the slack violation is more than -10 ns or the path violates zero-path delay, the command automatically generates **group_path** commands for the modules specified in the **-from**, **-through**, and **-to** options.

```
prompt> query_qor_snapshot -name timing_report -hierarchy \
-filter "-wns ,-10.0 -zero_path ,0" \
-output_group_paths "my_sdc"
```

The following example defines a subgroup query that creates three subgroups. The subgroups are named Group 1, Query 2, and Others. Subgroup Group 1 contains paths with WNS less than -10.0 or zero-path margin less than 0. Subgroup Query 2 contains paths not matched by subgroup Group 1 that also match the default filters. The Others subgroup contains any remaining paths that are not matched by the first two subgroups.

```
prompt> query_qor_snapshot -name timing_report \
-subgroup { "Group 1" -filter "-wns ,-10.0 -zero_path ,0" } \
-subgroup { }
```

CTS EXAMPLES

Before running the **query_qor_snapshot** command in CTS mode, you must run the **create_qor_snapshot** command to generate the snapshot data, as shown in the following example:

```
prompt> create_qor_snapshot -name clock_opt -clock_tree
```

The following example looks at all clock paths that match the ETM impossible pins filter. If the clock path has one or more ETM impossible pins, the command automatically generates appropriate **set_clock_tree_exceptions** commands for those clock paths.

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-etm_impossible_pins 1} \
-cts_set_exceptions_file {my_}
```

The following example looks at all clock paths that match the don't touch subtree filter. If the clock path has one or more don't touch subtree exceptions, the command automatically generates appropriate **remove_clock_tree_exceptions** commands for those clock paths.

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-dont_touch_subtree 1} \
-cts_clear_exceptions_file {my_}
```

In the following example, the **query_qor_snapshot** command reports all clocks with skew greater than 5 ns.

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-skew 5.0}
```

In the following example, the **query_qor_snapshot** command reports all clocks that have cells with input or output transition time over 2 ns:

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-transition_degradation 2}
```

In the following example, the **query_qor_snapshot** command reports all clocks that have ETM impossible pins and sets the ETM impossible pin threshold to 0.1.

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-etm_impossible_pins 1 -etm_impossible_threshold 0.1}
```

In the following example, the **query_qor_snapshot** command reports all clocks that have path segments with slew degradation over 3 ns:

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-slew_degradation 3}
```

In the following example, the **query_qor_snapshot** command reports all clocks that have over 50 logic levels:

```
prompt> query_qor_snapshot -clock_tree_only -name clk_report \
-cts_filters {-logic_level 50}
```

quit!

quits the application without posting an application exit dialog

SYNTAX

`quit!`

ARGUMENTS

None.

DESCRIPTION

This command is an alternative to the `quit` command. When called with the GUI up, the `quit` command posts an application exit dialog. To avoid having to "deal with" the exit dialog, the user can instead call the `quit!` command which is guaranteed to exit the application without posting a GUI exit dialog.

EXAMPLES

`prompt> quit!`

SEE ALSO

`quit(2)`

quit

Exits the shell.

SYNTAX

string **quit**

ARGUMENTS

The **quit** command has no arguments.

DESCRIPTION

The **quit** command exits from the application. It is basically a synonym for the **exit** command with no arguments.

EXAMPLES

The following example exits the current session:

```
prompt> quit
```

SEE ALSO

[exit\(2\)](#)

read

Reads from a channel.

SYNTAX

read

ARGUMENTS

The **read** command has no arguments.

DESCRIPTION

The **read** command reads data from the specified channel.

If the specified channel is in nonblocking mode, the command might not read as many bytes as requested; once all available input has been read, the command returns the available data rather than blocking for more input.

The **read** command translates end-of-line sequences in the input into newline characters according to the **-translation** option for the channel. For details, see the man page for the **fconfigure** command.

SEE ALSO

eof(n)
fblocked(n)
fconfigure(n)

read_bsdl

Reads the boundary-scan description language (BSDL) file for a boundary-scan design.

SYNTAX

```
status read_bsdl
      [-add_linkage_as_design_port true | false]
      file_name
```

Data Types

file_name string

ARGUMENTS

-add_linkage_as_design_port true | false

Enables or disables the addition of linkage ports specified in the input BSDL file in BSD patterns.

This option has no effect when the design netlist is already available prior to this command.

When the option is set to **true** and the design netlist is not available prior to this command, the linkage ports specified in the BSDL file are treated as design ports in BSD patterns.

When the option is set to **false** and the design netlist is not available prior to this command, the linkage ports specified in the BSDL file are not treated as design ports in BSD patterns.

The default value of this option is **false**, that is, linkage ports of BSDL files are not used in BSD patterns.

file_name

Specifies the name of the input BSDL file.

DESCRIPTION

The **read_bsdl** command reads the BSDL file for a boundary-scan design and generates an internal data structure for use with BSD pattern generation by the **create_bsd_patterns** command.

Before reading a BSDL file, you can optionally read in a netlist for the top-level design. This netlist can be the full netlist or a simplified representation containing using black boxes. If you use a black-box representation, the design must contain at least the I/O pads. After reading in the netlist, set the current design to the top level with the **current_design** command.

You must always specify the target and link libraries before running the **read_bsdl** command, even if you are not reading in a netlist representation. Otherwise, this command fails due to being unable to read the link libraries.

EXAMPLES

The following example reads a design netlist and BSDL file for a boundary-scan design, then generates patterns into various formats for the boundary-scan logic of the design:

```
prompt> set search_path "./lib $search_path"
prompt> set synthetic_library {standard.sldb dw_foundation.sldb}
prompt> set target_library {class.db}
prompt> set link_library [concat "" $target_library $synthetic_library]
prompt> read_file -format verilog chip_bsd.v # optional
prompt> current_design test # optional
prompt> link # optional
prompt> read_bsdl chip_bsd.bsdl
prompt> create_bsd_patterns
prompt> write_test -f stil_testbench -o design_stil_tb
prompt> write_test -f verilog -o design_verilog_tb
prompt> write_test -f wgl_serial -o design_wgl_tb
```

SEE ALSO

[create_bsd_patterns\(2\)](#)
[current_design\(2\)](#)
[read_file\(2\)](#)
[write_test\(2\)](#)

read_cell_expansion

Reads the cell expansion data, including the area, width, and height of each cell that is expanded.

SYNTAX

```
int read_cell_expansion
    input_file_name
    [-reset]
```

Data Types

input_file_name string

ARGUMENTS

input_file_name

Specifies the name of the input expansion data file. This is a required argument.

-reset

Resets all cell expansion cells.

DESCRIPTION

During congestion optimization, cells in congested regions are expanded to occupy more space to create lower density areas. The **read_cell_expansion** command reads the cell expansion data, including the area, width, and height of each cell that is expanded. The data can be used for better congestion correlation between the Design Compiler Graphical tool and the IC Compiler and IC Compiler II tools.

EXAMPLES

The following example reads a cell expansion file and applies it to the current design.

```
prompt> read_cell_expansion in.exp
```

SEE ALSO

write_cell_expansion(2)

read_db

Reads in one or more design or library files in Synopsys database (.db) format.

SYNTAX

```
string read_db
      file_names
```

Data Types

file_names list

ARGUMENTS

file_names

Specifies names of one or more files to be read.

DESCRIPTION

The **read_db** command reads design information from Synopsys database (.db) files into dc_shell.

This command is derived from the **read_file** command with the **-format db** option. For more information, see the man page for the **read_file** command.

SEE ALSO

read_file(2)

read_ddc

Reads in one or more design files in .ddc (Synopsys logical database) format.

SYNTAX

```
status read_ddc
  file_names
  [-scenarios scenario_list]
  [-active_scenarios active_scenario_list]
```

Data Types

<i>file_names</i>	list
<i>scenario_list</i>	list
<i>active_scenario_list</i>	list

ARGUMENTS

file_names

Specifies the names of one or more files to be read. If specifying more than one file name, enclose the names in braces ({}).

-scenarios *scenario_list*

Specifies the scenarios whose constraints are to be read from the .ddc file.

Constraints for any scenarios that are not listed are not read, which might save memory and runtime if the file is large and certain scenarios are not required in the current session.

If you do not use this option, all scenarios are read from the file. If you use this option with an empty *scenario_list* argument, no scenarios are read.

-active_scenarios *active_scenario_list*

Specifies a list of scenarios to be made active as the file is read. Any scenarios that are not listed are restored in the inactive state.

You can use this option only when you also specify the **-scenarios** option. The scenarios specified in the **-active_scenarios** option must be in the list of scenarios specified in the **-scenarios** option.

If you do not use this option, the active or inactive state of the scenarios are restored according to the state that was recorded when the file was written (unless the scenarios already exist).

DESCRIPTION

The **read_ddc** command reads design information from the Synopsys logical database (.ddc) files into memory.

This command is derived from the **read_file** command with the **-format ddc** option. For more information, see the man page for the **read_file** command.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

SEE ALSO

read_file(2)

read_file

Reads designs or libraries into memory, or reads libraries into the shell.

SYNTAX for dc shell

```
list read_file
  file_list
  [-define macro_names]
  [-format format_name]
  [-library library_name]
  [-rtl]
  [-single_file single_file_name]

  [-scenarios scenario_list
    [-active_scenarios active_scenario_list]]
  [-autoread
    -top top_design_name
    [-recursive]
    [-exclude exclude_list]
    [-param param_list]
    [-output_script file_name]
    [-verbose]
    [-rebuild]]]
```

Data Types

file_list	list
macro_names	list
format_name	string
library_name	string
single_file_name	string
scenario_list	list
active_scenario_list	list
top_design_name	string
exclude_list	list
param_list	list
file_name	string

SYNTAX for lc shell

```
list read_file
  file_list
```

Data Types

file_list	list
-----------	------

ARGUMENTS

file_list

Specifies a list of files or directories to read. When specifying more than one file or directory, separate the names with a space and enclose the list of names in braces ({}).

-define *macro_names*

Specifies a list of top-level macros. This option can be used only with the Verilog and SystemVerilog formats.

-format *format_name*

Specifies the format in which a design is read. The *format_name* can be one of the following formats:

Format	Description
ddc	Synopsys internal database format (default)
db	Synopsys internal database format (libraries only)
verilog	IEEE Standard Verilog
sverilog	IEEE Standard SystemVerilog
vhdl	IEEE Standard VHDL
equation	Synopsys equation format
pla	Berkeley (Espresso) PLA format
st	Synopsys State Table format

If the **-autoread** option is used, only verilog, sverilog, and vhdl formats are allowed. Using both **-format** and **-autoread** makes the autoread flow look for files in the given language that match the extensions in the corresponding extensions list by the **hdlin_autoread_verilog_extensions**, **hdlin_autoread_sverilog_extensions**, or **hdlin_autoread_vhdl_extensions** variable. By default, the **-autoread** option reads in all files it finds with Verilog, SystemVerilog, and VHDL extensions, so specifying the **-format** option is optional.

If **-format verilog** is used and the file is protected by encryption using **IEEE1735** standard or a block within the Verilog file is protected by the standard, support for reading of such files must be activated by setting the variable **hdlin_enable_ieee_1735_support** to **true**.

-library *library_name*

Remaps the work library to *library_name*. This option can be used only with the VHDL format.

By default, the **analyze** command stores all output in the work library. To store design elements in libraries other than library specified by using the **-work** option, use the **-library** option.

-rtl

Specifies that an RTL design is being read. This option can be used only with the Verilog or VHDL format.

When used, the **read_file** command invokes HDL Compiler directly without attempting to determine if the specified files are gate-level netlists.

You cannot use this option with the **-autoread** option.

-single_file *single_file_name*

Puts the designs in the *file_list* argument into the specified internal design file, regardless of the input format.

You cannot use this option with the **-autoread** option.

-work *library_name*

Remaps the work library in the same way as the **-library** option. It is an alias for the **-library** option for VHDL only.

You cannot use this option with the **-autoread** option.

-scenarios *scenario_list*

Specifies the scenarios whose constraints are to be read from the .ddc file. This option can be used only with the ddc format.

Constraints for any scenarios that are not listed are not read, which might save memory and runtime if the file is large and certain scenarios are not required in the current session.

If you do not use this option, all scenarios are read from the file. If you use this option with an empty *scenario_list* argument, no scenarios are read.

You cannot use this option with the **-autoread** option.

-active_scenarios active_scenario_list

Specifies a list of active scenarios when the file is read. Any scenarios that are not listed are restored in the inactive state. This option can be used only with the ddc format.

You can use this option only when you also specify the **-scenarios** option. The scenarios specified in the **-active_scenarios** option must be in the list of scenarios specified in the **-scenarios** option.

If you do not use this option, the active or inactive state of the scenarios are restored according to the state that was recorded when the file was written (unless the scenarios already exist).

You cannot use this option with the **-autoread** option.

-autoread

Enables the **-autoread** option for the **read_file** command, which is supported only for the Verilog, SystemVerilog, and VHDL formats.

When the **-autoread** option is used, the RTL source files listed in **list_files** (or reachable using the **-recursive** option) are read in, their dependencies are inferred, the files are ordered for a proper analyze phase regarding their dependencies, the files are analyzed (internally using the **analyze** command), and then the top design defined by **top** is elaborated in top-down mode.

-top top_design_name

Specifies the name of the top-level design. Elaboration starts at the specified design and elaborates the entire design hierarchy under the top design using the elaboration parameters defined by the optional **-param** option.

The current design is set to the design defined as top.

Any source file provided in *file_list* that is not required for top-down elaboration of the defined top module hierarchy is not analyzed.

This option is required when you specify the **-autoread** option. It is not valid without the **-autoread** option.

-recursive

Specifies that the command looks into the subdirectories of the directories specified by the *file_list* argument and recursively collects source files from those locations.

By default, the command looks into the specified directories, but it does not look in their subdirectories.

This option is available only with the **-autoread** option.

-exclude exclude_list

Specifies a list of files and directories that are not to be analyzed. If the command expands an item from the *file_list* argument, it checks the file or directory against all entries in this list and ignores the file or directory if it is covered by at least one of the entries.

This option is available only with the **-autoread** option.

-param param_list

Specifies a list of design parameters enclosed in quotes for the design's elaboration.

Parameters within the list must be separated by commas. A specification can be based on parameter order (for example, "8,7,5") or on parameter names (for example, "N=>8,M=>6"). You can mix ordered and named parameter specifications as long as the ordered parameters are listed first.

The full *param_list* syntax is summarized in the DESCRIPTION section of the **elaborate** command man page.

This option is available only with the **-autoread** option.

-output_script *file_name*

Creates a Tcl script that is compatible with Design Compiler and Formality. The file reading order for third-party tools and a DOT language file-dependency graph are embedded in the script as comments.

This option is available only with the **-autoread** option.

-verbose

Prints out more messages for the **-autoread** option.

This option is available only with the **-autoread** option.

-rebuild

Allows you to start a clean run with the **-autoread** option that analyzes all required files whether they were analyzed before.

The **-autoread** option runs by default in update mode. This means that if a file is changed, the file and all dependent files are reanalyzed.

This option is available only with the **-autoread** option.

DESCRIPTION

This command reads the designs specified in the *file_list* argument into memory.

The current design is automatically set to the first design that is read, unless the **-autoread** option is used and the **current_design** will be the design specified with the **-top** option.

The **read_file** command can also read the libraries in *file_list* into the shell. Libraries are the only .db files that can be read; user designs can no longer be read from .db files.

While it is good practice to always specify the **-format** option, if you do not specify this option, the tool attempts to infer the format based on the file name extensions, if any. The recognized extensions are .ddc for ddc format; .db, .pdb, .sdb, or .sldb for db format; .v or .verilog for Verilog format; .sv or .sverilog for SystemVerilog format; and .vhd or .vhdl for VHDL format. Extensions are not case-sensitive. If the file name ends in .gz, the preceding extension, if any, is used. For example, an extension of .v.gz is recognized as Verilog format. (The .gz extension is not supported for .ddc files.) If you specify multiple files on the same command line, their formats must all be the same. If the format cannot be inferred from the file names, the default format, ddc, is used.

Internally, designs are stored in design files. An internal design file is a "container" of designs and has a complete, unique, UNIX-type file name associated with it. The designs in a design file also have unique names, but designs with the same name can exist in different design files. For information about displaying design files and their contents, see the **list_designs** man page.

By default, when the tool reads files in a format other than ddc or db, it places each design in its own internal design file that uses the following naming convention: *input_file_path/design_name.ddc*. The names of files read in db or ddc format remain the same.

When the tool reads an HDL parameterized design file, the design is not converted to a .ddc file, but instead is parsed and stored in an intermediate format. Then, you can build the design by using the **elaborate** command or by instantiating the design in another HDL design.

Because internal database files at lower levels of hierarchy are automatically read when they are linked, you do not need to read them separately. Designs are not automatically linked at the time they are read. You can use the **link** command after the **read_file** command to ensure that referenced designs are read correctly. For information on automatic loading, see the **link** man page.

An input file can have either a simple or a complex file name. A simple file name has no directory specification, which means (in UNIX) that it does not contain a slash (/). Simple file names, such as adder.ddc or library.db, must be found in a directory listed in the **search_path** variable. A complex file name has a directory specification in it, which means that it does contain one or more slashes. Complex file names, such as ./test.ddc, ../test.ddc, or ~john/test/test.ddc, are not searched for in the **search_path** variable.

Internally, libraries are stored in library files. An internal library file is a "container" of libraries and has a complete, unique, UNIX-type file name associated with it. The libraries in a library file also have unique names, but libraries with the same name can exist in different library files. For information about displaying library files and their contents, see the **list_libs** man page.

By default, when the tool reads non-database format files, each library is placed in its own internal library file that uses the following naming convention: *input_file_path/file_name.db:library_name*. The names of files read in db format remain the same.

Multicorner-Multimode Support

By default, this command uses information from both active and inactive scenarios. You can select different scenarios by using the **-scenarios** option.

-autoread Option Support

The **-autoread** option reads in the source files of a design listed in the *file_list*, determines the dependencies between them, orders the files regarding its dependencies, analyzes them in the correct order to avoid errors due missed or misplaced files and elaborates the design starting at the specified top-level module. It retains the resulting GTECH representation in memory.

The dependencies are calculated only from the files or directories present in *file_list*. If *file_list* changes between consecutive calls with the **-autoread** option, the dependency inference is performed over the latest set of files provided. Based on this, all required sources must be present in *file_list* option (or reachable if the **-recursive** option is used) on each call with the **-autoread** option.

When the **-autoread** option is enabled, the **read_file** command reads in all files listed in *file_list* with Verilog, SystemVerilog, and VHDL extensions, but only files required for the top design elaboration will be analyzed. For analyzing all sources, see the **analyze** command man page with the **-autoread** option support.

You can specify the parameters required for elaborating the top design by using the **-param** option. Its syntax and usage is the same as described for the **-parameters** option of the **elaborate** command. See the **elaborate** man page for more information.

To locate the source files, the **-autoread** option uses the **search_path** variable to expand each item listed by the *file_list* command argument. It then determines whether the result is excluded by the **-exclude** option or the **hdlin_autoread_exclude_extensions** variable. If it is not excluded the language of the sources is inferred from the file extensions that match with the corresponding extensions list set by the **hdlin_autoread_verilog_extensions**, **hdlin_autoread_sverilog_extensions**, or **hdlin_autoread_vhdl_extensions** variable for Verilog, SystemVerilog, or VHDL language respectively.

You can also use the **-autoread** option when you want to specify explicit file names in the *file_list* argument that do not have one of the language-specific extensions, but you have explicit say the language using the **-format** option.

When expanding a directory, the command collects the files from the directory and recursively from its subdirectories if the **-recursive** option is set. The command then performs all extension checks on these files. If the **-format** option is set, only files with Verilog, SystemVerilog, or VHDL extensions are collected, based on the value of the option.

After the **-autoread** option collects all of the source files, it performs the following dependency checks:

- Detects analyze dependencies: Order RTL files for analyzing them the right order. For example, analyze the file that contains a VHDL entity before analyzing files that define architectures of that entity, or analyzes the file that contains a SV package declaration before the files that imports that package.
- Detects Verilog and SystemVerilog compilation unit dependencies: determines if a file needs to be analyzed in the same compilation unit with other files. For example, if a file defines macros, SV local parameter, SV enumerated values and the file is not explicitly included by the file that requires that definitions, then **-autoread** option and groups them in the same compilation unit in the correct order. This might not always be possible, such as when a macro is defined several times in different files and the **-autoread** cannot determine which of those alternatives is the right choice.
- Detects link dependencies: Schedule analyze stage for files required for elaboration of the design hierarchy. For example, if a (S)Verilog design that is instantiated in one source file is declared on a different source file provided in the *file_list*, the second file also requires to be analyzed for a complete top-down design elaboration.
- Detects include dependencies: If a (S)Verilog file is included in another source, and the file changes between two consecutive calls to the **-autoread** option (in the same DCSHELL session), this file and all files that include them will be scheduled for analyze to update the design.
- Infers the target library for VHDL files. However, if the **-library** option is specified, this step is skipped and VHDL files provided in *file_list* are analyzed into the specified design library.

After the dependency inference, all the required HDL files from the *file_list* (regarding its dependencies and the **-top** design defined) are analyzed, and then the design is elaborated from the top-level module. If no elaboration is desired, you can use the **analyze -autoread** command. The resulting GTECH representation is retained in memory.

It is possible to save the design to disk by using the **write** command.

When the **-autoread** option is used again after a file is changed, only the updated source files are analyzed and the design is elaborated. The updated designs are replaced in the unmapped design.

The **-autoread** option executes the dependency analysis only based on the current *file_list* information. Therefore, it is recommended to pass all RTL files that might have relevant dependency relationship in a single **read_file -autoread** command.

EXAMPLES

The following example uses simple and complex file names to read in a file of equations. This is a complex path specification, so **search_path** is not used.

```
prompt> read_file -format equation /usr/test/test.fnc
Loading file '/usr/test/test.fnc'
{test}
```

The following example uses a simple file name to specify the same file as shown in the previous example. Thus, its directory must appear in the **search_path**.

```
prompt> search_path = {/usr/test}
{/usr/test}
prompt> read_file -format equation test.fnc
Loading file '/usr/test/test.fnc'
{test}
```

The following example reads a file that contains multiple designs, so each design is assigned its own internal design file name. The asterisk (*) indicates the current design. For more information, see the **list_designs** man page.

```
prompt> read_file -format verilog foo.v
Loading file '/usr/test/foo.v'
{A B C}

prompt> list_designs
```

Design	File	Path
*	A	A.ddc /usr/test/dc
B	B.ddc	/usr/test/dc
C	C.ddc	/usr/test/dc

The following example shows that when you use the **-single_file** option, all designs are assigned the same file name:

```
prompt> read_file -format verilog -single_file mylib.ddc foo.v
Loading file '/usr/test/foo.v'
{A B C}

prompt> list_designs
```

Design	File	Path
*	A	mylib.ddc /usr/bill/dc
B	mylib.ddc	/usr/bill/dc
C	mylib.ddc	/usr/bill/dc

The following example uses simple and complex file names to read the library .db file into the shell. This is a complex path specification, so the **search_path** variable is not used.

```
prompt> read_file -format db /usr/test/test.db
Loading db file '/usr/test/test.db'
{test}
```

The following example shows that in order to specify the same file as shown in the example above as a simple file name, its directory

must appear in the **search_path** variable.

```
prompt> search_path = {/usr/test}  
{/usr/test}
```

```
prompt> read_file -format db test.db  
Loading db file '/usr/test/test.db'  
{test}
```

The following example assumes that the current directory is the source directory. It specifies the source file list at the command line and calls the command with the name of the top-level entity.

```
prompt> read_file {} -autoread -recursive -top E1
```

The next example specifies extensions for Verilog files that are different than the default (".v"), sets the source list and the exclude list, and calls the command with the name of the top-level module name, forcing it to only collect files with Verilog extensions.

```
prompt> set hdlin_autoread_verilog_extensions {.ve .VE}  
prompt> set my_sources {mod1/src mod2/src}  
prompt> set my_excludes {mod1/src/incl mod2/src/incl}  
prompt> read_file $my_sources -exclude $my_excludes \  
-autoread -format verilog -top TOP
```

Note that excluding include directories explicitly is only necessary if include files have the same extensions as source files and not all include files are included in the source.

read_floorplan

Reads a script that describes a floorplan into the current design.

SYNTAX

```
status read_floorplan
      file_name
      [-echo]
      [-verbose]
```

Data Types

file_name string

ARGUMENTS

file_name

Specifies the name of the file that contains the floorplan script to be read.

-echo

Specifies that each command is written out as it is executed.

-verbose

Displays the result of each command executed. Note that error messages are displayed regardless. Also note that this option is a non-standard extension to Tcl.

DESCRIPTION

The **read_floorplan** command reads in a script file that contains commands describing floorplan information.

Similar to the **source** command, the **read_floorplan** command is guided by variables that control script execution, such as the **sh_continue_on_error** and **sh_script_stop_severity** commands. The **read_floorplan** command uses the **sh_source_uses_search_path** variable to determine if the **search_path** command is used to find the script file.

By default, **read_floorplan** displays only error messages and summary output. It is possible to get additional information from the **read_floorplan** command using the **-echo** and **-verbose** options. The **-echo** option writes out each command as it appears in the script. The **-verbose** option echoes the result of each command after execution.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reads the floorplan script named *top.fp*:

```
prompt> read_floorplan top.fp
Reading floorplan ...
1
```

```

read_lib

Reads a technology library into the shell.

Starting with the K-2015.06 release, the Library Compiler tool is a separate installation that is no longer part of the synthesis tools installation. Therefore, to run the Library Compiler **read_lib** command in the Design Compiler tool, the two tools must be linked during the tool installation process. For information about the installation process and how to link the Library Compiler tool to the Design Compiler tool, see the Synthesis Tools Installation Notes and the Library Compiler Installation Notes for the K-2015.06 release.

SYNTAX

```
status read_lib
  file_name
  [-test_model CTL_file_list]
  [-html]
  [-symbol slib_filename]
  [-names_file file_list]
  [-imported_jcr jcr_file]
  [-format format]
  [-lib_messages lib_msgs]
  [-pliblibrary pliblibrary_file_name]
  [-no_warnings]
  [-pliblibrary -pliblibrary_filename]
```

Data Types

<i>file_name</i>	string
<i>CTL_file_list</i>	list

ARGUMENTS

file_name

Specifies the name of the library file to be read. A technology must be in Synopsys Library Compiler format.

-test_model *CTL_file_list*

Specifies a set of one or more CTL files as test model of cells in the library. The format of the *CTL_file_list* is <*cell_name*:>*file_name* where *cell_name* is optional and is to specify the particular cell a CTL file models. When the *cell_name* is missing, the environment name in the CTL file is used as the cell name it is modeling. When specifying more than one CTL file, enclose them in braces ({}).

-html

Specifies that library screener results are reported in HTML.

DESCRIPTION

The **read_lib** command reads a library file into the shell (or GUI). The library file is automatically compiled by the Synopsys Library Compiler. The library specified in *file_name* can have either a simple or complex file name. A simple file name has no directory specification, which means (in UNIX) that it does not contain a / (slash). Simple file names such as test.lib or library.db must be found in a directory listed in the **search_path** variable. A complex file name has a directory specification in it, which means that it does contain a slash. Complex file names such as ./test.lib or ~synopsys/dc/test.lib are not searched for in **search_path**.

You can read any number of libraries into the shell. Two libraries can have the same name in the system as long as they are read from different sources. The **list_libs** command shows all libraries present in the system.

The **read_lib** command will check the input model file library syntax against model syntax specified by **-model_type** option. If any content of the input model file library does not belong to the specified model, syntax error will be reported.

For details on library file syntax, see the Library Compiler documentation. Function statements and state information are ignored when reading technology library files if you do not have a Library Compiler license.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the library file *tech_lib.lib*, is read. This file contains technology information in Synopsys technology library entry format,

```
prompt> read_lib ~synopsys/libraries/tech_lib.lib
```

The following example reads a library file as well as a CTL file when the **-test_model** option is used:

```
prompt> read_lib bar.lib -test_model {usr1.ctl usr2:usr2.ctl}
```

The following examples read in a lvf, ccs_power or power_aware model file respectively when the **-model_type** option is used:

```
prompt> read_lib aocv.lib -model_type lvf
prompt> read_lib aocv.lib -model_type ccs_power
prompt> read_lib aocv.lib -model_type power_aware
```

The following example reads a library file and report screener messages in HTML:

```
prompt> read_lib bar.lib -html
```

SEE ALSO

[write_lib\(2\)](#)
[search_path\(3\)](#)

read_ocvm

Reads a parametric on-chip variation (POCV) derating factor table.

SYNTAX

```
status read_ocvm
      [-min]
      [-max]
      [-distance_row row_number]
      ocvm_file
```

Data Types

row_number integer
ocvm_file string

ARGUMENTS

-min

Specifies that the POCV derating table applies only to the minimum operating condition.

-max

Specifies that the POCV derating table applies only to the maximum operating condition.

By default, the POCV derating table applies to both the minimum and maximum operating conditions.

-distance_row *row_number*

This option is not used in the Design Compiler tool.

ocvm_file

Specifies the name of the POCV derating table file.

DESCRIPTION

The **read_ocvm** command reads POCV derating tables from a disk file. The tables are annotated onto one or more design objects: hierarchical cells, library cells, or designs. The POCV data is used to reduce pessimism and improve the accuracy of timing results by applying different derating factors based on the depth of each path (the number of successive gates in the path).

To use the POCV files read by the **read_ocvm** command and perform POCV analysis, set the **timing_pocvm_enable_analysis** variable to **true**.

To apply the table to only to the maximum operating condition, use the **-max** option when you run the **read_ocvm** command.

Multicorner-Multimode Support

This command uses information from the current scenario only. By default, if the design objects are library cells, the tables are applied to all scenarios. To apply the tables only to the current scenario, set the `timing_library_derate_is_scenario_specific` variable to `true` before you apply the tables to the library cells.

EXAMPLES

In the following example, the first command shows a POCV table file named test.pocvm, which contains a single table to be annotated on the design. The second command reads in and applies this table.

```
prompt> sh cat test.pocvm
version:      4.0
object_type:  design
rf_type:     rise
delay_type:   cell
derate_type: late
object_spec:
coefficient: 0.05
prompt> read_ocvm test.pocvm
```

SEE ALSO

`report_ocvm(2)`
`report_timing(2)`
`timing_pocvm_enable_analysis(3)`
`timing_library_derate_is_scenario_specific(3)`

read_parasitics

Reads net parasitics information from an SPEF, DSPF, or RSPF file, and uses it to annotate the current design.

SYNTAX

```
status read_parasitics
  [-syntax_only]
  [-elmore | -arnoldi]
  [-increment]
  [-pin_cap_included]
  [-net_cap_only]
  [-complete_with zero | wlm]
  [-path path_name]
  [-strip_path path_name]
  [-quiet | -verbose]
  [-dont_write_to_db]
  [file_list]
```

Data Types

path_name string
file_list list

ARGUMENTS

-syntax_only

Checks the parasitic data files for errors and reports any errors without actually applying the data to the design.

-elmore

Causes the tool to estimate delays based on the parasitics information using the Elmore delay model and to back-annotate the estimated delays, in addition to creating the RC tree. If neither **-elmore** or **-arnoldi** is specified, the RC tree is created without estimating or back annotating delays.

-arnoldi

Causes the tool to estimate delays based on the parasitics information using the Arnoldi delay calculator and to back-annotate the estimated delays, in addition to creating the RC tree. If neither **-elmore** nor **-arnoldi** is specified, the RC tree is created without estimating or back-annotating delays.

-increment

Retains any previously annotated parasitics on the nets listed in the parasitics file. This option is used for annotating hierarchical parasitics files. By default, the RC annotation specified in the parasitics file overwrites the previous parasitics annotations of the nets listed in the parasitics file.

-pin_cap_included

Specifies that the RC network includes the pin capacitance. By default, the RC network does not include them.

-net_cap_only

Back-annotates only the net capacitance values, not the pin-to-pin delay values. By default, both the capacitance values and the pin-to-pin delays are back-annotated.

-complete_with_zero | wlm

Causes the tool to automatically complete the RC tree after parsing. This option should be used if a parasitics file contains incomplete parasitics information; for example, if only a segment of a wire is annotated. During the RC completion phase, missing wire segments are automatically added.

If **zero** is specified, all newly added segments and nodes are considered to have 0 resistance and 0 capacitance. If **wlm** is specified, the capacitance and resistance values for a new segment are determined by the current wireload model.

-path path_name

Specifies the path from the current design to the specified subdesign for which the parasitics file has been created.

-strip_path path_name

Strips off the specified prefix path name from all object names in the parasitics file. This is usually a result of generating a parasitics file for a subdesign, and then using this subdesign as the current design.

-quiet

Skips the implicit **report_annotated_delay** report when the parasitics file has been read. By default, after reading the parasitics file, the **report_annotated_delay** command is executed automatically, which reports the back-annotated delays of all nets.

-verbose

Generates an annotation report after parsing.

-dont_write_to_db

Suppresses writing back to the Synopsys database (.db file). Use this option to save runtime when you do not need the parasitic data in the .db database.

file_list

Specifies a list of files from which to read parasitics information. The supported formats are Standard Parasitic Exchange Format (SPEF), Detailed Standard Parasitics Format (DSPF), and Reduced Standard Parasitics Format (RSPF).

DESCRIPTION

The **read_parasitics** command reads parasitics information from a disk file and back-annotates the data on the nets of the current design.

You can specify parasitics in either a reduced form or a detailed form:

- Reduced parasitics consist of an RC pi model specified for each driver pin of a net. An RC pi model contains two capacitors and one resistor. The first capacitor connects to the net driver pin. The resistor connects to the net driver pin and to a subnode to which the second capacitor connects. Both capacitors connect to ground. The parasitics file using the reduced form also specifies the pin-to-pin net delays.
- Detailed parasitics consist of a network of resistors and capacitors for each net specified in the parasitics file. The capacitors are with respect to ground. Coupling capacitors are not supported. Resistors between the nets and ground are ignored. Delays are computed via the Elmore delay model (using the **-elmore** option) or the Arnoldi delay model (using the **-arnoldi** option).

Net and instance pin names in the design must match instance names in the parasitics file. For example, if you create the parasitics file from a design using VHDL naming conventions, the design names must also use the same conventions.

To remove loads and delays annotated by using the **read_parasitics** command, use the **reset_design** or **remove_annotated_delay** command.

Multicorner-Multimode Support

This command uses information from the current scenario only. Define all scenarios with TLUPlus files and operating conditions settings before using this command. The parasitics files reading order must be the same as the scenario creation order.

EXAMPLES

The following command reads the parasitics file named adder.spf from disk and uses it to annotate the computed Elmore delays to pins and loads to nets. The parasitics file contains a description of the RC network for nets of a design.

```
prompt> read_parasitics adder.spf -elmore
```

The following example removes annotated delays and loads from the current design:

```
prompt> remove_annotated_delay
```

SEE ALSO

```
remove_annotated_delay(2)  
report_annotated_delay(2)  
reset_design(2)  
write_parasitics(2)
```

read_pin_map

Reads in a port-to-pin mapping file, which defines the design port-to-package pin mapping for a boundary-scan design.

SYNTAX

```
status read_pin_map  
      path_name
```

Data Types

path_name string

ARGUMENTS

path_name

Specifies the full name of the file containing the port-to-pin mapping for the design.

DESCRIPTION

The **read_pin_map** command allows you to read in a port-to-pin mapping file for a boundary-scan design. All the signal ports in the design must be listed in the port-to-pin mapping file. If a port listed in the port-to-pin mapping file is not a port of the design, it is assumed to be a linkage port. The **write_bsd1** command requires the design port-to-package pin mapping information in order to generate a boundary-scan description language (BSDL) file for a boundary-scan design.

To remove all port-to-pin mapping for a design, use the **remove_pin_map** command. To list all the port-to-pin mappings read in for the design, use the **report_packages** command.

EXAMPLES

The following is an example of a port-to-pin mapping file for a design:

```
PACKAGE = test_pkg;  
  
PORT = OUT5, PIN = (P41, P40, P39, P38, P37, P36);  
PORT = OUT2, PIN = (P26, P27, P28, P29, P30, P31);  
PORT = IN1, PIN = P1;  
PORT = IN2, PIN = P2;  
PORT = IN3, PIN = P3;  
PORT = EN, PIN = P4;  
PORT = RESETN, PIN = P5;
```

```
PORT = IN4, PIN = P6;
PORT = CLK, PIN = P7;
PORT = CLOCKDR, PIN = P8;
PORT = configENABLE, PIN = P9;
PORT = jtag_tdi, PIN = P10;
PORT = jtag_tdia, PIN = P11;
PORT = jtag_tms, PIN = P12;
PORT = jtag_tck, PIN = P13;
PORT = jtag_trst, PIN = P14;
PORT = configCAPTUREEx, PIN = P15;
PORT = configENABLEEx, PIN = P16;
PORT = OUT3, PIN = P17;
PORT = OUT6, PIN = P18;
PORT = OUT6enable, PIN = P19;
PORT = configCAPTURE, PIN = P20;
PORT = jtag_tdo, PIN = P21;
PORT = OUT1(3), PIN = P22;
PORT = OUT1(2), PIN = P23;
PORT = OUT1(1), PIN = P24;
PORT = OUT1(0), PIN = P25;
PORT = OUT4(3:0), PIN = (P32, P33, P34, P35);
PORT = CONFIGURATION(3:0), PIN = (P42, P43, P44, P45);
PORT = VDD, PIN = (P46, P48, P50);
PORT = GND, PIN = (P47, P49, P51);
```

The following example reads in a design port-to-package pin mapping file for a boundary-scan design:

```
prompt> read_pin_map bscan.map
```

SEE ALSO

```
get_attribute(2)
remove_pin_map(2)
```

read_saif

Reads a SAIF file and annotates switching activity information on nets, pins, ports, and cells in the current design.

SYNTAX

```
status read_saif
  -input file_name
  [-instance_name name]
  [-target_instance instance]
  [-ignore ignore_name]
  [-ignore_absolute ig_absolute_name]
  [-exclude exclude_file_name]
  [-exclude_absolute ex_absolute_file_name]
  [-names_file name_changes_log_file]
  [-scale scale_value]
  [-unit_base unit_value]
  [-khrate khrate_value]
  [-map_names]
  [-auto_map_names]
  [-verbose]
```

Data Types

<i>file_name</i>	string
<i>name</i>	string
<i>instance</i>	string
<i>ignore_name</i>	string
<i>ig_absolute_name</i>	string
<i>exclude_file_name</i>	string
<i>ex_absolute_file_name</i>	string
<i>name_changes_log_file</i>	string
<i>scale_value</i>	integer
<i>unit_value</i>	string
<i>khrate_value</i>	float

ARGUMENTS

-input *file_name*

Specifies the name of the SAIF file to be read. When the *file_name* ends with the .gz extension, the input file will be uncompressed automatically.

-instance_name *name*

Specifies the name of the instance of the current design as it appears in the SAIF file. The **read_saif** command assumes that the current design is instantiated as an instance, in the testbench used to generate the SAIF file. The current design appears as an instance in the SAIF file. The **read_saif** command annotates all subinstances in the hierarchy of the specified instance, and annotates the instance itself. Each instance name that you specify must be complete, but without any trailing hierarchy separator (/).

-target_instance *instance*

Specifies the target instance on which the switching activity, in the SAIF file, is to be annotated. If this option not specified, the current instance is assumed to be the target instance.

-ignore *ignore_name*

Specifies the name of an instance in the SAIF file for which switching activity is to be ignored. The **read_saif** command ignores switching activity within the hierarchy of that instance in the SAIF file. The **-ignore** argument can be a hierarchical name separated by a slash (/). The **-instance_name** is applied first. The **read_saif** command then strips off the prefix of a net name that matches the *name*, before deciding whether or not this net name is under the hierarchy specified by the **-ignore** option.

-ignore_absolute *ig_absolute_name*

Specifies the name of an instance in the SAIF file for which switching is ignored. But this option is not affected by the **-instance_name** argument. The **read_saif** command determines whether a net name is under the **-ignore** hierarchy before applying the **-instance_name** argument.

-exclude *exclude_file_name*

Specifies the name of a file that contains a list of names to be ignored. The **-exclude** option is useful when you want to ignore switching activity for several instances. The file must contain each *ignore_name* on a separate line, without the **-exclude** option. The ignored names are recognized after the **-instance_name** argument.

-exclude_absolute *ex_absolute_file_name*

Specifies the name of a file that contains a list of absolute names to be ignored. The absolute names are not affected by the **-instance_name** option.

-names_file *name_changes_log_file*

Specifies a previously created log file, which is usually the output of a **change_names -log_changes** command. The log file is used as the input to the **read_saif** command. While the design file can contain multiple name changes, the SAIF file contains only the original object names. So the object search by name might fail to find objects with names that were changed. The *name_changes_log_file* contains a list of **change_names** commands for cells, ports, and nets in the current design. The file provides mapping information so that **read_saif** can identify the correct objects, even if the names have changed. Note that *name_changes_log_file* is a text file, and it can be edited manually to include other name changes that are not captured by the **change_names** command.

-scale *scale_value*

Specifies the value of the scaling factor for the base synthesis time unit. 1 is the default value. The synthesis time unit is usually obtained automatically from the target library. In some cases when the time unit in the target library is unknown, the **read_saif** command issues a warning message that the intended synthesis time unit is assumed to be 1 ns (nanosecond). For example, this can occur when you run the **read_saif** command before running the **compile_ultra** command. If you see this warning message and the time unit in the intended target library is not 1 ns, then use the **-scale** and **-unit_base** options to specify the time unit of the intended target library. For example, if the intended time unit is 100 ps, specify **-scale 100 -unit_base ps**.

-unit_base *unit_value*

Specifies the base synthesis time unit. Allowed values for *unit_value* are **ns**, **us**, or **ps**. **ns** is the default. See the details of the **-scale** option for information on how to use it with the **-unit_base** option.

-khrate *khrate_value*

Specifies a default derating factor value to use for inertial glitches in the SAIF file. If **-khrate** is not specified, the tool uses the default derating factor of 0.5.

-map_names

Specifies that the SAIF name mapping mechanism is used to match the objects in the SAIF file with the design objects.

-auto_map_names

Specifies that a name mapping is to be created automatically using the SAIF file, and the created name mapping is to be used to read the SAIF file. The **-auto_map_names** flag has the effect of creating the name mapping information using the **saif_map -create_map** command and reading in the SAIF file information using the **read_saif -map_names** command.

-verbose

Shows detailed warnings when design objects in the SAIF file cannot be annotated on the design.

OBSOLETE ARGUMENTS

-rtl_direct

The flows involving forward RTL SAIF files, and flows involving the **read_saif -rtl_direct** is obsolete.

DESCRIPTION

The **read_saif** command reads a SAIF file, and annotates the switching activity attributes, **toggle_rate** and **static_probability** for nets, ports, and pins of the current design. The **report_power** command uses this information to calculate dynamic power values. If a particular object in the SAIF file is not found in the current design, the tool ignores the object and issues a warning message. The **read_saif** command returns 1 if at least one of the objects in the file is successfully annotated. Otherwise, it returns 0.

To specify the instance (and corresponding subinstances) you want to annotate, use the **-instance_name** option. To set the synthesis time unit, use **-unit_base** and **-scale**, unless you are certain that the synthesis time unit is 1 ns. To specify a default derating factor other than 0.5, use the **-khrate** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example annotates the switching activity on the current design, that has been instantiated as Test/U1 in the simulation testbench:

```
prompt> read_saif -input file -instance_name Test/U1
```

The following example reads directly from a compressed file and annotates the switching activity on the current design, that has been instantiated as Test/U1 in the simulation testbench:

```
prompt> read_saif -input file.gz -instance_name Test/U1
```

The following commands annotate the current design, that has been instantiated as Test/U1 in the simulation testbench, assuming that the library time unit is 10 ns:

```
prompt> read_saif -input file -instance Test/U1 -scale 10 \  
      -unit ns
```

```
prompt> read_saif -input file -instance Test/U1 -scale 10
```

The following commands demonstrate annotation of multiple designs. The *demo1* design is instantiated as Test1/U1, and the *demo2* design is instantiated as Test1/U2.

```
prompt> current_design mydesign
```

```
prompt> read_saif -input file_1 -instance Test1/U1 -scale 10
```

```
prompt> current_design demo2
```

```
prompt> read_saif -input file_2 -instance Test1/U2 -scale 10
```

The following examples illustrate the use of the **-names_file** option. In the first three commands, the name_changes.log file is created. In the fourth command, the name_changes.log file is used as input to the **read_saif** command. The name changes recorded in the name_changes.log file are used in the name-matching during the execution of the **read_saif** command.

```
prompt> read_ddc design.ddc
```

```
prompt> define_name_rules my_rules -restricted "A-Z"
```

```
prompt> change_names -rule my_rules -log_changes name_changes.log
```

```
prompt> read_saif -input file -instance Test/U1 \  
      -names name_changes.log
```

read_scan_def

Reads scan chain information from a SCANDEF file.

SYNTAX

```
int read_scan_def  
    file_name
```

Data Types

file_name string

ARGUMENTS

file_name

Specifies the name of the input SCANDEF file.

DESCRIPTION

The **read_scan_def** command reads in scan chain information from a SCANDEF file. Once the SCANDEF file is read, the tool automatically runs **check_scan_def** to validate that all scan chains are properly read.

The **read_scan_def** command allows you to optimize a design read in as a gate-level netlist while preserving its scan chain structure. After optimization, you can write out the up-to-date SCANDEF file by using the **write_scan_def** command.

EXAMPLES

The following example reads a gate-level design from the source file top.v and then reads the corresponding SCANDEF file top.scandef for the current design top. After optimization, the up-to-date SCANDEF file is written out with the **write_scan_def** command.

```
prompt> read_verilog -netlist top.v  
prompt> current_design top  
prompt> read_scan_def top.scandef  
prompt> compile_ultra -incr  
prompt> write_scan_def -output top.incr.scandef  
prompt> write -f verilog -h -o top.incr.v
```

SEE ALSO

`write_scan_def(2)`
`check_scan_def(2)`

read_sdc

Reads in a script in Synopsys Design Constraints (SDC) format.

SYNTAX

```
status read_sdc
  file_name
  [-echo]
  [-syntax_only]
  [-version sdc_version]
```

Data Types

<i>file_name</i>	string
<i>sdc_version</i>	string

ARGUMENTS

file_name

Specifies the name of the file that contains the SDC script to be read.

-echo

Indicates that each constraint is to be echoed as it is executed.

-syntax_only

Indicates that SDC script is processed only to check the syntax and semantics of the script.

-version *sdc_version*

Specifies the version of SDC to which the file conforms. Allowed values are 1.0, 1.1, 1.2, 1.3, 1.4, 1.5, 1.6, 1.7, 1.8, 1.9, 2.0, 2.1 and latest (the default).

DESCRIPTION

This command reads in a script file in Synopsys Design Constraints (SDC) format, which contains commands for use by PrimeTime or by Design Compiler in its Tcl mode. SDC is also licensed by external vendors through the Tap-in program. SDC formatted script files are Tcl scripts that use a subset of the commands supported by PrimeTime and Design Compiler.

By default, **read_sdc** executes the constraints as they are read. If errors occur before the script completes, it is possible that some constraints are applied, and some are not. You can use the **-syntax_only** option to check the script without applying any constraints. This also verifies conformance to the specified SDC version. If there are any errors during the checking phase, then the result of **read_sdc** is 0.

Like the **source** command, the **read_sdc** command is sensitive to variables that control script execution (for example, **sh_continue_on_error** and **sh_script_stop_severity**). The **read_sdc** command uses **sh_source_uses_search_path** to determine if **search_path** is used to find the script.

The **read_sdc** command supports several file formats. The file can be a simple ASCII script file, an ASCII script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler.

Note that SDC does not allow command abbreviation. Also note that the **exit** and **quit** commands do not cause the application to exit, but they do cause the reading of the SDC file to stop.

The latest SDC Version supports the following commands. Those added for versions 1.3 and later are noted. Some constraints that PrimeTime ignores are not listed.

For a complete guide to using SDC with Synopsys applications, see the *Using the Synopsys Design Constraints Format Application Note* which is available through SolvNET at <http://solvnet.synopsys.com>.

The usage of some of these commands is restricted when reading SDC. In some cases, some command options are not allowed. In some applications, some of the commands are not supported. For example, PrimeTime does not support the **set_logic*** commands. These commands are ignored when loaded in with **read_sdc**, with a message (for an example, see the EXAMPLES section). If a command that is not supported by SDC is found by **read_sdc**, it appears as an unknown command, with a message. The same condition exists for command options. If an option is not supported by SDC, a message is issued indicating that condition. However, if the option is unknown, a different message is issued.

Note that although **create_generated_clock** is supported (beginning with version 1.3), there is no provision for the **get_generated_clocks** shortcut, which is available in PrimeTime and Design Compiler. Generated clocks are simply clocks with additional attributes and in SDC, they are retrieved through the **get_clocks** command.

The following features are added for SDC Version 1.5 or later:

- **set_clock_latency -clock** option
- **set_timing_derate** command with all options
- **set_max_transition -clock_path -data_path -rise -fall** options
- **set_clock_uncertainty -rise/fall_from/to** options
- **set_operating_conditions -object_list** option synonyms for all **get_object** commands
- **get_objects -nocase** support independently with **-regexp**
- **get_objects -regexp** support, **get_objects -of_objects** support for **get_cells/get_nets/get_pins**

The following features are added for SDC Version 2.1 or later:

- The **set_sense** command with the **-type**, **-non_uate**, **-positive**, **-negative**, **-stop_propagation**, **-clock_leaf**, **-pulse**, **-clocks** options.
- The **-dynamic** option for the command **set_clock_latency**.
- The **-ignore_clock_latency** option for the command **set_max_delay**.
- The **-ignore_clock_latency** option for the command **set_min_delay**.

The following features are removed for SDC Version 2.1 or later, and are not recognized:

- The **set_clock_sense** command.
- The **-multiply_by** option for the command **set_driving_cell**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reads the SDC script named *top.sdc*:

```
prompt> read_sdc top.sdc -version 1.2
```

Reading SDC version 1.2...

1

The following example reads the SDC script *top2.sdc*. The script contains commands not supported by SDC, and CMD-005 messages are generated for those commands.

```
prompt> read_sdc -syntax_only top2.pt -version 1.2
```

Checking syntax/semantics using SDC version 1.2...

Error: Unknown command 'link_design' (CMD-005)

** Completed syntax/semantic check with 1 error(s) **

0

The following example shows the result when an unsupported command is in an SDC file. One SDC message is generated per instance of an unsupported command. At the end of the read, a summary of all unsupported commands in the file is generated. This SDC file was read into PrimeTime.

```
prompt> read_sdc t2.sdc -version 1.2
```

Reading SDC version 1.2...

Warning: Constraint 'set_logic_zero' is not supported by pt_shell. (SDC-3)

Warning: Constraint 'set_logic_zero' is not supported by pt_shell. (SDC-3)

Warning: Constraint 'set_logic_one' is not supported by pt_shell. (SDC-3)

Summary of unsupported constraints:

Information: Ignored 1 unsupported 'set_logic_one' constraint. (SDC-4)

Information: Ignored 2 unsupported 'set_logic_zero' constraints. (SDC-4)

1

The following example is a script that is not SDC-compliant, because it contains unsupported commands or command options:

```
current_design TOP
```

```
set_resistance -value 12.2 [get_nets i1t2]
```

The following example shows the output generated by **read_sdc** when reading the previous script. In SDC, **current_design** can be used only to get the current design; no arguments are allowed. Also, there is no **-value** option for **set_resistance**, so an appropriate message is generated.

```
prompt> read_sdc t3.tcl -echo -version 1.2
```

Reading SDC version 1.2...

current_design TOP

Error: extra positional option 'TOP' (CMD-012)

```
set_resistance -value 12.2 [get_nets i1t2]
```

Error: unknown option '-value' (CMD-010)

0

The following example shows the message generated when an option is supported by the command but not by SDC:

Information: The '-value' option for **set_resistance** is unsupported. (CMD-038)

read_sdf

Reads leaf-cell and net-timing information from a file in Standard Delay Format (SDF) and uses that information to annotate the current design.

SYNTAX

```
string read_sdf
  [-load_delay net | cell]
  [-path path_name]
  [-min_type sdf_min | sdf_typ | sdf_max]
  [-max_type sdf_min | sdf_typ | sdf_max]
  [-worst]
  [-min_file min_sdf_file_name]
  [-max_file max_sdf_file_name]
  sdf_file_name
```

Data Types

<i>path_name</i>	string
<i>min_sdf_file_name</i>	string
<i>max_sdf_file_name</i>	string
<i>sdf_file_name</i>	string

ARGUMENTS

-load_delay net | cell

Indicates whether load delays are included in net delays or in cell delays in the timing file being read. The load delay is the portion of the cell delay arising from the capacitive load of the net driven by the cell. The default is **cell**.

-path *path_name*

Specifies the path from the current design to the subdesign for which the timing file has been created.

-min_type **sdf_min** | **sdf_typ** | **sdf_max**

Specifies which of the SDF triplet delay values are to be read from the SDF file for minimum delay. Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max). If this is not specified, the command uses **sdf_min**.

-max_type **sdf_min** | **sdf_typ** | **sdf_max**

Specifies which of the SDF triplet delay values are to be read from the SDF file for maximum delay. Delays in SDF are represented in the form of triplets (sdf_min:sdf_typ:sdf_max). If this is not specified, the command uses **sdf_max**.

-worst

Indicates that **read_sdf** is to annotate the current design only with delays worse than the current annotated delays; this applies to annotated net and cell delays and annotated timing checks. For the hold timing check, the minimum numerical value is annotated after comparing the current annotated value and the new value. For all other timing checks and delays, the maximum numerical value is annotated after comparing the current annotated value and the new value. Use this option when the timing file contains conditional timing.

To annotate the worst timing delay and timing checks of all timing conditions for each pin-to-pin annotation, use the **remove_annotated_delay** command with the **-all** option and the **remove_annotated_check** command before using the **read_sdf** command with the **-worst** option. Note that this behavior does not depend on the type of timing arc being read (that is, whether the arc is a setup or a hold arc), even though it might appear that minimum values are read for hold timing arcs. The correct behavior is one where all the values read from SDF files are either minimum, typical, or maximum, regardless of the type (setup or hold).

-min_file min_sdf_file_name

Specifies the file from which minimum delay timing information is to be read. The timing file must be in SDF format version v1.0, v2.0, or v2.1. Use this option only if the minimum and maximum delays are in two separate SDF files. The default is for minimum and maximum delays to be in a single SDF file.

-max_file max_sdf_file_name

Specifies the file from which maximum delay timing information is to be read. The timing file must be in SDF format version v1.0, v2.0, or v2.1. Use this option only if the minimum and maximum delays are in two separate SDF files. The default is for minimum and maximum delays to be in a single SDF file.

sdf_file_name

Specifies the name of the file from which the timing information is to be read. The timing file must be in SDF format version v1.0, or v2.1.

DESCRIPTION

This command reads from a disk file SDF leaf-cell and net-timing information and uses it to annotate the current design. The timing file must be in SDF format v1.0 or v2.1. Instance-specific pin-to-pin cell and net delays are read from the SDF file and annotated on the current design. When you specify the **-path** option, the command annotates the current design with information from a timing file created for an instance of a subdesign of the current design. When you specify a subdesign, you cannot annotate the current design with the net delays to the ports of the subdesign.

The load delay, also known as extra source gate delay, is that portion of the cell delay caused by the capacitive load of the driven net. Some delay calculators consider the load delay part of the net delay; others consider the load delay part of the cell delay. By default, the **read_sdf** command treats the load delay as part of the cell delay in the timing file being read. Use the **-load_delay net** option to indicate that your timing file includes the load delay in the net delay instead of in the cell delay.

Setup and hold, recovery, and removal timing checks, when present in the timing file, are used to annotate the current design. The SDF constructs for setup and hold are "SETUP" and "HOLD". The SDF construct for recovery and removal are "RECOVERY", "REMOVAL" and "RECREM." \" replace sentences above with the following when SDFv3.0 is supported: Instance names in the design must match instance names in the timing file. For example, if the timing file is created from a design using VHDL naming conventions, the design must use VHDL naming conventions. To modify design names, use the **change_names** command.

To remove delays read and annotated by using the **read_sdf** command, use the **reset_design** or **remove_annotated_delay** command. To remove timing checks annotated with **read_sdf**, use the **remove_annotated_check** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example reads the *adder.sdf* timing file from disk and uses it to annotate the timing on the current design. The timing file contains load delays included in the cell delays.

```
prompt> read_sdf -load_delay cell adder.sdf
```

The following example reads the timing information of instance *u1* of design *MULT16* from the *mult16_u1.sdf* disk file, which contains

the timing for instance *u1* of design *MULT16*. The timing is annotated on the design *MY DESIGN*. In this case, load delay is included in the net delays.

```
prompt> current_design MY DESIGN  
prompt> read_sdf -load_delay net -path u1 mult16_u1.sdf
```

The following example reads minimum and maximum timing information from two separate SDF files and annotates the current design with delays corresponding to minimum and maximum operating conditions, respectively:

```
prompt> read_sdf -min_file min.sdf -max_file max.sdf
```

read_sverilog

Reads in one or more design or library files in SystemVerilog format.

SYNTAX

```
string read_sverilog
      file_names
      [-netlist]
      [-rtl]
```

Data Types

file_names list

ARGUMENTS

file_names

Specifies the names of one or more files to be read.

DESCRIPTION

The **read_sverilog** command reads design information from SystemVerilog files into dc_shell.

This command is derived from **read_file -format sverilog**. For more information, see the man page for the **read_file** command.

SEE ALSO

[read_file\(2\)](#)

read_tech_file

Read a technology section into the current library.

SYNTAX

```
status read_tech_file
      [-convert_sites site_name_pairs_list]
      tech_path
```

Data Types

tech_path string

ARGUMENTS

-convert_sites *site_name_pairs_list*

A list of technology file sites to convert. This option can only be used with the -technology option.

tech_path

The path to a technology file.

DESCRIPTION

The **read_tech_file** command reads a technology section into the current library. If there are sites defined in the technology file, the -convert_sites option can be used to map them from one name to another. The same option is allowed on the **read_def** command to make the site names match among all the input data.

When the **read_tech_file** command is used to replace the existing tech section in the library, the replacement tech must be compatible with the existing tech section. Being compatible means that the replacement tech must contain a super-set of the following list of objects:

Layer: The replacement tech must contain at least the same layers as the original, and they must be in the exact same order. The layer definition must match in layerNumber, name, maskName, purpose_name/number in the original tech file. The actual spacing rules defined for the layers can be different, and the replacement tech can have additional Layer definitions.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example read in a technology file "tcb90g.tf" into the current library.

```
prompt> read_tech_file tcbn90g.tf
Information: technology file '/user/joe/work/tcbn90g.tf' is loaded
{r4000}
```

SEE ALSO

`create_lib(2)`
`write_tech_file(2)`
`search_path(3)`

read_test_model

Reads a test model file.

SYNTAX

```
list read_test_model
  [-format ddc | ctl]
  [-design design_name]
  model_files
```

Data Types

design_name string
model_files list

ARGUMENTS

-format ddc | ctl

Specifies the format of the test model. A test model can be stored in a design .ddc file (default) or as ASCII text in a Core Test Language (CTL) file.

By default, the model is assumed to be in .ddc format.

-design *design_name*

Specifies the name of the design to which to attach the test model. This is meaningful only for CTL test models. By default, the model is attached to the current design.

model_files

Specifies the names of the test model files to read. This argument is required. When you specify the format as **ctl**, you can specify only one file.

DESCRIPTION

The **read_test_model** command reads test model files.

The test model files represent the test behavior of designs. The attributes that are represented include all DFT signals and their purpose, the test timing, and the sequence of events needed to shift test vectors in and out of the design. For more information about attributes that may be represented, see the *DFT Compiler Scan User Guide* and the *DFTMAX Compression User Guide*.

When the format is specified as **ddc**, you can specify multiple model files to read. Each model of each .ddc file is read in. Since .ddc models include the designation of the designs they model, the **-design** option is ignored.

The **read_test_model** command reads in only the test model and the interface definition of a design, and ignores any other

information. Since the gate implementation of a design is not loaded in the database, significant memory savings can be achieved. For a .ddc file containing only design interface definitions and test models, the **read_file** and **read_test_model** commands are synonymous.

When the format is specified as **ctl**, a single test model is read from a CTL (ASCII) file and is associated with the current design, or the design specified through the **-design** option. The CTL format is used for test models generated outside of a Synopsys environment.

A successful read of a model overwrites any test model information in memory.

Test models are stored on disk using the **write_test_model** or the **write** command. Transfer test models from one session to another either by storing full designs, or by storing only test models. Unless there is a requirement to hide a design's implementation, it is best to store the full designs, since it reduces the risk of confusion about the contents of the .ddc files.

EXAMPLES

The following command sequence stores full designs to disk. It facilitates external data management by having a single .ddc file for a design.

```
prompt> write -format ddc MyDesign -out MyDesign.ddc  
prompt> remove_design MyDesign  
prompt> read_test_model MyDesign.ddc
```

The following command sequence stores only the test model to a disk file. It requires the separate management of the implementation of the design.

```
prompt> write_test_model MyDesign -out MyDesign.ddc  
prompt> remove_design MyDesign  
prompt> read_file MyDesign.ddc
```

The last **read_file** command above is equivalent to a **read_test_model** command, because the *MyDesign.ddc* file contains only the design interface and the test model.

[write_test_model\(2\)](#)

read_test_protocol

Reads a STIL test protocol file into memory.

SYNTAX

```
status read_test_protocol
  [-verbose]
  [-test_mode test_mode_name]
  [-overwrite]
  [-section section_name]
input_file_name
```

Data Types

<i>test_mode_name</i>	string
<i>section_name</i>	string
<i>input_file_name</i>	string

ARGUMENTS

-verbose

Specifies that verbose output is displayed when set to **true**.

-test_mode *test_mode_name*

Specifies a test mode name to read and store a test protocol. If not specified, the current test mode is used by default. This option is only supported when updating the post-DFT test protocol.

-overwrite

Specifies to overwrite timing, procedures, or macros if they already exist in memory when reading in a new test protocol. For example, if there is already a protocol in the memory with timing specified, and you read in a new protocol with different timing, this option specifies to overwrite the existing timing with the new timing.

-section *section_name*

Specifies a section name of the protocol. With this option, the **read_test_protocol** command reads only the specified section and ignores others. The only valid parameter is **test_setup**, which describes the initialization sequence.

input_file_name

Specifies the name of the test protocol file in STIL format to read. The default file name is *current_design_name.spf*.

DESCRIPTION

This command reads a test protocol file into memory. Reading a test protocol file defines the scan test protocol for the current design.

The scan test protocol provides a means to formally define the process by which a design is tested, such as the sequence of scan-in vectors, parallel vectors, and scan-out vectors performed for each test pattern. The protocol defined for a design is used to drive scan-test design rule checking.

The format of the test protocol file is STIL. See the DFT Compiler, DFTMAX, and TetraMAX user guides for details of the protocol file format.

The **read_test_protocol** command enables you to define an arbitrary test protocol for a design by reading in a text file describing the protocol. Use **write_test_protocol** to write out an existing protocol for a design in the same text format.

Normally, this command removes any protocol that may be present in memory through the previous use of the **read_test_protocol** or **create_test_protocol** commands.

When the **read_test_protocol -section test_setup** command is executed before pre-DFT DRC has been performed, the **test_setup** section from the specified protocol file is read in and used in place of the default setup protocol created by DFT Compiler. The provided **test_setup** section must include all preconditioned signals defined by the **set_dft_signal** command, such as clock, set, reset, and constant signals. Any STIL **Loop** constructs are retained as-is.

To modify the default setup protocol used by pre-DFT DRC, you can write out the default test protocol, modify the **test_setup** section, then read it back in; see the EXAMPLES section for more information.

When the **read_test_protocol -section test_setup** command is executed after DFT insertion has been performed, the **test_setup** section of the in-memory test protocol created by DFT Compiler is merged with the **test_setup** section from the specified protocol file. This merged in-memory protocol is used for any subsequent DRC. Any STIL **Loop** constructs are unrolled during this merging process. If multiple test modes were created by DFT Compiler, you can update each one using the **-test_mode** option of this command, or the **current_test_mode** command.

If the test protocol file name is not specified for this command, the default is *current_design_name.spf*.

With the STIL protocol format, you cannot distinguish between a clock signal and an asynchronous signal. You must define asynchronous signals with the **set_dft_signal** command before reading your custom STIL protocol.

EXAMPLES

The following example reads a test protocol from the **newUPC1.spf** file:

```
prompt> read_test_protocol newUPC1.spf  
Reading test protocol file 'newUPC1.spf'...
```

The following example reads a test protocol for the **UPC1** design from the **UPC1.spf** default file:

```
prompt> read_test_protocol  
Reading test protocol file 'UPC1.spf'...
```

The following example defines the asynchronous signal **rstn** for design UPC1 and reads a test protocol from the file **UPC1.spf**:

```
prompt> set_dft_signal -type Reset -active_state 0 -port rstn  
prompt> read_test_protocol UPC1.spf
```

The following example reads a **test_setup** section of the protocol. For example, assume that the **init_sequence.spf** file has the following **test_setup** vector sequence:

```
MacroDefs {  
    "test_setup" {  
        W "_default_WFT_";  
        V { "A" = 0; "B" = 0; "CP" = 0; }  
        V { "A" = 1; "B" = 1; "CP" = P; }  
        V { "A" = 0; "B" = 0; "CP" = 1; "AA" = 1; "BB" = 1; }  
    }  
}
```

```
}
```

The following command reads in the initialization sequence and ignores the rest of the protocol file:

```
prompt> read_test_protocol -section test_setup init_sequence.spf
```

The following example creates a default test protocol, modifies it, and reads the modified **test_setup** back in:

```
prompt> create_test_protocol
```

```
prompt> write_test_protocol -output test_setup_mod.spf
```

(manually modify **test_setup** in file,
keeping pre-conditioned signals as needed)

```
prompt> read_test_protocol -section test_setup test_setup_mod.spf
```

The following example updates the post-DFT test setup protocol for two test modes:

```
prompt> insert_dft
```

```
prompt> read_test_protocol -section test_setup \  
-test_mode Internal_scan postDFT.spf
```

```
prompt> read_test_protocol -section test_setup \  
-test_mode ScanCompression_mode postDFT.spf
```

```
prompt> current_test_mode Internal_scan
```

```
prompt> dft_drc
```

```
prompt> current_test_mode ScanCompression_mode
```

```
prompt> dft_drc
```

SEE ALSO

```
create_test_protocol(2)  
dft_drc(2)  
remove_test_protocol(2)  
set_dft_signal(2)  
write_test_protocol(2)

```

read_verilog

Reads in one or more design or library files in Verilog format.

SYNTAX

```
status read_verilog
      [-netlist | -rtl]
      verilog_files
```

Data Types

verilog_files list

ARGUMENTS

-netlist

Specifies that the design being read is a structural or gate-level design. This option invokes a netlist reader optimized for gate-level designs. If any of the specified files contain RTL-level constructs, an error is issued. Use of the **-netlist** option might enable the tool to read larger gate-level designs than would otherwise be the case.

If the file is protected by encryption using **IEEE1735** standard or a block within the Verilog file is protected by the standard, support for reading of such files must be activated by setting the variable **hdlin_enable_ieee_1735_support** to **true**.

This option is mutually exclusive with the **-rtl** option.

-rtl

Specifies that the design being read is an RTL design. This option invokes the Verilog RTL reader directly without attempting to determine if the specified files are gate-level netlists.

This option is mutually exclusive with the **-netlist** option.

verilog_files

Specifies the name of one or more Verilog files to be read.

DESCRIPTION

The **read_verilog** command reads design information from Verilog files into memory.

If the automatic mode is on, the netlist reader (read with the **-netlist** option) is automatically invoked. If the input contains RTL constructs, the system automatically invokes the RTL reader (read with **-rtl** option).

This command is derived from **read_file -format verilog**. For more information, see the man page for the **read_file** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`read_file(2)`
`hdlin_enable_ieee_1735_support(3)`

read_vhdl

Reads in one or more designs or library files in VHDL format.

SYNTAX

```
string read_vhdl
      [-netlist]
      file_names
```

Data Types

file_names list

ARGUMENTS

-netlist

Specifies that the design being read is a structural or gate-level design. This option invokes a netlist reader optimized for gate-level designs. If any of the given files contains RTL-level constructs, the command issues an error. Using the **-netlist** option enables the command to read large gate-level designs.

file_names

Specifies the names of the design files to be read.

DESCRIPTION

This command reads design information from VHDL files into the appropriate shell. It is derived from the **read_file** command for use with VHDL files. For more information, see the man page of the **read_file** command.

SEE ALSO

[read_file\(2\)](#)

rebuild_mw_lib

Rebuilds the Milkyway library.

SYNTAX

```
status_value rebuild_mw_lib  
    libName
```

Data Types

libName string

ARGUMENTS

libName

Specifies the Milkyway library to be rebuilt. The value of *mw_lib* should be a valid library name. The library must be closed for this command to work.

DESCRIPTION

This command rebuilds a Milkyway library by scanning all designs in the associated library directory.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example rebuilds the current Milkyway library:

```
prompt> rebuild_mw_lib  
Scanning library...  
place.CEL;5  
place.CEL;4  
place.CEL;3  
place.CEL;2  
place.CEL;1  
place.EXP;1  
place.NETL;1  
place.PARA;1
```

Rebuilding library...
A total of 8 items have been rebuilt. (0 removed, 0 new added)
1

SEE ALSO

`close_mw_lib(2)`
`copy_mw_lib(2)`
`create_mw_lib(2)`
`current_mw_lib(2)`
`open_mw_lib(2)`
`rename_mw_lib(2)`
`report_mw_lib(2)`

redirect

Redirects the output of a command to a file.

SYNTAX

```
string redirect
  [-append] [-tee] [-file]
  | -variable
  | -channel] [-compress]
  [-bg]
  [-max_cores number_of_cores]
  target
  {command_string}
```

Data Types

<i>target</i>	string
<i>command_string</i>	string

ARGUMENTS

-append

Appends the output to *target*.

-tee

Like the unix command of the same name, sends output to the current output channel as well as to the *target*.

-file

Indicates that *target* is a file name, and redirection is to that file. This is the default. It is exclusive of *-variable* and *-channel*.

-variable

Indicates that *target* is a variable name, and redirection is to that Tcl variable. It is exclusive of *-file* and *-channel*.

-channel

Indicates that *target* is a Tcl channel, and redirection is to that channel. It is exclusive of *-variable* and *-file*.

-compress

Compress when writing to file. If redirecting to a file, then this option specifies that the output should be compressed as it is written. The output file is in a format recognizable by "gzip -d". You cannot specify this option with *-append*.

-bg

Indicates that the redirected command executes in the background and in parallel with other foreground commands downstream. The dc_shell returns immediately to execute the next command after this redirect command as long as there is only two redirect -bg executed at one point. If there are already two redirect -bg commands running, the next redirect -bg will be blocking. Also exit or

quit command blocks until all the background commands started with the -bg option are finished. Note the -bg option must be used together with the -file option and -max_cores option. No other options are allowed. Redirect command returns the PID of the background process when this option is specified.

Only limited set of dc_shell commands are supported within redirect -bg. When an unsupported command is executed within redirect -bg, an error message will be printed. To report all the supported commands, you can run the command **list_commands -bg**.

Some command would modify the design. To avoid potential QoR impact, use **enable_redirect_bg_commands -read_only** command to limit "read_only" command for redirect -bg.

-max_cores number_of_cores

Specifies the maximum number of CPU cores that can be used by multicore commands run within redirect -bg

target

Indicates the target of the output redirection. This is either a filename, Tcl variable, or Tcl channel depending on the command arguments.

command_string

The command to execute. Intermediate output from this command, as well as the result of the command, will be redirected to target. The *command_string* should be rigidly quoted with curly braces.

DESCRIPTION

The **redirect** command performs the same function as the traditional unix-style redirection operators > and >>. The *command_string* must be rigidly quoted (that is, enclosed in curly braces) in order for the operation to succeed.

Output is redirected to a file by default. Output can be redirected to a Tcl variable by using the *-variable* option, or to a Tcl channel by using the *-channel* option.

Output can be sent to the current output device as well as the redirect target by using the *-tee* option. See the examples section for an example.

The result of a **redirect** command which does not generate a Tcl error is the empty string. Screen output occurs only if errors occurred during execution of the *command_string* (other than opening the redirect file). When errors occur, a summary message is printed. See the examples.

Although the result of a successful **redirect** command is the empty string, it is still possible to get and use the result of the command that you redirected. Construct a **set** command in which you set a variable to the result of your command. Then, redirect the **set** command. The variable holds the result of your command. See the examples.

The **redirect** command is much more flexible than traditional unix redirection operators. With **redirect**, you can redirect multiple commands or an entire script. See the examples for an example of how to construct such a command.

Note that the builtin Tcl command **puts** does not respond to output redirection of any kind. Use the builtin **echo** command instead.

This -bg option is introduced to enable parallel processing on multicore hardware for performance reasons. It is also very important to understand that the *background_execute* is targeted for post-update reporting, analysis and design export commands. If any of the command executed in the background causes changes to netlist or any other data, those changes will not be brought back to the foreground job that is running. Also, please be aware that use of commands modifying the netlist or other data can cause memory blow up in the child process.

If you make use of the *change_names* command within redirect -bg, then you need to stop recording formality setup information before running the redirect -bg command. And use a new svf file within redirect -bg. Both the svf files should be given for formal verification.

The maximum number cores used in the main session will be reduced by the max cores of the redirect -bg job(s) that is running. You can make use of *parallel_execute* within *background_execute*

EXAMPLES

In the following example, the output of the plus procedure is redirected. The echoed string and the result of the plus operation is in the output file. Notice that the result was not echoed to the screen.

```
prompt> proc plus {a b} {echo "In plus" ; return [expr $a + $b]}
prompt> redirect p.out {plus 12 13}
prompt> exec cat p.out
In plus
25
```

In this example, a typo in the command created an error condition. The error message indicates that you can use **error_info** to trace the error, but you should first check the output file.

```
prompt> redirect p.out {plus2 12 13}
Error: Errors detected during redirect
      Use error_info for more info. (CMD-013)
prompt> exec cat p.out
Error: unknown command 'plus2' (CMD-005)
```

In this example, we explore the usage of results from redirected commands. Since the result of **redirect** for a command which does not generate a Tcl error is the empty string, use the **set** command to trap the result of the command. For example, assume that there is a command to read a file which has a result of "1" if it succeeds, and "0" if it fails. If you redirect only the command, there is no way to know if it succeeded.

```
redirect p.out { read_a_file "a.txt" }
# Now what? How can I redirect and use the result?
```

But if you set a variable to the result, then it is possible to use that result in a conditional expression, etc.

```
redirect p.out { set rres [read_a_file "a.txt"] }
if { $rres == 1 } {
    echo "Read ok!"
}
```

The **redirect** command is not limited to redirection of a single command. You can redirect entire blocks of a script with a single **redirect** command. This simple example with **echo** demonstrates this feature:

```
prompt> redirect p.out {
?     echo -n "Hello"
?     echo "world"
?
}
prompt> exec cat p.out
Hello world
prompt>
```

The **redirect** command allows you to tee output to the previous output device and also to redirect output to a variable. This simple example with **echo** demonstrates these features:

```
prompt> set y "This is "
This is
```

```
prompt> redirect -tee x.out {
```

```
    echo XXX
```

```
    redirect -variable y -append {
```

```
    echo YYY
```

```
    redirect -tee -variable z {
```

```
    echo ZZZ
```

```
    }
```

```
}
```

```
}
```

```
XXX
```

```
prompt> exec cat x.out
```

```
XXX
```

```
prompt> echo $y
```

```
This is YYY
```

```
ZZZ
```

```
prompt> echo $z
```

```
ZZZ
```

The following example demonstrates how **redirect** command with **-bg** option can be used to run a tcl procedure and a tcl script. The tcl procedure and tcl script can contain any of the dc_shell command supported by **-bg** option.

```
prompt> set_host_options -max_cores 4
```

```
prompt> redirect -bg -max_cores 1 -file x.out {MyTclProc}
```

```
prompt> redirect -bg -max_cores 1 -file y.out {source y.tcl}
```

```
prompt> echo $z
```

```
ZZZ
```

The following example demonstrates how **set_svf** command can be used within redirect -bg. If the reference design is from foo.v, then to verify the netlist after redirect -bg, the svf files compile.svf and redirect.svf should be used. And to verify the netlist after compile_ultra -incr, the svf files compile.svf and compile_incr.svf should be used.

```
prompt> set_host_options -max_cores 4
```

```
prompt> set_svf compile.svf
```

```
prompt> read_verilog foo.v
```

```
prompt> read_sdc foo.sdc
```

```
prompt> compile_ultra -spg
```

```
prompt> set_svf -off
```

```
prompt> redirect -bg -max_cores 1 -file x.out {set_svf redirect.svf; change_names -rules verilog -hier; ...}
```

```
prompt> set_svf compile_incr.svf
```

```
prompt> compile_ultra -spg -incr
```

```
ZZZ
```

enable_redirect_bg_commands(2)

remove_annotated_check

Removes annotated timing-check information.

SYNTAX

```
status remove_annotated_check
    -all | -from from_list | -to to_list
    [-rise | -fall]
    [-clock rise | fall]
    [-setup]
    [-hold]
    [-recovery]
    [-removal]
    [-nochange_low]
    [-nochange_high]
```

Data Types

from_list list
to_list list

ARGUMENTS

-all

Removes all annotated checks in the current design. This includes rise and fall values for setup, hold, recovery, removal, and nochange pin-to-pin timing checks. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments or options.

-from *from_list*

Specifies a list of leaf cell clock pins that are the startpoints of the timing arcs from which annotated checks are to be removed. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments or options.

-to *to_list*

Specifies a list of leaf cell data pins that are the endpoints of the timing arcs from which annotated checks are to be removed. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments or options.

-rise | -fall

Specifies whether the check to be removed is for data rise or fall transition. If you do not specify either **-rise** or **-fall**, both values are removed.

-clock rise | fall

Specifies whether the check to remove is for clock rising or falling. By default, checks for both clock rise and fall are removed.

-setup

Removes only setup timing-check information.

-hold

Removes only hold timing-check information.

-recovery

Removes only recovery timing-check information.

-removal

Removes only removal timing-check information.

-nochange_low

Removes only the nochange timing check against data low information.

-nochange_high

Removes only the nochange timing check against data high information.

DESCRIPTION

This command removes annotated timing checks between the specified pins. Data rise and fall and clock rise and fall annotated checks are removed by default.

You can use the **remove_annotated_check** command for pins at lower levels of the design hierarchy. These pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

If the design is not already linked, **remove_annotated_check** links it automatically.

The **remove_annotated_check** command removes annotated timing checks set by the **set_annotated_check** command, and also removes setup, hold, recovery, removal, or nochange annotated timing checks set by the **read_sdf** command. The **reset_design** command removes annotated timing checks in addition to other information.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes an annotated setup check between pins u1/u2/CP and u1/u2/D:

```
prompt> remove_annotated_check -setup -from u1/u2/CP -to u1/u2/D
```

The following example removes all annotated timing checks on the current design:

```
prompt> remove_annotated_check -all
```

SEE ALSO

[current_design\(2\)](#)
[link\(2\)](#)
[read_sdf\(2\)](#)

```
report_annotated_check(2)
reset_design(2)
set_annotated_check(2)
```

remove_annotated_delay

Removes the annotated delay between two pins.

SYNTAX

```
status remove_annotated_delay
  -all
  | -cell_all
  | -net_all
  | -non_clock_cell_all
  | -non_clock_net_all
  | -from from_list
  | -to to_list
```

Data Types

```
from_list    list
to_list     list
```

ARGUMENTS

-all

Removes all net- and cell-annotated delays in the current design. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments.

-cell_all

Removes all cell-annotated delays in the current design. You can specify **-cell_all** and **-net_all** together to remove all cell- and net-annotated delays.

-net_all

Removes all net-annotated delays in the current design. You can specify **-cell_all** and **-net_all** together to remove all cell- and net-annotated delays.

-non_clock_cell_all

Removes all cell-annotated delays in the current design except those on the clock network. You can specify **-non_clock_cell_all** and **-non_clock_net_all** together to remove all cell- and net-annotated delays not on the clock network.

-non_clock_net_all

Removes all net-annotated delays in the current design except those on the clock network. You can specify **-non_clock_cell_all** and **-non_clock_net_all** together to remove all cell- and net-annotated delays not on the clock network.

-from *from_list*

Specifies a list of leaf-cell pins or top-level ports that are the startpoints of the timing arcs from which to remove annotated delays. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments.

-to *to_list*

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs from which to remove annotated delays. You must specify either **-all**, **-from**, or **-to**; if you specify **-all**, you cannot specify any other arguments.

DESCRIPTION

This command removes annotated delays between the specified pins, which must be on the same net or on the same cell. Both rise and fall annotated delays are removed. There must be a timing arc between the pins in *from_list* and the pins in *to_list* or no annotated delay is removed.

You can use **remove_annotated_delay** for pins at lower levels of the design hierarchy. These pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

If the current design is hierarchical, you must link the design with the **link -all** command before using **remove_annotated_delay**.

To annotate net delay values between pins in a design, use **set_annotated_delay -net** command. To annotate cell delay values between pins in a design, use the **set_annotated_delay -cell** command. You must use **-from** and **-to** in the same manner you used them to set annotated values. For example, use **remove_annotated_delay -from** to remove an annotated delay set with **set_annotated_delay -from**. To remove an annotated delay set with **set_annotated_delay -to**, use **remove_annotated_delay -to**. To remove an annotated delay set with **set_annotated_delay -from -to**, use **remove_annotated_delay -from -to**.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example first shows the annotation of the delay to remove. The second command removes the annotated net delay between output pin Z of cell instance U1/U2/U3 and input pin A of cell instance U6:

```
prompt> set_annotated_delay -net <value> -from U1/U2/U3/Z -to U6/A
prompt> remove_annotated_delay -from U1/U2/U3/Z -to U6/A
```

This example first shows the annotation of the delay to remove. The second command removes the annotated, lumped net delay between output pin Z of cell instance U1/U2/U3 and all fanout pins on that net:

```
prompt> set_annotated_delay -net <value> -from U1/U2/U3/Z
prompt> remove_annotated_delay -from U1/U2/U3/Z
```

The following example removes all annotated net and cell delays from the current design:

```
prompt> remove_annotated_delay -all
```

[set_annotated_delay\(2\)](#)

remove_annotated_transition

Removes the annotated transition at a pin.

SYNTAX

```
status remove_annotated_transition  
-all
```

ARGUMENTS

-all

Removes the annotated transition time from every pin in the current design. You must specify either **-all** or **-at**; if you specify **-all**, you cannot specify any other arguments.

DESCRIPTION

This command removes annotated transitions at the specified pins. Both rise and fall annotated transitions are removed.

To annotate net-transition values at pins in a design, use the **set_annotated_transition** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes the annotated transition at every pin in the design:

```
prompt> remove_annotated_transition -all
```

The following example first shows the annotation of the transition to be removed. The second command removes the annotated transition at the output pin Z of cell instance U1/U2/U3:

```
prompt> set_annotated_transition value U1/U2/U3/Z  
prompt> remove_annotated_transition -at U1/U2/U3/Z
```

SEE ALSO

[report_timing\(2\)](#)
[reset_design\(2\)](#)
[set_annotated_transition\(2\)](#)

remove_annotations

Removes all annotated information on the design.

SYNTAX

status **remove_annotations**

ARGUMENTS

The **remove_annotations** command has no arguments.

DESCRIPTION

The **remove_annotations** command removes all annotations on the design, including delay, transition, resistance, capacitance, and check. These include the data set by the **set_annotated_check**, **set_annotated_delay**, **set_annotated_transition**, **set_resistance**, and **set_load** commands.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes all annotated information set by previous commands:

```
prompt> set_annotated_check 0.25 -from m2/st_reg[0]/CP \
           -to m2/st_reg[0]/D -setup
Warning: There is no 'setup_falling' timing arc between pins
'm2/st_reg[0]/CP' and 'm2/st_reg[0]/D'. (OPT-815)
1

prompt> set_annotated_delay -cell 0.03 -from m1/U18/A -to m1/U18/Z
Information: Annotated 'cell' delays are assumed to include load delay. (UID-282)
1

prompt> set_annotated_transition 0.07 m2/st_reg[0]/D
1

prompt> remove_annotations
1
```

remove_attribute

Removes an attribute from the specified objects.

SYNTAX

```
collection remove_attribute
  [-bus]
  [-quiet]
  object_list
  attribute_name
```

Data Types

<i>object_list</i>	list
<i>attribute_name</i>	string

ARGUMENTS

-bus

Indicates to remove the attribute from the bus as a whole, and not from each individual bus member.

-quiet

Turns off the warning messages that would otherwise be issued if the attribute or objects are not found.

object_list

Specifies a list of objects from which the attribute is to be removed.

attribute_name

Specifies the name of the attribute to be removed.

DESCRIPTION

This command removes the specified attribute from the specified objects. For a complete list of attributes, see the **attributes** man page.

This command returns the list of objects from which the attribute is removed. A returned empty string indicates that no object has been removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the attributes. However, for attributes such as **max_leakage_power**, which are scenario dependent, this command uses information from the current

scenario only.

EXAMPLES

This command removes the **output_not_used** attribute on a port:

```
prompt> remove_attribute [get_ports OUT1] output_not_used  
{OUT1}
```

In the following example, a warning message is issued because the cell named *U9* cannot be found:

```
prompt> remove_attribute [get_cells {U1 U9}] dont_touch  
Warning: Can't find object 'U9' in design 'example'  
{U1}
```

Using the **-quiet** option with the previous example inhibits the warning messages:

```
prompt> remove_attribute -quiet [get_cells {U1 U9}] dont_touch  
{U1}
```

In this example, the **dont_use** attribute of a library cell is removed:

```
prompt> remove_attribute [get_lib_cells tech_lib/GATE] dont_use  
{tech_lib/GATE}
```

In the following example, the specified attribute cannot be found:

```
prompt> remove_attribute [get_cells *] arrival
```

remove_auto_path_groups

Removes path groups for the current design.

SYNTAX

```
string remove_auto_path_groups
  [-prefix prefix]
  [-file file_name]
  [-verbose]
  [-user_path_groups_file user_file_name]
  [-skip]
```

Data Types

```
prefix      string
file_name   string
user_file_name string
```

ARGUMENTS

-prefix *prefix*

Specifies the prefix of the path group names. The default is synopsys_pg_.

-file *file_name*

Writes **remove_path_group** commands to the specified file.

-verbose

Activates the verbose mode.

-user_path_groups_file *user_file_name*

Specifies the file from which user path groups are restored. The default is auto_path_groups.user_path_groups.tcl.

DESCRIPTION

Removes path groups created by the **create_auto_path_groups** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

For examples, see the **create_auto_path_groups** command man page.

SEE ALSO

[create_auto_path_groups\(2\)](#)

remove_boundary_cell

Removes the boundary-cell configuration for the specified ports or core cells.

SYNTAX

```
status remove_boundary_cell
  -class core_wrapper | shadow_wrapper | bsd
  -ports port_list | -core core_cell_list
  [-function function_type]
```

Data Types

<i>port_list</i>	list
<i>core_cell_list</i>	string
<i>function_type</i>	string

ARGUMENTS

-class core_wrapper | shadow_wrapper | bsd

Specifies the name of the class for which the boundary-cell configuration is to be removed.

Valid values for this option are **core_wrapper**, **shadow_wrapper**, and **bsd**.

This option is required.

-ports *port_list*

Specifies the list of ports for which the boundary-cell configuration is to be removed.

There is no default value for this option. You must use either the **-ports** option or the **-core** option.

-core *core_cell_list*

Specifies the list of core cells for which the boundary cell configuration is to be removed.

When the *core_list* is not empty, the *port_list* specifies the ports of these core cells.

There is no default value for this option. You must use either the **-ports** option or the **-core** option.

-function *function_type*

Specifies the function of the specified ports for which the boundary cell configuration is to be removed.

Valid values for this option are as follows:

input
output
control
bidir
observe

```
input_inverted  
output_inverted  
bidir_inverted
```

There is no default value for this option.

DESCRIPTION

The **remove_boundary_cell** command removes the boundary-cell configuration on the specified core cells or ports for the specified class. The core cells or ports must exist in the current design.

EXAMPLES

The following command sets the boundary-cell configuration on *port1*:

```
prompt> set_boundary_cell -class core_wrapper -type WC_D1 \  
-safe_state none -port_list port1  
1
```

The following command sets the boundary-cell information on *port2*:

```
prompt> set_boundary_cell -class core_wrapper -type WC_S1_S \  
-safe_state 0 -port_list port2  
1
```

The following command removes the boundary cell configuration for the core wrapper class on the *port1* and *port2* ports:

```
prompt> remove_boundary_cell -class core_wrapper \  
-port_list {port1, port2}  
1
```

SEE ALSO

```
insert_dft(2)  
preview_dft(2)  
set_boundary_cell(2)  
set_bsd_configuration(2)  
set_wrapper_configuration(2)
```

remove_boundary_cell_io

Removes the boundary-cell I/O specifications from the current boundary-scan design.

SYNTAX

```
status remove_boundary_cell_io  
  [-all]  
  [-cell cell_list]
```

Data Types

cell_list string

ARGUMENTS

-all

Removes all boundary-cell I/O specifications from the design.

-cell *cell_list*

Removes all user-defined boundary I/O cells specified in the current design.

DESCRIPTION

The **remove_boundary_cell_io** command removes the boundary-cell I/O specifications from the current design. If you invoke **remove_boundary_cell_io** with no options, the command is ignored. You receive an informational message describing this action.

EXAMPLES

The following example removes the boundary-cell I/O specification from the design:

```
prompt> set_boundary_cell_io -type boundary \  
      -cell what testcase_bs_core_inst/bsr_gpio_3_inst \  
      -access {out_pi what testcase_bs_core_inst/U21/Z \  
              out_po what testcase_bs_core_inst/bsr_gpio_3_inst/U11/Z}  
  
prompt> remove_boundary_cell_io -cell {what testcase_bs_core_inst/bsr_gpio_3_inst}
```

The following example removes all boundary cell I/O specifications from the design:

```
prompt> set_boundary_cell_io -type boundary \  
      remove_boundary_cell_io
```

```
-cell what_testcase_bs_core_inst/bsr_gpio_3_inst \
-access {out_pi what_testcase_bs_core_inst/what_testcase_core_inst/U21/Z \
          out_po what_testcase_bs_core_inst/bsr_gpio_3_inst/U11/Z}

prompt> set_boundary_cell_io -type boundary \
-cell what_testcase_bs_core_inst/bsr_gpio_0_inst \
-access {out_pi what_testcase_bs_core_inst/what_testcase_core_inst/U19/Z \
          out_po what_testcase_bs_core_inst/bsr_gpio_0_inst/U22/Z}

prompt> remove_boundary_cell_io -all
```

SEE ALSO

[report_boundary_cell_io\(2\)](#)
[set_boundary_cell_io\(2\)](#)

remove_bounds

Removes bounds from the current design.

SYNTAX

```
status remove_bounds
  [-verbose]
  [-all]
  [-name bound_name_list]
  objects
```

Data Types

<i>bound_name_list</i>	list
<i>objects</i>	string

ARGUMENTS

-verbose

Prints information about what is being deleted.

-all

Removes all bounds from the current design. This command removes only bounds that have been created using the **create_bounds** command. Bounds created in an input PDEF file cannot be removed.

-name *bound_name_list*

Specifies to remove bounds with the given names.

objects

Specifies bound objects to be removed.

DESCRIPTION

This command removes bounds constraints from the current design. If you specify the **-all** option, all bounds are removed from the design, with the exception of those specified in an input PDEF file. If you give a list of bound names, the bounds with the specified names are removed. The ID is displayed every time a bound is created. You can use the **report_bounds** command to view the ID.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the bounds named *temp_0* and *temp_1*.

```
prompt> remove_bounds -name {temp_0 temp_1}
```

SEE ALSO

[create_bounds\(2\)](#)
[report_bounds\(2\)](#)
[set_cell_location\(2\)](#)
[update_bounds\(2\)](#)

remove_bsd_compliance

Removes the compliance ports specifications from the current boundary-scan design.

SYNTAX

```
status remove_bsd_compliance
  [-all]
  [-name pattern_name]
```

Data Types

pattern_name string

ARGUMENTS

-all

Removes all compliance port specifications from the design.

-name *pattern_name*

Removes all user-defined pattern names specified if present in the current design.

DESCRIPTION

The **remove_bsd_compliance** command removes the compliance ports specifications from the current design. If you invoke **remove_bsd_compliance** with no options, the command is ignored. You receive an informational message describing this action.

EXAMPLES

The following example sets and then removes the compliance port specification from the design:

```
prompt> set_bsd_compliance -name pat1 -pattern {my_bidi 0 my_eni 1}
prompt> remove_bsd_compliance -name pat1
```

The following example sets and then removes all compliance ports specifications from the design:

```
prompt> set_bsd_compliance -name pat1 -pattern {my_bidi 0 my_eni 1}
prompt> set_bsd_compliance -name pat2 -pattern {my_ini 0}
```

```
prompt> remove_bsd_compliance -all
```

SEE ALSO

remove_bsd_instruction

Removes boundary-scan instructions from the instruction list to be used by **insert_dft** for the current design.

SYNTAX

```
status remove_bsd_instruction  
      instruction_list
```

Data Types

instruction_list list

ARGUMENTS

instruction_list

Specifies a comma-separated list containing one or more boundary-scan instructions to remove from the set of boundary-scan instructions for the current design.

DESCRIPTION

The **remove_bsd_instruction** command specifies one or more boundary-scan instructions to be removed from the set of boundary-scan instructions to be implemented by **insert_dft** for the current design. You can specify only the BYPASS, EXTEST, SAMPLE, IDCODE, CLAMP, and HIGHZ instructions using this command.

EXAMPLE

The following example removes IDCODE and CLAMP from the list of boundary scan instructions to be used by the **insert_dft** command:

```
prompt> remove_bsd_instruction {IDCODE, CLAMP}
```

SEE ALSO

[insert_dft\(2\)](#)
[set_bsd_instruction\(2\)](#)

remove_bsd_linkage_port

Removes the linkage-ports specifications from the current boundary-scan design.

SYNTAX

```
status remove_bsd_linkage_port
  [-all]
  [-port_list port_list]
```

Data Types

port_list string

ARGUMENTS

-all

Removes all linkage-ports specifications from the design.

-port_list *port_list*

Removes all user-defined linkage ports specified in the current design.

DESCRIPTION

The **remove_bsd_linkage_port** command removes the linkage-ports specifications from the current design. If you invoke **remove_bsd_linkage_port** with no options, the command is ignored and you receive an informational message.

EXAMPLES

The following example removes the linkage port specification from the design:

```
prompt> set_bsd_linkage_port -port_list {my_bidi my_ini out1}
prompt> remove_bsd_linkage_port -port_list {my_bidi out1}
```

The following example removes all linkage ports specifications from the design:

```
prompt> set_bsd_linkage_port -port_list {my_bidi my_ini out1}
prompt> remove_bsd_linkage_port -all
```

SEE ALSO

`report_bsd_linkage_port(2)`
`set_bsd_linkage_port(2)`

remove_bsd_power_up_reset

Removes the power-up reset port specifications from the current boundary-scan design.

SYNTAX

```
status remove_bsd_power_up_reset
```

ARGUMENTS

The **remove_bsd_power_up_reset** command has no arguments.

DESCRIPTION

The **remove_bsd_power_up_reset** command removes the power-up reset port specifications from the current design.

EXAMPLES

The following example removes the power-up reset port specifications from the design:

```
prompt> set_bsd_power_up_reset -reset_pin_name in0 -active high \
           -delay 500 -cell_name U15
prompt> remove_bsd_power_up_reset
```

SEE ALSO

[report_bsd_power_up_reset\(2\)](#)
[set_bsd_power_up_reset\(2\)](#)

remove_buffer

Removes the buffer cells at a specified driver pin or net on a mapped design.

SYNTAX

```
status remove_buffer
  -from start_point
  -net net_list
  [-to end_point_list]
  [-level number_of_levels]
  cell_list
```

Data Types

<i>start_point</i>	list
<i>net_list</i>	list
<i>end_point_list</i>	list
<i>number_of_levels</i>	integer
<i>cell_list</i>	list

ARGUMENTS

-from *start_point*

Specifies the starting pin or port of the fanout tree from which the buffers or inverter pairs need to be removed. Only driver pins or driver ports can be specified for this option.

This option is mutually exclusive with the **-net** and **cell_list** options.

-net *net_list*

Specifies the starting net of the fanout tree from which the buffers or inverter pairs need to be removed. Only one net can be specified for this option and the driver pin of this net would be considered as the start for fanout traversal. This means that all of the load cells connected to the net are considered in the buffer tree.

This option is mutually exclusive with the **-from** and **cell_list** options.

-to *end_point_list*

Specifies the ending pins or ports where the fanout traversal stops. Only those buffers or inverter pairs that are in the fanin path of **-to** and the fanout path of **-from** or **-net** will be removed.

This option is mutually exclusive with the **-level** option.

-level *number_of_levels*

Specifies the number of levels for buffers or inverter pairs to be removed. If you specify a *number_of_levels* value less than the number of buffers or inverters between those specified by the *start_point_list* and *end_point_list* arguments, the command removes the buffers or inverter pairs only on the number of levels from the value of *end_point_list*. Valid **-level** values are from 1 to 1,000,000. The default value is 1.

This option is mutually exclusive with the **-to** option.

cell_list

Specifies the buffer or inverter cells to be removed. Each buffer is a cell name or a collection of netlist cells. When inverter cells are specified, they must be specified in pairs.

This option is mutually exclusive with the **-to** and **-from** options.

DESCRIPTION

This command removes buffer cells when you specify a *cell_list* and the buffer tree at the specified pins, or the net on a mapped design. When a driver pin or a net is given, the buffer tree is removed with this driver as the root. The buffer-tree removal process starts at the source and removes all buffer and inverter cells in its transitive fanout until it finds nonbuffer cells or when the **-level** number of transitive fanouts is reached.

This command does not remove buffer trees across the hierarchy.

This command can remove inverters only as pairs. You must specify both of the pairing inverters if you use the *cell_list* argument. The *end_point_list* specified in the **-to** option can contain only load pins of the second inverter in the inverter pair. An inverter pair is considered as one level when decrementing the **-level** option.

This command accepts the final implementation of buffer-tree removal, even if it negatively impacts the timing or Design Rule Checking (DRC) violations in the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes a buffer cell:

```
prompt> remove_buffer -from [get_pins cell1/O]
Disconnecting net 'net1' from pin 'cell2/I'.
Disconnecting net 'net2' from pin 'cell5/I'.
Disconnecting net 'net2' from pin 'cell2/O'.
Removing net 'net2' in design 'Top'.
Connecting net 'net1' to pin 'cell5/I'.
Removing cell 'cell2' in design 'Top'.
1
```

```
prompt> remove_buffer -net [get_nets net1]
Disconnecting net 'net1' from pin 'cell2/I'.
Disconnecting net 'net2' from pin 'cell5/I'.
Disconnecting net 'net2' from pin 'cell2/O'.
Removing net 'net2' in design 'Top'.
Connecting net 'net1' to pin 'cell5/I'.
Removing cell 'cell2' in design 'Top'.
1
```

```
prompt> remove_buffer cell2
Disconnecting net 'net1' from pin 'cell2/I'.
Disconnecting net 'net2' from pin 'cell5/I'.
Disconnecting net 'net2' from pin 'cell2/O'.
Removing net 'net2' in design 'Top'.
```

Connecting net 'net1' to pin 'cell5/I'.
Removing cell 'cell2' in design 'Top'.
1

SEE ALSO

[report_buffer_tree\(2\)](#)
[report_cell\(2\)](#)
[report_constraint\(2\)](#)

remove_buffer_tree

Removes the buffer tree at a specified driver pin.

SYNTAX

```
remove_buffer_tree
  [-from pin_list]
  [-all]
  [-source_of patterns]
```

Data Types

pin_list list

ARGUMENTS

-from *pin_list*

Specifies a list of driver pins or nets from which buffer trees are to be removed. This option is mutually exclusive with the **-all** and **-source_of** options.

-all

Removes all buffer trees from all nets. This option is mutually exclusive with the **-from**, **-threshold** and **-source_of** options. By default, this option is off.

-source_of *patterns*

Specifies a list of load pins. The command removes the buffer trees from the global drivers of the specified pins. If the cell of a specified pin is buffer, the cell itself is also removed. This enables you to remove a buffer tree without having to identify its source.

This option is mutually exclusive with the **-all** and **-from** options.

DESCRIPTION

This command removes the buffer tree for each specified driver pin and for the driver pin of each specified net. Unlike the **create_buffer_tree** command, the specified driver pin can be a hierarchical pin.

By default, the **remove_buffer_tree** command treats hierarchical boundaries as leaf loads and does not remove buffers across the hierarchy unless you use the **-hierarchy** option.

This command works only on a placed design. Physical libraries corresponding to the given logic library must be present. The capacitance and resistance per unit length, either derived from the physical library or specified by you, must be available.

This command does not guarantee a legal placement; however, this is the intended behavior and the optimizations generally rely on the **legalize_placement** command to legalize the design after the **remove_buffer_tree** command is issued.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes a buffer tree driven by pin a/O.

```
prompt> remove_buffer_tree -from [get_pins a/O]
```

The following example removes the buffer tree driving pin b/I.

```
prompt> remove_buffer_tree -source_of b/I
```

The following example forces all high fanout buffer trees in the design to be removed.

```
prompt> remove_buffer_tree -all
```

`report_net_fanout(2)`
`set_cost_priority(2)`

remove_bus

Removes a port bus or net bus.

SYNTAX

```
status remove_bus  
    object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of port or net buses to remove.

DESCRIPTION

This command removes port or net buses from a design. If port and net buses have the same name, both port buses and net buses are removed. Individual members of buses remain. The bus can be from the current design or one of its subdesigns. To delete a bus on a subdesign, it must be unique.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the specified port buses:

```
prompt> remove_bus {AB AC}
```

The following example removes the specified net buses:

```
prompt> remove_bus {BC BD}
```

In the following example, all buses with names that end in *s* are removed. If port and net buses have the same name, both buses are removed.

```
prompt> remove_bus *s
```

In the following example, all buses with names that start with *s* in the U1/U2 instance are removed. The U1/U2 instance is a unique instantiation of the design named bot.

```
prompt> remove_bus U1/U2/s*
```

SEE ALSO

`create_bus(2)`
`create_net(2)`
`remove_net(2)`

remove_case_analysis

Removes the case-analysis value from the specified input ports or pins.

SYNTAX

```
status remove_case_analysis  
port_or_pin_list | -all
```

Data Types

port_or_pin_list collection

ARGUMENTS

port_or_pin_list

Specifies the ports or pins from which to remove the case analysis value. You must specify either *port_or_pin_list* or **-all**.

-all

Remove case analysis for all ports or pins in the design where the **set_case_analysis** command has previously been set. You must specify either **-all** or *port_or_pin_list*.

DESCRIPTION

The **remove_case_analysis** command removes the case-analysis value previously specified on ports or pins. Case analysis is specified using the **set_case_analysis** command. You must specify either **-all** or *port_or_pin_list*. The tool issues an error message if neither argument is specified.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies that ports in0 and in2 are set to the constant logic value 0:

```
prompt> set_case_analysis 0 {in0 in2}  
prompt> report_case_analysis
```

```
Report : case_analysis
Design : middle
Version: 1997.01-development
Date  : Mon Jul 22 08:13:50 1996
*****
```

Pin name	Case analysis value
in2	0
in0	0

The following example removes the case analysis entry on port in2:

```
prompt> remove_case_analysis {in2}
prompt> report_case_analysis
```

```
*****  
Report : case_analysis
Design : middle
Version: 1997.01-development
Date  : Mon Jul 22 08:14:16 1996
*****
```

Pin name	Case analysis value
in0	0

SEE ALSO

[report_case_analysis\(2\)](#)
[set_case_analysis\(2\)](#)

remove_cell

Removes cells from the current design.

SYNTAX

```
status remove_cell  
cell_list | -all
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a list of cells to be removed from the current design. Each cell name must exist in the current design. You must specify either *cell_list* or **-all**.

-all

Removes all cells in the current design. You must specify either **-all** or *cell_list*.

DESCRIPTION

The **remove_cell** command removes cells or cell instances from the current design. The command also removes pins owned by the specified cells. The design or library cell to which the cell refers is not removed. If a cell instance is used, the parent design must be unique.

To create cells, use the **create_cell** command.

EXAMPLES

The following example uses **remove_cell** to remove the specified cells in the current design:

```
prompt> get_cells **  
{U1 U2 U3 U4 U5 U6 U7 U8}  
  
prompt> remove_cell {U1 U2}  
Removing cell 'U1' in design 'example'.  
Removing cell 'U2' in design 'example'.
```

```
prompt> get_cells """  
{U3 U4 U5 U6 U7 U8}
```

The following example removes all cells remaining in the current design:

```
prompt> remove_cell -all  
Removing cell 'U3' in design 'example'.  
Removing cell 'U4' in design 'example'.  
Removing cell 'U5' in design 'example'.  
Removing cell 'U6' in design 'example'.  
Removing cell 'U7' in design 'example'.  
Removing cell 'U8' in design 'example'.
```

```
prompt> get_cells """  
{}
```

In the following example, the cell instances *U1/temp1* and *U1/temp2* are removed. The design named *MID* must be unique.

```
prompt> remove_cell {U1/temp1 U1/temp2}  
Removing cell 'U1/temp1' in design 'MID'.  
Removing cell 'U1/temp2' in design 'MID'.
```

SEE ALSO

[create_cell\(2\)](#)
[current_design\(2\)](#)

remove_cell_degradation

Removes the **cell_degradation** attribute on specified ports or designs.

SYNTAX

```
status remove_cell_degradation  
      object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of names of input ports on which to remove the **cell_degradation** attribute.

DESCRIPTION

This command removes the **cell_degradation** attribute on the specified ports or designs.

To get information about optimization and design rule constraints, use the **report_constraint** command. To set the **cell_degradation** attribute, use the **set_cell_degradation** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the cell degradation value on the port named *input_1*:

```
prompt> remove_cell_degradation input_1
```

SEE ALSO

```
all_inputs(2)
all_outputs(2)
characterize(2)
compile(2)
remove_attribute(2)
report_constraint(2)
set_cell_degradation(2)
set_max_capacitance(2)
compile_fix_cell_degradation(3)
```

remove_clock

Removes clocks from the current design.

SYNTAX

```
status remove_clock  
    clock_list | -all
```

Data Types

clock_list list

ARGUMENTS

clock_list

Specifies a list of clocks to remove. You must specify either *clock_list* or **-all**.

-all

Specifies to remove all clocks. You must specify either **-all** or *clock_list*.

DESCRIPTION

This command removes the specified clock objects from the current design. You must specify either *clock_list* or **-all**.

If a clock to be removed is the only member of a path group, that path group is also removed. For information about path groups, see the **group_path** command man page.

To list all clock sources in the design, use the **report_clock** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes the clock named CLK1:

```
prompt> remove_clock CLK1
```

The following example removes all clocks from the current design:

```
prompt> remove_clock -all
```

SEE ALSO

`create_clock(2)`
`current_design(2)`
`group_path(2)`
`report_clock(2)`
`reset_design(2)`

remove_clock_gating

Directs the **compile -incremental** and **compile_ultra -incremental** commands to remove clock gating from objects clock-gated by Power Compiler.

SYNTAX

```
status remove_clock_gating
  [-gated_registers gated_register_list]
  [-min_bitwidth minsize_value]
  [-gating_cells clock_gating_cells_list]
  [-all]
  [-no_hier]
  [-verbose]
  [-undo]
```

Data Types

<i>gated_register_list</i>	list
<i>minsize_value</i>	integer
<i>clock_gating_cells_list</i>	list

ARGUMENTS

-gated_registers *gated_register_list*

Specifies that all registers in the *gated_register_list* are ungated.

-min_bitwidth *minsize_value*

Specifies that all registers in the register banks whose size is smaller than the *minsize_value* are ungated.

-gating_cells *clock_gating_cells_list*

Specifies that all objects gated by clock-gating cells in the *clock_gating_cells_list* are ungated and removes clock-gating cells from the design.

-all

Removes clock gating from all levels of hierarchy, unless the **-no_hier** option is used. If the **-no_hier** is specified, clock gating is only removed from the top level of the current design.

-no_hier

Removes clock gating from the top level of the current design only when used with the **-all** or **-min_bitwidth** options.

-verbose

Prints additional information as the command executes.

-undo

Removes directives specified by any previously executed **remove_clock_gating** commands. Based on the specified options, this option deletes directives specified by previously-executed **remove_clock_gating** commands. Using the **-undo** option before the **compile_ultra -incremental** command modifies the netlist to remove clock gating.

DESCRIPTION

This command directs the **compile -incremental** and **compile_ultra -incremental** commands to remove clock gating from objects (registers and clock-gating cells) clock gated by Power Compiler. This command provides a mechanism to selectively remove clock gating from various parts of the design. Power Compiler performs clock gating at the register transfer level (RTL) during the execution of the **compile_ultra -gate_clock** command.

Further down the compile flow, you might have to selectively remove some clock-gating elements from the design. The **remove_clock_gating** command provides a mechanism to do so without having to start at the RTL again.

This command provides directives to the **compile** and **compile_ultra** commands used with the **-incremental** option that perform circuit modifications to remove clock gating from the design. See the man pages for the **compile** and **compile_ultra** commands for more information on the **-incremental** options. This command also removes redundant clock-gating cells that do not gate anyclock-gating cells. Any associated test-observation logic is removed during optimization. All registers that are ungated are remapped to new sequential cells. This might result in new pin names for the registers. A register can be clock-gated by multiple clock gates in a multistage clock-gating design. If the register is ungated, all clock gating on the clock path for this register is removed. However, if a single clock gate is specified for removal, the remaining clock-gating cells still exist on the clock path of the register.

Pin-based timing exceptions set on the pins of the old register might have been set by the **set_max_delay**, **set_min_delay**, **set_multicycle_path** and **set_false_path** commands. These exceptions might not be properly transferred during the transformation if the new and old pin names do not match. The **remove_clock_gating** command issues a warning if there are pin-based timing exceptions on the register to be ungated.

It is good practice to run the **report_timing** command again to confirm that the pin-based exceptions are being properly applied after the registers are ungated during execution of the **compile** command with the **-incremental** option.

This command has no effect on a clock-gating cell or its gated registers if the clock gate or its parent hierarchical cell is marked **dont_touch** with the **set_dont_touch** command.

EXAMPLES

The following example provides a directive to the **compile_ultra -incremental** command to remove clock gating from all registers gated by the cell *clk_gate_pipeline_reg_A* and removes the cell:

```
prompt> remove_clock_gating -gating_cell clk_gate_pipeline_reg_A
```

The following example provides a directive to the **compile_ultra -incremental** command to remove clock gating from the gated registers *pipeline_reg_A[0]* and *pipeline_reg_A[2]*. If the clock-gating cell that gates these registers does not drive any other gating cell, it is also removed.

```
prompt> remove_clock_gating \
-gated_registers {pipeline_reg_A[0] pipeline_reg_A[2]}
```

The following example undoes the effect of the directive in the first example above, to remove the clock-gating cell *clk_gate_pipeline_reg_A* and ungate all registers gated by this cell. Run this command before running the **compile_ultra -incremental** command.

```
prompt> remove_clock_gating -undo \
-gating_cell clk_gate_pipeline_reg_A
```

The following example provides a directive to the **compile_ultra -incremental** command to remove clock gating from all gated registers and to remove all clock-gating cells from the current level of the design hierarchy:

```
prompt> remove_clock_gating -all -no_hier
```

The following example provides a directive to the **compile_ultra -incremental** command to remove clock gating from all gated registers and remove all clock-gating cells from all designs at or below the current level of the design hierarchy:

```
prompt> remove_clock_gating -all
```

remove_clock_gating_check

Removes setup and hold checks from the specified clock-gating cells.

SYNTAX

```
status remove_clock_gating_check
  [-setup]
  [-hold]
  [-rise]
  [-fall]
  object_list
```

Data Types

object_list list

ARGUMENTS

-setup

Removes setup checks from the specified clock-gating cells.

-hold

Removes hold checks from the specified clock-gating cells.

-rise

Removes the clock-gating constraint on the rising delays. If you do not specify either **-rise** or **-fall**, the default is to remove constraints on both rising and falling delays.

-fall

Removes the clock-gating constraint on the falling delays. If you do not specify either **-rise** or **-fall**, the default is to remove constraints on both rising and falling delays.

If you omit the **-setup** and **-hold** options, by default both types of checks are removed.

object_list

Specifies a list of designs, cells, pins, or clock objects from which to remove the clock-gating checks.

DESCRIPTION

The **remove_clock_gating_check** command removes clock-gating checks that were added using the **set_clock_gating_check** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes setup and hold checks from the CHIP1 design:

```
prompt> remove_clock_gating_check CHIP1
```

The following example removes only the setup checks on the clock-gating inputs of the CLK_GATE1 cell in the current design:

```
prompt> remove_clock_gating_check -setup CLK_GATE1
```

The following example removes only the fall hold checks on the clock-gating inputs of the CLK_GATE2 cell in the current design:

```
prompt> remove_clock_gating_check -fall -hold CLK_GATE2
```

SEE ALSO

`create_clock(2)`
`current_design(2)`

remove_clock_gating_style

Removes the clock gating style applied on a given set of hierarchical cells or power domains.

SYNTAX

```
status remove_clock_gating_style
  [-instances {cell_list}]
  [-power_domains {power_domain_list}]
  [-designs designs]
```

Data Types

<i>cell_list</i>	list
<i>power_domain_list</i>	list

ARGUMENTS

-instances {*cell_list*}

Specifies that the clock gating style should be removed from the given list of hierarchical cells.

-power_domains {*power_domain_list*}

Specifies that the clock gating style should be removed from the given list of power domains.

DESCRIPTION

This command removes the clock gating style previously specified with command **set_clock_gating_style** (with instance specific clock gating style enabled) on a given hierarchical cell, power domain or design. When the clock gating style is removed from a certain hierarchical instance, the style used for that instance is obtained according to the precedence described for **set_clock_gating_style** on section **Instance specific Clock-gating Style**.

When using this command with none of the options **-instances** and **-power_domains**, the style removed is the one previously set on the **current_design**.

The use of this command is subject to have instance specific clock gating style enabled, by setting variable **power_cg_iscggs_enable** to **true**.

EXAMPLES

The following example removes the clock gating style from instances **m1/b1** and **m2**.

```
prompt> remove_clock_gating_style -instances {m1/b1 m2}
```

SEE ALSO

`compile(2)`
`compile_ultra(2)`
`set_clock_gating_style(2)`

remove_clock_groups

Removes specific exclusive or asynchronous clock groups from the current design.

SYNTAX

```
status remove_clock_groups
  -logically_exclusive
  | -asynchronous
  | -physically_exclusive
  name_list | -all
```

Data Types

name_list list

ARGUMENTS

-logically_exclusive

Specifies that groups set for logically-exclusive clocks are to be removed. You must specify either **-logically_exclusive**, **-asynchronous**, or **-physically_exclusive**.

-asynchronous

Specifies that groups set for asynchronous clocks are to be removed. You must specify either **-asynchronous**, **-logically_exclusive**, or **-physically_exclusive**.

-physically_exclusive

Specifies that groups set for physically-exclusive clocks are to be removed. You must specify either **-physically_exclusive**, **-logically_exclusive**, or **-asynchronous**.

name_list

Specifies a list of clock groups to be removed, which matches the groups in the given names. Use the **set_clock_groups** command to predefine these names. Substitute the list you want for *name_list*. You must specify either the *name_list* argument or the **-all** option.

-all

Specifies to remove all groups set for exclusive or asynchronous clocks in the current design. You must specify either the **-all** option or the *name_list* argument.

DESCRIPTION

This command removes specific exclusive or asynchronous clock groups from the current design. These clock groups are specified by

the *name_list* from the current design. You must specify either **-logically_exclusive**, **-physically_exclusive**, or **-asynchronous**. You must specify either *name_list* or **-all**.

To find the names for existing groups, use the **report_clock** command with the **-groups** option.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes logically-exclusive clock groups named mux:

```
prompt> remove_clock_groups -logically_exclusive mux
```

The following example removes all asynchronous clock groups from the current design:

```
prompt> remove_clock_groups -asynchronous -all
```

SEE ALSO

[report_clock\(2\)](#)
[set_clock_groups\(2\)](#)

remove_clock_latency

Removes clock latency information from the specified objects.

SYNTAX

```
string remove_clock_latency
  [-fall]
  [-min]
  [-max]
  [-source]
  [-early]
  [-late]
  object_list
  [-rise]
```

Data Types

object_list list

ARGUMENTS

-fall

Specifies that the fall clock latency should be removed. By default, this is removed for both minimum and maximum clock latency.

-min

Specifies that the minimum clock latency should be removed. By default, this is removed for both rise and fall clock latency.

-max

Specifies that the maximum clock latency should be removed. By default, this is removed for both rise and fall clock latency.

-source

Specifies that clock source latency should be removed.

-early

Specifies that the late-clock source latency should be removed. If this option is not specified, both early and late clock latencies are removed.

-late

Specifies that the late clock source latency should be removed. If this option is not specified, both early and late clock latencies are removed.

object_list

Provides a list of clocks, ports, or pins.

-rise

Specifies that the rise clock latency should be removed. By default, this is removed for both minimum and maximum clock latency.

DESCRIPTION

The **remove_clock_latency** command removes user-specified clock network or clock-source latency information from specified objects. Clock-network latency is the time it takes for a clock signal on the design to propagate from the clock definition point to a register clock pin. Clock-source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. Clock-network and clock-source latency information is set on objects using the **set_clock_latency** command. See the **set_clock_latency** man page for more information.

You can remove selected portions of the clock latency by specifying options such as **-rise**, **-fall**, **-min**, **-max**, **-late**, and **-early**.

To report clock-network and clock-source latency information, use the **report_clock** command with the **-skew** option.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes clock latency information from the clock named CLK1:

```
prompt> remove_clock_latency [get_clocks CLK1]
```

The following example removes clock-source latency information from the CLK1 clock:

```
prompt> remove_clock_latency -source [get_clocks CLK1]
```

The following example removes only rise clock-source latency information from the CLK1 clock:

```
prompt> remove_clock_latency -rise -source [get_clocks CLK1]
```

SEE ALSO

`create_clock(2)`

`set_clock_latency(2)`
`set_clock_uncertainty(2)`
`set_input_delay(2)`

remove_clock_sense

Removes clock sense information from the specified pins.

SYNTAX

```
status remove_clock_sense
  [-all]
  [-clocks clock_list]
  pins
```

Data Types

<i>clock_list</i>	list
<i>pins</i>	list

ARGUMENTS

-all

Removes all clock sense information in the current design.

-clocks *clock_list*

Specifies the list of clocks for which the clock-sense information is removed. This option can remove only clock-sense information that has been set by using the **set_clock_sense** command with the **-clocks** option. It does not remove clock-sense settings from pins. By default, the clock-sense information is removed for all clocks passing through the specified pins.

pins

Specifies the pins from which to remove clock-sense information.

DESCRIPTION

This command removes user-specified clock-sense (unateness) information from specified pins and clocks. To set clock-sense information, use the **set_clock_sense** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes positive unateness defined on a pin named XOR/Z with respect to clock CLK1, but does not remove the negative unateness:

```
prompt> set_clock_sense -positive -clocks [get_clock CLK1] XOR/Z
prompt> set_clock_sense -negative XOR/Z
prompt> remove_clock_sense -clocks [get_clocks CLK1] XOR/Z
```

The following example removes all unateness information in the current design;

```
prompt> remove_clock_sense -all
```

SEE ALSO

[set_clock_sense\(2\)](#)

remove_clock_transition

Removes clock-transition attributes on the specified clock objects.

SYNTAX

```
status remove_clock_transition  
      clock_list
```

ARGUMENTS

clock_list

Specifies the clocks from which to remove the transition attributes.

DESCRIPTION

This command removes the clock-transition attributes on the specified clocks.

To list all clock-transition values that have been set, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes transition attributes on the clock named CLK:

```
prompt> remove_clock_transition CLK
```

The following example removes transition attributes on all clocks in the current design:

```
prompt> remove_clock_transition [all_clocks]
```

SEE ALSO

[create_clock\(2\)](#)

```
current_design(2)
report_clock(2)
reset_design(2)
set_clock_transition(2)
```

remove_clock_uncertainty

Removes clock-uncertainty information previously set by the **set_clock_uncertainty** command.

SYNTAX

```
string remove_clock_uncertainty
[object_list
 | -from from_clock
 | -rise_from rise_from_clock
 | -fall_from fall_from_clock
 -to to_clock
 | -rise_to rise_to_clock
 | -fall_to fall_to_clock]
[-rise]
[-fall]
[-setup]
[-hold]
```

Data Types

```
object_list      list
from_clock      list
rise_from_clock list
fall_from_clock list
to_clock        list
rise_to_clock   list
fall_to_clock   list
```

ARGUMENTS

object_list

Specifies a list of clocks, ports, or pins from which uncertainty information is to be removed. By default, uncertainty information is removed from all objects in the current design. Use either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options or the *object_list* option. These options are mutually exclusive; specify only one.

-from *from_clock*

Specifies the source and destination clocks for interclock uncertainty. Specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*. These options are mutually exclusive; specify only one.

-rise_from *rise_from_clock*

Specifies the source and destination clocks, but indicates that *uncertainty* applies only to the rising edge of the source clock. Use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-fall_from *fall_from_clock*

Specifies the source and destination clocks, but indicates that *uncertainty* applies only to the falling edge of the source clock. Use only one of the **-from**, **-rise_from**, or **-fall_from** options.

-to to_clock

Specifies the destination clocks for interclock uncertainty. Specify either the pair of **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to**, or *object_list*. These options are mutually exclusive; specify only one.

-rise_to rise_to_clock

Specifies the destination clocks for interclock uncertainty, but indicates that *uncertainty* applies only to the rising edge of the destination clock. Use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-fall_to fall_to_clock

Specifies the destination clocks for interclock uncertainty, but indicates that *uncertainty* applies only to the falling edge of the destination clock. Use only one of the **-to**, **-rise_to**, or **-fall_to** options.

-rise

Specifies that uncertainty is to be removed for only the rising clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-rise_to** instead.

-fall

Specifies that uncertainty is to be removed for only the falling clock edge. By default, uncertainty is removed for both rising and falling clock edges. This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use **-fall_to** instead.

-setup

Specifies that only setup check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

-hold

Specifies that only hold check uncertainty is to be removed. By default, both setup and hold check uncertainties are removed.

DESCRIPTION

This command removes clock uncertainty information previously set by the **set_clock_uncertainty** command from clocks, ports, or pins, or between specified clocks. If the command is issued without options, all clock uncertainty information is removed from the current design. To display clock uncertainty information, use the **report_clock** command with the **-skew** option.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes uncertainty information from a clock named CLK and a pin named clk_buf/Z:

```
prompt> remove_clock_uncertainty [get_clocks CLK]
prompt> remove_clock_uncertainty [get_pins clk_buf/Z]
```

The following example removes interclock uncertainties between the PHI1 and PHI2 clock domains:

```
prompt> remove_clock_uncertainty -from PHI1 -to PHI1
prompt> remove_clock_uncertainty -from PHI2 -to PHI2
prompt> remove_clock_uncertainty -from PHI1 -to PHI2
prompt> remove_clock_uncertainty -from PHI2 -to PHI1
```

SEE ALSO

`all_clocks(2)`
`create_clock(2)`
`report_clock(2)`
`set_clock_latency(2)`
`set_clock_transition(2)`
`set_clock_uncertainty(2)`

remove_congestion_options

Removes congestion options from the current design.

SYNTAX

```
status remove_congestion_options
  [-all]
  id_list
```

Data Types

id_list list

ARGUMENTS

-all

Removes all congestion options from the current design.

id_list

Removes congestion options with the specified IDs.

DESCRIPTION

The **remove_congestion_options** command removes the congestion options from the current design. If the **-all** option is specified, all congestion options are removed from the design. If a list of IDs is provided, the congestion options with the specified IDs are removed. The ID is displayed every time a regional congestion option is created, or it can be viewed by using the **report_congestion_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all congestion options:

```
prompt> remove_congestion_options -all
```

SEE ALSO

`report_congestion(2)`
`report_congestion_options(2)`
`set_congestion_options(2)`

remove_constraint

Removes all constraint attributes, clocks, and path delay information from the current design. Note that this command will be obsolete in the next release. It will be replaced by the **remove_sdc** command. Please adjust your scripts accordingly.

SYNTAX

```
status remove_constraint
  [-all]
  [-all_sdc]
```

ARGUMENTS

-all

Removes all target values from the current design.

-all_sdc

Removes all SDC constraints.

DESCRIPTION

This command removes **max_area**, **max_power**, **max_fanout**, and **max_transition** attributes from the current design. It also removes clock objects and all path delay information created by the **set_max_delay**, **set_min_delay**, **set_false_path**, **set_max_time_borrow**, and **set_multicycle_path** commands.

You can undo individual commands by using the **remove_attribute** or **reset_path** command. To remove clocks, use the **remove_clock** command.

The **reset_design** command removes all constraints and all attributes.

Multicorner-Multimode Support

This command applies to all active scenarios.

EXAMPLES

The following example removes all constraint information from the current design:

```
prompt> remove_constraint -all
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`remove_clock(2)`
`report_constraint(2)`
`reset_design(2)`
`reset_path(2)`
`set_max_area(2)`
`set_max_delay(2)`
`set_max_fanout(2)`
`set_max_time_borrow(2)`
`set_max_transition(2)`

remove_core_area

Removes the core area of the design.

SYNTAX

status **remove_core_area**

ARGUMENTS

The **remove_core_area** command has no arguments.

DESCRIPTION

This command removes the core area of the design.

EXAMPLES

The following example removes the core area of the current design:

```
prompt> remove_core_area  
1
```

SEE ALSO

[create_core_area\(2\)](#)

remove_data_check

Removes specified data-to-data checks previously set by the **set_data_check** command.

SYNTAX

```
string remove_data_check
  -from from_object
  | -rise_from from_object
  | -fall_from from_object
  -to to_object
  | -rise_to to_object
  | -fall_to to_object
  [-setup | -hold]
  [-clock clock]
```

Data Types

from_object collection
to_object collection

ARGUMENTS

-from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. Both rising and falling checks are removed. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-rise_from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. This is similar to the **-from** option, but applies to only rising delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-fall_from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be removed. This is similar to the **-from** option, but applies to only falling delays at the related pin. You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. Both rising and falling checks are removed. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-rise_to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. This is similar to the **-to** option, but applies to only rising delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-fall_to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be created. This is similar to the **-to** option, but applies to only falling delays at the constrained pin. You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-setup

Indicates that only the setup data check is to be removed. If neither **-setup** nor **-hold** is specified, both setup and hold checks are removed.

-hold

Indicates that only the hold data check is to be removed. If neither **-setup** nor **-hold** is specified, both setup and hold checks are removed.

-clock *clock*

Indicates that the data check for the specified clock at the related pin is to be removed. This option applies only if a previous **set_data_check** command used the **-clock** option to specify the same clock; otherwise, this option is ignored.

DESCRIPTION

The **remove_data_check** command specifies data-to-data check(s) to be removed between the *from* object and the *to* object for the specified options. These checks were previously set using the **set_data_check** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes a data-to-data check from and1/B to and1/A with respect to the rising edge of signals at and1/B. Both setup and hold checks are removed.

```
prompt> remove_data_check -rise_from and1/B -to and1/A
```

The following example removes setup data-to-data checks between and1/B and and1/A with respect to the rising edge of signals at and1/B and the falling edge of signals at and1/A, coming from startpoints triggered by the CK1 clock:

```
prompt> remove_data_check -rise_from and1/B \
-fall_to and1/A -setup -clock [get_clock CK1]
```

SEE ALSO

`report_timing(2)`
`set_data_check(2)`
`update_timing(2)`
`timing_enable_multiple_clocks_per_reg(3)`

remove_design

Removes designs or libraries from memory.

SYNTAX

```
status remove_design
  [design_list | -designs | -all]
  [-hierarchy]
  [-quiet]
```

Data Types

design_list list

ARGUMENTS

design_list

Specifies the designs or libraries to remove. The default is the current design. This argument cannot be used with the **-designs** or **-all** options. You can specify a design to be removed with or without an absolute path. To determine the absolute path of designs, use the **list_files** command.

-designs

Removes all designs in memory. This option cannot be used with the *design_list* argument or the **-all** option.

-all

Removes all designs and libraries in memory. This option cannot be used with the *design_list* argument or the **-designs** option.

-hierarchy

Removes all designs within the hierarchy of the designs in the *design_list* argument or in the current design. The default is not to remove any subdesigns.

-quiet

Turns off verbose mode that prints out messages showing the names of the designs or libraries that are being removed.

DESCRIPTION

This command removes designs or libraries from memory. If you do not specify any arguments, the current design is removed. When a design or library is removed, the memory it occupies is freed.

If all designs are removed from memory, then any scenarios that exist are automatically deleted. If necessary, **create_scenario** can be used to re-create deleted scenarios.

Note that memory is freed to be reused by this same process. However, memory is not returned to the operating system until you exit the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information. However, if all designs are removed, all scenarios are also removed.

EXAMPLES

The following example removes the current design:

```
prompt> current_design TEST
Current design is now 'TEST'
```

```
prompt> remove_design
Removing design 'TEST'
```

The following example removes a specified design and all subdesigns in the hierarchy:

```
prompt> remove_design -hierarchy TEST2
Removing design 'TEST2'
Removing design 'ADDER'
Removing design 'MUX8'
Removing design 'ND17'
```

The following example removes the design named RIGHT in the file named TOP.ddc:

```
prompt> remove_design {"/remote/user/designs/TOP.ddc:RIGHT"}
Removing design 'RIGHT'
```

The following example removes all design and library objects from memory:

```
prompt> remove_design -all
Removing design 'A'
Removing design 'B'
Removing library 'test_lib'
```

The following example shows that scenarios are deleted as a side-effect of deleting all designs from memory:

```
prompt> remove_design -designs
Removing design 'top'
Removing design 'mid'
Removing design 'bot'
Information: Removing all scenarios because all designs have been
removed. (UID-1040)
Information: Removed Scenario S1. (UID-1024)
Information: Removed Scenario S2. (UID-1024)
Information: Removed Scenario S3. (UID-1024)
```

SEE ALSO

[current_design\(2\)](#)
[rename_design\(2\)](#)
[list_files\(2\)](#)
[UID-1040\(n\)](#)

remove_dft_clock_gating_pin

Removes all DFT clock-gating pin specifications for the current design.

SYNTAX

```
status remove_dft_clock_gating_pin
```

ARGUMENTS

The **remove_dft_clock_gating_pin** command takes no arguments.

DESCRIPTION

The **remove_dft_clock_gating_pin** command removes all DFT clock-gating pin specifications that were defined by the **set_dft_clock_gating_pin** command for the current design.

EXAMPLES

In the following example, the command removes all the DFT clock-gating pin specifications for the current design:

```
prompt> remove_dft_clock_gating_pin
```

SEE ALSO

[set_dft_clock_gating_pin\(2\)](#)
[report_dft_clock_gating_pin\(2\)](#)

remove_dft_connect

Removes existing DFT connectivity specifications.

SYNTAX

```
status remove_dft_connect  
  [-all]  
  [label_name]
```

Data Types

label_name string

ARGUMENTS

-all

Removes all connectivity specifications.

label_name

Removes only the connectivity specification with the associated *label_name*.

DESCRIPTION

The **remove_dft_connect** command is used to remove DFT connectivity associations specified by the **set_dft_connect** command.

To remove a specific connectivity specification, specify the *label_name* of the association as the argument.

To remove all connectivity specifications, specify **-all**.

EXAMPLES

The following example first sets 3 connectivity specifications, then removes the specification associated with label CON2, and finally removes all specified connectivity by using the **-all** option:

```
prompt> set_dft_connect CON1 -source SE1 -type clock_gating_control \  
          -target [list U1 U2]  
  
prompt> set_dft_connect CON2 -source SE2 -type clock_gating_control \  
          -target [list U3 U4] -exclude U3/u
```

```
prompt> set_dft_connect CON3 -source SE3 -type scan_enable \
           -target [list ff1 ff2]
prompt> remove_dft_connect CON2
prompt> remove_dft_connect -all
```

SEE ALSO

`report_dft_connect(2)`
`set_dft_connect(2)`
`set_dft_signal(2)`

remove_dft_design

Removes the specified design so that it cannot be used for DFT insertion.

SYNTAX

```
status remove_dft_design
  -design_name design_name
  | -type design_type
  | -all
```

Data Types

```
design_name  string
design_type  string
```

ARGUMENTS

-design_name *design_name*

Identifies the design to be removed. This option is mutually exclusive with **-type** and **-all**.

-type *design_type*

Specifies the type of the DFT design to be removed. Valid types are DECODE, CONTROL_FORCE, Z_CONTROL_FORCE, OBSERV_DGEN, SHIFT_REG, BC_1, BC_2, BC_3, BC_4, BC_5, BC_7, BC_8, BC_9, BC_10, WC_D1, WC_D1_S, WC_S1, WC_S1_S, INSTRREG, TAP, TAP_UC, LBIST_CONTROLLER, LBIST_CODEC, LBIST_XCONTROLLER, LBIST_XCODEC, CLK_MUX, CLK_CHAIN, MBIST_CONTROLLER, MBIST_WRAPPER, and PAD.

This option is mutually exclusive with **-design_name** and **-all**.

-all

Removes all DFT designs. This option is mutually exclusive with **-design_name** and **-type**.

DESCRIPTION

The **remove_dft_design** command removes a design so that it is not used for DFT insertion.

You must use one of the three options: **-design_name**, **-type**, or **-all**. These options are mutually exclusive; use only one option for each invocation of the command.

EXAMPLES

The following example removes *my_des* so that it is not used for DFT insertion:

```
prompt> define_dft_design -design_name my_des \
    -type WC_D1 -interface \
    {shift_clk capture_clk h capture_en capture_en h \
    shift_en shift_dr h cti si h cto so h cfi \
    data_in h cfo data_out h}
```

```
prompt> ....
```

```
prompt> remove_dft_design -design_name my_des
```

The following example removes all DFT designs of type *BC_4*:

```
prompt> define_dft_design -design my_des1 -type BC_4 \
    -interface {capture_clk cap_clk h capture_en cen h \
    shift_dr shift h si ti h so to h data_in di h data_out do h}
```

```
prompt> define_dft_design -design my_des2 -type BC_4 \
    -interface {capture_clk cap_clk h capture_en cen h \
    shift_dr shift h si ti h so to h data_in di h data_out do h}
```

```
prompt> remove_dft_design -type BC_4
```

SEE ALSO

[insert_dft\(2\)](#)
[preview_dft\(2\)](#)
[report_dft_design\(2\)](#)

remove_dft_equivalent_signals

Removes all equivalent DFT signals specified with the **set_dft_equivalent_signals** command for the specified primary signal commands.

SYNTAX

```
status remove_dft_equivalent_signals  
      primary_signal
```

ARGUMENTS

primary_signal

Specifies the primary signal used in **set_dft_equivalent_signals** to specify valid equivalences for the set of signals.

DESCRIPTION

This command removes the equivalent set of signals specified using the **set_dft_equivalent_signals** command. Use this command to remove a given equivalence specified through **set_dft_equivalent_signals**.

EXAMPLES

The following example illustrates removing equivalent scan signals for *clk1*:

```
prompt> remove_dft_equivalent_signals clk1
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`report_dft_equivalent_signals(2)`
`set_dft_equivalent_signals(2)`
`set_dft_signal(2)`

remove_dft_location

Removes DFT hierarchy location specifications for the current design.

SYNTAX

```
status remove_dft_location  
[-type logic_type]
```

Data Types

logic_type string

ARGUMENTS

-type *logic_type*

Specifies the types of DFT hierarchy location specifications to be removed from the current design. The following values are valid for *logic_type*:

```
CODEC  
TCM  
LOCKUP_LATCH  
PIPELINE_SI_LOGIC  
PIPELINE_SE_LOGIC  
WRAPPER  
BSR  
TAP  
REC_MUX  
PLL  
SERIAL_CNTRL  
SERIAL_REG  
XOR_SELECT  
RETIMING_FLOP  
IEEE_1500
```

You can specify a list of multiple types with this option.

To remove a default DFT hierarchy location specification that was applied using the **set_dft_location** command without the **-include** option, do not specify a value for this option.

DESCRIPTION

The **remove_dft_location** command removes DFT hierarchy location specifications for the current design.

EXAMPLES

The following example removes the DFT hierarchy location for the design named *top*:

```
prompt> current_design top  
prompt> set_dft_location -include {CODEC} core_inst/CODEC  
prompt> remove_dft_location -type {CODEC}  
Removed DFT location 'core_inst/CODEC' for type 'CODEC' for design 'top'.  
1
```

SEE ALSO

[insert_dft\(2\)](#)
[report_dft_location\(2\)](#)
[set_dft_location\(2\)](#)

remove_dft_partition

Permanently removes a list of design DFT partitions associated with a design.

SYNTAX

```
status remove_dft_partition  
[list_of_partition_labels]
```

Data Types

list_of_partition_labels list

ARGUMENTS

list_of_partition_labels

Specifies the partitions to be removed from the specification.

DESCRIPTION

This command permanently removes a list of design DFT partitions associated with a design.

EXAMPLES

The following example removes the partitions defined as *part1* and *part2*:

```
prompt> define_dft_partition part1 -instances {U1 U2}  
prompt> define_dft_partition part2 -instances {U3 U4}  
prompt> remove_dft_partition {part1 part2}
```

SEE ALSO

current_dft_partition(2)
define_dft_partition(2)
insert_dft(2)

```
preview_dft(2)
report_dft_partition(2)
set_dft_signal(2)
set_scan_compression_configuration(2)
set_scan_configuration(2)
set_scan_path(2)
```

remove_dft_power_control

Removes the power controller block specification from the current design.

SYNTAX

status **remove_dft_power_control**

ARGUMENTS

The **remove_dft_power_control** command has no arguments.

DESCRIPTION

This command removes the power controller block specification from the current design.

Use the **set_dft_power_control** command to specify a power controller block specification. Use the **report_dft_power_control** command to report the current power controller block specification.

For more information, see the man page for the **set_dft_power_control** command.

EXAMPLES

In the following example, the current power controller block specification is removed:

```
prompt> remove_dft_power_control
```

SEE ALSO

report_dft_power_control(2)
set_dft_power_control(2)

remove_dft_signal

Removes from specified ports the attributes that identify those ports as DFT signals in the current design.

SYNTAX

```
status remove_dft_signal
  -view existing_dft | spec
  -port port_list
  -test_mode mode_name_list
  [-hookup_pin pin_name]
  [-usage use_type]
```

Data Types

<i>port_list</i>	list
<i>mode_name_list</i>	list
<i>pin_name</i>	string

ARGUMENTS

-view existing_dft | spec

Indicates the view to which the command applies. Valid views are **existing_dft** and **spec**.

Setting the view to **existing_dft** indicates that the command refers to the existing usage of a port. Use **existing_dft** to remove a specification made with the **set_dft_signal -view existing_dft** command.

Setting the view to **spec**, the default, indicates that the command refers to ports that the tool must use during DFT insertion. Use **spec** to remove a specification made with the **set_dft_signal -view spec** command.

This argument is required.

-port port_list

Specifies a list of ports to which the command applies.

-test_mode mode_name_list

Specifies the mode(s) to which the command applies. The default mode is **Internal_scan**. Specifying **all** as the *mode_list* indicates that the specification applies to all modes. Any mode other than the default mode or **all** must be created before running the command with this option.

-hookup_pin pin_name

Specifies the hookup pin to which the command applies.

DESCRIPTION

The **remove_dft_signal** command removes from specified ports the attributes that identify those ports as DFT signal ports in the current design. These attributes were placed on the ports with the **set_dft_signal** command.

EXAMPLES

The following example removes the DFT signal attributes from the *TM* port:

```
prompt> remove_dft_signal -port TM
```

SEE ALSO

[insert_dft\(2\)](#)
[preview_dft\(2\)](#)
[report_dft_signal\(2\)](#)
[set_dft_signal\(2\)](#)

remove_die_area

Removes the die area from the current design.

SYNTAX

```
status remove_die_area  
[-verbose]
```

ARGUMENTS

-verbose

Prints additional debugging messages.

DESCRIPTION

This command removes the die area from the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the die area from current design:

```
prompt> remove_die_area  
1
```

SEE ALSO

`create_die_area(2)`
`get_die_area(2)`

remove_disable_clock_gating_check

Restores clock-gating checks that were previously disabled by the **set_disable_clock_gating_check** command for the specified cells and pins.

SYNTAX

```
status remove_disable_clock_gating_check  
object_list
```

Data Types

object_list collection

ARGUMENTS

object_list

Specifies the cells and pins for which previously-disabled clock-gating checks are to be restored.

DESCRIPTION

This command restores clock-gating checks that were previously disabled by the **set_disable_clock_gating_check** command for the specified cells and pins.

Multicorner-Multimode Support

This command applies to all scenarios.

EXAMPLES

The following example restores disabled clock-gating checks for the an1/A pin:

```
prompt> remove_disable_clock_gating_check an1/A
```

The following example restores all disabled gating checks on the cells named U1 or U2:

```
prompt> remove_disable_clock_gating_check [get_cells {U1 U2}]
```

SEE ALSO

`set_disable_clock_gating_check(2)`

remove_disable_timing

Enables previously user-disabled timing arcs in the current design. It is equivalent to the **set_disable_timing -restore** command.

SYNTAX

```
status remove_disable_timing  
    object_list  
    [-from from_pin_name -to to_pin_name]  
    [-all_loop_breaking]
```

Data Types

```
object_list      list  
from_pin_name   string  
to_pin_name     string
```

ARGUMENTS

object_list

Specifies a list of cells, pins, ports, library pins, or library cells that are to be enabled. The cells or the cells of pins are no longer size only if you did not set size only.

-from *from_pin_name*

Specifies that arcs only from this pin on the specified cell are to be enabled. The *object_list* must contain only cells if **-from** and **-to** are specified.

-to *to_pin_name*

Specifies that arcs only to this pin on the specified cell are to be enabled. The *object_list* must contain only cells if **-from** and **-to** are specified.

-all_loop_breaking

Re-enables all stored loop-breaking timing arcs. This option applies to the entire design.

DESCRIPTION

The **remove_disable_timing** command enables timing through the specified cells, pins, or ports in the current design.

Any cell, pin, or port in the current design or its subdesigns can be disabled and thus re-enabled.

Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*.

Pins at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/pin_name*.

Ports at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/port_name*.

Library pins and library cells can also be disabled and re-enabled.

Note that for subdesigns in the hierarchy, you must specify instance names instead of design names.

In disabling, when the timing through a cell is disabled, only those cell arcs that lead to the output pins of the cell are disabled. When the timing through a pin or port is disabled, only those cell arcs that lead to or from that pin or port are disabled. The **remove_disable_timing** command has a reverse effect.

When the **-from** and **-to** pins are specified, all arcs between these pins on the cell are enabled.

Use **report_lib -timing_arcs** to list the timing arcs for a library cell. Use **report_design** to list the disabled arcs in the current design so as to check the enabling effect of the **remove_disable_timing** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

In the following example, all timing arcs between pins A and Z on cell U1/U1 in the current design are enabled:

```
prompt> remove_disable_timing U1/U1 -from A -to Z
```

In the following example, all timing arcs between pins D and Q on cell FD1 in the library named my_lib are enabled. This command enables arcs on a library cell; therefore, all instances of that library cell are affected in any design linked to the same library.

```
prompt> remove_disable_timing my_lib/FD1 -from D -to Q
```

SEE ALSO

`current_design(2)`
`remove_attribute(2)`
`report_lib(2)`
`reset_design(2)`
`set_disable_timing(2)`

remove_dp_int_round

Removes the rounding attribute from inferred multiplier and multiplier-based instantiated DesignWare cells.

SYNTAX

```
status remove_dp_int_round  
[cell_list | -all]
```

Data Types

cell_list list

ARGUMENTS

cell_list

Lists the cells from which the rounding attributes will be removed.

-all

Removes rounding attributes from all cells.

DESCRIPTION

This command removes the external and internal rounding attributes that are set by the **set_dp_int_round** command.

Note that when a design is compiled and has been internally rounded, constant propagation might occur in the design. If you remove the internal rounding attribute and compile again, the final netlist might fail the Formality check as constant propagation might disconnect some nets. It is not allowed to remove the internal rounding attribute on a design that has been compiled with internal rounding feature.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the external rounding value on cell *mult*:

```
prompt> remove_dp_int_round [find cell mult*]
```

The following example removes the external rounding value on all cells:

```
prompt> remove_dp_int_round -all
```

SEE ALSO

`set_dp_int_round(2)`

remove_driving_cell

Removes driving-cell attributes from the specified input or inout ports of the current design.

SYNTAX

```
status remove_driving_cell  
[ports]
```

Data Types

ports collection

ARGUMENTS

ports

Specifies the input or inout ports in the current design from which to remove the driving-cell attributes.

DESCRIPTION

This command removes attributes associated with an external driving cell from the specified input or inout ports in the current design.

To view drive information on ports, use the **report_port -drive** command.

The **characterize** command automatically sets driving-cell attributes on subdesign ports based on their context in the entire design.

Note that the **remove_driving_cell** command also removes any corresponding rise or fall drive resistance attributes from the **set_drive** command from the specified ports.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes driving-cell attributes from all input and inout ports:

```
prompt> remove_driving_cell [all_inputs]
```

SEE ALSO

`all_inputs(2)`
`characterize(2)`
`current_design(2)`
`report_port(2)`
`reset_design(2)`
`set_drive(2)`
`set_driving_cell(2)`

remove_from_collection

Removes objects from a collection, resulting in a new collection. The base collection remains unchanged.

SYNTAX

```
collection remove_from_collection
  [-intersect]
  collection1
  object_spec
```

Data Types

collection1 collection
object_spec list

ARGUMENTS

-intersect

Removes objects from *collection1* not found in *object_spec*. Without this option, removes objects from *collection1* that are found in *object_spec*.

collection1

Specifies the base collection to be copied to the result collection. Objects matching *object_spec* are removed from the result collection.

object_spec

Specifies a list of named objects or collections to remove. The object class of each element in this list must be the same as in the base collection. If the name matches an existing collection, the collection is used. Otherwise, the objects are searched for in the database using the object class of the base collection.

DESCRIPTION

The **remove_from_collection** command removes elements from a collection, creating a new collection.

If the base collection is homogeneous, any element of the *object_spec* that is not a collection is searched for in the database using the object class of the base collection. If the base collection is heterogeneous, any element of the *object_spec* that is not a collection is ignored.

If the *-intersect* option is not specified, which is the default mode, and if nothing matches the *object_spec*, the resulting collection is a copy of the base collection. If everything in the *collection1* option matches the *object_spec*, the result is the empty collection. With the *-intersect* option the results are reversed.

For background on collections and querying of objects, see the **collections** man page.

EXAMPLES

The following example from PrimeTime gets all input ports except "CLOCK".

```
prompt> set cPorts [remove_from_collection [all_inputs] CLOCK]
{in1 in2}
```

SEE ALSO

[add_to_collection\(2\)](#)
[collections\(2\)](#)

remove_from_rp_group

Removes a cell, relative placement group, or keepout from the specified relative placement groups.

SYNTAX

```
status remove_from_rp_group
  rp_groups
    -leaf cell_name
    -hierarchy group_name
    [-instance instance_name]
    -keepout keepout_name
```

Data Types

<i>rp_groups</i>	list or collection
<i>cell_name</i>	string
<i>group_name</i>	string
<i>instance_name</i>	string
<i>keepout_name</i>	string

ARGUMENTS

rp_groups

Specifies the relative placement groups from which to remove an item. The groups must all be in the same design.

If you do not specify this argument, no items are removed.

-leaf *cell_name*

Specifies the name of a leaf cell to remove from the specified relative placement groups. This option cannot be used with any other option.

-hierarchy *group_name*

Specifies the name of the relative placement group to remove from the specified relative placement groups.

This option can be used with the **-instance** option, but it is mutually exclusive with the **-leaf** and **-keepout** options.

-instance *instance_name*

Specifies the name of the hierarchical cell that contains the instantiated relative placement group specified in the **-hierarchy** option.

-keepout *keepout_name*

Specifies the name of the keepout to remove from the specified relative placement groups. This option cannot be used with any other option.

DESCRIPTION

This command removes an item from specified relative placement groups. The item can be either a leaf cell, a relative placement group (included or instantiated), or a keepout. This command is supported only for designs that do not contain multiply-instantiated designs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **remove_from_rp_group** command to remove a cell from an existing relative placement group:

```
prompt> get_rp_groups ripple::grp_ripple
{ripple::grp_ripple}

prompt> remove_from_rp_group ripple::grp_ripple\
-leaf carry_in_1
1
```

SEE ALSO

[add_to_rp_group\(2\)](#)
[create_rp_group\(2\)](#)
[get_rp_groups\(2\)](#)
[remove_rp_groups\(2\)](#)
[write_rp_groups\(2\)](#)

remove_generated_clock

Removes a generated_clock object.

SYNTAX

```
status remove_generated_clock  
    -all | clock_list
```

Data Types

clock_list list

ARGUMENTS

-all

Removes all generated clocks.

clock_list

Specifies a list of generated clock names.

DESCRIPTION

This command removes the generated clocks in the design. If the generated clocks are expanded, the actual clocks are also deleted. All of the attributes set on generated clocks (**false_paths**, **multicycle_paths**, and so on) are also removed.

To create a generated clock in the design, use the **create_generated_clock** command.

To show information about clocks and generated clocks in the design, use the **report_clock** command.

The **remove_generated_clock** command also deletes generated clocks that were defined by a library cell. Once removed, the generated clock will not return automatically until you run the **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes the generated clock named GEN1 from the design:

```
prompt> remove_generated_clock GEN1
```

The following example removes all generated clocks from the design:

```
prompt> remove_generated_clock -all
```

SEE ALSO

`create_generated_clock(2)`
`report_clock(2)`
`reset_design(2)`

remove_host_options

Removes all **-max_cores** specifications set by the **set_host_options** command.

SYNTAX

status **remove_host_options**

ARGUMENTS

The **remove_host_options** command has no options.

DESCRIPTION

The **remove_host_options** command unsets the parameters set by the **set_host_options** command.

The only such parameter is the **-max_cores** option. Running the **remove_host_options** command disables parallel execution.

EXAMPLES

The following example removes all **-max_cores** specifications set by the **set_host_options** command.

```
prompt> remove_host_options
```

SEE ALSO

report_host_options(2)
set_host_options(2)

remove_ideal_latency

Removes ideal latency information from the specified objects.

SYNTAX

```
string remove_ideal_latency
  [-rise | -fall]
  [-min | -max]
  object_list | -all
```

Data Types

object_list list

ARGUMENTS

-rise | -fall

Specifies that rise or fall ideal latency should be removed. By default, ideal latency is removed for both rise and fall ideal latency. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies that maximum or minimum ideal latency should be removed. By default, it is removed for both minimum and maximum delay analysis. The **-min** and **-max** options are mutually exclusive.

object_list

Specifies a list of ports or pins from which to remove ideal latency. The *object_list* argument and the **-all** option are mutually exclusive.

-all

Removes ideal network latency from all objects. The **-all** option and the *object_list* argument are mutually exclusive.

DESCRIPTION

This command removes from specified objects the user-specified ideal latency that was previously set by the **set_ideal_latency** command. See the **set_ideal_latency** man page for more details. You must either specify an *object_list* or use **-all**.

You can remove selected portions of ideal latency by specifying applicable **-rise**, **-fall**, **-min**, and **-max** options.

To list ideal latency values, use the **report_ideal_network** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes ideal latency from the output pin named Z of cell instance U1/U2/U3:

```
prompt> remove_ideal_latency {U1/U2/U3/Z}
```

The following example removes only rise ideal latency information from a port named A:

```
prompt> remove_ideal_latency -rise {A}
```

SEE ALSO

```
current_design(2)
remove_ideal_network(2)
remove_ideal_transition(2)
report_ideal_network(2)
report_timing(2)
set_auto_disable_drc_nets(2)
set_ideal_net(2)
set_ideal_network(2)
set_ideal_transition(2)
```

remove_ideal_net

Restores the ideal nets set by the **set_ideal_net** or **set_ideal_network -no_propagate** command to their initial nonideal state from the specified nets in the current design.

SYNTAX

```
status remove_ideal_net  
    net_list
```

Data Types

net_list list

ARGUMENTS

net_list

Specifies a list of net names from which to remove the **ideal_net** attribute. These nets must be visible from the current design.

DESCRIPTION

This command removes the **ideal_net** attribute from the individual nets specified in *net_list*; or restores the ideal nets that are set by the **set_ideal_net** command or the **set_ideal_network -no_propagate** command to their initial nonideal state from the specified nets in *net_list*. Those nets must be visible from the current design.

Ideal nets are networks of nets that are free from the `max_capacitance` and `max_fanout` design rule constraints. Ideal nets are useful to reduce DRC violations caused by clock trees, because these networks usually have high `max_capacitance` and `max_fanout` violations.

To remove the **auto_disable_drc_net** attribute from nets, use **set_auto_disable_drc_nets -none**. The **reset_design** command removes all attributes from the design, including the **ideal_net** and **auto_disable_drc_net** attributes. By default, the tool still treats clock networks as ideal nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the **ideal_net** attribute from individual nets in the design named *CLOCK_GEN*:

```
prompt> current_design CLOCK_GEN
prompt> remove_ideal_net [get_nets]
```

SEE ALSO

`reset_design(2)`
`set_auto_disable_drc_nets(2)`
`set_dont_touch(2)`
`set_dont_touch_network(2)`
`set_ideal_net(2)`

remove_ideal_network

Removes a set of ports or pins in an ideal network in the current design. Cells and nets in the transitive fanout of the specified objects are no longer treated as ideal.

SYNTAX

```
status remove_ideal_network  
    object_list | -all
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of objects (pins or ports) that are sources of an ideal network. If more than one object name is specified, enclose the objects in quotes or braces ({}). The source objects can be input ports on the design or any internal pin except pins at hierarchical boundaries. These objects must be visible from the current design.

This argument and the **-all** option are mutually exclusive.

-all

Removes all ideal networks from the current design.

This option and the *object_list* argument are mutually exclusive.

DESCRIPTION

This command removes the ideal network designation from ports or pins in an ideal network.

Ideal networks, which are an extension of ideal nets, incorporate automatic propagation of the **ideal** attribute. You specify only the source ports or source pins of the network. All nets, cells, and pins on the transitive fanin of these objects are treated as ideal by the **compile** command.

The **ideal_network** attribute is automatically spread by the tool and respread as needed during optimizations. The **remove_ideal_network** command returns to normal part or all of a network that was previously marked as ideal using the **set_ideal_network** command. See the **set_ideal_network** man page for details about the propagation rules.

In addition to disabling timing update and timing optimizations, all cells in the ideal network are set with the **dont_touch** attribute. When part or all of the network is restored to normal using **remove_ideal_network**, the original **dont_touch** status of cells is restored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets up an ideal network on objects in the design *CLOCK_GEN* and then removes part of the network:

```
prompt> current_design CLOCK_GEN
prompt> set_ideal_network {port1 port2
prompt> remove_ideal_network port2
```

SEE ALSO

```
remove_ideal_net(2)
report_ideal_network(2)
reset_design(2)
set_auto_disable_drc_nets(2)
set_dont_touch(2)
set_dont_touch_network(2)
set_ideal_latency(2)
set_ideal_net(2)
set_ideal_network(2)
set_ideal_transition(2)
```

remove_ideal_transition

Removes ideal transition information from the specified objects.

SYNTAX

```
status remove_ideal_transition
  [-rise | -fall]
  [-min | -max]
  object_list | -all
```

Data Types

object_list list

ARGUMENTS

-rise | -fall

Specifies that rise or fall ideal transition should be removed. By default, ideal transition is removed for both rise and fall ideal transition. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies that maximum or minimum ideal transition should be removed. By default, ideal transition is removed for both maximum and minimum ideal transition. The **-min** and **-max** options are mutually exclusive.

object_list

Specifies a list of ports or pins from which to remove ideal transition. This argument and the **-all** option are mutually exclusive.

-all

Removes ideal network transition from all objects. This option and the *object_list* argument are mutually exclusive.

DESCRIPTION

This command removes from specified objects the user-specified ideal transition that was previously set by the **set_ideal_transition** command. See the **set_ideal_transition** man page for more details.

You can remove selected portions of ideal transition by specifying applicable **-rise**, **-fall**, **-min**, and **-max** options.

To list ideal transition values, use the **report_ideal_network** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes ideal transition from the output pin named Z of cell instance U1/U2/U3:

```
prompt> remove_ideal_transition {U1/U2/U3/Z}
```

The following example removes only rise ideal transition information a port named A:

```
prompt> remove_ideal_transition -rise {A}
```

SEE ALSO

```
current_design(2)

set_ideal_transition(2)
```

remove_ignored_layers

Removes ignored routing layers for congestion analysis and RC estimation. This command is supported only in Desgin Compiler topographical mode.

SYNTAX

```
status remove_ignored_layers
  list_of_layers
  [-all]
  [-min_routing_layer]
  [-max_routing_layer]
```

Data Types

list_of_layers list

ARGUMENTS

list_of_layers

Specifies the routing layers that should no longer be ignored during congestion analysis and RC estimation.

-all

Specifies that no routing layers should be ignored during congestion analysis and RC estimation.

-min_routing_layer

Removes the global minimum routing layer constraint.

-max_routing_layer

Removes the global maximum routing layer constraint.

DESCRIPTION

This command removes the ignored setting from some or all routing layers, so that the layers are used during congestion analysis and RC estimation.

Note that congestion analysis and RC estimation require that at least one horizontal and one vertical layer not be ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command removes the ignored setting from all routing layers so that all layers are used for congestion analysis and RC estimation. It also removes the global minimum and maximum routing layer constraints:

```
prompt> remove_ignored_layers -all \
           -min_routing_layer -max_routing_layer
```

SEE ALSO

[report_ignored_layers\(2\)](#)
[report_lib\(2\)](#)
[set_ignored_layers\(2\)](#)

remove_input_delay

Removes input delay on the specified pins or input ports.

SYNTAX

```
status remove_input_delay
  [-clock clock [-clock_fall] [-level_sensitive]]
  [-rise] [-fall]
  [-max] [-min]
  ports_pins
```

Data Types

clock string or collection of one object
ports_pins collection

ARGUMENTS

-clock *clock*

Removes delay information relative to the specified clock edge. You can specify the clock as either a string or a collection of one object.

To remove input delay that has no relative clock, use the **remove_input_delay -clock ""** command.

By default, all input delay information is removed.

-clock_fall

Removes input delay relative to the clock falling edge.

By default, input delay relative to the clock rising edge is removed.

This option is used only with the **-clock** option.

-level_sensitive

Removes level-sensitive input delay.

By default, only nonlevel-sensitive input delay is removed.

This option is used only with the **-clock** option.

-rise

Removes rising delay on the specified ports and pins.

If you do not specify either the **-rise** or **-fall** option, both rising and falling delays are removed.

-fall

Removes falling delay on the specified ports and pins.

If you do not specify either the **-rise** or **-fall** option, both rising and falling delays are removed.

-max

Removes maximum input delays on the specified ports and pins.

If you do not specify either the **-max** or **-min** option, both maximum and minimum input delays are removed.

-min

Removes minimum input delays on the specified ports and pins.

If you do not specify either the **-max** or **-min** option, both maximum and minimum input delays are removed.

ports_pins

Specifies the ports or pins from which to remove the input delay.

DESCRIPTION

This command removes input-delay values for the specified ports and pins.

You set the input delay by using the **set_input_delay** or **characterize** command. By default, all input delay is removed from the specified ports and pins. To restrict the input-delay values that are removed, use the **-clock**, **-clock_fall**, **-min**, **-max**, **-rise**, or **-fall** options.

Use the **report_port** command to list input delays associated with ports. Use the **report_design** command to list input delays of internal pins.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes all input-delay values from all input ports in the current design:

```
prompt> remove_input_delay [all_inputs]
```

The following example removes the maximum-rise input-delay values from the IN1, IN3, and BIDIR12 ports:

```
prompt> remove_input_delay -max -rise {IN1 IN3 BIDIR12}
```

The following example removes all input delay relative to the falling edge of CLK2 for port IN1:

```
prompt> remove_input_delay -clock [get_clocks CLK2] -clock_fall \
[get_ports IN1]
```

The following example removes all input delay not relative to any clock for port IN4:

```
prompt> remove_input_delay -clock "" IN4
```

SEE ALSO

```
all_inputs(2)
current_design(2)
remove_output_delay(2)
report_design(2)
report_port(2)
reset_design(2)
set_input_delay(2)
set_output_delay(2)
```

remove_isolate_ports

Removes the specified ports from the list of ports that are isolated in the current design.

SYNTAX

```
status remove_isolate_ports  
      port_list
```

Data Types

port_list list

ARGUMENTS

port_list

Specifies the ports that to remove from the list of ports that are isolated in the current design. Port isolation must have been requested for these ports using the **set_isolate_ports** command.

DESCRIPTION

The **remove_isolate_ports** command removes the specified ports from the list of ports that are isolated in the current design.

This command does not remove the isolation cell inserted by a previous **compile** command. The isolation cell will be removed by a subsequent **compile** command issued after the **remove_isolate_ports** command, if the **max_area** attribute has been set on the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the port named *qout* from the list of ports being isolated:

```
prompt> remove_isolate_ports qout
```

SEE ALSO

`report_isolate_ports(2)`
`reset_design(2)`
`set_isolate_ports(2)`
`set_max_area(2)`

remove_isolation_cell

Removes the specified isolation cells from the design.

SYNTAX

```
status remove_isolation_cell  
  [-force]  
  -object_list cells
```

Data Types

cells list

ARGUMENTS

-force

Forces deletion of ISO/ELS cells for cells marked with the **dont_touch** attribute.

-object_list *cells*

Specifies the list of cells to be removed. This option is required.

DESCRIPTION

The **remove_isolation_cell** command removes isolation cells or enables level shifters. This command can be used only on a unqualified design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all isolation cells with string ISO in their name:

```
prompt> remove_isolation_cell -obj [get_cells *ISO*]
```

SEE ALSO

`insert_isolation_cell(2)`

remove_keepout_margin

Removes keepout margin of specified type for the specified cells/lib cells in the design.

SYNTAX

```
int remove_keepout_margin  
  [-type hard | soft]  
  [-derived]  
  object_list
```

Data Types

object_list list

ARGUMENTS

-type hard | soft

Specifies the type of keepout to be removed. The valid values are **hard** and **soft**. By default, keepouts of both soft and hard types are removed for the cells or library cells.

-derived

This option is provided to remove the user specified pin count based derived keepout margin values. User defined pin count based keepout margin values are set using the -tracks_per_macro_pin and/or -max_padding_per_macro and/or -min_padding_per_macro options of **set_keepout_margin** command.

object_list

Describes the list of cells or library cells for which keepouts are to be removed. The keepouts are deleted for all cells with FIXED_PLACEMENT or library cells in this list.

DESCRIPTION

This command removes keepouts for the specified cells/library cells. If you do not use the **-type** option, keepouts of both soft and hard type are deleted for the specified cells/library cells. If this command is run to delete a keepout when none exists for a cell/library cell, a warning message is printed out and no action is taken.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **remove_keepout_margin** command.

```
prompt> report_keepout_margin MY_CELL -type hard
Cell Name: MY_CELL
*****
Hard Keepout - 10.0000 10.0000 10.0000 10.0000
prompt> remove_keepout_margin -type hard MY_CELL
prompt> report_keepout_margin MY_CELL -type soft
Cell Name: MY_CELL
*****
Soft Keepout - 10.0000 10.0000 10.0000 10.0000
prompt> remove_keepout_margin -type hard MY_LIB_CELL
The following example will remove all derived keepouts in the design.
prompt> remove_keepout_margin -derived *S
```

SEE ALSO

[get_attribute\(2\)](#)
[report_keepout_margin\(2\)](#)
[set_keepout_margin\(2\)](#)

remove_level_shifters

Removes all of the level shifters from the design.

SYNTAX

```
status remove_level_shifters  
[-force]
```

ARGUMENTS

-force

Removes level shifters even if they are set with the **dont_touch** attribute, or if they were instantiated in the original netlist.

DESCRIPTION

This command removes all level shifters from the design, except those that you explicitly marked as **dont_touch** and those that you instantiated in the original netlist. To remove level shifters that have these restrictions, use the **-force** option.

This command provides the capability to remove pre-existing or tool-inserted level shifters, allowing you to perform custom voltage adjustments by manually inserting different level-shifter cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command removes level shifters in a design:

```
prompt> remove_level_shifters
```

SEE ALSO

remove_libcell_subset

Removes target library family constraints from specified cells or removes a target library family defined by the **define_libcell_subset** command.

SYNTAX

```
status remove_libcell_subset
  [-object_list cells]
  [-family_name name]
```

Data Types

<i>cells</i>	list
<i>name</i>	string

ARGUMENTS

-object_list *cells*

Specifies the cells from which to remove the target library family. The cells must be either sequential cells or instantiated combinational cells. You must specify either **-object_list** or **-family_name**. If neither **-object_list** nor **-family_name** is specified, an error occurs and the command quits.

-family_name *name*

Specifies the target library family to be removed. You must specify either **-family_name** or **-object_list**. If neither **-family_name** nor **-object_list** is specified, an error occurs and the command quits.

DESCRIPTION

This command removes the target library family specified by the **set_libcell_subset** command from the cells to be optimized, or it removes a target library family defined by the **define_libcell_subset** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the target library family from the u1 sequential cell:

```
prompt> remove_libcell_subset -object_list [get_cells u1]
```

The following example removes the special_flops target library family:

```
prompt> remove_libcell_subset -family_name special_flops
```

SEE ALSO

```
remove_libcell_subset(2)
report_libcell_subset(2)
set_libcell_subset(2)
define_libcell_subset(2)
```

remove_license

Removes a licensed feature.

SYNTAX

```
status remove_license  
    feature_list  
    [-keep num_licenses]
```

Data Types

```
feature_list    list  
num_licenses    integer
```

ARGUMENTS

feature_list

Specifies the list of features to remove. If you specify more than one feature, the list must be enclosed in braces ({}).

By looking at your key file, you can determine all of the features licensed at your site.

-keep *num_licenses*

Specifies the number of licenses to be retained for each feature after the command has completed. If this option is not specified, all of the features' licenses are checked in.

DESCRIPTION

This command removes the specified licensed features from the features you are currently using.

For multicore runs, where multiple licenses might be required for certain features, you can use the **-keep** option to restrict the number of licenses that are checked in. This is analogous to the **get_license -quantity** option.

The **list_licenses** command provides a list of the features that you are currently using.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the multivoltage license:

```
prompt> remove_license Galaxy-MV
```

The following example removes some, but not all, of the licenses required for a multicore **compile_ultra** run in Design Compiler:

```
prompt> list_licenses
```

Licenses in use:

- DC-Expert (4)
- DC-Ultra-Features (4)
- DC-Ultra-Opt (4)
- Design-Compiler

1

```
prompt> remove_license -keep 2 {DC-Expert DC-Ultra-Opt DC-Ultra-Features}
```

1

```
prompt> list_licenses
```

Licenses in use:

- DC-Expert (2)
- DC-Ultra-Features (2)
- DC-Ultra-Opt (2)
- Design-Compiler

1

SEE ALSO

[check_license\(2\)](#)
[license_users\(2\)](#)
[list_licenses\(2\)](#)
[get_license\(2\)](#)

remove_link_library_subset

Removes the link library subset constraint from the top-level design or from the specified instances.

SYNTAX

```
status remove_link_library_subset
  [-object_list cells]
  [-top]
```

ARGUMENTS

-object_list *cells*

Specifies the cells from which to remove the link library subset. The cells must be instances of hierarchical designs, macros, or pads. You must specify **-top**, **-object_list**, or both options.

-top

Removes the link library subset from the top-level design. You must specify **-top**, **-object_list**, or both options.

DESCRIPTION

This command removes the link library subset from the specified instances or the top-level design. The subset was specified previously by the **set_link_library_subset** command.

Multicorner-Multimode Support

This command applies to the current scenario only. The command is scenario-specific, so it must be specified in each scenario where you want it to take effect.

EXAMPLES

The following example removes the link library subset from the top-level design and from the u1 instance:

```
prompt> remove_link_library_subset -object_list [get_cells u1] -top
```

SEE ALSO

```
report_link_library_subset(2)
set_link_library_subset(2)
link_library(3)
```

remove_min_pulse_width

Removes a previously specified minimum pulse width constraint from specified clocks or clock pins.

SYNTAX

```
status remove_min_pulse_width
  [-low]
  [-high]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-low

Removes the minimum pulse width constraint only for low clock pulses (high-low-high).

-high

Removes the minimum pulse width constraint only for high clock pulses (low-high-low).

If you do not specify the *-low* or *-high* option, the command removes the minimum pulse width constraint for all types of clock pulses.

object_list

Specifies a list of clocks or clock pins in the current design from which to remove the minimum pulse width constraint. If you specify a clock, all clock pins connected to the clock have their minimum pulse width constraints removed. If you do not specify any objects, the minimum pulse width check is removed from all objects in the current design.

DESCRIPTION

The **remove_min_pulse_width** command removes pulse width checks previously specified by the **set_min_pulse_width** command for clock signals at clock pins of sequential devices. This command removes the constraints in all scenarios.

To generate a report of pulse width constraints, use the **report_constraint** or **report_min_pulse_width** command.

EXAMPLES

remove_min_pulse_width

1421

The following example removes a minimum pulse width requirement previously set for clock CK1.

```
prompt> remove_min_pulse_width [get_clocks CK1]
```

The following example removes a minimum pulse width requirement previously set for pin reg1/CK.

```
prompt> remove_min_pulse_width reg1/CK
```

SEE ALSO

`report_constraint(2)`
`report_min_pulse_width(2)`
`set_min_pulse_width(2)`

remove_multibit

Removes the multibit components from the current design. Removes or detaches cells from the multibit components in a design.

SYNTAX

```
status remove_multibit  
      object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of multibit components, cells, designs and cell instances to remove or detach. The objects must be from the current design. This argument is required.

DESCRIPTION

This command deletes multibit components from the design and detaches cells or cell instances from multibit components.

Specify multibit components in the *object_list* to remove the component from the design. Specify cells or cell instances in the list to detach the cell from the multibit component in which the cell is contained. Specify design objects to remove all the multibit components of the given design.

When design objects are specified, multibit components are removed only from the scope of the specified design. This command doesn't recursively remove multibit components from the sub designs within the specified design.

All the cell instances that were detached from their multibit components will be marked with the `remove_multibit` attribute.

This command does not delete cells from the design; it only manipulates multibit components in the design.

This command requires that the design be linked. If an attempt to link the design fails, the command is terminated.

EXAMPLES

The following example shows the multibit component status on the current design before any changes are made:

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 2007.02
Date  : Fri Aug 29 10:01:19 2007
*****
```

Attributes:

b - black box (unknown)
 h - hierarchical
 n - noncombinational
 r - removable
 u - contains unmapped logic

Multibit Component : y_reg

Cell	Reference	Library	Area	Width	Attributes
y_reg[3]	**SEQGEN**		0.00	1	n, u
y_reg[2]	**SEQGEN**		0.00	1	n, u
y_reg[1]	**SEQGEN**		0.00	1	n, u
y_reg[0]	**SEQGEN**		0.00	1	n, u
Total 4 cells			0.00	4	

Multibit Component : z_reg

Cell	Reference	Library	Area	Width	Attributes
z_reg[3]	**SEQGEN**		0.00	1	n, u
z_reg[2]	**SEQGEN**		0.00	1	n, u
z_reg[1]	**SEQGEN**		0.00	1	n, u
z_reg[0]	**SEQGEN**		0.00	1	n, u
Total 4 cells			0.00	4	

Total 2 Multibit Components

This example first removes all multibit components and then shows the updated report:

```
prompt> remove_multibit ***
1

prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 2007.02
Date  : Fri Aug 29 10:01:19 2007
*****
```

Attributes:

b - black box (unknown)
 h - hierarchical
 n - noncombinational
 r - removable
 u - contains unmapped logic

Total 0 Multibit Components

This example first removes the specified cell from the multibit component. The component remains with its width reduced by 1. The example then shows the updated report:

```
prompt> remove_multibit z_reg[2]
```

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 2007.02
Date  : Fri Aug 29 10:01:19 2007
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- u - contains unmapped logic

report_compile_options(2)
report_multibit(2)
set_multibit_options(2)
```

remove_net

Removes nets from the current design.

SYNTAX

```
status remove_net  
    net_list | -all  
    [-only_physical]
```

Data Types

net_list list

ARGUMENTS

net_list

Specifies a list of nets to remove from the current design. Each net name must exist in the current design. You must specify either *net_list* or **-all**.

-all

Removes all nets in the current design. You must specify either **-all** or *net_list*.

-only_physical

Removes only physical nets in the current design. The physical nets are those nets that do not connect to a logical netlist.

DESCRIPTION

This command removes nets or net instances from the current design. Net connections to pins or ports are disconnected.

You cannot remove bused nets with the **remove_net** command. Use the **remove_bus** command to remove bused nets. Scalar (single bit) nets that are components of a bused net cannot be removed. You must remove bused nets first.

To create nets, use the **create_net** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the nets in the current design:

```
prompt> get_nets "*"
{NET0 NET1 NET2 NET3 MY_CHECK PARITY}

prompt> remove_net "N*"
Removing net 'NET0' in design 'my_design'.
Removing net 'NET1' in design 'my_design'.
Removing net 'NET2' in design 'my_design'.
Removing net 'NET3' in design 'my_design'.

prompt> get_nets "*"
{MY_CHECK PARITY}
```

The following example removes all remaining nets in the current design:

```
prompt> remove_net -all
Removing net 'MY_CHECK' in design 'my_design'.
Removing net 'PARITY' in design 'my_design'.

prompt> get_nets "*"
{}
```

The following example removes the physical nets:

```
prompt> remove_net -only_physical {physnet1 physnet2}
```

The following example removes a net instance:

```
prompt> remove_net {U1/MY_NET U2/MY_NET}
Removing net 'U1' in design 'mydesign_1'.
Removing net 'U2' in design 'mydesign_2'.
```

SEE ALSO

`create_net(2)`
`current_design(2)`
`remove_bus(2)`

remove_net_routing_layer_constraints

Removes the routing layer constraints for the specified nets.

SYNTAX

status **remove_net_routing_layer_constraints**
 list_of_nets

Data Types

list_of_nets collection

ARGUMENTS

list_of_nets

Specifies the nets for which to remove the routing layer constraints.

DESCRIPTION

This command removes the routing layer constraints for the specified nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the routing layer constraints for a net named netA.

```
prompt> remove_net_routing_layer_constraints {netA} \
```

SEE ALSO

`report_net_routing_layer_constraints(2)`
`set_net_routing_layer_constraints(2)`

remove_net_search_pattern

Removes a net search pattern or all net search patterns.

SYNTAX

```
status remove_net_search_pattern  
-pattern id | -all
```

Data Types

id integer

ARGUMENTS

-pattern *id*

Specifies a pattern ID that you want to remove. When a pattern ID is removed, the corresponding delay estimation options specified for the search pattern by the **set_net_search_pattern_delay_estimation_options** command are also removed.

-all

Eliminates all search patterns in a design. When you specify the **-all** option, all delay estimation options that were specified by the **set_net_search_pattern_delay_estimation_options** command are removed.

DESCRIPTION

The **remove_net_search_pattern** command will remove either a specified net search pattern (using **-pattern**) or all net search patterns (using **-all**).

Once a pattern ID is removed, it cannot be reused. For example, if you have 10 existing patterns and you remove pattern ID 7 by using the **remove_net_search_pattern -pattern 7** command, even though pattern ID 7 is now empty, the next time you create a net search pattern, the pattern ID will be 11.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Here are some examples of how you can use the **remove_net_search_pattern** command:

```
prompt> remove_net_search_pattern -pattern 7
prompt> remove_net_search_pattern -all
```

SEE ALSO

[create_net_search_pattern\(2\)](#)

[set_net_search_pattern_delay_estimation_options\(2\)](#)
[report_net_search_pattern_delay_estimation_options\(2\)](#)
[set_net_search_pattern_priority\(2\)](#)
[report_net_search_pattern_priority\(2\)](#)
[get_matching_nets_for_pattern\(2\)](#)

remove_net_shape

Removes all net shapes in the current design.

SYNTAX

```
status remove_net_shape  
    net_shapes  
    [-verbose]
```

ARGUMENTS

The **remove_net_shape** command has no arguments.

DESCRIPTION

This command removes all net shapes in the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all net shapes in the current design. The current design has only two net shapes:

```
prompt> remove_net_shape  
Removed net shape HWIRE#7170.  
Removed net shape HWIRE#7171.  
1
```

SEE ALSO

[create_net_shape\(2\)](#)
[remove_user_shape\(2\)](#)

remove_ocvm

Removes parametric on-chip variation (POCV) derating previously set with the **read_ocvm** command.

SYNTAX

```
status remove_ocvm
  [-coefficient]
  [-derate]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-coefficient

This option is not used in the Design Compiler tool.

-derate

This option is not used in the Design Compiler tool.

object_list

Causes the POCV coefficients set on the cells or library cells in the *object_list* to be removed.

DESCRIPTION

This command removes user-specified parametric on-chip variation (POCV) coefficients that were previously set by the **read_ocvm** command. If the command is specified with no options, all POCV coefficients are removed.

To report the POCV derating information that has been set, use the **report_ocvm** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes the random advanced OCV coefficients from the library cell named *lib/bufA*:

```
prompt> remove_ocvm -coefficient lib/bufA
```

The following example removes all advanced OCV derate factors that were set using the **read_ocvm** command:

```
prompt> remove_ocvm -derate
```

The following example removes all advanced OCV derate factors from the current design:

```
prompt> remove_ocvm -derate [current_design]
```

SEE ALSO

[read_ocvm\(2\)](#)
[remove_ocvm\(2\)](#)
[report_ocvm\(2\)](#)
[timing_pocvm_corner_sigma\(3\)](#)
[timing_pocvm_enable_analysis\(3\)](#)

remove_output_delay

Removes output delay on pins or output ports.

SYNTAX

```
status remove_output_delay
  [-clock clock [-clock_fall] [-level_sensitive]]
  [-rise]
  [-fall]
  [-max]
  [-min]
  port_pin_list
```

Data Types

clock string or collection of one object
port_pin_list list

ARGUMENTS

-clock *clock*

Removes delay information relative to the specified clock edge. If **-clock** is not specified, all output delay is removed. To remove output delay that has no relative clock, use **remove_output_delay -clock ""**.

You can specify the clock as either a string or a collection of one object.

-clock_fall

Removes output delay relative to the clock falling edge. If you do not specify **-clock_fall**, output delay relative to the clock rising edge is removed.

This option is only used with the **-clock** option.

-level_sensitive

Removes level-sensitive output delay for the specified clock. If this option is not used, nonlevel-sensitive output delay is removed.

-rise

Removes rising delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-fall

Removes falling delay on *port_pin_list*. If you do not specify **-rise** or **-fall**, both rising and falling delays are removed.

-max

Removes maximum output delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum output delays are removed.

-min

Removes minimum output delays on *port_pin_list*. If you do not specify **-max** or **-min**, both maximum and minimum output delays are removed.

port_pin_list

Specifies a list of port or pin names in the current design. Output delay is removed from each object in *port_pin_list*. To specify more than one object, enclose the objects in quotes ("") or braces ({}).

DESCRIPTION

This command removes output delay values for objects in the current design. Output delay is set by the **set_output_delay** or the **characterize** command. By default, all output delay on each object in *port_pin_list* is removed. To restrict the removed output delay values, use the **-clock**, **-clock_fall**, **-min**, **-max**, **-rise**, or **-fall** option.

To list output delays associated with ports, use the **report_port** command.

To list output delays of internal pins, use the **report_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes all output-delay values from all output ports in the current design:

```
prompt> remove_output_delay [all_outputs]
```

This example removes output maximum-rise delay values from the OUT1, OUT3, and BIDIR12 ports:

```
prompt> remove_output_delay -max -rise {OUT1 OUT3 BIDIR12}
```

This example removes all output delays for port OUT1, relative to the falling edge of CLK2:

```
prompt> remove_output_delay -clock [get_clocks CLK2] \
    -clock_fall [get_ports OUT1]
```

This example removes all output-delay values not relative to any clock for the OUT2 port:

```
prompt> remove_output_delay -clock "" OUT2
```

SEE ALSO

remove_path_group

Removes a list of path groups from the current design.

SYNTAX

```
string remove_path_group  
      group_list
```

Data Types

group_list list

ARGUMENTS

group_list

Specifies the path groups to remove.

DESCRIPTION

The **remove_path_group** command removes a list of path groups from the current design.

Path groups control the optimization cost function and timing reports. You can see what path groups remain in the design by using the **get_path_groups** command.

To create other path groups, use the **group_path** command.

EXAMPLES

The command set below first creates two path groups named *grp1* and *grp2*, and then removes the groups:

```
prompt> group_path -name grp1 -to data_out  
1  
prompt> group_path -name grp2 -from input3 -to data_out  
1  
prompt> remove_path_group {grp1 grp2}  
1
```

SEE ALSO

`group_path(2)`
`report_path_group(2)`

remove_pin_guides

Removes all pin guides from the design.

SYNTAX

```
status remove_pin_guides
    -all | patterns
    [-verbose]
```

ARGUMENTS

-all

Removes all pin guides.

-verbose

Enables verbose output.

DESCRIPTION

This command deletes the pin guides from the design. Design Compiler in topographical mode does not support the removal of pin guides by name. Use the **-all** option to remove all pin guides in the design, or use the following command:

```
prompt> remove_pin_guides *
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all pin guides:

```
prompt> remove_pin_guides -all
```

SEE ALSO

remove_pin_map

Removes a design port-to-package pin mapping for a boundary-scan design.

SYNTAX

```
status remove_pin_map  
    package_name
```

Data Types

package_name string

ARGUMENTS

package_name

Specifies the name of the package in a port-to-pin mapping file read in for the design. The package name must match one of the package names specified in a port-to-pin mapping file previously read using the **read_pin_map** command.

DESCRIPTION

The **remove_pin_map** command allows you to delete a port-to-pin mapping for a boundary-scan design read in through the **read_pin_map** command.

Use the **report_packages** command to list the package names of the port-to-pin mappings files that you read in for the current design.

EXAMPLES

The following example deletes a design port-to-package pin mapping named *test_pkg* for a boundary-scan design:

```
prompt> remove_pin_map test_pkg
```

SEE ALSO

[get_attribute\(2\)](#)
[read_pin_map\(2\)](#)

remove_pin_name_synonym

Removes pin name synonym definitions.

SYNTAX

```
status remove_pin_name_synonym
  [-all]
  [synonym_list]
```

Data Types

synonym_list list

ARGUMENTS

-all

Removes all pin name synonym definitions. You must specify either the **-all** option or the *synonym_list* argument. The option and argument are mutually exclusive.

synonym_list

Removes pin name synonym definitions that match one of the pin name synonym strings in the list. You must specify either the **-all** option or the *synonym_list* argument. The option and argument are mutually exclusive.

DESCRIPTION

The **remove_pin_name_synonym** command deletes some or all pin name synonym definitions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples set and remove pin name synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD
1
prompt> set_pin_name_synonym SYN_QN QN
```

`set_pin_name_synonym(2)`

remove_placement_blockage

Removes placement blockages.

SYNTAX

```
status remove_placement_blockage
  patterns | -name name | -all
  [-verbose]
```

Data Types

<i>patterns</i>	collection
<i>name</i>	string

ARGUMENTS

patterns

Specifies the pattern by which this command finds and removes a placement blockage. The patterns can be a collection of blockages, or other formats, such as * or pb#* (removes all placement blockages) or pb#7789 (removes one placement blockage whose *object_id* is 7789).

The *patterns* argument, the **-name** option, and the **-all** option are mutually exclusive.

-name *name*

Specifies a name by which this command finds and removes a placement blockage. The name must be the same name specified for the placement blockage when it was created with the **create_placement_blockage** command. The name must not be a runtime name, such as pb#7789.

The *patterns* argument, the **-name** option, and the **-all** option are mutually exclusive.

-all

Removes all placement blockages in the current design.

The *patterns* argument, the **-name** option, and the **-all** option are mutually exclusive.

-verbose

Prints additional messages.

DESCRIPTION

This command removes all specified placement blockages.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all placement blockages:

```
prompt> remove_placement_blockage -all
```

The following example uses the *patterns* argument to remove placement blockages:

```
prompt> remove_placement_blockage \
[get_placement_blockages * -within {{2 2} {25 25}}]
```

SEE ALSO

`create_placement_blockage(2)`
`create_route_guide(2)`
`remove_route_guide(2)`

remove_port

Removes ports from the current design or its subdesign.

SYNTAX

```
status remove_port  
    port_list
```

Data Types

port_list list

ARGUMENTS

port_list

Specifies a list of ports to be removed from the current design. Each port name must exist in the current design.

DESCRIPTION

This command removes ports from the current design or its subdesign. Bused ports cannot be removed with **remove_port**; use **remove_bus** to remove bused ports. Also, scalar (single bit) ports that are components of a bused port cannot be removed. In this case, you must first remove the bused port.

To create ports, use the **create_port** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **remove_port** to remove ports from the current design:

```
prompt> get_ports ***  
{A1 A2, B1, B2, OUT1}  
  
prompt> remove_port "B**"  
Removing port 'B1' in design 'my_design'.  
Removing port 'B2' in design 'my_design'.  
1
```

```
prompt> get_ports ***
{A1 A2 OUT1}
```

In the following example, ports are removed from the subdesign *MID*. *U1* is an instance of the design *MID*.

```
prompt> remove_port [get_ports U1/p1 U1/p2]
Removing port 'U1/p1' in design 'MID'.
Removing port 'U1/p2' in design 'my_design'.
1
```

SEE ALSO

[create_port\(2\)](#)
[current_design\(2\)](#)
[remove_bus\(2\)](#)
[remove_unconnected_ports\(2\)](#)

remove_power_domain

Removes the specified power domains.

SYNTAX

```
status remove_power_domain  
    power_domains | -all
```

Data Types

power_domains collection

ARGUMENTS

power_domains

Specifies the power domains to be deleted. The name must be a simple (non-hierarchical) name.

This option is mutually exclusive with the **-all** option.

-all

Deletes all power domains in the current design. This option is mutually exclusive with the *power_domains* argument.

DESCRIPTION

The **remove_power_domain** command removes existing power domains. Before you can delete a power domain, you must remove all relationships between the power domain and any supply ports, supply nets, power switches, or child power domains.

The command fails if it cannot find any specified power domains or if there are any supply ports, supply nets, or power switches associated with the specified power domains.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the PD1 power domain:

```
prompt> remove_power_domain PD1
```

1

The following example removes power domains whose name start with PD:

```
prompt> remove_power_domain [get_power_domains -hierarchical PD*]  
1
```

SEE ALSO

`create_power_domain(2)`
`get_power_domains(2)`
`report_power_domain(2)`
`set_scope(2)`

remove_preferred_routing_direction

Removes the preferred routing direction for the given routing layers.

SYNTAX

```
string remove_preferred_routing_direction  
-layers list_of_layers
```

ARGUMENTS

-layers *list_of_layers*

Specifies the list or collection of layers for which the preferred routing directions are to be removed.

DESCRIPTION

This command removes the preferred routing direction for the routing layers specified from the design and the preferred routing direction for those routing layers that default to the one specified in the reference library.

This command issues a warning for layers that do not have a defined preferred routing direction in the reference library, since at least one preferred routing direction setting must exist for each layer.

The command issues appropriate warnings after the command is run when adjacent layers have the same routing direction after the execution of the command.

The command removes the setting from the design, and not the reference library. The change is to the persistent data and is reflected in the design database when the design is saved.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the preferred routing direction for layers *m1* and *m2*:

```
prompt> remove_preferred_routing_direction -layers {m5 m6}
```

SEE ALSO

`report_preferred_routing_direction(2)`
`set_preferred_routing_direction(2)`

remove_propagated_clock

Removes propagated clock latency previously set with the **set_propagated_clock** command, which restores ideal clock latency for the specified objects.

SYNTAX

```
status remove_propagated_clock  
-all | object_list
```

Data Types

object_list collection

ARGUMENTS

-all

Removes propagated clocking from all objects in the current scenario.

object_list

Specifies the clocks, ports, or pins from which to remove the propagated clock specification.

DESCRIPTION

This command removes propagated clocking previously set by the **set_propagated_clock** command from all objects or from specified clocks, ports, or pins in the current scenario. This restores ideal clocking for the specified objects.

Ideal clocking means clock networks have a specified latency (from the **set_clock_latency** command), or zero latency by default. Latency is the amount of time a clock signal takes to be propagated from the ideal waveform origin point to the clock pin of the sequential device.

Propagated clock latency is used for after final clock tree generation and layout. Ideal clock latency specifies a prelayout estimate of the clock tree delay.

You can override the propagated clock specification for an object by specifying an ideal latency for the object with the **set_clock_latency** command.

To report propagated clock attributes on clocks, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes propagated clock specification set on all clocks in the current scenario:

```
prompt> remove_propagated_clock [all_clocks]
```

To remove propagated clock specification set on all clocks, ports, and pins in the current scenario, use the **remove_propagated_clock -all** command.

SEE ALSO

[remove_attribute\(2\)](#)
[report_clock\(2\)](#)
[reset_design\(2\)](#)
[set_clock_latency\(2\)](#)
[set_propagated_clock\(2\)](#)

remove_route_guide

Removes the specified route guides.

SYNTAX

```
status remove_route_guide
  [-verbose]
  -name route_guide_name | -all | patterns
```

Data Types

<i>route_guide_name</i>	string
<i>patterns</i>	collection

ARGUMENTS

-verbose

Prints additional messages.

-name *route_guide_name*

Specifies the name of the route guide to remove.

The name must be the same name you used when you created the route guide with the **create_route_guide** command. Do not use a runtime name, such as "rg#7689".

This option is mutually exclusive with the *patterns* argument and the **-all** option, but you must specify one.

-all

This option removes all route guides in the current design.

This option is mutually exclusive with the **-name** option and the *patterns* argument, but you must specify one.

patterns

Specifies the route guides to remove. The patterns can be a collection of route guides or other formats, such as the following:

- * or rg* removes all route guides
- rg#7789 removes one route guide whose object_id is 7789

This argument is mutually exclusive with the **-name** and **-all** options, but you must specify one.

DESCRIPTION

The **remove_route_guide** command removes the specified route guides.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the route guides specified by the **get_route_guides** command:

```
prompt> remove_route_guide [get_route_guides -within {{2 2} {25 25}}]  
1
```

The following example removes all route guides:

```
prompt> remove_route_guide -all  
1
```

SEE ALSO

`create_placement_blockage(2)`
`create_route_guide(2)`
`get_placement_blockages(2)`
`remove_placement_blockage(2)`

remove_routing_rules

Removes nondefault routing rules in a design defined by the **define_routing_rule** command.

SYNTAX

```
int remove_routing_rules  
  [-all]  
  rule_name_list
```

Data Types

rule_name_list list

ARGUMENTS

-all

Removes all nondefault routing rules.

rule_name_list

Removes nondefault routing rules with the specified names.

DESCRIPTION

This command removes the nondefault routing rules defined in the design. If you use the **-all** option, all nondefault routing rules in the design are removed. If you specify a list of names, the nondefault routing rules in the list are removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the nondefault routing rule named *wire_rule1*.

```
prompt> remove_routing_rules wire_rule1
```

SEE ALSO

`define_routing_rule(2)`
`report_routing_rules(2)`

remove_rp_group_options

Removes relative placement (RP) group attributes from the specified relative placement groups.

SYNTAX

collection **remove_rp_group_options**

```
  rp_groups
  [-ignore]
  [-x_offset]
  [-y_offset]
  [-cell_orient_opt]
  [-auto_blockage]
  [-disable_buffering]
  [-allow_non_rp_cells]
  [-ignore_rows]
  [-max_rp_width]
  [-max_rp_height]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups from which to remove the specified relative placement group attributes.

-ignore

Removes the **-ignore** attribute, which indicates that the tool is to ignore this relative placement group during placement and not treat it as a relative placement group.

-x_offset

Removes the **-x_offset** attribute of the relative placement group.

-y_offset

Removes the **-y_offset** attribute of the relative placement group.

-cell_orient_opt

Removes the **-cell_orient_opt** attribute of the relative placement group.

-auto_blockage

Removes the **-auto_blockage** attribute of the relative placement group.

-disable_buffering

Removes the **-disable_buffering** attribute of the relative placement group.

-allow_non_rp_cells

Removes the **-allow_non_rp_cells** attribute of the relative placement group.

-ignore_rows

Removes the **-ignore_rows** attribute of the relative placement group.

-max_rp_width

Removes the **-max_rp_width** attribute of the relative placement group.

-max_rp_height

Removes the **-max_rp_height** attribute of the relative placement group.

DESCRIPTION

This command removes the attributes of the relative placement groups. This command is supported only for designs that do not contain multiply-instantiated designs. This command returns a collection containing the relative placement groups for which attributes have changed. If attributes have not changed for any group, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes attributes from a relative placement group:

```
prompt> remove_rp_group_options ripple::grp_ripple -ignore \
           -x_offset -y_offset
{ripple::grp_ripple}
```

SEE ALSO

`add_to_rp_group(2)`
`all_rp_groups(2)`
`create_rp_group(2)`
`get_rp_groups(2)`
`remove_from_rp_group(2)`
`remove_rp_groups(2)`
`set_rp_group_options(2)`
`write_rp_groups(2)`

remove_rp_groups

Removes a list of relative placement (RP) groups.

SYNTAX

```
status remove_rp_groups
  rp_groups | -all
  [-hierarchy]
  [-quiet]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies a list of relative placement groups to remove.

This argument and the **-all** option are mutually exclusive.

-all

Specifies that all relative placement groups will be removed.

This option cannot be used with either the *rp_groups* argument or the **-hierarchy** option.

-hierarchy

Specifies that all relative placement groups within the hierarchy of the groups in *rp_groups* will be removed. By default, subgroups are not removed.

This option cannot be used with the **-all** option.

-quiet

Turns off messages that would otherwise be issued as relative placement groups are removed.

DESCRIPTION

The **remove_rp_groups** command removes a list of relative placement groups. When a relative placement group is removed, the memory it occupies is freed, so the object is no longer in the design.

Relative placement usage is available with Design Compiler Ultra.

Note that memory is freed to be reused by this same process. However, memory is not returned to the operating system until you exit

the tool.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **remove_rp_groups** to delete a relative placement group.

```
prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> remove_rp_groups ripple::grp_ripple
Removing rp group 'ripple::grp_ripple'
1

prompt> get_rp_groups ripple::grp_ripple
Error: Can't find object 'grp_ripple'. (UID-109)

prompt> remove_rp_groups -all
Removing rp group 'mul::grp_mul'
Removing rp group 'example3::top_group'
1
```

SEE ALSO

[add_to_rp_group\(2\)](#)
[create_rp_group\(2\)](#)
[write_rp_groups\(2\)](#)

remove_rtl_load

Removes previously-set capacitance and resistance RTL load values from pins, ports, and nets.

SYNTAX

```
status remove_rtl_load  
    -all | pin_net_list
```

Data Types

pin_net_list list

ARGUMENTS

-all

Specifies that all RTL loads in the current design are to be removed. You must specify either **-all** or *pin_net_list*, but not both.

pin_net_list

Specifies a list of ports, pins, and nets in the current design whose RTL loads are to be removed. You must specify either **-all** or *pin_net_list*, but not both.

DESCRIPTION

The **remove_rtl_load** command removes RTL load information, previously annotated by the **set_rtl_load** or **calculate_rtl_load** command, from the specified objects or from all objects in the current design. If a net is specified, the RTL loads are removed from all pins of the net.

The **reset_design** command removes all attributes from the current design, including all capacitance and resistance RTL load values.

EXAMPLES

The following example removes RTL load values from each of the specified pins and ports:

```
prompt> remove_rtl_load {my_port my_ram/ADDR[*]}
```

The following example removes RTL load values from the pins of the net named *net1*:

```
prompt> remove_rtl_load my_hier/net1
```

The following example removes all RTL loads from the current design:

```
prompt> remove_rtl_load -all
```

SEE ALSO

`current_design(2)`
`reset_design(2)`
`set_rtl_load(2)`

remove_safety_core_groups

Removes safety core groups from the current design.

SYNTAX

```
status remove_safety_core_groups  
-all | group_names
```

Data Types

group_names list

ARGUMENTS

-all

Removes all the safety_core_groups defined in the current design.

group_names

Specifies the group names which need to be removed

DESCRIPTION

Removes (deletes) the specified groups from the current design.

SEE ALSO

[create_safety_core_group\(2\)](#)
[report_safety_core_groups\(2\)](#)

remove_safety_core_rules

Removes safety core rules from the current design.

SYNTAX

```
status remove_safety_core_rules
  [-all]
  [rule_names]
```

Data Types

rule_names list

ARGUMENTS

-all

Removes all the safety_core_rules defined in the current design.

rule_names

Specifies the rule names which need to be removed

DESCRIPTION

Removes the specified rules from the current design. If the specified rules are being referenced by any safety_core_group, the command will error out with an appropriate warning.

SEE ALSO

[create_safety_core_rule\(2\)](#)
[report_safety_core_rules\(2\)](#)

remove_safety_error_code_groups

Removes safety error code groups from the current design.

SYNTAX

```
status remove_safety_error_code_groups  
  [names]  
  [-all]
```

Data Types

names string

ARGUMENTS

names

Specifies the group names, which need to be removed.

-all

Removes all the safety_error_code_group defined in the current design.

DESCRIPTION

This command removes or deletes the specified group from the current design.

EXAMPLES

The following example deletes the specified safety_error_code_group.

```
prompt> remove_safety_error_code_groups group1
```

SEE ALSO

[create_safety_error_code_group\(2\)](#)
[report_safety_error_code_groups\(2\)](#)

remove_safety_error_code_rules

Removes safety error code rules from the design.

SYNTAX

```
status remove_safety_error_code_rules  
  [names]  
  [-all]
```

Data Types

names string

ARGUMENTS

names

Specifies the rule names, which need to be removed.

-all

Removes all the safety_error_code_rule defined in the current design.

DESCRIPTION

This command removes the specified rule from the design. If the specified rules are being referenced by any safety_error_code_group, the command displays error.

EXAMPLES

The following deletes the specified safety_error_code_rule.

```
prompt> remove_safety_error_code_rules rule1
```

SEE ALSO

[create_safety_error_code_rule\(2\)](#)

[remove_safety_error_code_rules](#)

1468

report_safety_error_code_rules(2)

remove_safety_register_groups

Removes safety register groups from the current design.

SYNTAX

```
status remove_safety_register_groups  
  [group_names]  
  [-all]
```

Data Types

group_names list

ARGUMENTS

group_names

Specifies the group names which need to be removed

-all

Removes all the safety_register_group defined in the current design.

DESCRIPTION

Removes (deletes) the specified groups from the current design.

EXAMPLES

The following example deletes the safety_register_group group1.

```
prompt> remove_safety_register_groups group1-
```

SEE ALSO

`create_safety_register_group(2)`
`report_safety_register_groups(2)`

`write_safety_register_data(2)`

remove_safety_register_rules

Removes safety register rules from the current design.

SYNTAX

```
status remove_safety_register_rules
  [rule_names]
  [-all]
```

Data Types

rule_names list

ARGUMENTS

rule_names

Specifies the rule names which need to be removed

-all

Removes all the safety_register_rules defined in the current design.

DESCRIPTION

Removes the specified rules from the current design. If the specified rules are being referenced by any safety_register_group, the command will error out with an appropriate warning.

SEE ALSO

[create_safety_register_rule\(2\)](#)
[report_safety_register_rules\(2\)](#)
[write_safety_register_data\(2\)](#)

remove_scaling_lib_group

Removes any previously specified scaling library group from the current design or from a subdesign.

SYNTAX

```
status remove_scaling_lib_group  
[-object_list objects]
```

Data Types

objects list

ARGUMENTS

-object_list *objects*

Specifies the cells or top-level ports from which to remove any requested scaling library groups. If you do not use this option, groups are removed from the top-level design.

DESCRIPTION

The **remove_scaling_lib_group** command removes the scaling library group set on the design objects that was previously by **set_scaling_lib_group** commands. After this removal, the tool will not perform scaling between libraries for voltage and/or temperature.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **remove_scaling_lib_group** command:

```
prompt> remove_scaling_lib_group -object_list top/inv
```

SEE ALSO

[remove_scaling_lib_group](#)

1473

```
create_scenario(2)
define_scaling_lib_group(2)
set_operating_conditions(2)
set_scaling_lib_group(2)
```

remove_scan_group

Removes an existing scan-group specification previously specified using the **set_scan_group** command.

SYNTAX

```
status remove_scan_group  
      scan_group_name
```

Data Types

scan_group_name string

ARGUMENTS

scan_group_name

Specifies the name of the scan group. The scan group must be a scan group previously defined using the **set_scan_group** command.

DESCRIPTION

This command removes an existing scan-group specification previously specified using the **set_scan_group** command.

The **remove_scan_group** command cannot remove scan groups under these two circumstances:

- The scan group you want to remove has not been previously defined using the **set_scan_group** command.
- The scan group you want to remove was included in a **set_scan_path** specification.

In such cases, **remove_scan_group** exits with a warning.

EXAMPLES

The following is an example of the **remove_scan_group** command:

```
prompt> remove_scan_group my_shift_reg
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`report_scan_group(2)`
`set_scan_group(2)`

remove_scan_link

Removes a scan-link specification for the current design.

SYNTAX

```
status remove_scan_link
  scan_link_name
  Wire | Lockup
  [-test_mode test_mode]
```

Data Types

<i>scan_link_name</i>	string
<i>test_mode</i>	string

ARGUMENTS

scan_link_name

Specifies the name of the scan link to be removed from the specification.

{Wire | Lockup}

Specifies the scan link type. **Wire** specifies a wire-scan link type. **Lockup** specifies a lock-up latch-scan link type.

-test_mode *test_mode*

Specifies the test mode of the specification. The default is *current_mode*.

DESCRIPTION

The **remove_scan_link** command removes a scan link specified through the **set_scan_link** command. Scan links connect scan cells, scan segments, and scan ports within scan chains. The tool supports scan links that are implemented as wires and scan-out, and lock-up latches.

The **scan_link_name** option must uniquely identify the scan link as a design object.

To see the scan links specified, use the **report_scan_link** command.

To review the scan link specifications, use the **preview_dft** command with the **-show** option set to **cells**.

To create scan links and add them to the current design, use the **insert_dft** command.

EXAMPLES

The following example declares a scan-out, lock-up latch named *a_lckup* and then removes it with **remove_scan_link**:

```
prompt> current_design WC66
prompt> set_scan_link a_lckup Lockup
prompt> remove_scan_link a_lckup Lockup
```

SEE ALSO

[set_dont_touch\(2\)](#)
[set_scan_configuration\(2\)](#)
[set_scan_element\(2\)](#)
[set_scan_link\(2\)](#)
[set_scan_path\(2\)](#)
[write\(2\)](#)

remove_scan_path

Removes the scan-path specification for the current design in **set_scan_path**.

SYNTAX

```
status remove_scan_path
  -chain scan_chain_name
  [-view existing_dft | spec]
  [-test_mode test_mode]
```

Data Types

scan_chain_name	string
test_mode	string

ARGUMENTS

-chain *scan_chain_name*

Specifies to use the scan path name provided, which must be a valid, existing scan-path name. If you do not specify a chain name, the command generates an error.

-view *existing_dft | spec*

Indicates the view to which the specification applies. When you specify **-view existing_dft**, the specification removal refers to the existing usage of a scan chain. This is used when working with DFT-inserted designs. For example, to inform the tool that chain A is being removed, use the following command:

```
prompt> remove_scan_path -chain A -view existing_dft
```

When you specify **-view spec**, the default for **-view**, the specification refers to scan chains that the tool must use during DFT insertion. For example, to instruct the tool to remove scan chain A, use the following command:

```
prompt> remove_scan_path -chain A -view spec
```

-test_mode *test_mode*

Specifies the mode to which the specification applies. The default mode is *Internal_scan*. Specifying **all** to make the specification apply to all modes. Any mode other than the default mode or **all** must be created prior to use.

EXAMPLES

The following example sets a scan path using **set_scan_path** and then removes the scan path using **remove_scan_path** the spec view:

```
prompt> current_design core
```

```
prompt> set_scan_path 1 -view spec  
prompt> remove_scan_path -view spec -chain 1
```

remove_scan_register_type

Removes existing scan-register types, previously set by **set_scan_register_type**, from specified cells or from the current design.

SYNTAX

```
status remove_scan_register_type  
[cell_or_design_list]
```

Data Types

cell_or_design_list list

ARGUMENTS

cell_or_design_list

Lists the names of cells or designs from which to remove the **-type** scan-register type specification. The default is the current design. Cells or designs on this list must already have had the **-type** specification placed on them by the **set_scan_register_type** command.

DESCRIPTION

The **remove_scan_register_type** command removes existing scan-register types set on specified cells or designs by the **set_scan_register_type** command. The register types are removed without changing the design.

If you invoke **remove_scan_register_type** without any options, the specification on the current design is removed.

To determine the current settings resulting from the previous use of the **set_scan_register_type** command, use the **report_scan_register_type** command.

EXAMPLES

The following example sets and then removes a **-type** specification on the cell *U1*:

```
prompt> set_scan_register_type -type {FD1S} U1  
prompt> remove_scan_register_type U1
```

SEE ALSO

`current_design(2)`
`set_scan_register_type(2)`

remove_scan_replacement

Removes the table entries specified through the **set_scan_replacement** command.

SYNTAX

```
status remove_scan_replacement  
[non_scan_seq_cell_list]
```

Data Types

non_scan_seq_cell_list list

ARGUMENTS

non_scan_seq_cell_list

Specifies a list of valid cells in the library that have entries in the scan-replacement table (entries are placed in the scan-replacement table by the **set_scan_replacement** command).

DESCRIPTION

The **remove_scan_replacement** command removes the scan-replacement entries for the cells in the *non_scan_seq_cell_list* from the scan-replacement table. The scan-replacement table contains one-to-one mappings of flip-flops to their equivalent scan flip-flops from the target library that are to be used by **insert_dft** or **compile -scan** when scan-replacing cell instances.

The scan replacement table entries are added by the **set_scan_replacement** command. Both **compile -scan** and **insert_dft** use this mapping table to do scan replacement. You can see the scan replacement table entries with the **report_scan_replacement** command.

EXAMPLES

In the following example, all entries for *FD1* are removed:

```
prompt> remove_scan_replacement FD1
```

SEE ALSO

```

remove_scan_skew_group

Removes scan skew groups defined by the **set_scan_skew_group** command.

SYNTAX

```
status remove_scan_skew_group  
      scan_skew_group_list
```

Data Types

scan_skew_group_list list

ARGUMENTS

scan_skew_group_list

Specifies the list of scan skew groups to remove. Wildcards are not supported.

DESCRIPTION

This command removes the specified scan skew groups, which were previously defined by the **set_scan_skew_group** command.

EXAMPLES

Consider a case where three scan skew groups are initially defined:

```
prompt> report_scan_skew_group  
*****  
Report : Scan Skew Group  
Design : top  
Version: J-2014.09  
Date  : Wed Jul 9 06:37:41 2014  
*****  
=====  
TEST MODE: all_dft  
VIEW   : Specification  
=====  
Scan_skew_group  
-----
```

Number of user-defined scan skew groups: 3
G1
G2
G3

To remove two of these scan skew groups, use the following command:

```
prompt> remove_scan_skew_group {G1 G3}
```

Now, only a single scan skew group remains:

```
prompt> report_scan_skew_group
```

```
*****
```

Report : Scan Skew Group

Design : top

Version: J-2014.09

Date : Wed Jul 9 06:37:41 2014

```
*****
```

```

remove_scan_suppress_toggling

Removes the existing user specifications that were provided through the **set_scan_suppress_toggling** command in terms of a list of scan flip-flops to be gated by the **insert_dft** command.

SYNTAX

```
status remove_scan_suppress_toggling
```

ARGUMENTS

The **remove_scan_suppress_toggling** command has no arguments.

DESCRIPTION

The **remove_scan_suppress_toggling** command removes all of the existing specifications provided through the **set_scan_suppress_toggling** command.

EXAMPLES

The following example shows how to issue the **remove_scan_suppress_toggling** command:

```
prompt> remove_scan_suppress_toggling
```

SEE ALSO

insert_dft(2)
report_scan_suppress_toggling(2)
set_scan_suppress_toggling(2)

remove_scenario

Removes the specified scenarios from memory.

SYNTAX

```
status remove_scenario  
    scenario_name | -all
```

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the name of the scenario to be deleted. You can specify only a single scenario. Wildcard characters are not supported. The scenario can be either an active or an inactive scenario.

This argument and the **-all** option are mutually exclusive; you must specify one.

-all

Specifies that all scenarios, both active and inactive, are to be deleted.

This option and the *scenario_name* argument are mutually exclusive; you must specify one.

DESCRIPTION

This command removes the specified scenario or all scenarios from memory. The command deletes all scenario-specific constraints defined in those scenarios.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example uses the **remove_scenario** command to delete all scenarios:

```
prompt> create_scenario MODE1
```

```
prompt> create_scenario MODE2
```

```
prompt> all_scenarios  
MODE 1 MODE 2
```

```
prompt> remove_scenario -all
```

```
prompt> all_scenarios
```

[current_scenario\(2\)](#)

remove_sdc

Removes all Synopsys Design Constraints (SDC).

SYNTAX

```
status remove_sdc
      [-keep_parasitics]
```

ARGUMENTS

-keep_parasitics

Specifies that the RC network has been created and it does not need to be removed.

DESCRIPTION

This command removes all constraints as defined in the current version of Synopsys Design Constraints.

The removal of annotated parasitics is expected when using the **remove_sdc** command. If you need this information after removing SDC information, reannotate the parasitics data by rerunning the **extract_rc** or **read_parasitics** command.

Multicorner-Multimode Support

This command applies to all active scenarios.

EXAMPLES

The following command removes all SDC information from the current design:

```
prompt> remove_sdc
```

SEE ALSO

```

remove_sense

Removes sense information defined on pins or cell timing arcs.

SYNTAX

```
status remove_sense
  [-type clock]
  [-clocks clock_list]
  [-all]
  pins
```

Data Types

<i>clock_list</i>	list
<i>pins</i>	list

ARGUMENTS

-type *clock*

Specifies the removal of sense from **clock** (the default) networks.

-clocks *clock_list*

Specifies the list of clocks for which the clock-sense information is removed. This option can remove only clock-sense information that has been set by using the **set_sense** command with the **-clocks** option. It does not remove clock-sense settings from pins. By default, the clock-sense information is removed for all clocks passing through the specified pins.

-all

Removes all clock sense information in the current design.

pins

Specifies the pins from which to remove clock-sense information.

DESCRIPTION

This command removes user-specified clock-sense (unateness) information from specified pins and clocks. To set clock-sense information, use the **set_sense** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes positive unateness defined on a pin named XOR/Z with respect to clock CLK1, but does not remove the negative unateness:

```
