prompt> set_sense -positive -clocks [get_clock CLK1] XOR/Z
prompt> set_sense -negative XOR/Z
prompt> remove_sense -clocks [get_clocks CLK1] XOR/Z
```

The following example removes all unateness information in the current design;

```
prompt> remove_sense -all
```

SEE ALSO

[set_sense\(2\)](#)

remove_target_library_subset

Removes target library subset constraints from the root design or from specified instances.

SYNTAX

```
status remove_target_library_subset
  [-object_list cells]
  [-top]
```

ARGUMENTS

-object_list *cells*

Specifies the cells from which to remove the target library subset. The cells must be instances of hierarchical designs, as subset restriction applies to those instances and their children.

-top

Removes the target library subset from the root design. If neither the **-top** option nor the **-object_list** option is specified, the **-top** option is used by default.

DESCRIPTION

This command removes the target library subset specified by the **set_target_library_subset** command with the **-library_list** option, or the Milkyway reference library subset specified with the **-milkyway_reflibs** option from the given instances or the root design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes the target library subset from the root design and from block *u1*:

```
prompt> remove_target_library_subset -object_list [get_cells u1] -top
```

The following example removes the clock_path target library subset from the root design:

```
prompt> remove_target_library_subset -clock_path -top
```

The following example removes the clock_path target library subset from block *u1*:

```
prompt> remove_target_library_subset -clock_path -object_list [get_cells u1]
```

The following example removes the clock_path target library subset from the root design and from block *u1*:

```
prompt> remove_target_library_subset -clock_path -object_list [get_cells u1] -top
```

SEE ALSO

check_target_library_subset(2)
compile(2)
report_target_library_subset(2)
set_operating_conditions(2)
set_target_library_subset(2)
target_library(3)

remove_terminal

Removes terminals.

SYNTAX

```
status remove_terminal  
    terminals  
    [-verbose]
```

Data Types

terminals list

ARGUMENTS

terminals

Specifies the terminals to remove.

-verbose

Prints more information.

DESCRIPTION

This command removes all specified terminals. If the input collection is empty, the command returns 0 to indicate failure.

If the specified collection of terminals contains invalid terminals, the command removes them from the collection and invokes the `remove_terminal` command with the updated collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all terminals whose name matches *clock**:

```
prompt> remove_terminal clock*  
1
```

SEE ALSO

`create_terminal(2)`
`get_terminals(2)`

remove_test_mode

Removes the mode declared by the **define_test_mode command**.

SYNTAX

```
status remove_test_mode  
      test_mode_label
```

ARGUMENTS

test_mode_label

Specifies the mode to remove.

DESCRIPTION

This command removes the mode declared by the **define_test_mode command**. The command only affects the mode and model information. It does not change the implementation of the design. In particular, for existing modes, it does not remove DFT logic. It simply removes the tool's knowledge about this logic.

EXAMPLES

The following example removes the specification test mode named *my_test_mode1*:

```
prompt> remove_test_mode my_test_mode1
```

SEE ALSO

`current_test_mode(2)`
`define_test_mode(2)`

remove_test_model

Permanently removes the test model associated with a design.

SYNTAX

```
status remove_test_model  
[-design design_name]
```

ARGUMENTS

-design *design_name*

Specifies the design from which to remove the test model. If this option is not specified, the current design is used.

DESCRIPTION

This command permanently removes the test model associated with a design. If no design name is specified, the test model for the current design is removed.

EXAMPLES

The following command removes the test model for the design named *my_design*:

```
prompt> remove_test_model -design my_design
```

SEE ALSO

`list_test_models(2)`
`read_test_model(2)`

remove_test_point_element

Removes the test-point element specification for a particular test-point type and a list of pin objects for the current design.

SYNTAX

```
status remove_test_point_element
  list_of_design_pin_objects
  [-type test_point_type]
```

Data Types

<i>list_of_design_pin_objects</i>	list
<i>test_point_type</i>	string

ARGUMENT

list_of_design_pin_objects

Specifies the list of design pin objects to which the **remove_test_point_element** command applies. Wildcards and collections are supported.

-type *test_point_type*

Specifies the test-point type to which the **remove_test_point_element** command applies. The following values are valid for *test_point_type*:

control_0
control_1
control_01
control_z01
force_0
force_z0
force_1
force_z1
force_01
force_z01
observe

DESCRIPTION

The **remove_test_point_element** command removes a user-defined test-point specification from the design for a particular test-point type and a list of design pin objects.

EXAMPLES

The following example shows how to remove the user-defined test-point specification for the **observe** type and for the pin *U0/Q* and *U1/Q*:

```
prompt> remove_test_point_element [list U0/Q U1/Q] -type observe
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`report_test_point_element(2)`
`set_test_point_element(2)`

remove_test_protocol

Removes a test protocol from memory for the current design.

SYNTAX

```
status remove_test_protocol
  [-design design_name]
  [-test_mode test_mode_name]
```

Data Types

<i>design_name</i>	string
<i>test_mode_name</i>	string

ARGUMENTS

-design *design_name*

Removes the protocol for the specified design name. When this option is not specified, the command removes the protocol from the current design.

-test_mode *test_mode_name*

Removes the test protocol from the specified test mode. When this option is not specified, the current test mode is used.

DESCRIPTION

The **remove_test_protocol** command removes a test protocol. When **-test_mode** is used, the command removes the protocol for the specified mode. Without this option, the command removes the protocol for the current mode. When **-design** is used, the command removes the protocol from the specified design. Without this option, the command removes the protocol from the current design.

EXAMPLES

The following example removes the test protocol from the current design named *my_design*:

```
prompt> remove_test_protocol
Removing test protocol from current design 'my_design'...
```

SEE ALSO

`create_test_protocol(2)`
`write_test_protocol(2)`

remove_track

Removes tracks from the current design.

SYNTAX

```
status remove_track
    -all | patterns | -layer layer [-dir X | Y]
        [-verbose]
```

Data Types

<i>patterns</i>	list
<i>layer</i>	collection of one item

ARGUMENTS

-all

Removes all tracks in the current design.

The *patterns*, **-all**, and **-layer** arguments are mutually exclusive; you must specify one of these arguments.

patterns

Matches the track names in the current design against the specified patterns. You can specify the patterns by using the following formats:

- An asterisk (*), which indicates all tracks
- "TRACK_*", which indicates all tracks
- Track names, which are in the format TRACK_*object_id*

The *patterns*, **-all**, and **-layer** arguments are mutually exclusive; you must specify one of these arguments.

-layer *layer*

Specifies the routing layer from which to remove the track. You can specify only one layer, either by layer name, layer number, or a collection containing one layer.

The *patterns*, **-all**, and **-layer** arguments are mutually exclusive; you must specify one of these arguments.

-dir X | Y

Specifies the direction of the routing tracks to be removed. The valid values are **X** and **Y**.

By default, the direction is the routing direction of the layer specified in the physical library.

The option must be used with the **-layer** option.

-verbose

Prints additional messages.

DESCRIPTION

This command removes the specified tracks from the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all tracks that are inside {{2 2} {25 25}}.

```
prompt> remove_track [get_tracks -within {{2 2} {25 25}}]  
1
```

The following example removes all tracks that are located on the metal2 layer.

```
prompt> remove_track [get_tracks -of_objects METAL2] -verbose  
Removing track TRACK_4683  
1
```

The following example removes the routing tracks from the routing layer named m3 on the floorplan.

```
prompt> remove_track -layer m3  
Warning: Direction is not specified. Using the layer preferred direction.  
(MWUI-125)  
1  
prompt> remove_track -layer m3 -dir X  
1
```

SEE ALSO

`create_track(2)`
`get_tracks(2)`
`report_track(2)`

remove_unconnected_ports

Removes unconnected ports or pins from cells, references, and subdesigns.

SYNTAX

```
status remove_unconnected_ports
  cell_list
  [-blast_buses]
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a list of cells or instances whose unconnected ports or pins are to be removed.

-blast_buses

Indicates that if a bus has a port that is unconnected, the bus is to be deleted, the unconnected ports are to be removed, and single-bit buses are to be created for the remaining ports.

DESCRIPTION

This command removes unconnected ports or pins from cells, references, and subdesigns. The current design must be linked and uniquified before you run this command. A port is considered unconnected if it is not connected on the inside of the design. The unconnected ports or pins of each cell in **cell_list** are removed from the cell, its reference, and its subdesign simultaneously so that the current design links after you apply **remove_unconnected_ports**.

After a port is removed, any unused nets in the top design and in the design from where the port was removed are cleaned up.

Unless you specify the **-blast_buses** option, bused ports are removed only if all ports of the bus are unconnected.

Note that if your design contains multiple-instance references to subdesigns, there is a possibility of encountering link errors when using **remove_unconnected_ports**. For example, consider the situation where two designs, A and B, reference subdesign C. Executing **remove_unconnected_ports** on design A might remove ports from subdesign C, so that design B then fails to link. The same situation occurs when design A is read in, **remove_unconnected_ports** is applied, and the original version of design A is read in again. To avoid this, uniquify the blocks or ungroup one of the designs.

This command honors **dont_touch** attributes placed on cells and designs. It is unaffected by **set_boundary_optimization** and **set_compile_directives** specifications.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes all unconnected ports that exist in the current design:

```
prompt> remove_unconnected_ports [find -hierarchy cell "*"]  
Removing port 'CI' from design 'uport1_DW01_addsub_5_0'  
Removing port 'CO' from design 'uport1_DW01_addsub_5_0'  
1
```

The following example removes all unconnected ports that exist in the current design, deletes any bus that has an unconnected port, and removes the unconnected ports of the bus:

```
prompt> remove_unconnected_ports\  
      -blast_buses [find -hierarchy cell "*"]  
Removing port 'A_4' from design 'uport1_DW01_addsub_5_0'  
Removing port 'A_3' from design 'uport1_DW01_addsub_5_0'  
Removing port 'B_4' from design 'uport1_DW01_addsub_5_0'  
Removing port 'B_3' from design 'uport1_DW01_addsub_5_0'  
Removing port 'CI' from design 'uport1_DW01_addsub_5_0'  
Removing port 'SUM_4' from design 'uport1_DW01_addsub_5_0'  
Removing port 'SUM_3' from design 'uport1_DW01_addsub_5_0'  
Removing port 'CO' from design 'uport1_DW01_addsub_5_0'  
1
```

SEE ALSO

[remove_port\(2\)](#)

remove_upf

Removes the UPF constraints from the design. This command is only supported in dc_shell.

SYNTAX

status **remove_upf**

ARGUMENTS

The **remove_upf** command has no arguments.

DESCRIPTION

The **remove_upf** command is used to clean up UPF data before a compile command is executed for the design.

EXAMPLES

The following example shows a typical use of the **remove_upf** command:

Loading the design RTL and libraries

```
prompt> load_upf upf_file_1
prompt> remove_upf
prompt> load_upf upf_file_2
prompt> compile_ultra
```

SEE ALSO

[compile_ultra\(2\)](#)
[load_upf\(2\)](#)

remove_user_attribute

Removes a user-specified attribute from a design or library object.

SYNTAX

```
list remove_user_attribute
  object_list
  attribute_name
  [-bus]
  [-quiet]
```

Data Types

```
object_list    list
attribute_name string
```

ARGUMENTS

object_list

Specifies a list of design or library objects from which to remove the attribute.

attribute_name

Specifies the name of the attribute to remove.

-bus

Removes the attribute from the bus as a whole, and not from each individual bus member.

-quiet

Turns off the warning message that is issued if the attribute or objects are not found.

DESCRIPTION

This command removes the user-specified attribute from the specified objects. For a complete list of attributes, see the **attributes** man page.

The command returns the list of objects from which the attribute is removed. If an empty string is returned, no object was removed.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command removes the **output_not_used** attribute on the *OUT1* port:

```
prompt> remove_user_attribute [get_ports OUT1] output_not_used  
{OUT1}
```

SEE ALSO

[set_attribute\(2\)](#)
[set_user_attribute\(2\)](#)
[attributes\(3\)](#)

remove_user_shape

Removes objects that are user shapes.

SYNTAX

```
status remove_user_shape  
  [-verbose]  
  user_shapes
```

Data Types

user_shapes collection

ARGUMENTS

-verbose

Prints additional information. If this option is not specified, the tool suppresses warning and error messages if no objects match. Syntax error messages are not suppressed.

user_shapes

Specifies an asterisk (*) as the pattern, and all user shapes are removed.

DESCRIPTION

This command removes user shapes. It returns 1 if successful or 0 if it fails.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes user shapes.

```
prompt> remove_user_shape *  
1
```

SEE ALSO

`create_user_shape(2)`
`remove_net_shape(2)`

remove_verification_priority

Removes the **verification_priority** attribute from the specified objects.

SYNTAX

```
status remove_verification_priority
  [-all]
  object_list
```

Data Types

object_list list

ARGUMENTS

-all

Removes the **verification_priority** attribute from all of the designs and instances in the designs.

object_list

Specifies a list of objects from which the attribute is to be removed.

DESCRIPTION

This command removes the **verification_priority** attribute from the specified objects.

EXAMPLES

The following example removes the **verification_priority** attribute from all of the designs:

```
prompt> remove_verification_priority -all
```

SEE ALSO

`get_attribute(2)`
`list_attributes(2)`

```
reset_design(2)
set_verification_priority(2)
```

remove_via

Removes vias from the current design.

SYNTAX

```
status remove_via
  [-verbose]
  [vias]
```

Data Types

vias collection

ARGUMENTS

-verbose

Prints additional messages.

vias

Specifies the vias to remove. If you do not specify this argument, all vias are removed.

DESCRIPTION

This command removes the specified vias from the current design. If you do not specify any vias, the command removes all vias from the design.

This command returns 1 if successful or 0 if it fails.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **remove_via** command to remove all the vias in the current design:

```
prompt> remove_via
1
```

SEE ALSO

`create_net_shape(2)`
`create_via(2)`
`remove_net_shape(2)`

remove_via_ladder_constraints

Removes the specified via ladder constraints.

SYNTAX

```
status remove_via_ladder_constraints
    -pins collection_of_pins
    -all
```

ARGUMENTS

DESCRIPTION

This command removes via ladder lists that were previously attached to logical pins by the **set_via_ladder_constraints** command.

This command removes via ladder constraints for all the pins if **-all** is specified or for specified pins with **-pins** option. Options **-all** and **-pins** are mutually exclusive. At least one of these must be provided.

A via ladder is a physical structure of connected vias and wires that is placed on top of a standard cell pin as a special connecting device. A via ladder can have, for example, two rows of via1, four columns of via2, and one row of via3 connected with a metal4 wire.

A named via ladder is defined by set of rules in the technology file.

This command is part of the user interface for via ladder insertions.

Note that via ladder insertion is supported only by the classic router.

EXAMPLES

The following command shows removing via ladder constraints on the U1/Z pin

```
prompt> remove_via_ladder_constraints -pins U1/Z
```

SEE ALSO

[set_via_ladder_constraints\(2\)](#)
[report_via_ladder_constraints\(2\)](#)

remove_via_ladder_rules

Removes via ladders rules for the block.

SYNTAX

status **remove_via_ladder_rules**

DESCRIPTION

This command removes via ladder rules for the block set using `set_via_ladder_rules`.

This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

```
prompt> remove_via_ladder_rules  
1
```

SEE ALSO

`set_via_ladder_rules(2)`
`report_via_ladder_rules(2)`

remove_via_rules

Removes via_rule objects from the current library.

SYNTAX

```
collection remove_via_rules
  [-all]
  via_rule_list
```

ARGUMENTS

-all

Removes all via rules.

RETURN VALUE

This command returns the removed via rule's count, an empty string if it fails, or a TCL_ERROR if there is a command syntax error.

DESCRIPTION

This command removes a list of via_rules from the current library.

EXAMPLES

The following example removes via rule named VR1

```
prompt> remove_via_rules VR1
1
```

SEE ALSO

[create_via_rule\(2\)](#)

```
get_via_rules(2)
report_via_rules(2)
```

remove_voltage_area

Removes voltage areas from the current design.

SYNTAX

```
status remove_voltage_area
  [-name list]
  -all | patterns
```

Data Types

patterns list

ARGUMENTS

-name *list*

Specifies the names of voltage areas to be removed.

-all

Removes all voltage areas in the current design.

patterns

Specifies the list of hierarchical cells that represent a voltage area.

DESCRIPTION

This command removes voltage areas from the design.

When a voltage area is removed, all its hierarchical cells are also disassociated with the voltage area. After one hierarchical cell is disassociated, its leaf child cells will be reassociated with its nearest ascent's voltage area, if any. If none of its ascents is associated with any voltage area, or it does not have any ascents, its leaf child cells will be free.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example removes voltage areas whose names begin with *tap*:

```
prompt> remove_voltage_area tap*
```

SEE ALSO

`create_voltage_area(2)`
`report_voltage_area(2)`

remove_wire_load_min_block_size

Removes the **wire_load_min_block_size** attribute from the current design.

SYNTAX

status **remove_wire_load_min_block_size**

ARGUMENTS

The **remove_wire_load_min_block_size** command has no arguments.

DESCRIPTION

This command removes the **wire_load_min_block_size** attribute from the current design. To set the wire-load minimum block size, use the **set_wire_load_min_block_size** command, with the wire-load mode enclosed in single quotes.

Use the **remove_wire_load_model** command to remove **wire_load_min_block_size** attributes.

EXAMPLES

The following example removes the **wire_load_min_block_size** attribute from the design named *TOP*:

```
prompt> current_design TOP  
prompt> remove_wire_load_min_block_size
```

SEE ALSO

[auto_wire_load_selection\(3\)](#)

link_library(3)

remove_wire_load_model

Removes wire-load model attributes from designs, ports, and hierarchical cells. This command is not supported in Design Compiler in topographical mode.

SYNTAX

```
status remove_wire_load_model
  [-min]
  [-max]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-min

Removes the wire-load model or selection group for minimum delay analysis only. If **-max** is specified, then both minimum and maximum delay wire-load models are removed.

-max

Removes the wire-load model or selection group for maximum delay analysis only. Any model set for minimum delay analysis is not affected.

object_list

Specifies a list of designs, ports, and cells from which to remove the wire-load model attributes.

DESCRIPTION

This command removes wire-load model attributes from designs, ports, and hierarchical cells of the current design (all specified in the *object_list*),

Using the **remove_wire_load_model** command is recommended, but you can also use the **reset_design** command to remove wire-load model attributes.

EXAMPLES

The following example removes wire-load model attributes from the design named *TOP*:

```
prompt> current_design TOP  
prompt> remove_wire_load_model
```

The following example removes the minimum wire-load model from the design list named *DESIGN_LIST*:

```
prompt> remove_wire_load_model -min DESIGN_LIST
```

SEE ALSO

`link_library(3)`

remove_wire_load_selection_group

Removes the wire-load model selection group from designs and cells of the current design.

SYNTAX

```
status remove_wire_load_selection_group
  [-min]
  [-max]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-min

Removes the selection group from designs and cells for minimum delay analysis only. Specifying neither or both **-max** and **-min** options removes both maximum and minimum wire-load selection groups.

-max

Removes the selection group from designs and cells for maximum delay analysis only. Specifying neither or both **-max** and **-min** options removes both maximum and minimum wire-load selection groups.

object_list

Removes the minimum or maximum selection group from the specified designs and cells in the list.

DESCRIPTION

This command removes the **wire_load_model_selection_group** and **wire_load_model_selection_group_lib** attributes from designs and cells. If none of designs or cells is specified, this command removes the attributes of current design.

The removal of the selection group can be for minimum delay analysis, maximum delay analysis, or both. This command removes the wire-load selection group for minimum delay and maximum delay analysis if neither **-min** nor **-max** is specified.

For a more detailed report on wire-load selection groups associated with designs or cells use the **report_wire_load** command.

EXAMPLES

remove_wire_load_selection_group

1528

The following example removes the selection group for the current design:

```
prompt> current_design TOP
prompt> remove_wire_load_selection_group 2layermetal
```

The following example removes the selection group from a subdesign named *LOW* and hierarchical cell *U1/U2* in the *TOP* design:

```
prompt> current_design TOP
prompt> remove_wire_load_selection_group {LOW U1/U2}
```

rename

Renames or deletes a command.

SYNTAX

```
string rename
      old_name
      new_name
```

ARGUMENTS

old_name

Specifies the current name of the command.

new_name

Specifies the new name of the command.

DESCRIPTION

Renames the *old_name* command so that it is now called *new_name*. If *new_name* is an empty string, then *old_name* is deleted. The *old_name* and *new_name* arguments may include namespace qualifiers (names of containing namespaces). If a command is renamed into a different namespace, future invocations of it will execute in the new namespace. The **rename** command returns an empty string as result.

Note that the **rename** command cannot be used on permanent procedures. Depending on the application, it can be used on all basic builtin commands. In some cases, the application will allow all commands to be renamed.

WARNING: **rename** can have serious consequences if not used correctly. When using **rename** on anything other than a user-defined Tcl procedure, you will be warned. The **rename** command is intended as a means to wrap other commands: that is, the command is replaced by a Tcl procedure which calls the original. Parts of the application are written as Tcl procedures, and these procedures can use any command. Commands like **puts**, **echo**, **open**, **close**, **source** and many others are often used within the application. Use **rename** with extreme care and at your own risk. Consider using **alias**, Tcl procedures, or a private namespace before using **rename**.

EXAMPLES

This example renames `my_proc` to `my_proc2`:

```
prompt> proc my_proc {} {echo "Hello"}
prompt> rename my_proc my_proc2
prompt> my_proc2
```

```
Hello
prompt> my_proc
Error: unknown command 'my_proc' (CMD-005).
```

SEE ALSO

[define_proc_attributes\(2\)](#)

rename_design

Renames a design in memory, or moves a list of designs to a file.

SYNTAX

```
status rename_design
  design_list
  [target_name]
  [-prefix prefix_name]
  [-postfix postfix_name]
  [-dont_link_with_original_name]
  [-update_links]
```

Data Types

```
design_list    list
target_name   string
prefix_name   string
postfix_name string
```

ARGUMENTS

design_list

Specifies a list of designs to be renamed.

target_name

Specifies the new name of the design. If *design_list* has only one design, *target_name* will be the new design name. If *design_list* has multiple designs, *target_name* must be a file name and all the designs in *design_list* are moved to the specified file with their base design names. You must specify either *target_name*, or *-prefix*, or *-postfix*. These arguments are mutually exclusive; you can only specify one.

-prefix prefix_name

Specifies the prefix name that is inserted in front of design names of designs in *design_list*. One of *target_name*, *-prefix*, or *-postfix* is required, but they are mutually exclusive.

-postfix postfix_name

Specifies the postfix name that is appended to the design names of designs in *design_list*. One of *target_name*, *-prefix*, or *-postfix* is required, but they are mutually exclusive.

-dont_link_with_original_name

Specifies that the linker should not use the design's original name when it matches up reference names with design names. See the "Interaction With the Linker" section for more information.

-update_links

This option is obsolete and will be removed in a future release. The behavior formerly enabled by this option is automatically

enabled.

DESCRIPTION

The most simple use of this command is to assign a new name to a single design.

Within a file containing the design, every design name must be unique. An error occurs if the name of the new design you specified already exists in the file.

You can also use **rename_design** to move a specified list of designs to a file that can accept multiple designs.

To save these files to disk, use the **write_file** command.

Interaction With the Linker

When a design is renamed, any references to that design in the current hierarchy are updated to refer to the new design name.

By default, the design being renamed retains information about its original HDL template name and parameters. As a result, the design can continue to be instantiated by subsequent references to the old HDL template name and parameters. This behavior can be desirable if you are renaming simply to shorten a long design name, for example. If you don't want this behavior, use the **-dont_link_with_original_name** option. If you specify this option, the renamed design drops its association with the original HDL template name and parameters, and the design can only be instantiated using the new name.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example renames the design named *TEST* to *BILL*:

```
prompt> rename_design TEST BILL
Renaming design 'TEST' to 'BILL'
1
```

In this example, the **get_designs** command is used with the **rename_design** command to move all designs currently read into memory to the same file named *all.ddc*:

```
prompt> list_designs -show_file
Design      File      Path
-----      -----      -----
T2          T2.ddc    /usr/project
AD          AD.ddc    /test
HA          HA.ddc    /test

prompt> rename_design [get_designs *] /usr/project/all.ddc
Renaming design 'T2' to '/usr/project/all.ddc:T2'
Renaming design 'AD' to '/usr/project/all.ddc:AD'
Renaming design 'HA' to '/usr/project/all.ddc:HA'
1

prompt> list_designs -show_file
Design      File      Path
-----      -----      -----
```

```
T2      all.ddc  /usr/project  
AD      all.ddc  /usr/project  
HA      all.ddc  /usr/project  
1
```

A file must be specified as the second argument of the **rename_design** command, as shown in the following error example:

```
prompt> rename_design {A B C} all.ddc:TEST3  
Error: Cannot copy multiple designs to a single design  
0
```

The *-prefix* and *-postfix* options provide a convenient and efficient way to rename multiple designs. For instance, the following script prepends the string *NEW_* to the name of design *D*, and changes links for its instance cells:

```
prompt> get_cells -hierarchical -filter "ref_name == D"  
{b_in_a/c_in_b/d1_in_c b_in_a/c_in_b/d2_in_c}  
  
prompt> rename_design D -prefix NEW_  
Information: Renaming design /test_dir/D.ddc:D to /test_dir/D.ddc:NEW_D. (UIMG-45)  
  
prompt> get_cells -hierarchical -filter "ref_name == D" ;# no such cells!  
prompt> get_cells -hierarchical -filter "ref_name == NEW_D"  
{b_in_a/c_in_b/d1_in_c b_in_a/c_in_b/d2_in_c}
```

rename_mw_lib

Renames a Milkyway library.

SYNTAX

```
status rename_mw_lib
  -from lib_name
  -to lib_name
```

Data Types

lib_name string

ARGUMENTS

-from *lib_name*

Specifies the name of the Milkyway library that is to be renamed. The specified Milkyway library must not be open in the current session.

-to *lib_name*

Specifies the new name of the Milkyway library.

DESCRIPTION

This command renames a Milkyway library.

If this library is a reference library of another main library, you may need to use the **set_mw_lib_reference** command to update reference library information in the main library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example changes the name of the library from *access05* to *access06*:

```
prompt> rename_mw_lib -from access05 -to access06
```

SEE ALSO

`copy_mw_lib(2)`

replace_clock_gates

Replaces manually-inserted clock gates with Power Compiler clock gates.

SYNTAX

```
status replace_clock_gates
  [-global]
  [-no_hier]
```

ARGUMENTS

-global

Performs hierarchical clock-gate replacement in all subdesigns as one global step.

-no_hier

Limits clock-gate replacement to the top level of the current design.

DESCRIPTION

This command performs clock-gating replacement of manually-inserted clock gates with Power Compiler clock gates. Before using this command, you can use the **set_clock_gating_style** command to specify the structure of the clock-gating circuitry to be inserted. If no style is explicitly set, a default clock-gating style is applied. See the man page for the **set_clock_gating_style** command for more details about the default clock-gating style.

Manually-inserted clock gates can introduce problems on the clock net, which can cause incorrect operation after synthesis. By replacing the manually-inserted clock gates with Power Compiler clock gates, correct operation of the synthesized circuit is ensured. Furthermore, the clock gates are properly recognized by Power Compiler. As such, the gate-level commands, such as **rewire_clock_gating** and **remove_clock_gating**, are available to optimize the clock-gated netlist. During physical synthesis, the clock gates are grouped together with their driven modules and registers.

Replacement of manually-inserted clock gates with Power Compiler clock gates is especially useful when you want to clock gate an entire module. In many cases such module-level clock gates cannot be inserted automatically. The **replace_clock_gates** command is recommended for creating module-level clock gating.

Before clock-gating replacement can be performed, the clock ports must be identified with the **create_clock** command. All combinational cells that are not buffers or inverters will be considered for clock gating unless they are excluded with the **set_module_clock_gates** command. Clock-gate replacement can only be applied to combinational cells that perform simple AND/NOR or OR/NAND functionality on the clock net. Also, the clock must drive registers or modules that are triggered by the same clock edge. The clock-gating style must be compatible with the functionality of the combinational cell and the edge type of the gated registers.

Only options of clock-gating style that have to do with structure of the clock gates are honored. Options that have to do with fanout or multi-stage clock-gating are not taken into account. Also, observation circuitry will not be created.

For example, with a latch-based clock-gating style, only cells with AND/NOR functionality driving positive-edge registers, and cells with OR/NAND functionality driving negative-edge registers will be replaced. If a clock net drives both positive- and negative-edge registers, or if the clock net is fed to an output port, the manually-inserted clock gates for that clock net will not be replaced. Black-box modules and modules with clock ports that drive special sequential cells (such as memory cells) can be module-level clock gated by specifying the edge type with the **set_replace_clock_gates** command. Furthermore, if a latch-free clock-gating style is selected, the enable inputs to the manually-inserted clock gate should be driven by registers that are clocked by a clock signal that is compatible with the clock input to the clock gate.

When the **-no_hier** option is omitted, clock-gate replacement is performed on all subdesigns. Every subdesign is processed independently. Otherwise, only the top level of the current design is processed.

To control the names of modules, cells, and gated clock nets created by this command, you could set different naming style variables listed at the end.

EXAMPLES

The commands in the following example show the typical flow for using the **replace_clock_gates** command. After reading or elaborating the design and defining the clock ports, you set the clock-gating style to specify how to perform clock gate replacement. The **replace_clock_gates** command replaces the manually-inserted clock gates.

```
prompt> read_verilog design.v
prompt> current_design top
prompt> link
prompt> set_clock_gating_style -sequential latch
prompt> create_clock clk
prompt> replace_clock_gates
```

power_cg_module_naming_style(3)
```

replace_synthetic

Implements all synthetic library parts of a design using generic logic.

SYNTAX

```
status replace_synthetic  
[-ungroup]
```

ARGUMENTS

-ungroup

Ungroups all implemented synthetic library parts into their containing designs. If **-ungroup** is not specified, synthetic library parts are implemented as a level of hierarchy.

DESCRIPTION

This command will be obsolete in a future release. Use of this command is not recommended. This command processes all synthetic library parts in a hierarchical design. The processing is a subset of the synthetic library part processing performed by the **compile** command. A simple area-based resource sharing step is called on the design, followed by implementing all parts with minimum area implementations. To disable resource sharing, set the **hdlin_resource_allocation** variable to **none**. Alternatively, you can call **set_resource_allocation none** for the design.

Several high-level optimizations during compile (including timing-driven resource sharing) depend on synthetic library parts. Using **replace_synthetic** before **compile** disables these optimizations.

Use **replace_synthetic** to interface to tools that do not recognize unimplemented, synthetic library parts. Use **replace_synthetic** before using FSM **extract**, or before writing a pre-compile description for simulation.

The **replace_synthetic** command does not process references that are marked **dont_touch**.

EXAMPLES

The following example implements synthetic parts in the current design:

```
prompt> replace_synthetic
```

SEE ALSO

`compile(2)`
`hlo_resource_allocation(3)`

report_activity

Reports switching activity.

SYNTAX

```
int report_activity
  [-rtl]
  [-driver]
  [-show_zeros]
  [-scenarios scenario_list]
```

Data Types

scenario_list list

ARGUMENTS

-rtl

Reports switching activity similar to the **report_saif -rtl_saif** command in Design Compiler. The object types listed are port, sequential cell ("seq-cell") and tristate cells ("tri-cell").

-driver

Reports drivers based on their logic function. Two special situations occur: 1) a driver with an unknown function ("no-func") and 2) signals that have no driver at all ("no-driver"). The logic function listed are: primary input ports ("primary-input"), primary inout ports ("primary-inout"), sequential pins ("seq-pin"), tristate pins ("tri-pin"), combinational pins ("comb-pin"), unknown function ("no-func"), and no drivers ("no-driver"). If user essential activity points have been created, these will be printed in a second report as well.

-show_zeros

Include zero-valued columns in the report. By default, zero-valued columns are suppressed in the report.

-scenarios *scenario_list*

Specifies the scenarios to be considered. If this option is not specified, then only those scenarios are considered which contain the modes and corners specified through **-modes** and **-corners** options. Output of the command is generated separately for each scenario. If none of the **-modes**, **-corners**, or **-scenarios** options are specified, the command reports for the current scenario in the design.

DESCRIPTION

Reports the switching activity type for objects. The objects that are reported depends on the command options used. By default, this command mimics the **report_saif** command in Design Compiler. With the **-rtl** option this command mimics the **report_saif -rtl_saif** command in Design Compiler. With the **-driver** option this command prints out a driver-centric report.

Multicorner-Multimode Support

By default, this command works on the current scenario. To specify different scenarios, use the **-scenarios** option.

EXAMPLES

The following examples report switching activities for the current design.

```
prompt> report_activity
```

```
report_activity

report_ahfs_options

Generates a report about the automatic high-fanout synthesis options.

SYNTAX

integer **report_ahfs_options**

ARGUMENTS

The **report_ahfs_options** command has no arguments.

DESCRIPTION

This command reports all of the options set for running automatic high-fanout synthesis. See the **set_ahfs_options** command man page for the default values of the options and a description of how each option can control the automatic high-fanout synthesis flow.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the current automatic high-fanout synthesis options:

```
prompt> report_ahfs_options

Report AHFS options:
*****
AHFS options for the design:
  Enable port punching: ON
  Default Reference : buffer_1
  Preserve Boundary Phase : OFF
  No Port Punching on these hier cells : ""
  Global Route: ON
```

1

SEE ALSO

`set_ahfs_options(2)`

report_annotated_check

Displays all annotated timing checks on the current design.

SYNTAX

```
status report_annotated_check  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command lists all annotated timing checks in the current design. The pin-to-pin timing checks reported are setup and hold.

To list annotated delays, use the **report_annotated_delay** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated report:

```
prompt> report_annotated_check  
*****  
Report : annotated_check  
Design : counter  
Version: v3.1  
Date  : Tue Apr 14 19:42:25 1992  
*****  
  
Cell Name  From   To    Rise   Fall   Timing Check  
-----
```

```
U1      c    d     -0.20  -0.20  hold
U1      c    d      2.20   2.20   setup
```

SEE ALSO

[remove_annotated_check\(2\)](#)
[report_annotated_delay\(2\)](#)
[reset_design\(2\)](#)
[set_annotated_check\(2\)](#)

report_annotated_delay

Displays delays annotated on cells and nets of the current design.

SYNTAX

```
status report_annotated_delay
  [-cell]
  [-net]
  [-nosplit]
  [-summary]
  [-min]
```

ARGUMENTS

-cell

Reports delay data annotated on cells only. By default, both cell- and net-annotated data are reported.

-net

Reports delay data annotated on nets only. By default, both cell- and net-annotated data are reported.

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-summary

Reports the total number of cell and net delay arcs and how many are annotated with delay data. An arc is considered annotated with delays only if all the four delay values (rise, fall, min, max) are present on it.

-min

Reports minimum delay data annotated on cells and nets of the current design. If you do not use this option, the command reports maximum delay data instead.

DESCRIPTION

The **report_annotated_delay** command lists all delay data annotated on cells and nets in the current design. The cell-annotated delay data consists of pin-to-pin delays. The net-annotated delay data consists of pin-to-pin delays, net capacitance values, and net resistance values.

Note that the delay values reported are the resulting cell and net delays used in the **report_timing** command and might be different from your annotated values if the delays were annotated using the **-load_delay net** option of the **read_sdf** or **set_annotated_delay** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated delay report:

```
prompt> report_annotated_delay
```

```
*****
Report : annotated -cell
Design : counter
Version: v3.0
Date  : Tue Apr 14 19:42:25 1992
*****
```

Cell Name	From	To	Rise	Fall
CO	A	Z	100.00	100.00

```
*****
Report : annotated -net
Design : counter
Version: v3.0
Date  : Tue Apr 14 19:42:25 1992
*****
```

Net Name	From	To	Rise	Fall	Load	Res.
h	ffc/QN	w/A	200.00	200.00	50.00	200.00
h	ffc/QN	m/B	200.00	200.00	50.00	200.00
h	ffc/QN	r/B		50.00	200.00	
m	m/Z	CO/A	200.00	200.00	40.00	100.00

SEE ALSO

[read_sdf\(2\)](#)
[remove_annotated_delay\(2\)](#)
[reset_design\(2\)](#)
[set_annotated_delay\(2\)](#)

report_annotated_transition

Displays annotated transitions on all pins of the current design.

SYNTAX

```
status report_annotated_transition  
-nosplit
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_annotated_transition** command lists annotated transition times at every pin in the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of an annotated transition time report:

```
prompt> report_annotated_transition  
report_annotated_transition  
Pin Name    max_rise    max_fall    min_rise    min_fall  
-----  
U0/A        10.00      -          -          17.00  
U1/A        -          -          -          9.10  
U1/Z        -          -          -          7.00  
1
```

SEE ALSO

`remove_annotated_transition(2)`
`reset_design(2)`
`set_annotated_transition(2)`

report_app_options

Generates a report of application options.

SYNTAX

Boolean **report_app_options**

ARGUMENTS

The **report_app_options** command has no arguments.

DESCRIPTION

This command generates a report of application options which are set before. The command has no arguments.

EXAMPLES

The following example reports application options.

```
prompt> report_app_options
set_app_options -name name1 -value value1
set_app_options -name name2 -value value2
set_app_options -name name3 -value value3
```

SEE ALSO

[set_app_options\(2\)](#)
[reset_app_options\(2\)](#)

report_app_var

Shows the application variables.

SYNTAX

```
string report_app_var
  [-verbose]
  [-only_changed_vars]
  [pattern]
```

Data Types

pattern string

ARGUMENTS

-verbose

Shows detailed information.

-only_changed_vars

Reports only changed variables.

pattern

Reports on variables matching the pattern. The default is "*".

DESCRIPTION

The **report_app_var** command prints information about application variables matching the supplied pattern. By default, all descriptive information for the variable is printed, except for the help text.

If no variables match the pattern, an error is returned. Otherwise, this command returns the empty string.

If the **-verbose** option is used, then the command also prints the help text for the variable. This text is printed after the variable name and all lines of the help text are prefixed with "#".

The Constraints column can take the following forms:

{val1 ...}

The valid values must belong to the displayed list.

val \leq a

The value must be less than or equal to "a".

```
val \>= b
```

The value must be greater than or equal to "b".

```
b \<= val \<= a
```

The value must be greater than or equal to "b", and less than or equal to "a".

EXAMPLES

The following are examples of the **report_app_var** command:

```
prompt> report_app_var sh*
Variable      Value   Type  Default Constraints
-----
sh_continue_on_error  false  bool  false
sh_script_stop_severity none  string none  {none W E}
\.\.
```

```
prompt> report_app_var sh* -verbose
Variable      Value   Type  Default Constraints
-----
sh_continue_on_error  false  bool  false
# Allows source to continue after an error
sh_script_stop_severity none  string none  {none W E}
# Indicates the error message severity level which would cause
# a script to stop executing before it completes
\.\.
```

SEE ALSO

[get_app_var\(2\)](#)
[set_app_var\(2\)](#)
[write_app_var\(2\)](#)

report_area

Displays area information for the current design or instance.

SYNTAX

```
status report_area
  [-nosplit]
  [-physical]
  [-hierarchy]
  [-designware]
  [-individual_site_def_util]
```

ARGUMENTS

-nosplit

Prevents line splitting. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical

Reports the size of the core area and the aspect ratio of the design.

-hierarchy

Reports the area used by cells across the design hierarchy. Reports the absolute value and the percentage of area consumed by each of the cells across the hierarchy. This option also reports the details of area contribution by combinational, non-combinational, and macro or black box cells. The "black boxes" column includes macro area.

-designware

Reports the area of synthetic cells. There are two types of synthetic cells:

- Datapath cells
The datapath cells are extracted complex datapath cells.
- DesignWare singleton cells
The DesignWare singleton cells are instantiated or inferred synthetic component cells.

The report shows the total synthetic cell area and the total datapath cell area. If the synthetic cells are ungrouped during compile, the report shows the estimated area of the ungrouped synthetic cells.

-individual_site_def_util

Reports the utilization of all the sites in variable floorplan. It is used in combination with -physical option.

DESCRIPTION

The **report_area** command lists the area statistics for the current instance or the current design. The report includes combinational, non-combinational, and total area information. If you set the **current_instance** command, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

The number of combinational cells, number of sequential cells, and the number of macros/black boxes only include leaf cells.

Note that the number of macros reported by the **report_area** command is based on information from the logic libraries. This number can differ from what is returned by the **all_macro_cells** command, which is based on information from the physical libraries. For the purposes of the **report_area** command, macros and leaf-level black box cells are reported together. The **report_area** macro_cell count also includes padcells and power switches. Hierarchical black-box cells are not counted because no area is associated with them.

Also note that the core area numbers reported by the **report_area** command is the bounding box of the core area rather than the defined rectilinear shape.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example generates an area report:

```
prompt> report_area
*****
Report : area
Design : top
Version: H-2013.03-SP1
Date  : Wed Apr 17 18:44:40 2013

SEE ALSO

report_design(2)
 set_max_area(2)

report_attribute

Reports the attributes of a cell, net, pin, port, instance, or design.

SYNTAX

```
string report_attribute
  [-cell]
  [-design]
  [-hierarchy]
  [-instance]
  [-net]
  [-port]
  [-pin]
  [-reference]
  [-nosplit]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-cell

Reports attributes of cells in the current instance or current design. The output is sorted alphanumerically by cell name.

-design

Reports attributes of the current instance or current design.

-hierarchy

Reports attributes for objects in the hierarchy tree.

-instance

Reports attributes of instances in the current instance or current design.

-net

Reports attributes of nets in the current instance or current design. The output is sorted alphanumerically by net name.

-port

Reports attributes of ports in the current instance or current design.

-pin

Reports attributes of pins in the current instance or current design.

-reference

Reports attributes of references in the current design.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most design information is listed in fixed-width columns. If information for a field exceeds the column width, the next field begins on a new line, starting in the correct column.

object_list

Specifies a list of objects to report.

DESCRIPTION

This command reports the attributes of specified objects. An object can be a cell, net, pin, port, instance, or design.

The *object_list* argument takes precedence over all other options. For example, the following two commands are the same:

```
prompt> report_attribute "U1" -hierarchy -cell
prompt> report_attribute "U1"
```

Instance-specific attributes are reported only at the top level of the hierarchy. If an object has no attributes, no attributes are reported. Only attributes specified directly on the design object are reported. Inherited attributes are not reported.

If you set the current instance, the report is generated for the design of that instance; otherwise the report is generated for the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example displays the default attribute report for the current design:

```
prompt> report_attribute
```

...

Design	Object	Type	Attribute Name	Value
test	U1	cell	boundary_optimization	true
test	U1	cell	test_dont_fault	1
test	U1	cell	dont_touch	true
test	test	design	structure	true
test	test	design	flatten	true
test	test	design	flatten_effort	1
test	cntl	net	net_capacitance	1.000000
test	d	net	net_capacitance	0.000000
test	in	net	net_capacitance	1.000000
test	U1/A	pin	probe_point	true
test	U1/A	pin	dont_touch_network	true
test	U1/Z	pin	dont_touch_network	true
test	cntl	port	load	7.000000

```
test      d          port   load      9.000000
test      in         port   max_fanout 2.000000
test      in         port   max_transition 4.000000
```

The following example reports attributes for cells in the current design:

```
prompt> report_attribute -cell
```

...

Design	Object	Type	Attribute Name	Value
test	U1	cell	boundary_optimization	true
test	U1	cell	test_dont_fault	1
test	U1	cell	dont_touch	true

The following example reports attributes for the design named test:

```
prompt> report_attribute -design
```

...

Design	Object	Type	Attribute Name	Value
test	test	design	structure	true
test	test	design	flatten	true
test	test	design	flatten_effort	1

The following example reports attributes for nets in the current design:

```
prompt> report_attribute -net
```

...

Design	Object	Type	Attribute Name	Value
test	cntl	net	net_capacitance	1.000000
test	d	net	net_capacitance	0.000000
test	in	net	net_capacitance	1.000000

The following example reports attributes for ports in the current design:

```
prompt> report_attribute -port
```

...

Design	Object	Type	Attribute Name	Value
test	cntl	port	load	7.000000
test	d	port	load	9.000000
test	in	port	max_fanout	2.000000

The following example reports attributes for pins in the current design:

```
prompt> report_attribute -pin
```

...

Design	Object	Type	Attribute Name	Value
test	U1/A	pin	probe_point	true
test	U1/A	pin	dont_touch_network	true
test	U1/Z	pin	dont_touch_network	true

The following example reports attributes for instances in the current design:

```
prompt> report_attribute -instance
```

...

Design	Object	Type	Attribute Name	Value
UPC5	H1/U9/B	pin	test_dont_fault	2
UPC5	H1/U50	cell	test_dont_fault	1

The following example reports attributes for subdesigns:

```
prompt> report_attribute -hierarchy
```

...

Design	Object	Type	Attribute Name	Value
TOP	TOP	design	default_latch_type_exact	LD3
TOP	TOP	design	flatten	true
TOP	MINUS1	net	dont_touch	true
ADDER	U1	cell	boundary_optimization	true
ADDER	ADDER	design	default_latch_type_exact	LD3
ADDER	ADDER	design	default_flip_flop_type	Ia1.0(Q)
ADDER	CARRY	net	dont_touch	true
ADDER	U1	cell	boundary_optimization	true
ADDER	ADDER	design	default_latch_type_exact	LD3
ADDER	ADDER	design	default_flip_flop_type	Ia1.0(Q)
ADDER	CARRY	net	dont_touch	true
ADDER	U3/A	pin	dont_touch_network	true
FULL_SUBTRACTOR	U2	cell	boundary_optimization	true
FULL_SUBTRACTOR	FULL_SUBTRACTOR	design	structure	true

report_auto_floorplan_constraints

Reports constraints set for initializing floorplan.

SYNTAX

```
status report_auto_floorplan_constraints
[-control_type]
[-shape]
[-side_length]
[-side_ratio]
[-core_utilization]
[-boundary]
[-orientation]
[-coincident_boundary]
[-core_offset]
[-row_core_ratio]
[-flip_first_row]
[-honor_pad_limit]
[-site_def]
[-use_site_row]
[-origin_offset]
[-row_pattern]
```

ARGUMENTS

-control_type

Reports the control type of the core or die. The default is ratio.

-shape

Reports the core boundary shape. The default is rectangular (R).

-side_length

Reports the length of the edges of the core shape.

-side_ratio

Reports the ratio of the edges of the core shape.

-core_utilization

Reports the core utilization. The default is 0.7.

-boundary

Reports the boundary of the core shape.

-orientation

Reports the orientation of the specified core shape.

-coincident_boundary

Reports whether to keep the same existing boundary.

-core_offset

Reports the distance between the side of the core and boundary.

-row_core_ratio

Reports the channel ratio between cell rows. The default is 1.0.

-flip_first_row

Reports whether the command flips the first row at the bottom of the core area for horizontally placed cell rows or flips the leftmost row for vertically placed cell rows. By default, this option is enabled.

-honor_pad_limit

Reports whether to adjust the core and die size to honor pad-limited designs.

-site_def

Reports the site def name used.

-use_site_row

Reports whether to create the site rows.

-origin_offset

Reports the location of lower-left corner of the die boundary bounding box with respect to the origin of the block.

-row_pattern

Reports the row pattern used for floorplan.

DESCRIPTION

This command reports the constraints that create a floorplan with a boundary, core, site arrays (or rows), and wire tracks.

EXAMPLES

The following example reports the constraint of utilization to be 0.8.

```
prompt> report_auto_floorplan_constraints -core_utilization  
1
```

The following example reports the preferred core shape to be rectangle (R).

```
prompt> report_auto_floorplan_constraints -shape  
1
```

The following example reports the preferred core length to create the floorplan.

```
prompt> report_auto_floorplan_constraints -side_length  
1
```

SEE ALSO

`set_auto_floorplan_constraints(2)`

report_auto_ungroup

Displays information about the cell hierarchies that have been ungrouped using the **compile** command with either the **-auto_ungroup area** or the **-auto_ungroup delay** option. Note: This command will be obsolete in a future release.

SYNTAX

```
status report_auto_ungroup
  [-nosplit]
  [-full]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the auto ungroup information appears in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-full

Displays the full hierarchy in the report. By default, if there is a submodule in multiple locations in a hierarchy, the submodule's components are listed only once, with an ellipsis (...) indicating the contents of a previously displayed module.

DESCRIPTION

This command displays the cell instances that are ungrouped using the **compile** command with either the **-auto_ungroup area** or the **-auto_ungroup delay** option. The auto ungroup information is stored on the current design. To produce a report of the hierarchies that are ungrouped during the compile process, set the current design to be the same as the compiled design.

EXAMPLES

The following is an example of an auto ungroup report of the current design:

```
prompt> report_auto_ungroup
*****
Report : Auto Ungrouping
Design : hier
Version: 2001.08
Date  : Mon Oct 9 16:44:38 2000
*****
```

Instance			
Name	Cell Name	Num. Insts	
H1	sub1	6	
H2	sub2	6

`compile(2)`

report_autofix_configuration

Reports the global AutoFix specification applied to the current design.

SYNTAX

```
status report_autofix_configuration  
[-type fix_type]
```

Data Types

fix_type string

ARGUMENT

-type *fix_type*

Specifies the fixing type to report. The valid *fix_type* values are:

```
all  
clock  
set  
reset  
xpropagation  
internal_bus  
external_bus  
bidirectional
```

The default is **all**.

DESCRIPTION

The **report_autofix_configuration** command reports the global AutoFix specification applied to the current design. By default, all fixing type specifications are reported. To report only a particular fixing type, use the **-type** option.

EXAMPLES

The following is an example of the **report_autofix_configuration** command:

```
prompt> report_autofix_configuration -type all
```

```
*****
```

```
Report : Autofix configuration
Design : my_current_design
Version: A-2007.12
Date  : Fri Dec 28 05:38:07 2007
*****
```

```

Fix latches:   Disable
Fix clocks used as data:   Disable
```

SEE ALSO

```
reset_autofix_configuration(2)
set_autofix_configuration(2)
```

report_autofix_element

Reports all local AutoFix specifications applied to the current design.

SYNTAX

```
status report_autofix_element
  [-type fix_type]
  [list_of_design_objects]
```

Data Types

fix_type string
list_of_design_objects list

ARGUMENTS

-type *fix_type*

Specifies the fixing type to report. The valid *fix_type* values are:

all
clock
set
reset
xpropagation
internal_bus
external_bus
bidirectional

The default is **all**.

list_of_design_objects

Restricts the report to local specifications applied to the specified design objects. Valid object types depend on the fixing type, as follows:

clock - cell (hierarchical and leaf)
set - cell (hierarchical and leaf)
reset - cell (hierarchical and leaf)
xpropagation - cell (hierarchical and leaf)
internal_bus - net
external_bus - net
bidirectional - port

DESCRIPTION

The **report_autofix_element** command reports the local AutoFix specifications applied to design objects in the current design. By default, all local specifications for all fixing types are reported. To report only a particular fixing type, use the **-type** option. To restrict the report to only particular design objects, specify the object list.

EXAMPLES

The following is an example of the **report_autofix_element** command:

```
prompt> report_autofix_element

*****
Report : Autofix element
Design : my_current_design
Version: A-2007.12

report_autounroup_options

Specifies the options to control autounrouping.

SYNTAX

status **report_autounroup_options**

DESCRIPTION

You can use this command to report the controls used for autounrouping.

EXAMPLES

The following example shows how to use report_autounroup_options .

```
prompt> set_autounroup_options -start_level 3 -keep_parent_hierarchies SDC,UPF
prompt> report_autounroup_options
*****
Report : autounroup_options
Design : shift32
Version: S-2021.06-SP3-ALPHA
Date   : Fri Oct 1 03:16:19 2021
*****
```

Name	Value
keep_parent_hierarchies	SDC UPF
start_level	3

report_background_jobs

Reports all the completed and running background jobs submitted to run by the **redirect -bg** command.

SYNTAX

```
status report_background_jobs  
[-reset]
```

ARGUMENTS

-reset

Removes the completed jobs from the list of tracked jobs.

DESCRIPTION

This command reports all the jobs that were submitted to run by the **redirect** command with the **-bg** option.

All the completed and running background job are reported.

To omit the completed jobs, use the **-reset** option with the **report_background_jobs** command.

The return value of the command is the total number of incompletely jobs. If you want to check if there is any background jobs running, you could check the return value of this command. If the return value is 0, there is no background jobs running; if the return value is greater than 0, there are background jobs running.

EXAMPLES

The following example shows a **report_background_jobs** run.

```
prompt> redirect -bg -max_cores 1 -file rep.out {source rep.tcl}  
prompt> report_background_jobs
```

The following example checks if there is any background job running.

```
prompt> set numBgJobs [eval "report_background_jobs"]  
prompt> echo $numBgJobs
```

SEE ALSO

`redirect(5)`

report_block_abstraction

Reports information about the specified block abstraction instance.

SYNTAX

```
status report_block_abstraction  
[block_list]
```

Data Types

block_list list

ARGUMENTS

block_list

Specifies the block abstraction instances to be reported. The option value can be a collection of block abstraction instances or name patterns.

The command fails if it cannot find any of the specified block abstraction instances.

If this option is not specified, the command reports all block abstraction instances in the current design.

DESCRIPTION

The **report_block_abstraction** command reports details about the block abstractions that are linked to the current design.

The information reported for each block includes the block reference name; block instance name; block version; full path of the library from which the block was loaded; date and time of last modification of the block; cell count and compression statistics for each of the blocks, as well as the top-level design with blocks; UPF information; TLUPlus settings; parasitic data of the block; and user-defined scenario mappings between the top level and the blocks.

Multicorner-Multimode Support

This command uses information from all scenarios.

EXAMPLES

The following example reports all the block abstraction instances in the current design:

```
prompt> report_block_abstraction
```

```
*****
```

report_boundary_cell

Reports the boundary-cell configuration specified for the current design.

SYNTAX

status **report_boundary_cell**

ARGUMENTS

The **report_boundary_cell** command has no arguments.

DESCRIPTION

This command reports the boundary-cell configuration specified for ports or core cells of the current design.

The following format is used to report the boundary-cell configuration:

Boundary Cell Structures	Status
Class:	<class_name>
Function:	<function_type>
Ports:	<port_name>
Cells:	<core_list>
Type:	<cell_type>
Design Name:	<design_name>
Register IO Implementation:	<impl_name>
Use Dedicated Wrapper Clock:	<boolean>
Safe State:	<state>
...	

EXAMPLES

The following example reports the boundary-cell configuration for the core wrapper class on *port1* and *port2*:

```
prompt> set_boundary_cell -class core_wrapper -type WC_D1 \
           -safe_state none B-port_list port1
1

prompt> set_boundary_cell -class core_wrapper -design my_des1 \
           -safe_state 0 -function input -port_list port2 \
```

```
-register in_place -use_dedicated TRUE  
1
```

```
prompt> report_boundary_cell
```

```
*****
```

```
Report : Boundary Cell
```

```
Design : M1
```

```
Version: W-2004.12
```

```
Date : Thu Sep 16 09:46:38 2004
```

```

report_boundary_cell_io

Displays options set by the `set_boundary_cell_io` command.

SYNTAX

status **report_boundary_cell_io**

ARGUMENTS

The **report_boundary_cell_io** command has no arguments.

DESCRIPTION

The **report_boundary_cell_io** command displays options set by the **set_boundary_cell_io** command on the current design.

The command reports the boundary-cell I/O pins set by the **set_boundary_cell_io** command.

EXAMPLES

The following is an example of the **report_boundary_cell_io** command:

```
prompt> report_boundary_cell_io
```

```
*****
Report : Boundary Cell IO

report_bounds

Reports bounds in the design.

SYNTAX

```
status report_bounds  
    -all | bound_objects | -name name_list
```

Data Types

<i>bound_objects</i>	list
<i>name_list</i>	list

ARGUMENTS

-all

Reports all bounds that were created with the **create_bounds** command. Bounds from an input PDEF file are not reported with this command.

This option is mutually exclusive with the *bound_objects* argument and the **-name** option, but you must specify one.

bound_objects

Specifies the bound objects. The bound objects can be specified by the **get_bounds** command.

This argument is mutually exclusive with the **-all** option and the **-name** option, but you must specify one.

-name *name_list*

Reports bounds with the specified names.

This option is mutually exclusive with the **-all** option and the *bound_objects* argument, but you must specify one.

DESCRIPTION

The **report_bounds** command generates reports on the user-specified bounds constraints in the design, as specified by the **create_bounds** command.

If **-all** is used, all bounds in the design created by **create_bounds** are reported. Bounds created by an input PDEF file are not reported.

If a list of bound names is specified, those bounds are reported. This report includes the bound name, the type of the bound, the effort level, and the list of cells that belong to the bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports bounds of names *test_1* and *test_2*:

```
prompt> report_bounds -name {test_1 test_2}

Report bounds:
*****
Bound Name: test_1, type: high effort auto group bound
Cells: a b c d
Bound Name: test_2, type: soft moving bound {10 20 30 40}
Cells: e f
*****
```

report_bsd_buffers

Displays information about BSR signal buffer chains.

SYNTAX

status **report_bsd_buffers**

ARGUMENTS

The **report_bsd_buffers** command has no arguments.

DESCRIPTION

This command displays information about BSR signal buffer chains in a boundary-scan-inserted design. Information about the pad and BSR instance names is shown, along with buffer instance name information for each BSR signal.

EXAMPLES

The example shows the report generated by the **report_bsd_buffers** command:

```
prompt> report_bsd_buffers
*****
Report : BSD Buffers
Design : M1
Version: F-2011.09-SP3
Date  : Thu Dec 22 03:40:36 2011

SEE ALSO

[set_bsd_configuration\(2\)](#)

report_bsd_compliance

Displays options set by the **set_bsd_compliance** command.

SYNTAX

```
integer report_bsd_compliance
```

ARGUMENTS

The **report_bsd_compliance** command has no arguments.

DESCRIPTION

The **report_bsd_compliance** command displays the options set by the **set_bsd_compliance** command on the current design.

The command reports the compliance pins and the bit pattern set for them by **set_bsd_compliance**.

EXAMPLES

The example shows the compliance report generated by **report_bsd_compliance**:

```
prompt> report_bsd_compliance
*****
Report : BSD Compliance
Design : TOP
Version: Z-2007.03
Date   : Fri Sep 22 08:44:55 2006

report_bsd_instruction

Displays options set by the **set_bsd_instruction** command.

SYNTAX

```
status report_bsd_instruction
  [-view spec | existing_dft]
  [-instruction list_of_instruction_names]
```

Data Types

list_of_instruction_names list

ARGUMENTS

-view **spec** | **existing_dft**

Specifies the view on which to report. Valid options are **spec** and **existing_dft**. If not specified, the tool reports both the **spec** and **existing_dft** views.

-instruction *list_of_instruction_names*

Specifies the name of an instruction or a list of instructions on which to report. If no instructions are specified, the tool reports all defined instructions.

DESCRIPTION

This command displays the options set by the **set_bsd_instruction** command on the current design.

It reports on register, opcode, capture value, input and output clock conditions, signature, internal scan pin, instruction enable pins, private, and timing of the instructions.

EXAMPLES

The following command reports on both the **spec** and the **existing_dft** view:

```
prompt> report_bsd_instruction
```

```
*****
```

```
Report : BSD Instruction
Design : TOP
```

set_scan_path(2)

report_buffer_tree

Reports the buffer tree and its level information at the given driver pin.

SYNTAX

```
status report_buffer_tree
  [-from start_point_list | -net net_list]
  [-depth max_depth]
  [-connections]
  [-hierarchy]
  [-physical]
  [-nosplit]
```

Data Types

<i>start_point_list</i>	list
<i>net_list</i>	list
<i>max_depth</i>	int

ARGUMENTS

-from *start_point_list*

Specifies the starting point of the buffer tree. The starting point is defined as level 0 of the tree. The *start_point_list* must contain only pins or ports. This option and the **-net** option are mutually exclusive.

-net *net_list*

Specifies a net as the starting point of the buffer tree. The *net_list* must contain only nets. This option and the **-from** option are mutually exclusive.

-depth *max_depth*

Reports only the *max_depth* levels of buffers in the tree. The default is to report the buffer tree until a real load or hierarchical boundary is reached.

-connections

Shows the net connections in the report. By default, the net connections are not shown.

-hierarchy

Shows the buffer tree across the hierarchy. By default, the report terminates at hierarchical boundaries.

-physical

Displays the location for each pin, with the coordinates in microns.

-nosplit

Prevents line splitting, making it easier to write scripts to extract information from the report output. By default, the design

information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_buffer_tree** command reports a buffer tree at the given driver pins or driver nets. It reports the full name of the driver pin (which includes the name of the cell), the name of the library cell, and the level of the driver relative to the starting point. The starting point is defined as level 0 of the tree.

Reporting terminates at the non-buffer pins, hierarchical boundaries (except when the **-hierarchy** option is used), or when the level reported exceeds the value specified by *max_depth*.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report a buffer tree:

```
prompt> report_buffer_tree -from cell1/O
```

The following example shows how to report a buffer tree with net connections:

```
prompt> report_buffer_tree -connections -from cell1/O
```

SEE ALSO

all_fanout(2)
balance_buffer(2)
clean_buffer_tree(2)
create_buffer_tree(2)
remove_buffer_tree(2)
report_constraint(2)
report_hierarchy(2)
report_net_fanout(2)

report_buffer_tree_qor

Displays quality-related properties of the buffer trees at the given driver pins.

SYNTAX

```
status report_buffer_tree_qor
  [-from list_of_driving_pins_or_nets]
```

Data Types

list_of_driving_pins_or_nets list

ARGUMENTS

-from *list_of_driving_pins_or_nets*

Specifies the starting points of the buffer trees to be reported.

DESCRIPTION

The **report_buffer_tree_qor** command reports quality-related properties of the buffer trees at given driver pins or driver nets. The report is presented as a spreadsheet containing the following columns:

1. Number of sinks (non-buffer loads)
2. Number of buffers and inverters
3. Number of buffer levels
4. Buffers' area
5. Number and value of design rule violations; max_tran, max_cap and max_fanout
6. Total negative slack on the sinks
7. Worst slack among the sinks
8. Maximum immediate fanout in the tree (max. sub-tree fanout)
9. Name of the driving pin

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to report the quality of all buffer trees with the number of sinks exceeding 100:

```
prompt> report_buffer_tree_qor \
    -from [all_high_fanout -nets -threshold 100 -through]
```

```

report_bus

Lists the bused ports and nets in the current instance or in the current design.

SYNTAX

```
status report_bus  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the output report. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays information about buses in the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

Buses are indexed in an ascending order in the report. If a bus is named in a descending order, the numbers in the "Step" column are negative. Bussed pins are not listed in the report because the bus commands operate only on design ports (not reference ports).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command displays bus information on the current design:

```
prompt> report_bus  
*****  
Report : bus  
Design : SUBTRACTOR  
Version: v2.0  
Date  : Fri Mar 16 14:22:01 1991  
*****  
Bussed Port Dir From To Step Width Type
```

```
-----
A      in      0  3  1  4 array
B      in      0  3  1  4 array
DIFF    out     0  3  1  4 array
-----  
Bussed Net   From   To   Step  Width Type
-----  
A          0  3  1  4 array
B          0  3  1  4 array
DIFF        0  3  1  4 array
```

SEE ALSO

[create_bus\(2\)](#)
[remove_bus\(2\)](#)

report_case_analysis

Reports case analysis on ports or pins.

SYNTAX

```
string report_case_analysis
  [-all]
  [-nosplit]
```

ARGUMENTS

-all

Reports the built-in constant pins of the design that are considered for startpoints of constant propagation. Propagation of logic constants is only done if the **set_case_analysis** command was executed, or the variable **case_analysis_with_logic_constants** or **disable_case_analysis** is set to **true**.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_case_analysis** command reports case analysis entries specified with the **set_case_analysis** command. The report lists all pins and ports on which case analysis is specified. The list does not report where the logic constant values are propagated.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example specifies that pins *U1/U2/A* and *U1/U3/CI* are set to a constant of logic 1:

```
prompt> set_case_analysis 1 {U1/U2/A U1/U3/CI}
```

```
prompt> report_case_analysis
```

```
*****
```

```
Report : case_analysis
Design : middle
Version: 1997.01
Date  : Mon Jul 22 17:04:17 1996
*****
```

Pin name	User case analysis value
U1/U2/A	1
U1/U3/CI	1

SEE ALSO

[remove_case_analysis\(2\)](#)
[set_case_analysis\(2\)](#)

report_cell

Displays information about cells in the current instance or current design.

SYNTAX

```
status report_cell
  [-nosplit]
  [-connections]
  [-verbose]
  [-physical]
  [-only_physical]
  [-significant_digits digits]
  [cells]
```

Data Types

<i>digits</i>	integer
<i>cells</i>	collection

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-connections

Displays all pins of the cell and the connected nets.

-verbose

Displays verbose connection information. For each input pin, the tool displays the net and the driver pins on that net. For each output pin, the tool displays the net and the load pins on that net.

-physical

Reports the orientation and location of the cell.

-only_physical

Reports information for physical-only cells.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are 0 through 13 and the default is 6. Using this option overrides the value set by the **report_default_significant_digits** variable.

cells

Specifies the cells and instances to show in the report. If not specified, all cells in the current instance are listed.

DESCRIPTION

This command displays information and statistics about cells in the current instance or current design. If *current_instance* is set, the report is generated for the design of that instance; otherwise the report is generated for the current design.

Parameterized cells are attributed by the letter *p* and contain parameters that control aspects of the designs they instantiate. The actual values of a cell's parameters appear at the bottom of the report.

Control logic cells are designated as type *c* in the report generated by **report_cell**. Use this information to identify control logic cells when using the **group** command. Group control logic cells with the cells that they control.

This command does not display constant cells. To display constant cells, use the following command:

```
get_cells -hierarchical * \
    -filter "@ref_name==**logic_0** || @ref_name==**logic_1**"
```

Use the **-connections** option to list the nets connected to each pin.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a cell report:

```
prompt> report_cell
*****
Report : cell
Design : CONTROL
Version: E-2010.12
Date  : Wed Sep 22 14:09:15 2010
*****
```

Attributes:

- b - black box (unknown)
- bo - allows boundary optimization
- BO - reference allows boundary optimization
- c - control logic
- d - dont_touch
- D - reference or design is dont_touched
- h - hierarchical
- n - noncombinational
- p - parameterized
- r - removable
- S - synthetic module
- u - contains unmapped logic

P1      DW01_add    50.00 S, p
-----
```

Total 18 cells 206.00

Flip-Flop Types:

- 1 - Default type MX1, MX1P, MX2, MX2P, MX3, MX3P, MX4, MX4P
- 2 - Exact type LMNO1

HDL Parameters:

P1 - width => 16

The following is an example of a verbose cell connection report for the t_bar cell:

```
prompt> report_cell -connections -verbose {t_bar}
```

```
*****
Report : cell
  -connections
  -verbose
Design : counter
Version: E-2010.12
Date   : Wed Sep 22 21:28:33 2010
*****
```

Connections for cell 't_bar':

```

Reference:      IVA
Library:       lsi_10k
Area:          1
dont_touch:    FALSE
```

Input Pins	Net	Net Driver Pins	Driver Pin Type
A	t	t/Z	Output Pin (EO)

Output Pins	Net	Net Load Pins	Load Pin Type
Z	t_bar	zero/B	Input Pin (OR2)

1

The following command reports on all of the registers in the current design:

```
prompt> report_cell [all_registers]
```

report_hierarchy(2)
report_net(2)
report_reference(2)
report_default_significant_digits(3)
```

report_cell_mode

Generates a report of the instance modes.

SYNTAX

```
status report_cell_mode
  [-nosplit]
  [instance_list]
```

Data Types

instance_list list

ARGUMENTS

-nosplit

Prevents line splitting. By default, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

instance_list

Indicates that the mode report is to include only the specified cells. By default, all cells that have modes are included.

DESCRIPTION

This command reports which cells have modes, and for each mode, shows whether the mode is currently enabled or disabled. This reports reflects the mode specifications of the **set_cell_mode** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example reports that two cells in the design have modes: the *Uram1* cell and the *Uram2* cell.

```
prompt> report_cell_mode
```

```
*****
```

```
Report : mode
```

Design : top_design

Cell	Mode(Group)	Status
Uram1/core(RAM2_core)	read(rw) write(rw)	ENABLED ENABLED
Uram2/core(RAM2_core)	read(rw) write(rw)	ENABLED ENABLED

The following example reports that modes are specified for the two RAMs that have modes in the design. Ram *Uram1* is set in mode read, and Ram *Uram2* is set in mode write. This means all timing arcs of RAM *Uram1* associated with mode read are enabled, and all timing arcs associated with mode write are disabled.

```
prompt> set_cell_mode read Uram1/core
prompt> set_cell_mode write Uram2/core
prompt> report_cell_mode
```

Report : mode
Design : top_design

Cell	Mode(Group)	Status
Uram1/core(RAM2_core)	read(rw) write(rw)	ENABLED disabled
Uram2/core(RAM2_core)	read(rw) write(rw)	disabled ENABLED

SEE ALSO

[set_cell_mode\(2\)](#)

report_check_library_options

Reports the values or the status of the options set by the **set_check_library_options** command.

SYNTAX

```
status report_check_library_options
  [-physical]
  [-logic_vs_physical]
  [-logic]
  [-default]
```

ARGUMENTS

-physical

Reports the values or the status of the options set by the **set_check_library_options** command to check between physical libraries.

-logic_vs_physical

Reports the values or the status of the options set by the **set_check_library_options** command to check between logical libraries and physical libraries.

See the **-logic_vs_physical** option in the **set_check_library_options** man page for more information.

-logic

Reports the values or the status of the options set by the **set_check_library_options** command to check between logical libraries.

See the **-logic** option in the **set_check_library_options** man page for more information.

-default

Reports the default values of all library-checking options. If this option is not specified, the current values of the options are reported.

DESCRIPTION

The **report_check_library_options** command reports the values or the status of the options set by the **set_check_library_options** command. The **report_check_library_options** command provides information about options used for checking between logical libraries, options used for checking between physical libraries, and options used for checking between logical libraries and physical libraries.

Use the **report_check_library_options** command after running **set_check_library_options**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, **report_check_library_options** checks all data for the specified *test.mw* library, and then reports the option values:

```
prompt> set_check_library_options -cell_footprint -bus_delimiter
```

```
prompt> report_check_library_options -logic_vs_physical  
1
```

```
Report options for check_library  
*****
```

```
Check cell area      : false  
Check cell footprint: true  
Check bus delimiter : true  
Cell names          : (null)  
Logic libraries     : (null)  
Physical libraries  : (null)
```

```
1
```

SEE ALSO

[check_library\(2\)](#)
[set_check_library_options\(2\)](#)

report_clock

Displays clock-related information.

SYNTAX

```
status report_clock
  [-attributes]
  [-skew]
  [-nosplit]
  [-groups]
  [-scenarios scenario_list]
  [clock_names]
```

Data Types

<i>scenario_list</i>	list
<i>clock_names</i>	collection

ARGUMENTS

-attributes

Lists all clocks in the current design, and for each clock, shows the clock name, period, waveform, source, and clock attributes such as "p" for propagated clock or "G" for generated clock. This is the default report.

-skew

Reports the clock network skew information set on the design by the **set_clock_uncertainty** command. This information includes rise delay, fall delay, plus uncertainty, and minus uncertainty of the clock network.

-nosplit

Prevents line splitting. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-groups

Reports the clock groups information set on the design by the **set_clock_groups** command.

-scenarios *scenario_list*

Reports clocks for the specified scenarios of a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately. If you do not specify this option, only the current scenario is reported. The **-scenarios** option and *clock_names* argument are mutually exclusive.

clock_names

Lists the clocks that are to be reported. Substitute the collection you want for *clock_names*.

DESCRIPTION

This command displays all clock-related information for a design. The report contents are controlled by the options used. If you do not specify any option, the attributes report is displayed by default.

The **report_transitive_fanout -clock_tree** report shows the fanout network of every clock source in the design.

To view a list, or create a collection, of all clocks in the design, use the **all_clocks** command.

The **-scenarios** option and *clock_names* argument are mutually exclusive.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

report_clock_gating

Reports the Power Compiler tool's clock-gating details.

SYNTAX

```
status report_clock_gating
  [-no_hier]
  [-verbose]
  [-gated]
  [-ungated]
  [-gating_elements]
  [-only cell_list]
  [-nosplit]
  [-physical]
  [-multi_stage]
  [-style]
  [-structure]
  [-scenarios scenario_list]
  [-enable_conditions]
```

Data Types

<i>cell_list</i>	list
<i>scenario_list</i>	list

ARGUMENTS

-no_hier

Reports the clock-gating information only for the top level of the current design. If this option is not specified, all levels of hierarchy, starting from the current design, are reported.

-verbose

Reports more detailed information such as, test information and a list of related registers to the clock-gating cells. By default, this information is not included in the report.

-gated

Reports the names of all gated registers, along with the names of the corresponding clock-gating elements.

-ungated

Reports the names of all ungated registers, along with the unmet clock-gating conditions.

-gating_elements

Reports the names of all clock-gating elements, along with their style, setup, and hold times, inputs, and outputs.

-only *cell_list*

Reports information only for the clock-gating cells or gated and ungated registers listed in *cell_list*. By default, information is displayed for all clock-gating cells and ungated and gated registers.

-nosplit

Prevents line splitting and facilitates writing applications to extract information from the report output. Most design information is listed in fixed-width columns. If information for a field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical

Reports the physical locations and distance statistics of clock-gating cells and gated registers, along with other clock-gating information. This option can be used only with the **-gating_elements** option.

-multi_stage

Reports multistage clock-gating statistics in the clock-gating summary.

-style

Reports the clock-gating style of all clock gates in the current design.

-structure

Reports the clock-gating structure summary and the clock-gating structure details. Information about the clock-gating cells and gated registers is classified according to the clock domains where they belong. Additional information regarding fanout and clock latency on each clock-gating element is also displayed.

This option can only be combined with the **-scenarios** option.

-scenarios scenario_list

Produces a set of reports for the specified scenarios of a multicorner-multimode design when used with the **-structure** option. To get reports for all active scenarios, use the **[all_scenarios]** with the **-scenarios** option. If you do not specify this option, only the current scenario is reported.

-enable_conditions

Reports the enable conditions of all clock-gating cells connected to registers. A Boolean equation is used to represent the enable conditions as a sum of products: '&' is the AND operation, '|' is the OR operation and, '!' is the NOT operation. This option can only be combined with the following options: the **-only** option to report specific clock gates and registers, the **-nosplit** option to display enable conditions on a single line, and the **-high_effort** option to maximize the terms to show.

DESCRIPTION

The **report_clock_gating** command reports information about clock-gating cells and gated and ungated registers in the current design. To generate the report, the **report_clock_gating** command uses clock-gating attributes added on the clock-gating cells, by Power Compiler. Any clock gating added by other means, such as clock gating inferred by or instantiated in the RTL code, lacks these attributes and does not appear in the report.

Self-gating cells inserted by Power Compiler are also excluded from this report. Use **report_self_gating** command to get information about them.

When you run the command without any option, the report lists the number of clock-gating elements, the number of gated and ungated registers with percentages of the total, and the total number of registers.

When you use the **-multi_stage** option, the summary also includes statistics of multistage clock-gating. These statistics include the number of multistage clock-gating elements (such as clock gates that have other clock gates in their fanout), the average multistage fanout (defined as the average number of clock gates in the fanout of the multistage clock-gating elements), the number of gated cells (registers and clock gates), and the maximum and average number of stages per leaf of the clock tree (gated registers, but not gated clock gates). Use one or more of the other options to get more detailed information.

Irrespective of the use of any option, the command always prints a "Report by Origin" table (additional to the summary), which includes

the following information:

- The number and percentage of tool-inserted clock gating elements.
- The number and percentage of pre-existing clock gating elements.
- The number and percentage of gated registers.
- The number and percentage of registers gated by tool-inserted clock gating elements.
- The number and percentage of registers gated by pre-existing clock gating elements.
- The number and percentage of ungated registers.
- The total number of registers.

If the design contains multibit registers, the "Report by Origin" table also includes information about bitwidth, i.e.:

- The number and percentage of gated bits.
- The number and percentage of bits gated by tool-inserted clock gating elements.
- The number and percentage of bits gated by pre-existing clock gating elements.
- The number and percentage of ungated bits.
- The total number of bits.

This information is displayed as an additional column of the "Report by Origin" table. All the percentages of registers (and bits) are computed over the total amount of registers (and bits). Note that, if the design is multistage, the registers (and bits) can be simultaneously gated both by tool-inserted and pre-existing clock gating elements. Therefore, their corresponding percentages will not add up to 100% in general (even if there are no ungated registers).

When you use the **-gating_elements** option, a "(d)" flag next to the name of a clock-gating cell indicates that the clock-gating cell or its parent hierarchical cell is marked dont_touch with the **set_dont_touch** command. This means that this clock-gating cell is not modified or removed.

When you use the **-structure** option, the command generates the clock-gating structure summary and clock gating structure details in the reports. The clock-gating structure summary reports the total number of registers (gated and ungated) and the number of clock gates and gated elements for each clock-gating stage, for each clock domain. The clock-gating structure details shows, for each clock domain and each clock gating stage, all clock-gating cells, their respective fanout, clock latency, and gated elements. This option can be combined only with the **-scenarios** option.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example shows a report generated when the **report_clock_gating** command is issued without any option. The report shows that out of 6 registers, 4 are gated and 2 are ungated. Note that the only existing clock gate was inserted by the tool. As a result, there are 0 registers (and consequently bits) gated by pre-existing clock gating elements. Since at least one of the registers is multibit, the "Single-Bit Equivalent" column is included. Its values are consistent with the fact that all the gated registers have 2 bits, while all the ungated registers are single-bit registers. For simplicity, the "Multibit Decomposition" table is not included in this example, even though it is printed by the report because the design is multibit.

```
prompt> report_clock_gating
```

```
*****
Report : clock_gating
Design : top
Version: R-2020.09-BETA
Date  : Fri 31 Jul 20:45:04 2020
*****
```

Clock Gating Summary

Number of Clock gating elements	1	
Number of Gated registers	4 (66.67%)	
Number of Ungated registers	2 (33.33%)	
Total number of registers	6	

Clock Gating Report by Origin			
	Actual (%) Count	Single-Bit (%) Equivalent	
Number of tool-inserted clock gating elements	1 (100.00%)		
Number of pre-existing clock gating elements	0 (0.00%)		
Number of gated registers	4 (66.67%)	8 (80.00%)	
Number of tool-inserted gated registers	4 (66.67%)	8 (80.00%)	
Number of pre-existing gated registers	0 (0.00%)	0 (0.00%)	
Number of ungated registers	2 (33.33%)	2 (20.00%)	
Number of registers	6	10	

The following example shows a report generated with the **-multi_stage** option for a multistage clock-gated design. A multistage clock gate is a clock-gating cell that drives another clock-gating cell. The report shows three clock-gating elements, ten gated registers, and no ungated registers. Two of the three clock gates are multistage and their average multistage fanout is 1.0, indicating that the clock path consists of a chain of three clock gates. The following diagram illustrates the testcase:

CG1 -----> CG2 ---+--> CG3 -----> 8x FF | ----> 2x FF

Eight registers have three stages on their clock path, and two registers have only two stages, bringing the average number of stages to $2.8 = ((8*3 + 2*2)/10)$. The number of gated cells is $12 = 10$ (registers) + 2 (gated clock gates, CG2 and CG3). For simplicity, the "Report by Origin" table is not included in this example, since all the clock gating elements are pre-existing.

prompt> **report_clock_gating -multi_stage**

```
*****
Report : clock_gating
  -multi_stage
Design : top_level
Version: Q-2019.12
Date  : Mon Apr 27 15:45:26 2020
*****
```

Clock Gating Summary		
Number of Clock gating elements	3	
Number of Gated registers	10 (100.00%)	
Number of Ungated registers	0 (0.00%)	
Total number of registers	10	
Number of multi-stage clock gates	2	
Average multi-stage fanout	1.0	
Number of gated cells	12	
Maximum number of stages	3	
Average number of stages	2.8	

The following example shows a report generated when the **report_clock_gating** command is issued without any option. The design is multistage and all the registers only have 1 bit. The following diagram illustrates the testcase:

```
clk ---> CG1 ---+---> CG2 -----> 4x FF || | ----> 4x FF | ---> 2x FF
```

The clock gate CG1 is pre-existing, while CG2 is tool-inserted. As a result, the four registers gated by CG2 are simultaneously reported as pre-existing and tool-inserted. This is an example of a design in which the sum of the following percentages is greater than 100%:

- The percentage of registers gated by tool-inserted clock gating elements.
- The percentage of registers gated by pre-existing clock gating elements.
- The percentage of ungated registers.

This is because the number of tool-inserted gated registers plus the number of pre-existing gated registers is greater than the number of gated registers given that these sets are mutually inclusive. Note that the "Single-Bit Equivalent" column was not included in the "Report by Origin" table, since there are no multibit registers. For simplicity, the "Report by Origin" table will not be included in any further example.

```

Clock Gating Summary

Number of Clock gating elements	2
Number of Gated registers	8 (80.00%)
Number of Ungated registers	2 (20.00%)
Total number of registers	10

Clock Gating Report by Origin

	Actual (%)	Count
Number of tool-inserted clock gating elements	1 (50.00%)	1
Number of pre-existing clock gating elements	1 (50.00%)	1
Number of gated registers	8 (80.00%)	8
Number of tool-inserted gated registers	4 (40.00%)	4
Number of pre-existing gated registers	8 (80.00%)	8
Number of ungated registers	2 (20.00%)	2
Number of registers		10

The following example shows a report generated by the **report_clock_gating** command (with no options) when multi-bit registers are present in the design. The report shows the **Clock Gating Summary** table and an additional table titled **Clock Gating Multibit Decomposition**, with information about single-bit and multi-bit registers found in the design. This additional table is present only if multi-bit registers are found in the design.

There are 26 single-bit registers in the example, 3 of them are ungated. Also, there are 7 multi-bit registers in the design, two of them are 2-bit registers and the rest are 4-bit. Both 2-bit registers are gated, while only four of the 4-bit registers are gated.

The **Clock Gating Multibit Decomposition** table has a column titled **Actual Count** which represents the physical cell count. On the other hand, the **Single-bit Equivalent** column shows how the count would look if every multi-bit register were converted to the single-bit equivalent ones. Notice that the counts in the **Clock Gating Summary** table are based on the **Single-bit Equivalent** column; this

is to make easier the comparison of different clock-gating schemes independently of multi-bit register availability in the library that is being used. It is the **Single-bit Equivalent** count what is taken into account for load balancing purposes.

Clock Gating Cell Report

Clock Gating Bank : clk_gate_lowout_reg

STYLE = latch, MIN = 3, MAX = 2048, HOLD = 0.00, SETUP = 0.00, OBS_DEPTH = 5

INPUTS :

clk_gate_lowout_reg/CLK = clk
clk_gate_lowout_reg/EN = n_80

OUTPUTS :

clk_gate_lowout_reg/ENCLK = n45

Clock Gating Summary

Number of Clock gating elements	1
Number of Gated registers	4 (66.67%)
Number of Ungated registers	2 (33.33%)
Total number of registers	6

The following example displays additional information about the gated register and its gating cell:

prompt> **report_clock_gating -gated**

```
*****
Report : clock_gating
-gated
Design : low_design
Version: 2000.11
Date  : Thu Jul 26 20:41:33 2001
*****
```

Gated Register Report

Clock Gating Bank	Gated Register
clk_gate_lowout_reg	lowout_reg[3] lowout_reg[2] lowout_reg[1] lowout_reg[0]

Clock Gating Summary

Number of Clock gating elements	1
Number of Gated registers	4 (66.67%)
Number of Ungated registers	2 (33.33%)
Total number of registers	6

The **-ungated** option displays additional information about ungated registers and the reason they were not gated. If clock gating was inserted with the **insert_clock_gating** command, a brief report is printed, which catches four ungated reasons. But if clock-gating was inserted with the **compile[ultra]-gate_clock** command, additional reasons are captured and reported. Also, for some of these reasons there is a "What next" recommendation on how to fix it.

report_clock_gating_check

Prints a report of the clock-gating checks.

SYNTAX

```
string report_clock_gating_check
  [-nosplit]
  [-significant_digits digits]
  [instance_list]
```

Data Types

digits integer
instance_list list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the same column.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are from 0 through 13; the default is 2. Using this option overrides the value set by the variable **report_default_significant_digits**.

instance_list

Specifies designs (all gated clock checks in the specified design), clocks, cells, or pins for which to generate a clock-gating report. By default, the report is generated for the current design.

DESCRIPTION

The **report_clock_gating_check** command reports the clock-gating checks and the setup hold values. Information displayed about the specified objects include instance of the cell, enable pin, clock pin, setup/hold time for rise, setup/hold time for fall, user-specified high/low active waveform and clock-gating check attributes. The attributes show from where the clock-gating check was originally defined:

- i Automatically inferred by Design Compiler
- p Power Compiler inserted the check
- l Defined by the library cell

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports user-defined clock-gating checks:

```
prompt> set_clock_gating_check -setup 0.27 -hold 0.38
```

```
prompt> report_clock_gating_check
```

```
*****
```

Report : clock gating check

Design : top_design

Version: X-2005.09

Date : Fri Nov 11 14:47:08 2005

```
*****
```

Cell	Rise	Fall	Enable	Clock	Setup	Hold	Setup	Hold	Low/High	Attr
------	------	------	--------	-------	-------	------	-------	------	----------	------

g1/U1	A	B	0.27	0.38	0.27	0.38	High		i
g1/U2	A	B	0.27	0.38	0.27	0.38	Low		i
g1/U3	B	A	0.27	0.38	0.27	0.38	High		i
g1/U4	A	B	0.27	0.38	0.27	0.38	Low		i

Disabled:

None

Attr:

i:auto inferred, p:power compiler inserted, l:library cell defined

In the following example, the first command sets clock-gating checks on the design named *test*. The second command sets a clock gating check on the *g1/U2* cell with a non-controlling interval of *high*. The third command disables the clock-gating check on the *g1/U3/B* pin. The fourth command generates a clock-gating check report.

The (*) indicates user override of the non-controlling interval for cell *g1/U2*, which is different from what was determined internally. There are no Power Compiler clock-gating checks in this design. There is one clock-gating check that is disabled on pin *g1/U3/B*.

```
prompt> set_clock_gating_check -setup 0.33 -hold 0.42 test
```

```
prompt> set_clock_gating_check -high -setup 0.21 -hold 0.29 g1/U2
```

```
prompt> set_disable_clock_gating_check g1/U3/B
```

```
prompt> report_clock_gating_check
```

```
*****
```

Report : clock gating check

Design : test

Version: X-2005.09

Date : Fri Nov 11 14:52:18 2005

```

ARGUMENTS

-type report_type

Specifies the type of report to be generated. Allowed values are as follows:

- **transition** - specifies a transition time report.
- **latency** - specifies a latency report.
- **skew** - specifies a skew report. You cannot use the **-launch**, **-capture**, **-rise**, **-fall**, **-min**, **-max**, and **-lesser_than** options if you specify a skew report. You can use the **-include_uncertainty_in_skew** option only in a skew, interclock_skew, or summary report.
- **interclock_skew** - specifies an interclock skew report. You cannot use the **-launch**, **-capture**, **-rise**, **-fall**, **-min**, **-max**, and **-lesser_than** options if you specify an interclock skew report. You can use the **-include_uncertainty_in_skew** option only in a skew, interclock_skew, or summary report.
- **summary** - specifies a summary report that shows the worst instances of transition time, latency, and skew over the clock networks or subnetworks of interest. You can use only the **-clock**, **-to_list**, **-from_list**, **-include_uncertainty_in_skew**, **-nosplit**, and **-significant_digits** options if you specify a summary report.

For non-summary reports, report entries are ordered with respect to the specified attribute of interest (transition time, latency, or skew). All skews reported are "local" skews. For an explanation of local skew, see the DESCRIPTION section.

-clock clock_list

Specifies a list of clock networks to be used in the report. A subreport is produced for every clock in *clock_list*, unless you additionally specify a *to_list* or a *from_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *clock_list* and issues a warning. By default, if you do not specify *clock_list*, all clocks in the design that have associated clock networks are used in the report.

-from_clock from_clock_list

Specifies a list of clock networks to be used as from-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report considers every clock in the *from_clock_list*, unless you additionally specify a *from_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *from_clock_list* and issues a warning. By default, if you do not specify a *from_clock_list*, all clocks in the design that have associated clock networks are used as from-clocks in the report.

-to_clock to_clock_list

Specifies a list of clock networks to be used as to-clocks in the current interclock skew report. This option can be used only in an interclock skew report. The report considers every clock in the *to_clock_list*, unless you additionally specify a *to_list* that has no network intersection with a given clock. In that case, the tool drops these clocks from the *to_clock_list* and issues a warning. By default, if you do not specify a *to_clock_list*, all clocks in the design that have associated clock networks are used as to-clocks in the report.

-to to_list

Specifies the list of sequential clock network pins or ports to consider as to-pins in the current report. If any named pin is not the clock pin of a sequential device (such as a sink pin), the tool replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list with a warning message.

For skew reports, the from-to skew sense is defined by the pins in the *from_list* and the *to_list*, respectively. If the *to_list* is not specified, by default all sink pins in the given clock networks are used. Thus, specifying *to_list* reduces the topological scope of the report. For transition time and latency reports, *from_list* and *to_list* are concatenated and treated as a single list. If neither list is specified, *to_list* is assumed to be populated with all sink pins in the given clock networks.

-from from_list

Specifies a list of sequential clock network pins or ports to consider as from-pins in the current report. If a named pin is not the clock pin of a sequential device, the tool replaces that pin with all sequential clock pins in the transitive fanout of the named pin. If there

are no sequential clock pins in the pin's transitive fanout, the pin is dropped from the list with a warning message.

For skew reports, the from-to skew sense is defined by the pins in the *from_list* and the *to_list*, respectively. If the *from_list* is not specified, by default all sink pins in the given clock networks are used. Specifying the *from_list* reduces the topological scope of the report. For transition time and latency reports, the *from_list* and *to_list* are concatenated and treated as a single list. If neither is specified, the *from_list* is assumed to be populated with all sink pins in the given clock networks.

-setup

Specifies that only the setup data path is to be used in the report, and that the skews, latencies, or transition times reported must correspond to those used by the **report_timing** command in the verification of setup constraints. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed. This option cannot be used in summary reports.

-launch

Specifies that only pins launching data are to be used in the report, and that latencies or transition times reported must correspond to those used by the **report_timing** command for sequential device clock pins that are launching data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and the *to_list*. In all other reports, the **-launch** and **-capture** options are mutually exclusive. If neither option is specified, **-launch** is assumed. This option cannot be used in summary or skew reports.

-rise

Specifies that the active transition is a rising edge for sequential device clock pins in the current report. The **-rise** and **-fall** options are mutually exclusive. If neither option is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself. This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. This option cannot be used in summary or skew reports.

-min

Specifies that the reports are to be sorted by minimum latencies or transition times. The **-min** and **-max** options are mutually exclusive. If neither option is specified, the reports are sorted in the same manner as described for the **-nworst** option. This option cannot be used in summary or skew reports. To check the quality of a balanced clock tree network, you can generate two latency reports, one with **-min** and one with **-max**.

-nworst worst_entries

Specifies the number of worst report entries to be reported per clock domain. The default value is 1. Entries are sorted with respect to the attribute of interest (transition time, latency, or skew) specified with **-type report_type**.

The worst entries are those most likely to cause a violation. For example, if you request a latency report using **-setup** and **-capture**, the smallest *worst_entries* are listed, sorted in ascending order, because small capture latencies for setup paths are more likely to lead to a violation than large capture latencies. For skew reports, the worst entries always correspond to the largest skews over the specified domain. The above definition of "worst" can be overridden by use of the **-min** or **-max** options. This option cannot be used in summary reports.

-greater_than lower_limit

Specifies that only those entries whose attribute value (latency, transition time, or skew) is greater (more positive) than *lower_limit* are shown. This option cannot be used in summary reports.

-lesser_than upper_limit

Specifies that only those entries whose attribute value (latency, transition time, or skew) is less (more negative) than *upper_limit* are shown. This option cannot be used in summary or skew reports.

-slack_lesser_than slack_upper_limit

Specifies that only those entries whose slack value is less (more negative) than *slack_upper_limit* are shown. For skew report entries, slack is the worst slack over all paths launched by the from-pin and captured by the to-pin. For transition time or latency report entries, slack is defined as the worst slack of all paths either launched by a transition at the sink pin (if **-launch** is used) or captured by a transition at the sink pin (if **-capture** is used).

Using this filter can greatly increase the runtime of this report. However, when used with **-capture**, the effect on runtime should be small, since the tool is able to make use of cached slack values to avoid expensive recomputation. This option cannot be used in summary reports.

-include_uncertainty_in_skew

Specifies that the user-defined uncertainty between the sequential devices in a launch/capture pair is to be considered a component of skew. This option can be used only in skew and summary reports.

-verbose

Specifies that a more detailed report is to be generated. Instead of a single line per pin, verbose reports trace the entire source-to-sink path through a clock network to show how the final reported attribute (skew, latency, or transition time) was accumulated over the course of the path. This option cannot be used in summary reports.

-show_clocks

Specifies that the launching and capturing clocks are to be shown for every interclock skew entry in the report. This is useful if the *from_clock_list* or the *to_clock_list* contains more than one clock each. This option can only be used in interclock skew reports.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-significant_digits digits

Specifies the number of digits after the decimal point to be displayed for time values in the generated report. Allowed values are 0-13. The default value is determined by the **report_default_significant_digits** variable, whose default value is 2. Use this option if you want to override the default. This option controls only the number of digits displayed, not the precision used internally for analysis. For analysis, the tool uses the full precision of the platform's fixed-precision, floating-point arithmetic capability.

-nets

Shows nets in verbose path traces. The default is not to show nets. To show the delay for the nets, use the **-input_pins** option. This option is similar to its counterpart in the **report_timing** command.

-capacitance

Shows the total (lumped) capacitance in verbose path traces. The default is not to show capacitance. For each driver pin, the total capacitance driven by the driver is displayed in a column preceding both incremental path delay and transition time. When **-nets** is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins. This option is similar to its counterpart in the **report_timing** command.

-attributes

Shows in verbose path traces the attributes specified in the **timing_report_attributes** variable. The current set of attributes supported are **dont_touch**, **dont_use**, **map_only**, and **size_only** for cells, and **dont_touch** and **ideal_net** for nets. This option is similar to its counterpart in the **report_timing** command.

-physical

Shows the locations of the pins and the capacitive loads for the pins and nets in verbose path traces. The loads are displayed as a pair of values of which the first is the wire capacitance of the net and the second value is the total capacitance driven by the driver. If the pin location cannot be determined, the cell location is displayed, with the coordinates in microns. This option is similar to its counterpart in the **report_timing** command.

-filter_false_paths

Causes the command to eliminate false paths from consideration during calculation of local register-to-register skew, resulting in more accurate (less pessimistic) reporting of skew. The default behavior is to not eliminate false paths from consideration.

-variation

Reports the mean and standard deviation of the statistical time increment for each source-to-sink path element in a **-verbose** report. This option works only when parametric on-chip variation (POCV) analysis has been enabled by setting the **timing_pocvm_enable_analysis** variable to true. By default, statistical parameters are not reported.

-scenarios scenario_list

Reports clock timing for a specified set of scenarios and skips reporting of inactive scenarios.

-max

Specifies that the reports are to be sorted by maximum latencies or transition times. The **-min** and **-max** options are mutually exclusive. If neither option is specified, the reports are sorted in the same manner as described for the **-nworst** option. This option cannot be used in summary or skew reports. To check the quality of a balanced clock tree network, you can generate two latency reports, one with **-min** and one with **-max**.

-fall

Specifies that the active transition is a falling edge for sequential device clock pins in the current report. The **-rise** and **-fall** options are mutually exclusive. If neither option is specified, the active transition at a latch or flip-flop is deduced from the launch or capture role and the behavior of the sequential device itself. This option enables you to answer "what if" questions regarding latency and transition time at sequential device clock pins. This option cannot be used in summary or skew reports.

-capture

Specifies that only pins capturing data are to be used in the report, and that the latencies or transition times reported must correspond to those used by the **report_timing** command for sequential device clock pins that are capturing data. In skew reports, the role is implicit from the from-to sense indicated by the *from_list* and the *to_list*. In all other reports, the **-launch** and **-capture** options are mutually exclusive. If neither option is specified, **-launch** is assumed. This option cannot be used in summary or skew reports.

-hold

Specifies that only the hold data path is to be used in the report, and that the skews, latencies, or transition times reported must correspond to those used by the **report_timing** command in the verification of hold constraints. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed. This option cannot be used in summary reports.

DESCRIPTION

This command generates a report of clock timing information for the current design.

Several reporting options allow you to examine skew, latency, and transition time attributes of a specified clock network or subnetwork at various levels of generality. By default, the report displays the values of these attributes only at sink pins (that is, the clock pins of sequential devices) of the clock network. Use the **-verbose** option to display source-to-sink path traces. If you specify several clock domains, **report_clock_timing** generates a separate subreport for each domain.

At the highest level of abstraction is the summary style report, which provides only a list of maxima and minima of the skew, latency, and transition time attributes over the given networks. At a lower level of abstraction are the transition, latency, and skew type reports, called list style reports, in which you can sort, filter, and display the worst set of sink pins in the given network with respect to a single attribute of interest. For skew reports, each report entry is a pair of sink pins and their relative skew. For transition time or latency reports, each entry corresponds to a single sink pin. The lowest level of abstraction is provided by the verbose mode, which replaces every sink pin in a list style report with a corresponding source-to-sink path trace.

In both summary and list style reports, the right column is an attribute column. Corresponding to each sink pin, the character symbols in this column indicate the following:

Symbol	Meaning
w	Worst-case operating condition
b	Best-case operating condition
r	Rising transition
f	Falling transition
p	Propagated clock to this pin
i	Clock inversion to this pin
e	Exception on this pin
-	Launching transition
+	Capturing transition

In verbose mode, back-annotations on path elements in the timing path are indicated by a character symbol. For definitions of these character symbols, see the man page for the **report_timing** command.

Skews reported by **report_clock_timing** are local skews only. Local skew exists from one sink pin to another only as long as the associated sequential devices are connected via a data path in the appropriate from-to sense. Note that even if all data paths between the sequential devices are false because of user-defined exceptions, the skew still qualifies as local skew if the devices are connected topologically.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example shows a typical summary style report:

```

```

ARGUMENTS

-clock_trees *clock_tree_list*

Reports only the clock trees specified in *clock_tree_list*. By default, the command reports all currently defined clock trees.

This option and the **-scenarios** option are mutually exclusive; you can use only one.

-summary

Prints a summary table for the clock trees. The summary table includes the following columns:

- Clock
The name of the clock tree.
- Sinks
The number of sinks in the clock tree.
- CTBuffers
The number of clock tree cells inserted by clock tree synthesis.
- ClkCells
The total number of cells in the clock tree, including preexisting gates.
- Skew
The clock tree skew.
- LongestPath
The longest path delay seen by the clock.
- Total DRC
The total number of DRC violations in the clock tree.
- BufferArea
The area of all the CTBuffers in the clock tree.

The **-summary** option can be used with the **-local_skew** option or combined with the **-local_skew** and **-local_skew_skip_icg** options. When you combine **-summary** with **-local_skew -local_skew_skip_icg**, the following columns are added to the report:

- LocalSkew
The Local skew value of the clock.
- LLatency
The largest latency value.
- SLatency
The smallest latency value.

-structure

Prints the complete structure of the clock tree. This report traverses through exceptions such as explicit float pins and implicit and explicit exclude pins.

-drc_violators

Lists the design rule checking (DRC) violations that occur in the clock trees up to the endpoints (default sinks or don't touch subtrees), including violations beyond exceptions on stop pins, exclude pins, and float pins but excluding violations on don't buffer nets, don't touch subtrees, nets inside interface logic models, and nets connected to boundary cells or pad cells.

-settings

Prints the clock tree settings specified by the **set_clock_tree_options** command, and references available for buffering, design rule checking (DRC) constraints, the list of available routing layers, and so on.

-exceptions

Prints a detailed list of clock tree exceptions.

-show_all_sinks

Reports all default sinks in the exception report when used with the **-exceptions** option.

-from from_list

Specifies the list of pin names whose fanout clock tree is reported.

-to to_list

Specifies the list of pin names to which the clock paths are reported. The specified pins must be clock tree sink pins. This option can be used with the **-operating_condition** and **-clock_trees** options.

-operating_condition condition

Reports the clock tree based on the specified condition.

-level_info

Reports information on the clock tree by level.

-high_fanout_net net_or_pin_list

Reports a tree built by the clock tree synthesis based high-fanout net synthesis engine. This option can be used alone or in combination with the following options:

- **-summary**
- **-structure**
- **-level_info**
- **-drc_violators**
- **-operating_condition**
- **-nosplit**

-premesh

Reports the clock network that has a clock mesh, starting from the clock root to the mesh driver inputs. This option treats the mesh driver inputs as stop pins and ignores the portion of the clock tree beneath the mesh. You can run this option as a standalone process or in combination with the following options:

- **-clock_tree**
- **-summary**
- **-structure**
- **-exceptions**
- **-drc_violators**
- **-operating_condition**
- **-nosplit**

-postmesh

Reports the clock network that has a clock mesh, starting from the inputs of the clock drivers that are the load pins of the clock mesh. This option does not report the clock network from the clock root to the clock mesh. You can run this option as a standalone process or in combination with the following options:

- **-clock_tree**

- **-summary**
- **-structure**
- **-exceptions**
- **-drc_violators**
- **-operating_condition**
- **-nosplit**

When you specify this option by itself, the command reports the longest path, the shortest path, and the skew among all subtrees, starting from the load pins of the clock mesh. In addition, the clock mesh is treated as ideal so that every point of the clock mesh has the same arrival time. Using this option with other options is equivalent to using the **-from load_pins_of_the_clock_mesh** option.

-nosplit

Prevents line splitting to allow ease of use to create scripts to extract information from the report output. By default, the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-all_drc_violators

Forces the **report_clock_tree** command to list all DRC violations in the clock trees, including violations beyond exceptions and violations on don't touch subtrees but excluding violations on don't buffer nets, nets inside interface logic models, and nets connected to boundary cells or pad cells.

-partial_structure_within_exceptions

Prints the part of the clock tree structure that is within explicit exclude and float pin exceptions. The clock structure beyond explicit exclude and float pin exceptions is not printed. Use the **-structure** option to print the complete clock structure.

-skew_group skew_groups_string

Reports the clock skew information only for the specified skew groups. You can separate each skew group with a space in the specified *skew_groups_string*. The default skew group name is **default**. For each specified skew group, the skew information is printed for all clocks that propagate to the skew group. You can only use this option with **-clock_trees** and **-summary**. If you did not specify the **-skew_group** option but ran the **commit_skew_group** command successfully, the clock skew information of all skew groups is reported.

-histogram_transition file_name

Reports the clock pin transition delay information to the specified file in histogram format.

-histogram_capacitance file_name

Reports the clock pin capacitance information to the specified file in histogram format.

-histogram_rcdelay file_name

Reports the RC delays between clock drivers and load pairs to the specified file in histogram format.

RC-delay histograms must be reported after clock tree synthesis gets valid delay data on clock nets.

-histogram_fanout file_name

Reports clock pin fanout numbers to the specified file in histogram format.

-histogram_rcdelay_to_sink file_name

Reports the RC delays per sink between clock drivers and each valid sink to the specified file in histogram format.

RC-delay histograms must be reported after clock tree synthesis gets valid delay data on clock nets.

-local_skew

Reports local skews for clock sink pairs with data dependencies. Local skew is the worst-case clock arrival time difference between a pair of registers with data dependency. The local skew report prints out a certain number of the worst local-skew clock pins, as controlled by the **-nworst** option.

The **-local_skew** option can be combined with **-summary**. When you combine these options with the **-local_skew_skip_icg** option, three additional columns (local skew and the largest and smallest local skew of each clock), are added to the summary report. This usage is supported only when you use the **-local_skew_skip_icg** option with the **-local_skew** option.

You can choose to have a histogram report by using the **-histogram_local_skew** option. You use the **-clock**, **-launch_pins**, and **-capture_pins** options to select which clock pin pairs to include in the local skew report.

-histogram_local_skew file_name

Reports local skew to the specified file in histogram format.

-local_skew_skip_icg

Skips integrated clock gating cells in the local skew report.

-nworst number_of_pin_pairs

Limits the number of clock pin pairs in the local skew report. Only the specified number of pin pairs with the worst local skew are included in the report. If a histogram is enabled for the local skew report, the histogram report file includes all local skew pin pairs, regardless of the **-nworst** option. By default, the value of **-nworst** is 1.

-launch_pins launch_pin_list

Includes only the pin pairs with the specified launch pins in the local skew report.

-capture_pins capture_pin_list

Includes only the pin pairs with the specified capture pins in the local skew report.

-number_of_bins bin_number

Specifies the number of bins that are used to generate the histogram report. Use this option when you specify at least one of the histogram reporting options: **-histogram_transition**, **-histogram_capacitance**, **-histogram_rcdelay**, **-histogram_fanout**, **-histogram_rcdelay_to_sink**, and **-histogram_local_skew**. By default, the number of bins is 10.

-sink_group

Enables the sink group reporting feature.

This option works only with the **-clock_trees** option and the **-sink_group_*** options. If you use any other options, they are either ignored or the tool issues an error message.

-sink_group_ignore_cts_exceptions

Ignores the clock tree synthesis exceptions, except for nonstop exceptions, when traversing the clock tree to find the sink groups.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_timing_relationship_limit limit

Reports sink groups that have timing relationships with other sink groups that are less than or equal to the specified limit.

If you set the limit to zero, the command reports only sink groups without any timing relationship.

By default, the limit is infinite and the command reports all sink groups with timing relationships.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_sort_by_clock | sink_group

Sorts the first-level text output either by clock or by sink group. When you specify **clock**, the sort key is the sink number under the clock. When you specify **sink_group**, the sort key is the timing relationship number. A tie is broken by the clock or sink group

name.

By default, the sink group report is sorted by clock.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_sort_order ascending | descending

Specifies whether the sink group report is sorted in ascending or descending order.

By default, the sink group report is sorted in ascending order.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_timing_relationship_file file_name

Writes the timing relationships of the sink pairs across the whole design; without considering any sink group information. Depending on the design, the file size could be huge, so use this option with caution.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_detail_file file_name

Writes detailed sink group information, such as a detailed list of clocks and sinks, to the specified file.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_ignore_buf_inv

Treats buffer and inverter cells as transparent cells during analysis if there is no clock or generated clock driving them.

This option is ignored if you do not also use the **-sink_group** option.

-sink_group_ignore_icg

Treats integrated clock gating cells as transparent cells during analysis if there is no clock or generated clock driving them.

This option is ignored if you do not also use the **-sink_group** option.

-scenarios list_of_scenarios

Specifies the list of active scenarios that the command reports. By default, the command reports only the current scenario.

The **-scenarios** and the **-clock_trees** options are mutually exclusive; you can use only one.

-interclock_timing

Allows you to report interclock timing relationships, which includes worst negative slack (WNS), cumulative negative slack (CNS), the number of violating paths (NVP), and local skew for the WNS path.

If you specify this option, the tool ignores any other options you specify.

DESCRIPTION

The **report_clock_tree** command obtains information on clock trees. The command reports the structural and timing characteristics of a compiled clock tree.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

In the following example, the **report_clock_tree** command is run on a previously-compiled clock tree called CLK1, and the reported results are based on a clock route estimator:

```
prompt> report_clock_tree -clock_trees CLK1
```

In the following example, the **report_clock_tree** command is run on a precompiled clock tree named CLK1. The report includes a listing of all logical DRC violations and a report of clock tree settings.

```
prompt> report_clock_tree -clock_trees CLK1 \
-drc_violators -settings
```

In the following example, the **report_clock_tree** command is run on a precompiled clock tree named CLK1. The report includes hierarchical level information on the clock tree netlist structure, the distribution clock tree delays, DRC violations, and all exceptions.

```
prompt> report_clock_tree -clock_trees CLK1 \
-structure -drc_violators -exceptions
```

In the following example, the **report_clock_tree** command is run on a precompiled clock tree named clk. The report includes a listing of all clock tree exceptions in the clock tree.

```
prompt> report_clock_tree -clock_trees clk -exceptions
```

```

In the following example, the **report_clock_tree** command is run on a previously compiled clock tree called CLK1, and two histogram report files are generated. The histogram report of transition delay of all clock pins in clock tree CLK1 is written to the tran_hist.rpt file. The histogram report of RC-delay between all the driver-load pin pairs in clock tree CLK1 is written to the rc_hist.rpt file. The histogram reports are generated by using the default bin number value of 10.

```
prompt> report_clock_tree -clock_trees CLK1 \
-histogram_transition tran_hist.rpt \
-histogram_rcdelay rc_hist.rpt
```

In the following example, the **report_clock_tree** command generates a sink group report.

```
prompt> report_clock_tree -sink_group \
-sink_group_detail_file a
```

Collecting setup paths:
... 20% ... 40% ... 60% ... 80% ... 100%
Done.

Saving sink_group timing relationship detail into file a.pair ...
Saving sink_groups information into file a.detail ...

Legends:
(SG) = total number of sink_groups which belong to this clock
(S) = total number of sinks from all of the sink_groups which belong to this clock
(S1) = total number of sinks of current sink_group
(A1) = total timing relationship number associated with sinks of current sink_group
(F1) = timing relationship number starting from any sink of current sink_group
(T1) = timing relationship number ending to any sink of current sink_group
(A2) = total timing relationship number associated with sinks of the two sink_groups
(F2) = timing relationship number starting from current sink_group to another sink_group
(T2) = timing relationship number starting from another sink_group to current sink_group
Format:
<clock_name> (clock) SG / S

SEE ALSO

report_collection

Output a tabular report of attribute values for elements in a collection.

SYNTAX

```
report_collection
  collection
  [-type report_type]
  [-header header_type]
  [-max_rows value_count]
  [-columns column_specification]
  [-nosplit]
```

Data Types

<i>collection</i>	string
<i>report_type</i>	list
<i>header_type</i>	string
<i>value_count</i>	int

ARGUMENTS

collection

Specifies the collection on which to report. The collection may be homogeneous or heterogeneous. The report comprises a header with information about the report such as the application name and version and the date and a tabular report on attribute values for elements of the collection. The tabular report content is determined by the report requested with the *-type* option. The attributes on which the report is generated is determined by the argument to the *-columns* option.

-type report_type

This option accepts an argument of a list of valid report type names. A report type is one of the following values: "values" | "statistics" | "distribution". If the option is omitted, the default report type is "values". The report types may be combined in a list to output multiple reports in one run. Each invocation of the command produces a single report header output unless it is suppressed with the *-header* option.

The "values" report is a tabular output of attribute values for the collection elements, with one row of values per collection element. The report columns comprises formatted attribute values for the objects.

The "statistics" report type outputs the following statistical data about the attribute values

* Minimum, lower quartile, median upper quartile, and maximum values for numeric attributes.
* The mean and standard deviation for numeric attributes.
* Number of null attribute values for each attribute.
* Number of valid attribute values for each attribute.
* Number of unique attribute values for each attribute.

The "distribution" report type outputs a header section with information about the report, followed by the following statistical values about the data.

* Number of null attribute values for each attribute.
* Number of valid attribute values for each attribute.
* Number of unique attribute values for each attribute.
* Distribution of values with number of occurrences of each attribute value..

If both "statistics" and "distribution" reports are requested, the overlapping portion of the two reports is output only once.

-header header_type

This option accepts one of the following valid argument values: "standard" | "none". If the option is omitted, the default header type is "standard". The "standard" header consists of the report name, object type, product name, product version, and the report date. Precise object types are always shown for "statistics" and "distribution" type reports. For "values" report, it is shown if the collection is homogenous or small. If the collection is heterogeneous and large, the object type shown for "values" report is "heterogeneous".

-max_rows value_count

This option indicates how many rows of data to include in the report. This number indicates the number of collection elements on which the report is produced. If the **collection** is very large, you may want to use the **-max_rows** option to limit the size of your report. Number of lines in the report may be greater than the **-max_rows** argument value if some data rows require multiple lines to output.

-columns column_specification

Indicates the set of attributes on which to report and their order in the report. At a minimum, *column_specification* is a list of attribute names of elements of the collection.

The special attribute name "object_class" may be used to include the element object class names, such as "cell" or "net", in the report output.

If the option is omitted, then the object full names and object class (or type) names are output by default.

Each attribute name may be followed by a list of token-value pairs to indicate report column formatting directives. The value tokens for formatting are *width*, *justify*, *label*, and *fit*. All column formatting specifications are optional.

width token is followed by a positive integer to value indicate the desired width of the column in number of characters. If not given, then the attribute value is queried for the first 100 elements of the collection and the longest value string determines the width of the column.

justify is followed by one of "left" or "right" to indicate the value's alignment in the column. If not given, then numeric attributes are justified right and other attributes are justified left.

By default, the column headers show the name of the attribute. *label* is followed a string to display in the report column header in place of the attribute name.

fit is followed by one of the following valid argument values: "split" | "none" | "truncate" | "wrap" | "elide_left" | "elide_center" | "elide_right". This option indicates how to format an attribute value that is too long to fit in the column's width. If option is omitted, the default formatting is "split". However, if the option **-nosplit** is given, then the default formatting becomes "none". Explicit *fit* values given in a column specification overrides the default set by **-noSplit**.

The "split" formatting inserts a newline after the value which is too long and continues the tabular row on the next line, justifying the next value to the correct column.

The "none" formatting does nothing to reformat a value that is too long, continuing with the next column value. Therefore, the remainder of the tabular row will not be aligned with column headers.

The "truncate" formatting truncates the value to the width of the column, discarding the remainder of the value.

The "wrap" formatting truncates the value to the column and continues the rest of the tabular row on the same row. The remainder of the value is output on the following line(s), taking as many lines as is needed to finish outputting the rest of the value.

The "elide_left" formatting truncates the beginning of the value and adds the elision string "..." at the beginning of the value.

The "elide_center" formatting omits the middle of the value and inserts the elision string "..." at the center of the value.

The "elide_right" formatting truncates the end of the value and adds the elision string "..." at the end of the value.

-nosplit

This option indicates that the default column formatting used for a value is that is too long for the column width is "none", rather than the default "split". See the **-columns** option description below for more details.

DESCRIPTION

This command outputs a tabular report of attribute values for elements of the given collection. The attribute values in the report are determined by the list of attributes given as the **-columns** option argument. The columns in the tabular report will be ordered by order of attributes in the list. The command **list_attributes** may be called to see a list of attributes defined for an object class.

The **-column** option also accepts additional optional column formatting specifications in the attribute list. You may specify the header label and the width for each column, how to justify the value, and how to fit a value in a column when the value is too long to fit within the column width.

If the collection is large, the report size may be limited by indicating a **-max_rows** value. The commands **filter_collection** and **sort_collection** may be called to filter and sort a collection based on some criteria prior to creating a report for the collection elements.

Statistical and value distribution reports on the collection elements may be produced using the **-type** option arguments "statistics" and "distribution", respectively. Report types may be combined in a list.

EXAMPLES

The following example from IC Compiler II creates a statistical report on a collection of cells along with a value distribution output.

```
prompt> set cells [get_cells -hierarchical *]
prompt> report_collection $cells -type {statistics distribution}
```

The following example, also from IC Compiler II, creates a report on a collection of cells with the full_name, area, and number_of_pins attribute values.

```
prompt> set cells [get_cells U*]
prompt> report_collection $cells -columns {full_name area number_of_pins}
```

The next example creates the same report but limits the width of the full_name column to 26 characters, designating "elide_center" formatting for full_name values that are longer than 26 characters.

```
prompt> report_collection $cells -columns \
    {{full_name {width 26} {fit elide_center}}} \
    area number_of_pins
```

The next examples limits the output to the first 10 objects in the collection.

```
prompt> report_collection $cells -columns \
    {{full_name {width 26} {fit elide_center}}} \
    area number_of_pins -max_rows 10
```

The next example first sorts the original collection of cells by the area attribute value in descending order, limiting the resulting collection to the top 10 area values. The example then creates a report for the resulting collection.

```
prompt> set sorted_cells [sort_collection -dictionary \
    $cells {area- full_name} -limit 10]
prompt> report_collection $sorted_cells -columns \
    {{full_name {width 26} {fit elide_center}}} \
    area number_of_pins
```

The next example reports on a sorted collection as in the above example but further limits the report to the first 10 objects in the collection. Note that this command may produce a report that is different from the above example. Limiting the sort to the first 10 values may have produced a collection with more than 10 objects since multiple objects may share the same area value.

```
prompt> set sorted_cells [sort_collection -dictionary \
    $cells {area- full_name} -limit 10]
prompt> report_collection $sorted_cells -columns \
    {{full_name {width 26} {fit elide_center}}} \
```

```
area number_of_pins} -max_rows 10
```

[list_attributes\(2\)](#)

report_compile_options

Displays information about the **compile** command options for the design of the current instance if set; or for the current design otherwise.

SYNTAX

```
status report_compile_options  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays the **compile** command directives of the current instance or current design and all of the designs in the hierarchy. The compile directives determine how a design is optimized.

If you set **current_instance**, the report is generated for the design of that instance; otherwise the report is generated for the current design.

EXAMPLES

The following is an example of a compile options report for the design *AN2_DESIGN*:

```
prompt> report_compile_options  
*****  
Report : compile_options  
Design : AN2_DESIGN  
Version: 1998.02  
Date  : Fri Dec 29 14:24:08 1997  
*****  
  
Design          Compile Option    Value  
-----  
AN2_DESIGN      flatten         false
```

```
structure      true
structure_boolean false
structure_timing  true
-----
```

In the following example, compile options are set for the design *encoder*, and a report is generated:

```
prompt> set_structure false
prompt> set_flatten true
prompt> report_compile_options
```

```
*****
Report : compile_options
Design : encoder
Version: 1998.02
Date  : Fri Dec 29 14:24:08 1997
*****
```

Design	Compile Option	Value
encoder	flatten	true
	flatten_effort	low
	flatten_minimize	single
	flatten_phase	false
	structure	false
	structure_boolean	false
	structure_timing	false

In the following example, cost priority and multiple port nets options are set for the design *encoder*, and a report is generated:

```
prompt> set_cost_priority -delay
prompt> set_fix_multiple_port_nets -feedthroughs -outputs
prompt> report_compile_options
```

```
*****
Report : compile_options
Design : encoder
Version: 1998.02
Date  : Fri Dec 29 14:24:08 1997
*****
```

Design	Compile Option	Value
encoder	flatten	true
	flatten_effort	low
	flatten_minimize	single
	flatten_phase	false
	structure	false
	cost_priority	max_delay
	fix_multiple_port_nets	feedthroughs outputs

SEE ALSO

```
compile(2)
set_cost_priority(2)
set_fix_multiple_port_nets(2)
set_flatten(2)
set_structure(2)
```

report_compile_spg_mode

Displays the tool settings updated by the **set_compile_spg_mode** command.

SYNTAX

status **report_compile_spg_mode**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **report_compile_spg_mode** command displays the tool settings updated by the **set_compile_spg_mode** command. The **set_compile_spg_mode** command sets tool settings to improve timing correlation with IC Compiler II or IC Compiler.

The command is supported only in topographical mode.

EXAMPLES

The following example shows the usage of the command:

```
prompt> report_compile_spg_mode
```

SEE ALSO

set_compile_spg_mode(2)

report_congestion

Reports the congestion statistics.

SYNTAX

```
status report_congestion
  [-effort minimum | low | medium | high]
  [-list_cells_over_grcViolation grcViolation_threshold]
```

Data Types

grcViolation_threshold integer

ARGUMENTS

-effort minimum | low | medium | high

Specifies the global routing effort level when the tool generates a global route congestion map.

The lower effort has a faster runtime but results in a more pessimistic congestion number. The higher effort has a better congestion result but requires a longer runtime. The default is **medium**.

This option applies only when the routing stage is **global**.

-list_cells_over_grcViolation *grcViolation_threshold*

Reports the cells in the congested region when GRC violation threshold is provided. Cells are presorted to list design with most congested cells.

DESCRIPTION

Note that congestion optimization and reporting is available only with Design Compiler Graphical.

This command computes and displays congestion statistics for the current design.

If you call this command two or more consecutive times without any changes to the design, global routing is skipped for the second time and the report is based on the global routing done in the first command.

For congestion analysis purposes, the design is divided into small regions called global routing cells (GRCs). A given global routing cell is considered overcongested if the actual number of wires passing through the global routing cell is greater than the number of available tracks in the global routing cell.

By default, the available tracks in the global routing cell are automatically filled based on the layer pitch. That is, the space between adjacent tracks always equals the layer pitch, not the distance of two actual tracks. If you want to use actual tracks instead of layer-pitch-based tracks, set the **dct_enable_track_auto_fill** variable to **false**.

In the congestion report, the Overflow value is the total number of wires in the design global routing cells that do not have a corresponding track available. The Max value corresponds to the highest number of overutilized wires in a single global routing cell. The GRCs value is the total number of overcongested global routing cells in the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **report_congestion** command:

```
prompt> report_congestion
*****
Report : congestion
Design : test_design
Version: A-2007.12
Date  : Mon Oct 29 10:43:51 2007
*****
```

Both Dirs: Overflow = 5 Max = 1 (5 GRCs) GRCs = 5 (11.90%)
H routing: Overflow = 5 Max = 1 (5 GRCs) GRCs = 5 (11.90%)
V routing: Overflow = 0 Max = 0 (0 GRCs) GRCs = 0 (0.00%)

1

```
prompt> report_congestion -list_cells_over_grc_violaiton 30
*****
```

```
Report : congestion
Design : many_rom
Version: I-2013.12-SP1-CS2
Date  : Mon Jan 6 22:00:39 2014
*****
```

Both Dirs: Overflow = 590305 Max = 33 (1 GRCs) GRCs = 85938 (67.13%)
H routing: Overflow = 275009 Max = 29 (1 GRCs) GRCs = 43141 (33.70%)
V routing: Overflow = 315296 Max = 33 (1 GRCs) GRCs = 42797 (33.43%)

Cells in Congested Regions:

Design	Cell	Reference	Congestion
many_rom	sub_Syn1st27909	SBC5LND2V1D1	33
many_rom	sub_Syn1st28217	SBC5LND2V1D2	31
1			

SEE ALSO

[set_congestion_options\(2\)](#)

report_congestion_options

Reports congestion options in the design.

SYNTAX

```
status report_congestion_options
  [-all]
  id_list
```

Data Types

id_list list

ARGUMENTS

-all

Report all congestion options.

id_list

Reports congestion options with the specified IDs.

DESCRIPTION

The **report_congestion_options** command reports the congestion options in the design. If **-all** is used, all congestion options in the design are reported. If a list of IDs is specified, only congestion options with the specified IDs are reported. The command first reports the design-wide congestion options. It will then report the regional congestion options, if any. The regional congestion options report includes the ID, the coordinates, and the values.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example report of the congestion options:

```
prompt> report_congestion_options -all
```

Report congestion options:

```
*****
Congestion parameters for the design:
Horizontal threshold: 0.8 (default)
Vertical threshold: 0.8 (default)
Maximum utilization: 0.95 (default)
Regional congestion options:
ID 0: {0 0 20 20}, MAX_UTIL: 0.5
*****
```

SEE ALSO

`remove_congestion_options(2)`
`report_congestion(2)`
`set_congestion_options(2)`

report_constraint

Displays constraint-related information about a design.

SYNTAX

```
status report_constraint
  [-all_violators]
  [-verbose]
  [-significant_digits digits]
  [-max_area]
  [-max_delay]
  [-critical_range]
  [-min_delay]
  [-max_capacitance]
  [-min_capacitance]
  [-max_transition]
  [-max_fanout]
  [-cell_degradation]
  [-max_toggle_rate]
  [-min_porosity]
  [-max_dynamic_power]
  [-max_leakage_power]
  [-max_total_power]
  [-max_net_length]
  [-connection_class]
  [-multiport_net]
  [-nosplit]
  [-min_pulse_width]
  [-min_period]
  [-scenarios scenario_list]
  [-ignore_infeasible_paths]
```

Data Types

digits integer
scenario_list list

ARGUMENTS

-all_violators

Displays a summary of all of the optimization and design rule constraints with violations in the current design. The **-verbose** option provides detailed information about constraint violations. Multiple violations for a given constraint are listed in order from largest to smallest violation.

-verbose

Displays more detail about constraint calculations.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are to be reported. The *digits* value must be between 0 and 13. The default is 2. This option overrides the value set by the **report_default_significant_digits** variable.

-max_area

Displays only the max_area constraint information. The default behavior (without this option and similar options) is to display all optimization and design rule constraints.

-max_delay

Displays only the max_delay and setup information.

-critical_range

Displays only the critical_range information. The critical_range is a design rule that directs the tool to optimize near-critical paths along with the most critical path.

-min_delay

Displays only the min_delay and hold information.

-max_capacitance

Displays only the max_capacitance constraint information. The max_capacitance constraint is a design rule that limits the total capacitance on a net.

-min_capacitance

Displays only the min_capacitance constraint information. The min_capacitance constraint is a design rule that ensures a minimum total capacitance on a net.

-max_transition

Displays only the max_transition constraint information. The max_transition constraint is a design rule that limits the transition time on a net. If the library uses the cmos2 delay model, this option shows the max_edge_rate information.

-max_fanout

Displays only the max_fanout constraint information. The constraint is a design rule that limits the fanout_load on a net.

-cell_degradation

Displays only the cell_degradation constraint information. The cell_degradation constraint is a design rule that limits the total capacitance on a net, with the limit depending on the transition times at the inputs of the cell.

-max_toggle_rate

Displays only the max_toggle_rate constraint information.

-min_porosity

Displays only the min_porosity constraint information. The min_porosity constraint is an optimization constraint for routability.

-max_dynamic_power

Displays only the max_dynamic_power constraint information. The default behavior (without this option and similar power-related options) is to display all types of power constraint information. Queries for power constraint information are valid only if a power-related license is available.

-max_leakage_power

Displays only the max_leakage_power constraint information.

-max_total_power

Displays only the max_total_power constraint information.

-max_net_length

Displays only max_net_length constraint information. The max_net_length constraint is a design rule that limits the route length of a net. For more information, see the man page for the **set_max_net_length** command.

-connection_class

Displays only the connection_class constraint information. The connection_class constraint is displayed only if there is a connection_class violation. For more information, see the man page for the **set_connection_class** command.

-multiport_net

Displays only the multiport_net constraint information. This constraint specifies whether multiple output ports can be connected to a given net. For more information, see the man page for the **set_fix_multiple_port_nets** command.

-nosplit

Prevents line splitting and facilitates writing applications to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column.

-min_pulse_width

Displays only the min_pulse_width constraint information. The min_pulse_width constraint is a design rule that limits the minimum duration of clock pulses in the clock network.

-min_period

Displays only the minimum period constraint information. The min_period constraint is a design rule that sets a minimum period on a clock signal. The min_period check is supported only for ideal clocks.

-scenarios scenario_list

Reports constraints for the specified scenarios of a multi-scenario design. Each scenario is reported separately. Inactive scenarios are not reported.

If you do not use this option, the **report_constraint** command reports constraints on all active scenarios, except when you use the **-all_violators** or **-verbose** option. If you use these options but not the **-scenarios** option, the **report_constraint** command reports constraints only on the current scenario.

-ignore_infeasible_paths

Ignores all the paths flagged as infeasible during the latest compilation.

DESCRIPTION

The **report_constraint** command displays the following information for the constraints on the current design:

- Whether the constraint was violated or met
- By how much the constraint value was violated or met
- The design object that was the worst violator

The maximum delay information shows cost by path group. This includes violations of setup time on registers or ports with output delay, as well as violations of **set_max_delay** commands. The total maximum delay cost is the sum of each group's weighted cost. For details on creating path groups, refer to the **group_path** command man page. To see the current path groups in the design, use the **report_path_group** command.

The minimum delay cost includes violations of hold time on registers or ports with output delay as well as violations of **set_min_delay** commands.

In the path delay reports, if a pin drives a high-fanout net, this is indicated in the report by a # symbol between the incremental and path timing values. Creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example shows brief constraint information for the current design:

```
prompt> report_constraint
```

```

report_cross_probing

Reports cross-probing data for specified cells and ports.

SYNTAX

```
status report_cross_probing
  [-nosplit]
  [-original_hierarchy]
  objects
```

Data Types

objects collection

ARGUMENTS

-nosplit

Prevents line splitting in the cross-probing report. Most of the design information is listed in fixed-width columns. In the absence of this option, if the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-original_hierarchy

Changes the format of the report by adding an additional line per object to display an object's original RTL hierarchy. Sometimes a cell undergoes a series of operations, such as ungrouping, name changes, and optimization that collapses the hierarchy and renames the cell. The **-original_hierarchy** option displays the RTL hierarchical name by which the cell was originally created and helps to identify where the cell originated.

objects

Specifies the cell and port objects to show in the report.

DESCRIPTION

This command displays cross-probing information about specified cells and ports in a report format.

You must have a design that was analyzed and elaborated or synthesized using Design Compiler version I-2013.12 or later. The tool provides information about where the cell or port was created, specifying which file and line number the object came from. If the object was tool generated, the file and line number are not applicable and are represented by a hyphen (-). In this case, the report specifies whether the origin of the object comes from UPF, the DFT engine, or another source.

Objects in the design that were merged can result in an object with multiple source locations in the report. Objects with multiple source positions appear multiple times in the report, and, for clarity, the object name is indented for lines other than the first source line.

The tool reports the following information for each specified object:

Type : The type of design object, either a cell or port.

Reference : For cells, this is the library reference cell. For ports, this is either IN, OUT, or INOUT.

Filename : The base name of the file. If this information is not available, the tool displays a hyphen (-).

Line : The line number associated with the file. If this information is not available, the tool displays a hyphen (-).

Origin : The origin associated with the object. For example, this value can be rtl, datapath, upf, clock_gating, self_gating, or dft.

If this information is not available, the tool displays a hyphen (-).

Object : The object name. If an object has multiple source positions,

the object name is indented for lines other than the first source line.

Object / Original Hierarchy : If the -original_hierarchy option is used, you will see this column instead of the Object column.

For each object, the first row in this column shows the object name.

For each object, the second row in this column shows the object's original hierarchy.

At the end of the report, mapping from the base name to the absolute file name is provided. You need to verify the existence of the file because the design or original source files might have been moved or deleted after the design was read in.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a **report_cross_probing** report:

```
prompt> set objects [get_ports]
{top_i top_o}
prompt> set objects [add_to_collection $objects [get_cells -hierarchical]]

report_cross_probing_files

Shows a list of cross-probing files and their status.

SYNTAX

```
status report_cross_probing_files  
[-errors_only]
```

ARGUMENTS

-errors_only

Reports files whose status are not OK.

DESCRIPTION

This command prints out a list of the cross-probing files that are stored in the database and the status of each file. The file status can be one of the following:

Status:

OK - No issues found

Missing - File is missing

No Permissions - User has no read permissions

Modified - File contents have been modified

If the status of a file is marked as Modified, the file content has been modified since the file was read. The Missing status might also indicate that the path exists, but it is a directory.

You can use this command to determine if the set of cross-probing file paths stored in the database are valid before using the GUI for cross-referencing. You can also list which RTL files need to be copied to the destination site if the design is being moved to a new location.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of the **report_cross_probing_files** command:

```
prompt> report_cross_probing_files

report_crpr

Reports the clock reconvergence pessimism calculated between specified register clock pins or ports.

SYNTAX

```
status report_crpr
  -from from_latch_clock_pin
  -to to_latch_clock_pin
  [-from_clock from_clock]
  [-to_clock to_clock]
  [-setup | -hold]
  [-significant_digits digits]
```

Data Types

<i>from_latch_clock_pin</i>	string
<i>to_latch_clock_pin</i>	string
<i>from_clock</i>	string
<i>to_clock</i>	string
<i>digits</i>	integer

ARGUMENTS

-from *from_latch_clock_pin*

Specifies the clock pin of the launching sequential device or clock-gating check to be reported. A constrained input port may also be used.

-to *to_latch_clock_pin*

Specifies the clock pin of the capturing sequential device or clock-gating check to be reported. A constrained output port may also be used.

-from_clock *from_clock*

Specifies the clock that fans out to the launching sequential device.

-to_clock *to_clock*

Specifies the clock that fans out to the capturing sequential device.

-setup

Reports the clock reconvergence pessimism for a setup data path. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed.

-hold

Reports the clock reconvergence pessimism for a hold data path. The **-setup** and **-hold** options are mutually exclusive. If neither option is specified, **-setup** is assumed.

-significant_digits digits

Specifies the number of digits to the right of the decimal point that are to be reported. Allowed values are 0 through 13. If this option is not specified, the number of significant digits is determined by the **report_default_significant_digits** variable, which has a default value of 2.

DESCRIPTION

This command reports the clock reconvergence pessimism calculated between specified register clock pins or ports. The command displays the following information about the calculation of the clock reconvergence pessimism between the two specified sequential elements:

- The name of the common pin in the clock network
- The clock edges (rising or falling) that propagate through the common point to the launching and capturing registers
- The value of the **timing_crpr_threshold_ps** variable
- A tabulation of the arrival times for both clock edges at the common point and their associated clock reconvergence pessimism (crp_rise and crp_fall)
- The clock reconvergence pessimism used along with the reasoning behind the selection of crp_rise or crp_fall used for that report
- The potential range of accuracy of the clock reconvergence pessimism value that will appear in the corresponding timing report is displayed. The range of accuracy depends upon the value of the **timing_crpr_threshold_ps** variable.

If the **timing_remove_clock_reconvergence_pessimism** variable is set to **false**, clock reconvergence pessimism removal is inactive and no report can be generated. To determine the current value of the variable, type the following command:

```
prompt> printvar timing_remove_clock_reconvergence_pessimism
```

The **-from_clock** and **-to_clock** options allow you to generate a report for only the specified clocks. By default, a report is issued for all clocks that fanout to each sequential device.

Two clock reconvergence pessimism values are calculated for each potential common point in the design:

- The crp_rise value is calculated from rising arrival times at the common point.
- The crp_fall value is calculated from falling arrival times at the common point.

The value of clock reconvergence pessimism used in the report depends upon what clock edges propagate through the common point to the clock pins of the launching and capturing devices. For example, if a rising edge through the common point triggers the launching device and also triggers the capturing device, then a rising clock reconvergence pessimism value (crp_rise) is used. Similar reasoning applies for a falling edge propagating through the common point and subsequently launching and capturing data leading to a falling clock reconvergence pessimism value being used (crp_fall). If a rising edge through the common point launches the data and a falling edge through the common point captures it, then a mismatch in sense occurs.

If a mismatch occurs and the **timing_clock_reconvergence_pessimism** variable is set to **normal**, then the minimum of crp_rise and crp_fall is used. If a mismatch occurs and the variable is set to **same_transition**, then the clock reconvergence pessimism is reported as 0. This selection process is reported in the selection details section of the report. To determine the current value of the **timing_clock_reconvergence_pessimism** variable, type the following command:

```
prompt> printvar timing_clock_reconvergence_pessimism
```

When the capturing sequential device is a level-sensitive latch, 2 clock reconvergence pessimism values are reported. The first value corresponds to the opening edge of the latch and appears in the timing report. The second value corresponds to the closing edge of the device. The selection details section also reports the decision-making process behind both clock reconvergence pessimism values. In this case, since the opening and closing clock edges at the latch will always be different, there will always be a mismatch in clock edges for one of them.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the clock reconvergence pessimism calculated between the *ffa* and *ffd* sequential elements for a setup data path:

```
prompt> report_crpr -from ffa/CP -to ffd/CP -setup
```

```
*****
```

Report : CRP Calculation

report_datapath_gating

Reports the status of datapath gating in the current design.

SYNTAX

```
status report_datapath_gating
  [-instances]
  [-nosplit]
  [-ungated]
  [-gated]
```

ARGUMENTS

-instances

Specifies that a breakdown per instance of the number of gated and ungated operators should be reported.

-nosplit

Prevents line-splitting and facilitates writing applications to extract information from the report output. Most design information is listed in fixed-width columns. If information for a field exceeds the column width, the next field begins on a new line, starting in the correct column.

-ungated

Print out all the ungated operators.

-gated

Print out all the gated operators with their optimization modes.

DESCRIPTION

The **report_datapath_gating** command reports the status of datapath gating in the current design. The report is divided into two sections, one section reports datapath gating breakdown per instance and the other section reports a gating breakdown global summary. The global summary is generated when the **-instances** option is not used. The ungated cell number reported in the instance report and ungated report might underestimate the number of ungated cells. Some cells that are ungrouped due to small bit-width might not be reported.

EXAMPLES

The following example is a sample output of the **report_datapath_gating** command output without options.

The output is limited to a summary of the datapath gating performed in the entire design.

```
prompt>report_datapath_gating
```

```
*****
Report : datapath_gating

report_delay_calculation

Displays the actual calculation of a timing arc delay value for a cell or net.

SYNTAX

```
status report_delay_calculation
  -min
  -max
  -from from_pin
  -to to_pin
  [-nosplit]
  [-crosstalk]
  [-from_rise_transition from_rise_value]
  [-from_fall_transition from_fall_value]
  [-derate]
```

Data Types

<i>from_pin</i>	string
<i>to_pin</i>	string
<i>from_rise_value</i>	float
<i>from_fall_value</i>	float

ARGUMENTS

-min

Specifies that the report must show how a minimum delay value is computed. If you do not specify this option, the report shows how a maximum delay value is computed.

-max

Specifies that the report must show how a maximum delay value is computed. This is the default behavior. This option cannot be used with the **-min** option.

-from *from_pin*

Specifies the starting point of a timing arc within a design. This option must be used along with **-to *to_pin***. When this option is specified, you cannot specify a collection of multiple pins. For a cell timing arc, the pins must represent a common leaf cell's input and output pins, which have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. The specified pins must be associated with library cell instances connected by the net. Port names are allowed in place of a pin name for net arcs. A hierarchical pin is not a valid pin for this option.

-to *to_pin*

Specifies the ending point of a timing arc within a design. This option must be used along with **-from *from_pin***. When this option is specified, you cannot specify a collection of multiple pins. For a cell timing arc, the pins must represent a common leaf cell's input and output pins, which have a timing arc specified between them in the library. For a net timing arc, the pins must be a driver and a load on a common net. The specified pins must be associated with library cell instances connected by the net. Port names are allowed in place of a pin name for net arcs. A hierarchical pin is not a valid pin for this option.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the delay data is listed in fixed-width columns. If the text for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-crosstalk

Reports the crosstalk information for a net arc. The arc is specified by *from_pin* and *to_pin*.

-from_rise_transition *from_rise_value*

Specifies the from rise transition value used by the delay calculation. The specified value is in main library units.

-from_fall_transition *from_fall_value*

Specifies the from fall transition value used by the delay calculation. The specified value is in main library units.

-derate

Reports derating components and derated delay.

DESCRIPTION

This command provides detailed timing calculation information about the specified cell or net timing arc. You can use this information for debugging or verifying timing data in a technology library. Before using this command to display details of a cell timing arc, read the technology library file into the system using the **read_lib** command. The **read_lib** command automatically compiles the library and enables the **report_delay_calculation** command for cell timing arcs. Otherwise, the built-in security mechanism terminates the command when issued for a cell timing arc. This restriction does not apply to net timing arcs.

Both operating conditions and wire-load models are taken into account when making delay calculations. Timing ranges are not taken into account because they typically apply to an entire path.

The **-crosstalk** option on net arc reports the aggressor and victim information for both rise and fall. The option prints coupling capacitance, the driving library cell, and the clocks reaching the net (both victim and aggressor). The aggressors have "Switching Bump," which is used for prioritizing the aggressors and also have aggressor attributes (active or screened).

The **-derate** option reports the derating components and derated delay about the specified cell or net timing arc. It displays AOCV/POCV derating information if AOCV/POCV is applied on the specified arc.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

report_delay_estimation_options

Reports the parameters that influence delay estimation. This command is supported only in topographical mode.

SYNTAX

```
status report_delay_estimation_options
```

ARGUMENTS

The **report_delay_estimation_options** command has no arguments.

DESCRIPTION

The **report_delay_estimation_options** command reports the parameters previously set with the **set_delay_estimation_options** command. These parameters influence preroute delay estimation used during placement and routing.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following commands set and report the preroute delay estimation options:

```
prompt>set_delay_estimation_options \
-min_unit_horizontal_capacitance 0.0015 \
-min_unit_vertical_capacitance 0.0010 \
-min_unit_horizontal_resistance 0.15 \
-min_unit_vertical_resistance 0.10 \
-density_outside_block 0.2

prompt> report_delay_estimation_options
```

...

Delay estimation options for the design:

Minimum horizontal unit capacitance: 0.0015
Minimum vertical unit capacitance: 0.001
Minimum horizontal unit resistance: 0.15
Minimum vertical unit resistance: 0.1

Density outside block: 0.2

SEE ALSO

`set_delay_estimation_options(2)`

report_design

Displays attributes of the current design.

SYNTAX

```
status report_design
  [-nosplit]
  [-physical]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Design information is listed in fixed-width columns. If information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-physical

This option is ignored by Design Compiler.

DESCRIPTION

The **report_design** command lists information about the attributes of the design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a design report:

```
prompt> report_design
*****
Report : design
Design : my_design
Version: F-2011.09
Date  : Tue Jun 7 15:16:17 2011
*****
```

Design allows ideal nets on clock nets.

Library(s) Used:

sc_max (File: /usr/lib/ref/db/sc_max.db)

report_design_lib

Lists the design units contained in the specified libraries.

SYNTAX

```
status report_design_lib
  [-libraries]
  [-designs]
  [-architectures]
  [-packages]
  [library_list]
```

Data Types

library_list list

ARGUMENTS

-libraries

Indicates that libraries, and not their contents, are to be listed.

-designs

Indicates that designs in libraries (Verilog modules, VHDL entities, or configurations) are to be listed.

-architectures

Indicates that designs in libraries, plus their architectures, are to be listed.

-packages

Indicates that packages in specified libraries are to be listed.

library_list

Specifies a list of libraries whose contents are to be displayed. If no *library_list* is specified, all libraries are displayed.

DESCRIPTION

The **report_design_lib** command lists the contents of specified libraries.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **report_design_lib** to list the contents of the current design libraries:

```
prompt> report_design_lib
*****

report_design_mismatch

Reports design mismatches that were circumvented to allow linking the design.

SYNTAX

```
status report_design_mismatch
  [-summary]
  [-class all | netlist | library]
```

ARGUMENTS

-summary

Summarizes the report.

-class all | netlist | library

Specifies whether to print netlist, library, or all mismatches.

DESCRIPTION

The **report_design_mismatch** command reports netlist mismatches that were circumvented (by modifying the netlist) to allow linking the design. Circumventing design mismatches prevents formal verification.

EXAMPLES

The following example shows an output of the **report_design_mismatch** command.

```
prompt> report_design_mismatch
```

```

link_allow_design_mismatch(3)

report_device_group

For DCNXT only, reports the number, area, and percentage of cells for each device group in the design. Also shows the number, area, and percentage of cells in user-specified narrow and/or wide device groups. Since the device group attribute is specified on the library cells, hierarchical cells do not have a device group. So, their usage is reported under the "undefined" device group category.

SYNTAX

```
status report_device_group
  [cell_list]
  [-narrow_device_groups groups]
  [-wide_device_groups groups]
  [-nosplit]
  [-verbose]
```

Data Types

<i>cell_list</i>	list
<i>groups</i>	list

ARGUMENTS

cell_list

Specifies a list of cells to report the device groups. If not specified, the report is generated on all cells of the current design.

-narrow_device_groups *groups*

Specifies the list of device groups to be considered as narrow devices. The value of the *groups* argument is a list of device group identifiers. Each identifier is a non-empty string that can contain alphanumeric characters and the underscore character ("_"). If you do not specify this option, the narrow device groups specified earlier using the **set_device_group_type** command are used; otherwise, no narrow device groups are reported.

-wide_device_groups *groups*

Specifies the list of device groups to be considered as wide devices. The value of the *groups* argument is a list of device group identifiers. Each identifier is a non-empty string that can contain alphanumeric characters and the underscore character ("_"). If you do not specify this option, the wide device groups specified earlier using the **set_device_group_type** command are used; otherwise, no wide device groups are reported.

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-verbose

Lists all the cells belonging to each device group. If this option is not specified, the default summary report shows only the number and percentage of cells.

DESCRIPTION

This command reports the number, area, and percentage of cells in each device group for the specified list of cells. The report also shows separately, the number, area, and percentage of black box and non black box cells in each group.

The device group is set of the library cells of the design with the **device_group** attribute set using the **set_attribute** command. The attributes can be any string values, but the values must be related to the device group of the cell to be meaningful. Any cells in the design that have no device group attribute are included in the "undefined" group. Hierarchical cells are an example of such cells. To report the device group for a hierarchical cell, get the list of cells it contains using [**get_cells -hierarchical hierarchical_cell/***] and pass it as the **cell_list** argument of the **report_device_group** command.

Use the **-narrow_device_groups** option to specify the list of device groups that are to be considered as narrow. When you specify this option, the specified narrow device groups are marked by a letter "N" and it appears in the last column of the corresponding row in the report. The total number, area, and percentage of cells in all the narrow device groups is also reported. Note that the narrow device groups specified with the **-narrow_device_groups** option overrides any narrow device groups specified in a previous command. Specifically, when you specify **-narrow_device_groups {}**, the command does not report any narrow device groups even if you have previously defined narrow device groups. However, if you do not specify the **-narrow_device_groups** option, the narrow device groups that you specified by using the **set_device_group_type** command, are used to report the details of the narrow device groups.

Use the **-wide_device_groups** option to specify the list of device groups that are to be considered as wide. When you specify this option, the specified wide device groups are marked by a letter "W" and it appears in the last column of the corresponding row in the report. The total number, area, and percentage of cells in all the wide device groups is also reported. Note that the wide device groups specified with the **-wide_device_groups** option overrides any wide device groups specified in a previous command. Specifically, when you specify **-wide_device_groups {}**, the command does not report any wide device groups even if you have previously defined wide device groups. However, if you do not specify the **-wide_device_groups** option, the wide device groups that you specified by using the **set_device_group_type** command, are used to report the details of the wide device groups.

Use the **-verbose** option to list all the cells that belong to each device group. Without this option, the command generates a summary that reports only the number, area, and percentage of cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the summary of cells in each device group for the current design:

```
prompt> report_device_group

report_dft_clock_controller

Reports the on-chip clocking controller specification for the current design.

SYNTAX

```
status report_dft_clock_controller  
[-view existing_dft | spec]
```

ARGUMENTS

-view existing_dft | spec

Indicates the view to which the command applies. Valid views are **existing_dft** and **spec**.

Setting the view to **spec** indicates that the command applies to DFT-inserted clock controllers. This is the default.

Setting the view to **existing_dft** indicates that the command refers to user-defined clock controllers.

DESCRIPTION

This command displays the current on-chip clocking controller specification applied to the current design.

Use the **set_dft_clock_controller** command to specify an on-chip clocking controller specification. Use the **reset_dft_clock_controller** command to reset the current on-chip clocking controller specification.

For more information, see the man page for the **set_dft_clock_controller** command.

EXAMPLES

The following command reports the `clock_controller` controller specification for the current design.

```
prompt> report_dft_clock_controller -view spec
```

```

report_dft_clock_gating_configuration

Displays the options specified by the **set_dft_clock_gating_configuration** command.

SYNTAX

```
status report_dft_clock_gating_configuration
```

ARGUMENTS

This command takes no arguments.

DESCRIPTION

This command displays the options that were specified with the **set_dft_clock_gating_configuration** command on the current design.

EXAMPLES

The following example shows the report generated by the **report_dft_clock_gating_configuration** command:

```
prompt> set_dft_clock_gating_configuration -exclude_elements \
    {U_block_a/cg1 U_block_b/cg1}

`set_dft_clock_gating_configuration(2)`
`reset_dft_clock_gating_configuration(2)`

report_dft_clock_gating_pin

Displays the specification specified by the **set_dft_clock_gating_pin** command.

SYNTAX

```
integer report_dft_clock_gating_pin
```

ARGUMENTS

This command takes no arguments.

DESCRIPTION

This command displays the options that were specified with the **set_dft_clock_gating_pin** command on the current design.

When the reported test pin of a clock-gating cell is active low and controlled by a ScanEnable or TestMode signal, the control signal is reported as ScanEnable_inverted or TestMode_inverted, respectively.

EXAMPLES

The following example shows the report generated by the **report_dft_clock_gating_pin** command. Consider a set of **set_dft_clock_gating_pin** commands as follows:

```
set_dft_clock_gating_pin {sub1/clk_gate_out1_reg} -pin_name TE \
    -control_signal ScanEnable -active_state 1

set_dft_clock_gating_pin {sub2/clk_gate_out1_reg} -pin_name TE \
    -control_signal ScanEnable -active_state 0

set_dft_clock_gating_pin {sub3/clk_gate_out1_reg} -pin_name TE \
    -control_signal TestMode -active_state 1

set_dft_clock_gating_pin {sub4/clk_gate_out1_reg} -pin_name TE \
    -control_signal TestMode -active_state 0
```

The output of the **report_dft_clock_gating_pin** command for these commands is:

```
prompt> report_dft_clock_gating_pin
*****

<name1>	<type1>
...	
-----	-----

EXAMPLES

The following example reports all user-specified DFT designs:

```
prompt> define_dft_design -design_name my_des \
  -type WC_D1 -interface {shift_clk capture_clk h \
  capture_en capture_en h shift_en shift_dr h \
  cti si h cto so h cfi data_in h cfo data_out h}
1

prompt> define_dft_design -design my_des1 -type BC_4 \
  -interface {capture_clk cap_clk h capture_en cen h \
  shift_dr shift h si ti h so to h data_in di h data_out do h}
1

prompt> define_dft_design -design my_des2 -type BC_4 \
  -interface {capture_clk cap_clk h capture_en cen h \
  shift_dr shift h si ti h so to h data_in di h data_out do h}
1
```

```
prompt> report_dft_design
```

```
Design Name    Design Type
```

```
-----  
my_des      WC_D1  
my_des1     BC_4  
my_des2     BC_4  
-----
```

SEE ALSO

```
define_dft_design(2)  
insert_dft(2)  
preview_dft(2)  
remove_dft_design(2)
```

report_dft_drc_rules

Reports DFT DRC specifications that affect how certain DRC rule violations affect DFT insertion.

SYNTAX

```
status report_dft_drc_rules
  [-violation drc_list]
  [-cell cell_list]
```

Data Types

drc_list string
cell_list string

ARGUMENTS

-violation *drc_list*

Restricts the report to the specified DRC violations.

-cell *cell_list*

Restricts the report to the specified cells.

DESCRIPTION

The **report_dft_drc_rules** command reports modifications to how certain DRC rule violations affect DFT insertion, as specified by the **set_dft_drc_rules** command. The list of violation IDs supported by this command is:

- TEST-504 (warning) Cell %s has constant 0 value.
- TEST-505 (warning) Cell %s has constant 1 value.
- D17 (warning) D17 Clock input I of <type> S couldn't capture data.

By default, the command reports all DFT DRC specifications applied by the **set_dft_drc_rules** command. You can use the **-violation** and **-cell** options to restrict the scope of the report.

Use the **set_dft_drc_rules** command to apply DFT DRC rule specifications. Use the **reset_dft_drc_rules** command to reset all DFT DRC rule specifications.

EXAMPLES

The following example applies some DFT DRC specifications to the design:

```
prompt> set_dft_drc_rules -warning {TEST-504}
prompt> set_dft_drc_rules -warning {TEST-505} -cell {BLK1 BLK2}
prompt> set_dft_drc_rules -ignore {TEST-505} -cell {USPAREGATES}
```

The following command reports all DFT DRC specifications:

```
prompt> report_dft_drc_rules
```

Violation Name	Default Action	Specified Action	Range/Cell list
<hr/>			
TEST-504	omit	allow	all cells
TEST-505	omit	allow	BLK1
	omit	allow	BLK2
	omit	ignore	USPAREGATES

The following command restricts the report to a single rule type:

```
prompt> report_dft_drc_rules -violation {TEST-504}
```

Violation Name	Default Action	Specified Action	Range/Cell list
<hr/>			
TEST-504	omit	allow	all cells

The following command restricts the report to specific cells:

```
prompt> report_dft_drc_rules -cell {BLK1 BLK2}
```

Violation Name	Default Action	Specified Action	Range/Cell list
<hr/>			
TEST-504	omit	allow	all cells
TEST-505	omit	allow	BLK1
TEST-505	omit	allow	BLK2

report_dft_equivalent_signals

Reports all of the equivalent DFT signals specified with **set_dft_equivalent_signals** command.

SYNTAX

status **report_dft_equivalent_signals**

ARGUMENTS

The **report_dft_equivalent_signals** command has no arguments.

DESCRIPTION

This command reports the equivalent set of signals specified using the **set_dft_equivalent_signals** command.

EXAMPLES

The following example reports all equivalent scan signals:

```
prompt> report_dft_equivalent_signals
```

SEE ALSO

[insert_dft\(2\)](#)

report_dft_hierarchical_pins

Reports the ports and hierarchical pins created during DFT insertion.

SYNTAX

```
status report_dft_hierarchical_pins
  [-added_by_dft true | false]
  [-ports_only false | true]
  [-summary_only false | true]
```

ARGUMENTS

-added_by_dft true | false

When set to **true**, ports and pins created during DFT insertion are reported. When set to **false**, reports uniquely ports that existed prior to DFT insertion. The default is **true**.

-ports_only false | true

Controls whether to report only ports, or ports and hierarchical pins. The default is **false**.

-summary_only false | true

Specifies whether to report a summary instead of the entire object table. The default is **false**.

DESCRIPTION

This command displays a report of ports and/or hierarchical pins created during DFT insertion.

EXAMPLES

The following example shows reports generated by **report_dft_hierarchical_pins**:

```
prompt> report_dft_hierarchical_pins
```

```

report_dft_insertion_configuration

Displays options set by the **set_dft_insertion_configuration** command.

SYNTAX

status **report_dft_insertion_configuration**

ARGUMENTS

The **report_dft_insertion_configuration** command has no arguments.

DESCRIPTION

This command displays options set by the **set_dft_insertion_configuration** command on the current design.

EXAMPLES

The following is an example of the **report_dft_insertion_configuration** command:

```
prompt> report_dft_insertion_configuration
```

```
*****
Report : DFT insertion configuration
Design : A
Version: 2003.12
Date  : Wed Aug 20 17:37:20 2003

report_dft_location

Reports the DFT hierarchy location specifications for the current design.

SYNTAX

```
status report_dft_location  
[-all]
```

ARGUMENTS

-all

Reports all DFT hierarchy location specifications.

DESCRIPTION

The **report_dft_location** command is used to report the DFT hierarchy location specification for the current design.

EXAMPLES

The following example reports the default DFT hierarchy locations for various logic types for the design named *des_unit*:

```
prompt> current_design des_unit  
Current design is 'des_unit'.  
{des_unit}  
prompt> report_dft_location  
Design Name          DFT PARTITION NAME      DFT TYPE        DFT Hierarchy Location  
=====  
des_unit            default_partition       BSR           <top>  
des_unit            default_partition       CODEC          <top>  
des_unit            default_partition       LOCKUP_LATCH   <local>  
des_unit            default_partition       XOR_SELECT    <top>  
des_unit            default_partition       RETIMING_FLOP <local>  
des_unit            default_partition       TAP           <top>  
des_unit            default_partition       TCM           <top>  
des_unit            default_partition       PIPELINE_SE_LOGIC <top>  
des_unit            default_partition       PIPELINE_SI_LOGIC <top>  
des_unit            default_partition       PLL           <local>  
des_unit            default_partition       REC_MUX        <local>  
des_unit            default_partition       SERIAL_CNTRL  <top>  
des_unit            default_partition       SERIAL_REG    <top>
```

```
des_unit      default_partition      WRAPPER      <top>
des_unit      default_partition      IEEE_1500    <top>
1
```

The following example reports user specified DFT hierarchy locations for the design named *des_unit*:

```
prompt> current_design des_unit
Current design is 'des_unit'.
{des_unit}
prompt> set_dft_location -exclude {REC_MUX LOCKUP_LATCH BSR TAP} UTEST_LOGIC
Warning: Specified hierarchy name 'UTEST_LOGIC' doesn't exists in the current design 'des_unit'. (UIT-1112)
Accepted DFT location specification.
1
prompt> set_dft_location -include {TCM} UTCM
Warning: Specified hierarchy name 'UTCM' doesn't exists in the current design 'des_unit'. (UIT-1112)
Accepted DFT location specification.
1
prompt> report_dft_location
Design Name      DFT PARTITION NAME      DFT TYPE      DFT Hierarchy Location
=====
des_unit      default_partition      BSR          <top>

report_dft_partition

Displays design partition information attached to a design.

SYNTAX

status **report_dft_partition**

ARGUMENTS

The **report_dft_partition** command has no arguments.

DESCRIPTION

The **report_dft_partition** command displays design partition information about a design.

EXAMPLES

The following example shows a design partition report for the *CORE* design:

```
prompt> report_dft_partition
*****
Report : DFT PARTITION Definition
Design : CORE
Version: B-2008.09
Date  : Fri Jun 13 16:36:29 2008
*****
```

Cells or Designs defined in Partition 'part1':

`set_scan_configuration(2)`
`set_scan_path(2)`

report_dft_power_control

Reports the power controller block specification for the current design.

SYNTAX

status **report_dft_power_control**

ARGUMENTS

The **report_dft_power_control** command has no arguments.

DESCRIPTION

This command displays the current power controller block specification applied to the current design.

Use the **set_dft_power_control** command to specify a power controller block specification. Use the **remove_dft_power_control** command to remove the current power controller block specification.

For more information, see the man page for the **set_dft_power_control** command.

EXAMPLES

The following command reports the power controller block specification for the current design.

```
prompt> report_dft_power_control
Power Controller Instance Name: 'U_PWC'
1
```

SEE ALSO

[remove_dft_power_control\(2\)](#)
[set_dft_power_control\(2\)](#)

report_dft_signal

Displays options specified by the **set_dft_signal** command.

SYNTAX

```
status report_dft_signal
  [-view spec | existing_dft]
  [-test_mode mode_name_list | all]
  [-port list_of_port_names]
  [-type signal_type]
```

Data Types

<i>mode_name_list</i>	list
<i>list_of_port_names</i>	list
<i>signal_type</i>	string

ARGUMENTS

-view spec | existing_dft

Specifies the view to report. Valid values are **spec** and **existing_dft**. If not specified, the **spec** view is the default.

-test_mode mode_name_list | all

Specifies the test mode(s) to report. If not specified, the tool reports on the current test mode, as displayed by the **current_test_mode** command. If no test modes were created, the tool reports on the default test mode. If **all** is specified, the tool displays the configurations of all test modes.

-port list_of_port_names

Specifies the name of a port or a list of ports on which to report. If no ports are specified, the tool reports on all defined ports.

-type signal_type

Specifies the signal type on which to report.

DESCRIPTION

This command displays options set by the **set_dft_signal** command on the current design.

The command reports on signal types, active states, hook-up pins, and timing of the ports.

EXAMPLES

The following command specifies a report on the test mode named *mymodeA*:

```
prompt> report_dft_signal -test_mode mymodeA
```

```
*****
```

```

report_direct_power_rail_tie

Reports all library pins on which the **direct_power_rail_tie** attribute is set to **true**.

SYNTAX

status **report_direct_power_rail_tie**

ARGUMENTS

The **report_direct_power_rail_tie** command has no arguments.

DESCRIPTION

This command reports all library pins on which the **direct_power_rail_tie** attribute is set to **true**.

If the value of the **direct_power_rail_tie** attribute on a library pin is **true**, then all pins in the design for which this is the library pin, it won't connect it to a tieoff cell for connecting it to constant signal. Instead, it will keep them connecting to generic constant signals, so that during power routing these pins can be connected directly to power rails.

To remove the **direct_power_rail_tie** attribute, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command reports all library pins that have the **direct_power_rail_tie** attribute set to **true**:

```
prompt> report_direct_power_rail_tie target_lib/leaf_cell/GND  
target_lib/leaf_cell/GND
```

SEE ALSO

[set_direct_power_rail_tie\(2\)](#)

report_disable_timing

Reports disabled timing arcs in the current design.

SYNTAX

```
string report_disable_timing  
    [-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line starting in the correct column.

DESCRIPTION

The **report_disable_timing** command reports disabled timing arcs in the current design. Timing arcs can be disabled in three ways. The first way is by using the **set_disable_timing** command. The second and third ways are both through automatically disabled arcs by the synthesis timing engine. This automatic disabling occurs in order to break timing loops or when propagating constants in the design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example disables the timing arc of a cell named *U1/U2* from pin *A* to pin *Z*:

```
prompt> set_disable_timing {U1/U2} -from A -to Z
```

```
prompt> report_disable_timing
```

```
*****  
Report : disable_timing  
Design : middle  
*****
```

```
Flags : c case-analysis
```

C Conditional arc
 I loop breaking
 u user-defined
 L stored loop breaking

Cell or Port	From	To	Flag
U1/U2	A	Z	u
U1/U2	B	Z	L

The following example disabled the timing arc of a cell named *ff1* from pin *CP* to pin *TE* and *TI* as a result of a case-analysis constant propagation to pin *TE* of cell *ff1*. Note that the L flag appears only when such arcs exist.

```
prompt> set_case_analysis 0 {ff1/TE}
```

```
prompt> report_disable_timing
```

```
*****
Report : disable_timing
Design : middle
*****
```

Flags : c case-analysis
 C Conditional arc
 I loop breaking
 u user-defined

Cell or Port	From	To	Flag
ff4	CP	TI	c
ff4	CP	TE	c

SEE ALSO

`set_case_analysis(2)`
`set_disable_timing(2)`

report_dont_touch

Reports dont_touch cells or nets in the current design along with their dont_touch types.

SYNTAX

```
status report_dont_touch
  [objects | -class class_name]
  [-nosplit]
```

Data Types

objects collection
class_name string

ARGUMENTS

objects

Reports the specified dont_touch cells or nets.

The **-class** and *objects* arguments are mutually exclusive; you can use only one option.

If neither option is specified, the **report_dont_touch** command reports all cell and net dont_touch objects.

-class *class_name*

Reports dont_touch objects for the specific class along with their dont_touch types. The *class_name* value can be **cell** or **net**.

The **-class** and *objects* arguments are mutually exclusive; you can use only one option.

If neither option is specified, the **report_dont_touch** command reports all cell and net dont_touch objects.

-nosplit

Prevents line splitting. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_dont_touch** command displays information about the dont_touch cells and nets in the current design.

If the current instance is set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design. Objects that do not have the **dont_touch** attribute are ignored.

Use the **-class** option to report only dont_touch cells or dont_touch nets. You can also specify a collection of cells or nets to report.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a dont_touch report with the **-class** and **-nosplit** options:

```
prompt> report_dont_touch -class cell -nosplit
```

```
*****
```

```
Report : dont_touch
```

```
Design : des_chip
```

```
Version: E-2010.12-SP2
```

```
Date : Tue Feb 8 19:40:39 2011
```

```
*****

report_dp_smartgen_options

Displays datapath strategies available to the current design.

SYNTAX

status **report_dp_smartgen_options**

ARGUMENTS

The **report_dp_smartgen_options** command has no arguments.

DESCRIPTION

This command lists the enabled and disabled datapath strategies available to the current design. These strategies provide control over some of the optimizations done by datapath generators.

EXAMPLES

The following is an example of a report generated by **report_dp_smartgen_options**:

```
prompt> report_dp_smartgen_options
```

```
*****
```

```
Datapath smart generation options...
```

```
*****
```

```
Smart generation:      enabled  
Default values:       auto
```

SEE ALSO

[set_dp_smartgen_options\(2\)](#)

report_extraction_options

Reports the options that influence postroute extraction.

SYNTAX

```
status report_extraction_options
  [-scenarios scenario_list]
  [-all]
```

Data Types

scenario_list list

ARGUMENTS

-scenarios *scenario_list*

Specifies the scenarios for which to report the extraction options.

The options for each scenario are reported separately. If you specify a nonexistent scenario, the tool just skips that scenario.

By default, only the options for the current scenario are reported.

-all

Reports the setting for all extraction options, whether the it is explicitly set or not. If you do not specify the this option, the command reports only those options explicitly set with the **set_extraction_options** command.

DESCRIPTION

The **report_extraction_options** command reports the parameters that influence the postroute extraction.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example runs the **report_extraction_options** command:

```
prompt> set_extraction_options \
    -max_process_scale 1.4 -min_process_scale 0.6
```

```
prompt> report_extraction_options
```

```
*****
```

```

report_failsafe_fsm_groups

Reports failsafe fsm groups of the current design.

SYNTAX

```
status report_failsafe_fsm_groups  
[group_names]
```

Data Types

group_names list

ARGUMENTS

group_names

Specifies the group names which need to be reported

DESCRIPTION

Prints a report of the specified failsafe fsm group. If nothing is specified, it reports all the groups in the current design.

EXAMPLES

The following example reports the specified failsafe_fsm_group.

```
prompt> report_failsafe_fsm_groups group1
```

SEE ALSO

create_failsafe_fsm_group(2)
create_failsafe_fsm_rule(2)
set_failsafe_fsm_rule(2)

report_failsafe_fsm_rules

Reports failsafe fsm rules from the current design.

SYNTAX

```
status report_failsafe_fsm_rules  
[rule_names]
```

Data Types

rule_names list

ARGUMENTS

rule_names

Specifies the rule names which need to be reported

DESCRIPTION

Prints a report of the specified failsafe fsm rules. If nothing is specified, it reports all the rules in the current design.

EXAMPLES

The following example reports the specified failsafe_fsm_rule.

```
prompt> report_failsafe_fsm_rules rule1
```

SEE ALSO

`create_failsafe_fsm_rule(2)`
`report_failsafe_fsm_rules(2)`

report_fsm

Displays state-machine attributes and information for the design of the specified instance or all the instances

SYNTAX

```
status report_fsm
[-nosplit]
[-design design_list]
[-verbose]
[-state_transition]
[-show_error_states]
[-all]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-design *design_list*

Prints the report for the specified design. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-verbose

Prints a detailed report for the FSM. software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-state_transition

Prints the transitions of the states of the FSM with all the input combinations. software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-show_error_states

Prints the error_states of the FSM. software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-all

Gives a brief report of all the FSMs. software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays state-machine attributes and information for the design of the current instance or for the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

EXAMPLES

The following is an example of a state-machine report:

```
prompt> report_fsm
*****
Report : FSM
Design : fsm
Version: R-2020.09-SP1-VAL
Date   : Tue Nov 10 06:03:17 2020

set_fsm_preserve_state(2)
set_fsm_state_vector(2)
```

report_gui_stroke_bindings

Print a report on the dictionaries and the stroke-command bindings they contain..

SYNTAX

```
report_gui_stroke_bindings  
[-dictionary dictionary_name]
```

ARGUMENTS

-dictionary *dictionary_name*

Specify which dictionary should have its bindings reported. If not specified then all dictionaries will be reported.

DESCRIPTION

This command takes the data returned by get_gui_stroke_bindings and formats it into a report that is human-readable. The report prints out the stroke-to-command bindings for all dictionaries.

This command is defined as a part of the strokes Tcl package, and the command is automatically imported into the global namespace when the package is loaded.

EXAMPLES

```
ca_shell> report_gui_stroke_bindings
```

Dictionary: Graphics

stroke	cmdType	cmd
5	builtin	Pan_Center_Rect
852	builtin	Zoom_Full
258	builtin	Zoom_Full
159	builtin	Zoom_Out_Rect
357	builtin	Zoom_Out_Rect
753	builtin	Zoom_In_Rect
951	builtin	Zoom_In_Rect
654	builtin	Pan_Center_Rect
456	builtin	Pan_Center_Rect
123698741	builtin	Zoom_In_Rect
147896321	builtin	Zoom_In_Rect

```
s:14789      tcl_cmd    myTclCmd  
14789      tcl_cmd    myTclCmd %rect
```

SEE ALSO

[set_gui_stroke_preferences\(2\)](#)
[set_gui_stroke_binding\(2\)](#)
[report_gui_stroke_builtin\(2\)](#)

report_gui_stroke_builtins

Print a report on the non-Tcl commands available for stroke bindings..

SYNTAX

```
report_gui_stroke_builtinss  
[-dictionary dictionary_name]
```

ARGUMENTS

-dictionary *dictionary_name*

Specify which dictionary should have its builtins reported. If not specified then only the global builtins will be printed.

DESCRIPTION

This command takes the data returned by get_gui_stroke_bindings and formats it into a report that is human-readable. The report prints out the non-Tcl commands that can be used in stroke bindings.

This command is defined as a part of the strokes Tcl package, and the command is automatically imported into the global namespace when the package is loaded.

EXAMPLES

```
ca_shell> report_gui_stroke_builtins
```

Built-In Commands:

```
name  
----  
Zoom_In_Rect  
Zoom_Out  
Pan_Center_Rect  
Zoom_Out_Rect  
Zoom_Full  
Zoom_In
```

SEE ALSO

`set_gui_stroke_preferences(2)`
`set_gui_stroke_binding(2)`
`report_gui_stroke_bindings(2)`

report_heterogeneous_fanout

Displays supply net information for nets whose loads have different supplies.

SYNTAX

```
status report_heterogeneous_fanout
  [-nosplit]
  [-nets net_list]
  [-pins pin_list]
  [-cells cell_list]
  [-verbose]
```

Data Types

<i>net_list</i>	list
<i>pin_list</i>	list
<i>cell_list</i>	list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line in the same column.

-nets *net_list*

Specifies to process only those nets in the *net_list*.

This option is mutually exclusive with the **-pins** and **-cells** options. One of those three options is required.

-pins *pin_list*

Specifies to process only nets driven by one pin in the *pin_list*. Inout pins are ignored.

This option is mutually exclusive with the **-nets** and **-cells** options. One of those three options is required.

-cells *cell_list*

Specifies to process only those nets that are driven by output pins of one cell in the *cell_list*.

This option is mutually exclusive with the **-pins** and **-nets** options. One of those three options is required.

-verbose

Shows additional information on the report table, consisting of Power domain names for the supplies, if there are Voltage and ISO violations for the analyzed nets, the last domain crossing before a load pin and which supplies are PST equivalent.

DESCRIPTION

The **report_heterogeneous_fanout** command reports paths with heterogeneous fanout and the related supplies. The command also reports which heterogeneous fanout topologies will not cause an error for UPF implementation.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports information on the net driven by the hierarchical pin mid_1/in.

```
prompt> report_heterogeneous_fanout -pins mid_1/in
```

```
*****
Report : heterogeneous_fanout
Design : TOP
Date   : Fri Apr 30 16:46:41 2021
*****
```

```
Number of pins with heterogeneous fanout found: 1
```

```
-----  
Global driver: 'in[0]' (TOP_SS.power, TOP_SS.ground)
```

```
-----  
Pin Name Load Pin Name Related Supplies
```

```
-----  
mid_1/in out[5]      (TOP_SS.power, TOP_SS.ground)  
          out[4]      (TOP_SS.power, TOP_SS.ground)  
          out[1]      (TOP_SS.power, TOP_SS.ground)  
          out[0]      (OTHER_SS.power, TOP_SS.ground)
```

```
-----  
Equivalent Supplies: N/A
```

SEE ALSO

[get_related_supply_net\(2\)](#)

report_hierarchy

Displays the reference hierarchy of the current instance or the current design.

SYNTAX

```
status report_hierarchy
  [-nosplit]
  [-full]
  [-noleaf]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-full

Displays the full hierarchy. By default, components of submodules in multiple locations in a hierarchy are listed only once. An ellipsis (...) indicates the contents of a previously-displayed module.

-noleaf

Indicates that the leaf library cells are to be excluded from the reference hierarchy report.

DESCRIPTION

This command displays the indented reference hierarchy of the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a hierarchy report:

```
prompt> report_hierarchy
```

```

report_host_options

Prints a report of multi-CPU processing options as defined by the **set_host_options** command.

SYNTAX

status **report_host_options**

ARGUMENTS

The **report_host_options** command has no arguments.

DESCRIPTION

By default, the **report_host_options** command prints a report of the multi-CPU processing options defined by the **set_host_options** command used by IC Compiler.

EXAMPLES

The following is an example of the **report_host_options** command:

```
prompt> report_host_options
```

SEE ALSO

`remove_host_options(2)`
`set_host_options(2)`

report_icc2_options

Reports the options used to invoke the IC Compiler II session from within Design Compiler Graphical or DC Explorer physical mode.

SYNTAX

```
int report_icc2_options  
  [-verbose]  
  [-check]
```

ARGUMENTS

-verbose

Prints out verbose messages, if any.

DESCRIPTION

The **report_icc2_options** command reports the options used to launch the IC Compiler II session from within Design Compiler Graphical or DC Explorer physical mode. Use the **set_icc2_options** command to specify the options used to invoke the IC Compiler II session.

EXAMPLES

The following example reports the options that were set using the **set_icc2_options** command:

```
prompt> report_icc2_options  
*****  
report_icc2_options  
*****
```

Options specified for IC Compiler II DP:
Work Directory : dcg_icc2_link
Keep Work Directory : Yes
IC Compiler II Executable : /your_location/icc2_shell
IC Compiler II Library :
 /LIBS/lib1.ndm
 /LIBS/lib2.ndm
IC Compiler II golden UPF files : NIL.
IC Compiler II Technology file : NIL.

1

SEE ALSO

`start_icc2(2)`
`start_icc2_dp(2)`
`set_icc2_options(2)`

report_icc_dp_options

Reports the options used to invoke the floorplan exploration session from Design Compiler Graphical. If you do not specify the options using the **set_icc_dp_options** command, **report_icc_dp_options** reports the default settings.

SYNTAX

```
status report_icc_dp_options
  [-check]
  [-verbose]
```

ARGUMENTS

-check

Performs the startup checks and issues errors, if any.

-verbose

Prints verbose messages, if any.

DESCRIPTION

This command reports the options used to launch the floorplan exploration session from Design Compiler Graphical. Use the **set_icc_dp_options** command to specify the options used to invoke floorplan exploration. If you do not specify the options using the **set_icc_dp_options** command, **report_icc_dp_options** reports the default settings. After using **set_icc_dp_options** and **report_icc_dp_options**, use the **start_icc_dp** command to begin floorplan exploration.

EXAMPLES

The following example reports the options and performs the startup checks:

```
prompt> report_icc_dp_options -check
```

SEE ALSO

[compile_ultra\(2\)](#)

```
set_icc_dp_options(2)
start_icc_dp(2)
```

report_ideal_network

Displays information about ports, pins, nets, and cells on ideal networks in the current design.

SYNTAX

status **report_ideal_network**

[**-net**]
[**-cell**]
[**-load_pin**]
[**-timing**]
[*object_list*]

Data Types

object_list list

ARGUMENTS

-net

Lists all nets in the specified ideal networks. By default, nets are displayed for all ideal networks.

-cell

Displays all cells in the specified ideal networks. By default, cells are displayed for all ideal networks.

-load_pin

Displays load pins (boundary pins) of the specified ideal networks, along with any ideal timing set on them using the **set_ideal_latency** and **set_ideal_transition** commands. By default, load pins are displayed for all ideal networks.

-timing

Displays all internal pins (for example, non-source and non-boundary pins) in the specified ideal networks that have ideal timing set on them using the **set_ideal_latency** and **set_ideal_transition** commands. By default, internal pins with timing are displayed for all ideal networks.

object_list

Defines a list of source ports or source pins of the specified ideal networks to be displayed. By default, the source pins and source ports for all ideal networks in the current design are displayed.

DESCRIPTION

This command displays information about the ideal networks in the current design. If no arguments are specified, all ideal network sources in the current design are displayed. If you specify a list of source pins or ports, the command displays information about the

ideal networks at these objects. By default, source pins, internal pins with ideal timing, load (boundary) pins, nets, and cells are displayed. You can force a subset of this information to be displayed using the options listed above.

The "Latency" and "Transition" columns show the minimum and maximum values set for both rising and falling edges. You set these values with the **set_ideal_latency** and **set_ideal_transition** commands.

Ideal networks are an extension of ideal nets that incorporate automatic propagation of the **ideal** attribute. You specify only the source ports or pins of the network; all the nets, cells, and pins on the transitive fanin of these objects are treated as ideal by the **compile** command. The **ideal_network** attribute is automatically spread by the tool, and respread as needed during **compile** optimizations.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows an ideal network report:

```

prompt> set_ideal_network {reset1 reset2}
prompt> set_ideal_latency 5.2 reset1
prompt> set_ideal_transition 0.6 reset1
prompt> report_ideal_network

report_ignored_layers

Reports the routing layers that are ignored during congestion analysis and RC estimation. This command is supported only in topographical mode.

SYNTAX

```
status report_ignored_layers
```

ARGUMENTS

The **report_ignored_layers** command has no arguments.

DESCRIPTION

This command reports the routing layers that are ignored during congestion analysis and RC estimation.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the **report_ignored_layers** command:

```
prompt> report_ignored_layers
```

SEE ALSO

`remove_ignored_layers(2)`
`report_lib(2)`
`set_ignored_layers(2)`

report_inbound_cell

Displays information about inbound cells in the current instance or current design.

SYNTAX

```
status report_inbound_cell
  [-summary]
  [-hierarchical]
  [cells]
```

Data Types

cells collection

ARGUMENTS

-summary

Displays only the summary part of the report. Other arguments will be ignored.

-hierarchical

Report inbound cells in all submodules of the specified object. If this option is not specified, do not report inbound cells in submodules.

cells

Specifies the inbound cells and instances to show in the report. If not specified, all inbound cells in the current instance are listed.

DESCRIPTION

This command displays statistics about inbound cells in the current design. It also displays information about all inbound cells in the current instance or current design. If *current_instance* is set, cells in the design of that instance will be listed; otherwise cells in the current design will be listed.

For clarification on cell information shown in the report, visit the man page of report_cell command.

EXAMPLES

The following is an example of an inbound cell report:

```
prompt> report_inbound_cell
```

```
*****
Report : inbound_cell
Design : CONTROL
Version: N-2017.09-SP2
Date  : Wed Nov 22 02:41:41 2017

report_interclock_relation

Displays common multiple-clock periods between clocks of different periods or edge information for paths launched and captured by two different clocks. For multicorner-multimode designs, this command reports the interclock relations in the current design.

SYNTAX

```
status report_interclock_relation
  [-from from_clock_names
   | -rise_from from_clock_names
   | -fall_from from_clock_names] [-to to_clock_names]
   | -rise_to to_clock_names
   | -fall_to to_clock_names]
  [-nosplit]
  [-significant_digits digits]
  [-edge]
  [-setup]
  [-hold]
```

Data Types

```
from_clock_names    string
to_clock_names    string
digits          integer
```

ARGUMENTS

-from *from_clock_names*

Restricts reporting to only the paths that are launched by these clocks.

-rise_from *from_clock_names*

Restricts reporting to only the paths that are launched by the rising edges of these clocks.

-fall_from *from_clock_names*

Restricts reporting to only the paths that are launched by the falling edges of these clocks.

-to *to_clock_names*

Restricts reporting to only the paths that are captured by these clocks.

-rise_to *to_clock_names*

Restricts reporting to only the paths that are captured by the rising edges of these clocks.

-fall_to *to_clock_names*

Restricts reporting to only the paths that are captured by the falling edges of these clocks.

-nosplit

Prevents line splitting in the report, which makes it easier to extract information from the report for other applications.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point to report. Allowed values are 0 through 13. The default is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-edge

Displays the launch and capture edge information for a paths driven by two different clocks.

-setup

Displays the edge information for only the setup paths. This option can be used only with the **-edge** option.

-hold

Displays the edge information for only the hold paths. This option can be used only with the **-edge** option.

DESCRIPTION

This command displays information about the timing relationships between different clocks that control data transfers between registers in a timing path.

In cases where the clock periods are not the same, the least common multiple of the clock periods becomes the common clock period. Each clock is expanded by repeating the original clock waveform until the common clock period is reached. The new longer waveform becomes the clock used for interclock timing. Depending on the clock periods, the clock expansion can fail if the common clock period is too large.

By default, each line of this report shows a pair of clocks, one that launches a timing path and one that captures the data at the end of the path. The line shows the period of each clock and the common multiple of each period. If no common period is reached between those two clocks, a dash appears where the common period is normally displayed.

If you use the **-edge** option, the command reports the launch and capture edge information for the path driven by two different clocks. Each line of the report shows a pair of clocks, one that launches a timing path and one that captures the data at the end of the path. It displays the period of each clock and the launch and capture edge information, including the edge type (rising or falling), for both the setup and hold paths, having the most restrictive timing requirement.

If you use the **-from** option, the report is restricted to paths launched by the specified clock.

If you use the **-to** option, the report is restricted to paths captured by the specified clock.

If you use the **-rise_from**, **-fall_from**, **-rise_to**, or **-fall_to** option, the report is restricted to only the paths launched or captured by the specified edge type.

EXAMPLES

The following example shows the report when the design has two clocks: *ck1* with a period of 10 and *ck2* with a period of 12. The report shows that the common period is 60 and the multipliers used to obtain the common period are 6 and 5, respectively.

```
prompt> report_interclock_relation
```

```
*****
```

```
Report : Interclock Relation
```

```
A common period of '-' means a full cycle was not expanded.
```

```
*****
```

```
From Period1 Count1 To Period2 Count2 Common
```

```
ck1    10.00   6   ck2  12.00   5   60.00
ck2    12.00   5   ck1  10.00   6   60.00
```

The following example shows the same command using the **-edge** option. The "setup edge" column shows the launch and capture times and the respective edge types (r for rising or f for falling) that result in the smallest setup time requirement. The "hold edge" column shows the same information for the path having the smallest hold time requirement.

```
prompt> report_interclock_relation -edge
```

```
*****
Report : Interclock Relation
*****
From Period1 To Period2  setup edge      hold edge
                  launch  capture  launch  capture
-----
ck1 10.00  ck2 12.00    10(r)   12(r)   60(r)  60(r)
ck1 10.00  ck1 10.00    0(r)    10(r)   0(r)   0(r)
ck2 12.00  ck1 10.00   48(r)   50(r)   0(r)   0(r)
ck2 12.00  ck2 12.00    0(r)    12(r)   0(r)   0(r)
```

report_internal_loads

Displays internal loads on the nets in the current design.

SYNTAX

```
status report_internal_loads  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays all internal loads specified on nets with the **set_load** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of the internal-loads report:

```
prompt> report_internal_loads  
*****  
Report : internal_loads  
Design : comb_internal  
Version: v2.0  
Date  : Fri Nov 30 12:44:23 1990  
*****
```

Attributes:
p - includes pin load

Net	Load	Attributes
-----	------	------------

```
-----  
n1          3.0000  p  
n2          4.5000
```

SEE ALSO

[report_design\(2\)](#)
[set_load\(2\)](#)

report_isolate_ports

Displays the status of port isolation on ports on which isolation was requested.

SYNTAX

```
status report_isolate_ports  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line in the same column.

DESCRIPTION

The **report_isolate_ports** command displays all ports on which isolation was requested and on which isolation cells were inserted.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of the report that is generated when you run the **report_isolate_ports** command:

```
prompt> report_isolate_ports  
report_isolate_ports  
*****  
Report : isolate_ports  
Design : pi1

[set_isolate_ports\(2\)](#)

report_isolation_cell

Displays information about isolation cells in the current scope.

SYNTAX

```
status report_isolation_cell
  [isolation_cells]
  [-domain power_domains]
  [-isolation_strategy isolation_strategy_names]
  [-ports pins_ports]
  [-verbose]
  [-nosplit]
```

Data Types

<i>isolation_cells</i>	list
<i>power_domains</i>	list
<i>isolation_strategy_names</i>	string
<i>pins_ports</i>	list

ARGUMENTS

isolation_cells

Specifies the isolation cells that are to be reported. If the specified supply cells do not exist in the current scope, the command fails.

By default, all isolation cells in the current scope are reported.

-domain *power_domains*

Specifies the power domains on which to report all isolation cells. If the power domains specified do not exist in the current scope, the command fails.

-isolation_strategy *isolation_strategy_names*

Specifies the names of the isolation strategies on which to report all isolation cells having the specified isolation strategy. When specifying the isolation strategy, a single power domain must be specified. If the specified isolation strategy is not a part of the specified power domain, the command fails.

-ports *pins_ports*

Reports isolation cells that are isolating the specified pins and ports.

-verbose

Reports the isolation strategy information in addition to the isolation cells information.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line,

starting in the correct column.

DESCRIPTION

The `report_isolation_cell` command enables you to get detailed information about all isolation cells within the current scope. If the `-domain` option is specified, all isolation cells in the specified domains are reported. If the `-isolation_strategy` option is specified, all isolation cells under the specified strategy for the given power domain are reported.

By default, the report displays the following information:

- The name of the port and pin isolated by the isolation cell
- The direction of the port
- The instance name of the isolation cell
- The library reference cell name of the isolation cell.

If you specify the `-verbose` option, the report also displays details of the isolation strategy:

- The name of the isolation strategy
- The location of the cell dictated by the strategy
- The enable signal
- The sense value
- The clamp value
- The elements to which the strategy applies
- The No Isolation information
- The power and ground nets of the strategy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports on all of the isolation cells in the current scope:

```
prompt> report_isolation_cell
```

```
-----  
Power Domain : bot  
=====
```

```
| Port | Port Dir.| ISO Cell Name | ISO Lib Cell | ISO Strategy |

report_keepout_margin

Reports keepout margins of a specified type for the specified cells in the design.

SYNTAX

```
int report_keepout_margin
  [-type hard | soft]
  [-original]
  [-parameters]
  [-all_derivable]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-type hard | soft

Specifies the type of keepout to be reported. The valid values are **hard** or **soft**. By default, keepouts of both soft and hard types are reported for the cells or library cells.

-original

Reports the original keepout margin values which are set using `set_keepout_margin` command and orientation of the cell when the keepout margin is set on the cell.

-parameters

Reports the following pin count based parameter values.

1. tracks_per_macro_pin
2. min_padding_per_macro
3. max_padding_per_macro

-all_derivable

Reports all the derivable keepout margin values for the cells specified in the object list. Keepout margin values set on the cells, derivable from the lib cells and pin count based values in case of macros.

object_list

Describes the list of cells or library cells for which keepouts are to be reported. Keepouts are reported for all cells with `FIXED_PLACEMENT` or library cells in specified in *object_list*.

DESCRIPTION

This command reports keepouts for the specified cells or library cells. If no hard or soft keepout exists the specified cell or library cell, and this command is called to report on it, a warning message is printed out and no action is taken. This command prints out the margin parameters for a keepout. These are of the form {left_x, bottom_y, right_x, top_y}. All units are in microns.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports hard keepouts for cells in an object list named *MY_CELL*.

```
prompt> report_keepout_margin -type hard MY_CELL
```

The following example reports hard keepouts for library cells in an object list named *MY_LIB_CELL*.

```
prompt> report_keepout_margin -type hard MY_LIB_CELL
```

The following example reports the original hard keepout margin values set on the cell in object list named *MY_CELL*.

```
prompt> report_keepout_margin -type hard MY_CELL -original
```

The following example reports all the pin count based parameters which will be used during the calculation of pin count based keepout margins for macro cells

```
prompt> report_keepout_margin -parameters
```

The following example reports all the derivable keepout margin values for the cells in object_list named *MY_CELL*

```
prompt> report_keepout_margin MY_CELL -all_derivable
```

SEE ALSO

[remove_keepout_margin\(2\)](#)

report_latch_loop_groups

Reports the latch data pins involved in loops of transparent latches.

SYNTAX

```
list report_latch_loop_groups
  [-of_objects pin_list]
  [-loop_breakers_only]
  [-path_breakers_only]
  [-nosplit]
```

Data Types

pin_list list

ARGUMENTS

-of_objects *pin_list*

A collection of data pins of transparent latches. Only pins of loop groups containing the specified pins are reported. By default, the command reports all latch data pins involved with transparent latch loops, as well as latch data pins outside of loops that have their **is_latch_loop_breaker** attribute set to **true**.

-loop_breakers_only

Restrict reporting to only the pins that are loop-breaker latch data pins actually contained in transparent latch loops.

-path_breakers_only

Restricts reporting to only the pins that have their **is_latch_loop_breaker** pin attribute set to **true**. By default, all transparent latch data pins within the loop group are reported.

-nosplit

Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line-splitting and facilitates writing software to extract information from the report output.

DESCRIPTION

When sequential loops of transparent latches exist in a design, a loop group containing all the latch data pins of intersecting loops is formed. The command **report_latch_loop_groups** analyzes the design and reports the latch data pins involved with loops. The report also includes some latch data pins outside loops. Combinational pins are not included in the results.

Latch data pins outside of loops can be reported if the latch is being treated by the tool as a latch loop-breaker data pin, even if it is not inside a latch loop. This can happen when you request that the pin be treated this way using the **set_latch_loop_breakers** command,

or if the tool has selected the pin to be treated as a loop-breaker data pin to save runtime. For more information about how this can happen, see the man page for the **timing_through_path_max_segments** variable.

The report lists the name of the latch data pin, a number identifying the latch loop group to which the pin belongs, and attributes describing whether the pin is a loop breaker latch, and why.

The number identifying the latch loop group is an arbitrary number. Within a given report, the latch data pins that are part of the same loop group report the same group number. For latch data pins that are not part of a loop group, "NA" is shown instead of a loop group number.

This command has no effect if the variable **timing_enable_through_paths** is not enabled.

EXAMPLES

The following example uses **report_latch_loop_groups** to report all latch loops in the design:

```
prompt> report_latch_loop_groups
*****
Report : latch_loop_groups
Design : test
Version: 2012.06
Date  : Mon Aug 4 09:51:19 2012
*****
Attributes
  b loop breaker d pin
  p long path breaker d pin, but not in a loop
  u user requested to be a loop breaker using set_latch_loop_breaker
  a user requested to avoid with set_latch_loop_breaker -avoid

report_level_shifter

Displays information about level-shifter cells in the current scope.

SYNTAX

```
status report_level_shifter
  [level_shifter_cells]
  [-domain power_domains]
  [-verbose]
  [-nosplit]
  [-macro]
```

Data Types

<i>level_shifter_cells</i>	list
<i>power_domains</i>	list

ARGUMENTS

level_shifter_cells

Specifies the level-shifter cells that are to be reported. If the specified supply cells do not exist in the current scope, the command fails. By default, all level-shifter cells in the current scope are reported.

-domain *power_domains*

Specifies the power domains to report all level-shifter cells in the design belonging to the power domains. If the power domain specified does not exist in the current scope, the command fails. This argument is optional and can be used to selectively report level-shifter cells.

-verbose

Reports the level-shifter strategies along with the level-shifter cells.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_level_shifter** command enables you to get detailed information about all level-shifter cells in the current scope. If the **-domain** argument is specified, all level-shifter cells in the specified domains are reported. The report consists of two or three parts, depending on whether or not the **-verbose** option is specified.

- The first part contains the level-shifter summary check for a power domain. The summary reports the number of violating level-shifter cells that are marked dont_touch and those that are not marked dont_touch. It also reports the total number of level-shifter cells belonging to the power domain.
- If the **-verbose** option is specified, the second part of the report provides the details of the level-shifter strategy. The details include the name, type, applies_to/elements, threshold voltage, location, and no shift of the strategy.
- The third part of the report shows the following information about the level-shifter cells:
 - Name of the level-shifter cell
 - Reference name
 - Input and output power net and ground net information, including name and voltage
 - Main power and ground net name and direction
 - Whether or not there is a violation and the reason for the violation
 - Input and output ranges of the level shifter.

Only one range is reported if the input and output ranges are the same.

 - Type of level shifter.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the information about all level-shifter cells in the current scope:

prompt> report_level_shifter

Power Domain : PDT

```
*****
Level shifter check summary
*****
No. of violating level shifters - dont_touch : 0
No. of violating level shifters - no dont_touch : 0
No. of level shifters in domain : 4
*****
```

[-multibit]
```

Data Types

op_cond_name string
library_name string
cell_list string

ARGUMENTS

-all

Lists all timing-related, power-related, electromigration-related, and FPGA-related information.

This option applies only to logic libraries.

-ccs_recv

Lists CCS and receiver information for library cells.

This option applies only to logic libraries.

-em

Lists all detailed electromigration-related information.

This option applies only to logic libraries.

-fpga

Lists all detailed FPGA-related information, such as parts and I/O cell attributes.

This option applies only to FPGA libraries.

-k_factors

Lists scaling information for library cells.

This option applies only to logic libraries.

-power

Lists all detailed power-related information.

This option applies only to logic libraries.

-power_label

Lists the power labels for all power arcs, if specified, in a tabular form.

This option applies only to logic libraries.

-table

Lists each cell's state-table description in compact form.

This option applies only to logic libraries.

-full_table

Lists each cell's state-table description in tabular, expanded form.

This option applies only to logic libraries.

-timing

Lists all detailed timing-related information.

This option applies only to logic libraries.

-timing_arcs

Lists all cell timing arcs.

This option applies only to logic libraries.

-timing_label

Lists the timing labels for all timing arcs, if specified, in a tabular form.

This option applies only to logic libraries.

-noise

Lists all detailed noise-related information in the specified library.

This option applies only to logic libraries.

-vhdl_name

Lists the cells and ports whose database (.db) names are different from their VHDL names.

This option applies only to logic libraries.

-yield

Lists failure rate information for library cells.

This option applies only to logic libraries.

-switch

Lists pin switch function information and cell-level steady state current information.

Use the **-pg_pin** option to display the switch function of a power or ground pin.

This option applies only to logic libraries.

-pg_pin

Lists power and ground pin information, such as the PG pin definition and the voltage name to which a signal pin has been linked and the PG type.

This option applies only to logic libraries.

-char

Lists cell characterization information, such as sensitization and pre-driver model.

This option applies only to logic libraries.

-operating_condition

Lists all library operating condition information.

When this is the only option selected, the **report_lib** command reports only operating condition information; no other information is reported.

-op_cond_name op_cond_name

Lists operating condition information by name.

When this is the only option selected, the **report_lib** command reports only operating condition information, no other information is reported.

-routing_rule

Lists nondefault routing rule information from physical libraries.

This option applies only to physical libraries.

-rwm

Lists routing wire model information from physical libraries.

In a routing wire model report, the original routing wire model is printed out, which includes overlap wire ratio, adjacent wire ratio, wire ratio and wire length of both directions. Also reported is capacitance (in database units) per micron for each layer and for each direction (based on each layer's wire ratio), based on the default operating condition. The report shows resistance per square (in database units) for each direction based on the default operating condition. These derived numbers provide useful information before applying the routing wire-model using the **set_routing_wire_model** command.

This option applies only to physical libraries.

-user_defined_data

Lists detailed information about the user-defined groups and attributes.

This option applies to both logic libraries and physical libraries.

library_name

Specifies the name of the library to report.

This argument is required.

cell_list

Specifies a list of cells about which information is to be reported. The default is to report information about all cells in the logic library or physical library.

This option applies to both logic libraries and physical libraries.

-jcr

Lists the Job Completion Record information stored in the library.

This option applies only to logic libraries.

-pattern_must_join_pin

Report pattern must-join related items.

-pattern_must_join_pin_exclusion_list lib_cell_pin_list

Specifies the collection of lib_pins that don't need the pattern must-join report. This option needs to go with -pattern_must_join_pin.

-noise_arcs

Lists all cell noise arcs.

This option applies only to logic libraries.

DESCRIPTION

The **report_lib** command displays information about the specified logic library, physical library, or symbol library.

By default, a logic library report displays a list of operating conditions, timing ranges, and wire load models, as well as a listing of all the cells in the library annotated with their attributes. You can restrict the set of cells by using the **cell_list** argument.

Any library object added by using the **update_lib** command is marked with an asterisk (*) following its name, to identify those objects that have been added since the initial library was created with the **read_lib** command.

The **-timing**, **-noise**, **-table**, **-full_table**, **-timing_label**, **-power_label**, **-em**, **-power**, **-yield**, **-pg_pin**, and **-switch** options can be used only with a logic library that was read in from a library source (.lib) file. If the library is read in from a database (.db) file, an error message is issued.

A physical library report displays a list of available layers, a list of vias, a list of sites and a list of cells. If a **cell_list** is specified with **report_lib**, the report includes only the specified cells; otherwise all cells in the given physical library are listed.

A symbol library report displays a list of the names of symbol definitions contained in the library **library_name**. It also reports the route grid and meter scale for the library.

To generate a report, the specified library must be loaded into memory, unless it is found in the search path. The **list_libs** command displays the libraries that are currently loaded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command generates a report for the *mylib* logic library. This type of report includes names of the library cells, wire load models, timing ranges, and operating conditions, the date the library was created, and the date the library was generated.

```
prompt> report_lib mylib
```

```

slew_lower_threshold_pct_fall: 20
slew_upper_threshold_pct_fall: 80

slew_derate_from_library: 0.6
```

Components:

Attributes:

- af - active falling
- ah - active high
- al - active low
- ar - active rising
- b - black box (function unknown)
- ce - clock enable
- cg - clock gating integrated cell
- ub - unbuffered
- pgt - pass gate
- ctl - has CTL test model
- d - dont_touch
- iso - isolation cell
- ls - level shifter
- mo - map_only
- 1p0g - power only, no ground
- 0p1g - ground only, no power
- 0p0g - no power/ground
- p - preferred
- hp - hold_preferred
- pwrg - power gating cell
- r - removable
- s - statetable
- sa0 - dont_fault stuck-at-0
- sa1 - dont_fault stuck-at-1
- sa01 - dont_fault both stuck-at-0 and stuck-at-1
- sz - use_for_size_only
- t - test cell. t(scan_type) as
 - t(mux_ff) - muxed flip-flop
 - t(mux_Id) - muxed latch
 - t(clk_scan) - clocked scan
 - t(clk_scan_Id) - clocked scan latch
 - t(lssd_dld) - double latch LSSD
 - t(lssd_sld) - single latch LSSD
 - t(lssd_clk) - clocked LSSD
 - t(lssd_auxclk) - auxiliary clock LSSD
- u - dont_use
- udp - usable for datapath generators
- ufc - user_function_class. ufc(type) as
 - ufc(u) - user-defined
 - ufc(a) - automatically generated
- imc - macro cell
- switch_cg - switch cell (coarse grain)
- ret - retention cell
- ao - always on cell
- gicg - generic integrated clock gating
- va - variation-aware ccs timing modeling
- val - variation-aware ccs leakage power modeling
- fil - filler cell
- tap - tap cell
- decap - decap cell
- pll - pll cell

Pin Attributes:

- ao - always on pin
- lse - level shifter enable pin

isoe - isolation cell enable pin
 scmr - standard cell main rail

Cell	Footprint	Attributes
AN2		
OR2		
...		
1		

The following command generates a logic library report that lists all CCS and receiver information for the library cells:

```
prompt> report_lib mylib -ccs_recv
```

```
*****
Report : library
Library: mylib
Version: C-2009.06
*****
```

Components:

Attributes:

- af - active falling
- ah - active high
- al - active low
- ...
- ccs - composite current source
- c_ccs - compact ccs timing modeling
- ccsn - ccs noise data modeling
- recv - receiver model
- ...
- tap - tap cell
- decap - decap cell
- pll - pll cell

Pin Attributes:

- ao - always on pin
- lse - level shifter enable pin
- isoe - isolation cell enable pin
- scmr - standard cell main rail

Cell	Footprint	Attributes
AN2		ccs, recv
OR2		ccs
...		
1		

The following command generates a report on library timing in the *AND2* cell of the *tech_lib* logic library:

```
prompt> report_lib tech_lib -timing AND2
```

```
*****
Report : library
Library: tech_lib
Version: C-2009.06
*****

For details about library electromigration report contents and syntax, see the *Library Compiler Modeling Timing, Signal Integrity, and Power in Technology Libraries User Guide*.

The following command generates a report on timing arcs in the *tech_lib* logic library. The *INV_NEW* cell is identified as having been added using the **update_lib** command:

```

prompt> report_lib tech_lib -timing_arcs
...
          Arc          Arc Pins
Cell   Attributes # Sense/type  From    To When
-----
AND        0 pos unate   A      Z
           1 pos unate   B      Z
INVET      0 neg unate  A      Z
INV_NEW    0 neg unate  A      Z
...

```

If the **-timing_arcs** option is not used, the last five columns do not appear.

The following command generates a report for a symbol library. The report includes the names of all symbol definitions, the route_grid, and the meter_scale:

```
prompt> report_lib sym_lib.sdb
```

The following command generates a report that displays timing arcs for the inverter cell from the *tech.lib* logic library:

```
prompt> report_lib tech_lib -timing_arcs inverter
```

The following example generates a report that displays noise arcs for the inverter cell from the *tech.lib* logic library:

```
prompt> report_lib tech_lib -noise_arcs inverter
```

The following is an example of a compact report on state-table information in the *tech.lib* logic library:

```
prompt> report_lib tech_lib -table
```

State table descriptions:

CELL(D_LATCH):

```
PIN(Q): CD, D, G  
TABLE: HNLNLLLL  
END_PIN Q;
```

```
PIN(QN):

report_libcell_subset

Reports the target library family specified on sequential and instantiated combinational cells.

SYNTAX

```
status report_libcell_subset
  [-object_list cells]
  [-nosplit]
```

Data Types

cells list

ARGUMENTS

-object_list *cells*

Specifies the cells for which to report the target library family.

-nosplit

Specifies not to split lines when column fields overflow.

DESCRIPTION

This command reports information about the target library subset that is specified on the cells.

Note that the command only reports the library subset information that is explicitly user-defined.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the target library family for the u1 sequential cell:

```
prompt> report_libcell_subset -object_list [get_cells u1]
*****
```

```
Report : library cell subset
Design : chip
```

Version: G-2012.06
Date : Wed Mar 21 16:16:58 2012

ARGUMENTS

-object_list *cells*

Specifies the cells on which to report the link library subset.

-top

Requests a report of the link library subset on the top-level design.

-scenarios *scenarios*

Specifies the scenarios for which to report the link library subset. Note that the command does not report inactive scenarios.

By default, only the current scenario is reported.

-nosplit

Specifies not to split lines when column fields overflow.

DESCRIPTION

This command reports the link library subset on the design based on the specified options.

If neither the **-object_list** nor **-top** option is specified, all the link library subsets set in the design are reported.

If a cell specified in the **-object_list** option does not have a subset set directly on it, but there is a subset on a parent instance or on the top-level design, the report lists the subset in effect on the cell and indicates that it was "Inherited".

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example reports the link library subset for the top-level design and for the u1 instance:

```
prompt> report_link_library_subset -top -object_list [get_cells u1]
```

SEE ALSO

```
remove_link_library_subset(2)
set_link_library_subset(2)
link_library(3)
```

report_logic_levels

Displays logic levels information about a design

SYNTAX

```
status report_logic_levels
  [-to to_list]
  [-from from_list]
  [-through through_list]
  [-exclude exclude_list]
  [-nworst paths_per_endpoint]
  [-max_paths max_path_count]
  [-start_end_pair]
  [-group group_name]
  [-slack_greater_than greater_slack_limit]
  [-slack_lesser_than lesser_slack_limit]
  [-path_type path_type]
  [-sort_paths_by sort_path_value]
  [-num_bins number_of_bins]
  [-bin_width bin_width_number]
  [-max_paths_to_report max_path_report_count]
  [-export_csv_file]
  [-summary_only]
  [-nosplit]
```

Data Types

<i>to_list</i>	list
<i>from_list</i>	list
<i>through_list</i>	list
<i>exclude_list</i>	list
<i>paths_per_endpoint</i>	integer
<i>max_path_count</i>	integer
<i>group_name</i>	string
<i>greater_slack_limit</i>	float
<i>lesser_slack_limit</i>	float
<i>path_type</i>	string
<i>sort_path_value</i>	string
<i>number_of_bins</i>	integer
<i>bin_width_number</i>	integer
<i>max_path_report_count</i>	integer
<i>output_csv_file_name</i>	string

ARGUMENTS

-to *to_list*

Specifies the to pins, ports, nets, or clocks. Path endpoints are the output ports or data pins of registers. If you specify a clock, the command considers all endpoints that are constrained by the clock.

-from *from_list*

Specifies the from pins, ports, nets, or clocks. Path startpoints are the input ports or clock pins of registers. If you specify a clock, the command considers all startpoints clocked by the clock.

-through *through_list*

Reports only paths that pass through the named pins, ports, or clocks.

-exclude *exclude_list*

Excludes all data paths from/through/to the named pins, ports, nets, and cell instances. Any data path that starts from, contains, or ends on a listed object is excluded. If you specify a cell instance, data paths that include any pin of that cell instance are excluded. This option has higher precedence than the **-from**, **-through**, **-to**, and similar options.

This option is not applied to clock pins.

-nworst *paths_per_endpoint*

Specifies the maximum number of paths to get per endpoint. The default is 1, which gets only the single worst path ending at a given endpoint.

-max_paths *max_path_count*

Specifies the maximum number of paths to analyze per path group. The default is 100000.

-start_end_pair

Limits the analysis of paths returned to the single worst timing path per each combination of startpoint and endpoint found. No other paths are included that have the same startpoint and same endpoint.

-group *group_name*

Restricts the analysis to paths in this *group_name*. Use the **group_path** or **create_clock** command to group paths.

-slack_greater_than *greater_slack_limit*

Selects only those paths with a slack greater than *greater_slack_limit*. The **-slack_greater_than** option can be combined with the **-slack_lesser_than** option to select only those paths inside or outside of a given slack range. The specified value is in main library units.

-slack_lesser_than *lesser_slack_limit*

Selects only those paths with a slack less than *lesser_slack_limit*. The **-slack_greater_than** option can be combined with the **-slack_lesser_than** option to select only those paths inside or outside of a given slack range. The specified value is in main library units. The default value for this option is 0.0. Be default, the command will analyze only the -ve slack paths due to this default setting.

-path_type *path_type*

Specifies the type of path to be considered for logic level analysis. By default, the all paths are considered.

-sort_paths_by *sort_path_value*

Specifies the criterion on which to sort the paths which will be displayed in the logic level path report section. Only the top paths specified by option **-max_paths_to_report** will be reported after sorting.

-num_bins *number_of_bins*

Specifies the number of bins to be used in the Logic level distribution section. If this option is not specified, the tool uses default value of 10.

-bin_width *bin_width_number*

Specifies the width of the bin to be used in the Logic level distribution section. If both **-num_bins** & **-bin_width** options are specified, then only **-num_bins** is used. When **-bin_width** option is specified, the tool computes the number of bins based on this width value.

-max_paths_to_report *max_path_report_count*

Specifies the number of paths to be reported in the logic level path report section.

-export_csv_file *output_csv_file_name*

Specifies the file name for the csv file. The entire contents of the report will be exported to the specified csv file in csv (comma separated values) format.

-summary_only

If this option is specified, then only the summary section is printed. Logic level distribution section & Logic level path report for each of the path groups are not reported.

-nosplit

Prevents line splitting and facilitates writing application to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command reports the logic levels information about the design.

By default, the command analyses only -ve slack paths from all path groups with a maximum of 100000 paths for each path group.

The command collects the paths according to the user specifications and calculates the logic levels in those paths. Logic levels are the number of mapped cells in the path excluding buffers and invertors. It then compares it against the threshold specified by the user before or automatically computed one and determines whether it violates the threshold or not. It also collects other information about the path such as WNS, start and end point, start and end clocks and reports them.

The report has three sections.

Summary section

In this section, logic level and timing information are reported for cumulative and each of the path groups. The cumulative information is reported as "All path groups".

The columns in this section are customizable through setting of **logic_level_report_summary_format** variable.

GROUP	REQUIRED PERIOD	NUM OF WNS	MAX PATHS	LEVEL
All Path Groups	n/a	n/a	2310	13
CLOCK	0.0100	-2.3289	1600	13
custom_group1	0.0100	-2.3174	166	12
custom_group2	0.0100	-2.3006	544	13

Summary section is followed by Logic level distribution section & Logic level path report section for cumulative and each of the path groups. The cumulative information is reported under the path group name "All path groups".

Logic level distribution section

In this section, logic level distribution of paths for the particular path group are reported. The columns in this section are not customizable and are fixed.

LOGIC LEVELS	NUMBER OF PATHS	PERCENTAGE OF PATHS
0 to 1	4	0%
2 to 3	22	1%

4 to 5	1017	44%
6 to 7	908	39%
8 to 9	47	2%
10 to 11	205	9%
12 to 13	107	5%

Logic level path report

In this section, logic level & timing information for the top paths for the particular path group are reported. The columns in this section are customizable through setting of **logic_level_report_group_format** variable.

WNS	LEVELS	LOGIC	THRESHOLD	START POINT	END POINT
-1.3106	13	4 REG_BLK/DATA_OUT_reg[0]/CK	4	UPC_BLK/DATA_OUT_reg[7]/D	
-1.3072	11	4 REG_BLK/DATA_OUT_reg[0]/CK	4	UPC_BLK/DATA_OUT_reg[3]/D	
-1.2999	10	4 REG_BLK/DATA_OUT_reg[0]/CK	4	UPC_BLK/DATA_OUT_reg[3]/D	
-1.2991	11	4 REG_BLK/DATA_OUT_reg[0]/CK	4	UPC_BLK/DATA_OUT_reg[9]/D	
-1.2979	12	4 REG_BLK/DATA_OUT_reg[0]/CK	4	UPC_BLK/DATA_OUT_reg[5]/D	

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example sets the global logic level threshold to 5 and then runs logic level report for path group "CLOCK"

```
prompt> set_analyze_rtl_logic_level_threshold 5
prompt> report_logic_levels -group CLOCK
```

The following example invokes the reporting command with csv file option.

```
prompt> report_logic_levels -export_csv_file ll.csv
```

report_logicbist_configuration

Displays options specified by the **set_logicbist_configuration** command.

SYNTAX

```
status report_logicbist_configuration  
[-test_mode mode_name_list | all]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list* | all

Specifies the test mode(s) to report. If not specified, the tool reports on the *current_test_mode* that can be displayed by the **current_test_mode** command. If no test modes were created, the tool defaults to the default LogicBIST compression mode. If **all** is specified, the tool displays the scan configurations of all LogicBIST compression test modes, including the default test mode (**all_dft**).

DESCRIPTION

This command displays options specified by the **set_logicbist_configuration** command on the current design.

EXAMPLES

The following is an example of a LogicBIST compression configuration report:

```
prompt> report_logicbist_configuration  
*****  
Report : LogicBIST Configuration  
Design : top  
Version: L-2016.03-VAL  
Date  : Thu Apr  7 05:34:04 2016  
*****  
=====
```

TEST MODE: my_bist_mode
VIEW : Specification

```
=====
Shift Clock          CLK1

report_min_pulse_width

Displays minimum pulse width check information about specified sequential device clock pins.

SYNTAX

```
status report_min_pulse_width
  [-all_violators]
  [-significant_digits digits]
  [-nosplit]
  [-scenarios scenario_list]
  [pin_list]
```

Data Types

<i>digits</i>	int
<i>scenario_list</i>	list
<i>pin_list</i>	list

ARGUMENTS

-all_violators

Indicates that only violating minimum pulse width checks are reported.

-significant_digits *digits*

Specifies the number of reported digits to the right of the decimal point. Allowed values are 0-13; the default is determined by the **report_default_significant_digits** variable, which default value is 2. Use this option if you want to override the default.

-nosplit

Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the width of the column, the next field begins on a new line, starting in the correct column. The **-nosplit** option prevents line splitting and facilitates writing software to extract information from the report output.

-scenarios *scenario_list*

Reports min pulse width constraint in scenarios given in the list. If this option is not given, min pulse width constraints on all scenarios are reported.

pin_list

Specifies a list of clock pins of sequential devices to report. By default, the report contains all clock pins in the current design. If non-clock pins are specified, they will be ignored.

DESCRIPTION

The **report_min_pulse_width** command displays the following information for the minimum pulse width check: required pulse width, actual pulse width, and by how much the constraint is violated or met (slack). This information is listed in order of decreasing slack starting with the worst violator.

Minimum pulse width violations can also be reported with the **report_constraint** command.

EXAMPLES

The following example generates a report of all minimum pulse width violations in the current design.

```
prompt> report_min_pulse_width
```

```
*****
Report : min_pulse_width
Design : test
Version: F-2011.09-SP
Date  : Tue Oct 18 13:24:39 2011
*****
```

Pin	Required pulse width	Actual pulse width	Slack	Scenario
ff1/cp(low)	2.00	0.87	-1.13(VIOLATED)	
ff2/cp(low)	2.00	1.41	-0.59(VIOLATED)	
ff2/cp(high)	0.60	0.59	-0.01(VIOLATED)	
ff1/cp(high)	0.60	1.13	0.53(MET)	

SEE ALSO

```
remove_min_pulse_width(2)
report_constraint(2)
set_min_pulse_width(2)
report_default_significant_digits(3)
```

report_misViolation_summary

Displays information about multi-input switching cells tied to same net in current design.

SYNTAX

```
status report_misViolation_summary
```

DESCRIPTION

This command displays information and statistics about MIS cells tied to same net in the current design. It displays the total number of MIS cells in the design as well as the number cells fixed by decomposition and the number of cells skipped from decomposition. For the skipped MIS cells, the report shows the number of cells for each category of reasons due to which the cells could not be fixed during decomposition.

The sequential MIS cells and combinational MIS cells with sequential arcs are skipped during MIS cells decomposition and they are reported under the category of **unspecified reason**.
The MIS cells with setting of **set_compile_directives -local_optimization false** are skipped during MIS cells decomposition and they are reported under the category of **unspecified reason**.
The MIS cells for which there were no equivalent cells found in the library are also skipped during MIS cells decomposition and they are reported under the category of **unspecified reason**.
The MIS cells which failed during decomposition are reported under the category of **unspecified reason**.

EXAMPLES

The following is an example of a MIS violation summary report.

```
prompt> report_misViolation_summary
*****
Report: MIS Violation Summary.
Design: MyDesign

Number Of Violators : 3551
Fixed : 375
Skipped :
  dont-touch : 54
  non-combinational : 3062
  local optimization off : 25
  non-decomposable : 10
  no-driver : 15
  unconstrained : 9
  unspecified reason : 1
```

SEE ALSO

`compile_enable_mis_cells_decomposition(3)`
`compile_dft_log_print_mis_info(3)`

report_missing_constraints

Reports missing constraints in current design.

SYNTAX

```
status report_missing_constraints
  [-class class_list]
  [-clock_tracing_mode tracing_mode]
```

Data Types

class_list list
tracing_mode string

ARGUMENTS

-class *class_list*

Specifies a list of missing constraint classes to be reported. You can enter the following classes:

- clocks
- input_delay
- output_delay
- pin_load
- driving_lib_cell

-clock_tracing_mode *tracing_mode*

Specifies tracing mode for tracing clocks from missing clock pins. You can specify the following modes:

- simple
- advanced

When the option is set to simple (the default), the tool traces only ports as clocks. When the option is set to advanced, the tool traces ports and register outputs as clocks.

DESCRIPTION

This command reports missing constraints of the specified classes in current design. If no class is specified, the command reports all missing constraints of all the classes in current design.

This command is for DC Explore only.

SEE ALSO

`create_missing_constraints(2)`

report_mode

Prints a report of the instance modes.

SYNTAX

```
string report_mode
  [-nosplit]
  [instance_list]
```

Data Types

instance_list list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. By default, most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

instance_list

Indicates that the mode report is to include only the specified cells. By default, all cells that have modes are included.

DESCRIPTION

This command reports which cells have modes and for each mode, specifies that the mode is currently enabled or disabled. This reports reflects the mode specifications of the **set_mode** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports that two cells in the design have modes: the *Uram1* cell and the *Uram2* cell.

```
prompt> report_mode
```

```
*****
```

```
Report : mode
Design : top_design
*****
```

Cell	Mode(Group)	Status
Uram1/core(RAM2_core)	read(rw)	ENABLED
	write(rw)	ENABLED
Uram2/core(RAM2_core)	read(rw)	ENABLED
	write(rw)	ENABLED

The following example reports that modes are specified for the 2 RAMs that have modes in the design. Ram *Uram1* is set in mode read, and Ram *Uram2* is set in mode write. This means all timing arcs of RAM *Uram1* associated with mode read are enabled, and all timing arcs associated with mode write are disabled.

```
prompt> set_mode read Uram1/core
```

```
prompt> set_mode write Uram2/core
```

```
prompt> report_mode
```

```
*****
Report : mode
Design : top_design
*****
```

Cell	Mode(Group)	Status
Uram1/core(RAM2_core)	read(rw)	ENABLED
	write(rw)	disabled
Uram2/core(RAM2_core)	read(rw)	disabled
	write(rw)	ENABLED

SEE ALSO

[reset_mode\(2\)](#)
[set_mode\(2\)](#)

report_multibit

Displays information about multibit components in the current design or the subdesign.

SYNTAX

```
status report_multibit
  [-nosplit]
  [-hierarchical]
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-hierarchical

Report multibit components in all submodules of the specified object. If this option is not specified, do not report multibit components in submodules.

object_list

Specifies a list of cells and multibit components to show in the report. If this option is not specified, all multibit components in the current design are listed. For specified cells, the report is done on multibit components that contain the specified cells.

DESCRIPTION

The **report_multibit** command displays information and statistics about multibit components in the current design or specified instances. A multibit component exists in a design due to the instantiation of a multibit library cell in the RTL, inference from the HDL source, or usage of the **create_multibit** command. A multibit component is a grouping of register cells targeted for possible implementation using a multibit register (or multiple multibit registers) for the register bits of the group.

The data displayed by this command might not be accurate if the design cannot be linked.

EXAMPLES

The following example shows a report on all of the multibit components in the current design:

```
prompt> report_multibit
```

```
*****
Report : multibit
Design : subtest
Version: 1998.02
Date  : Fri Aug 29 10:01:19 1997

Total 1 Multibit Components

The following example shows hierarchically report multibit components in the instance *mid0*:

```
prompt> report_multibit -hierarchical mid0
```

```
*****
Report : multibit
Design : top
Version: G-2012.06-ALPHA4
Date  : Fri Mar 2 14:53:33 2012
*****
```

Attributes:

- b - black box (unknown)
- h - hierarchical
- n - noncombinational
- r - removable
- u - contains unmapped logic

Multibit Component : q0_reg

Cell	Reference	Library	Area	Width	Attributes
mid0/inst1/q0_reg[1]	**SEQGEN**		0.00	1	n, u
mid0/inst1/q0_reg[0]	**SEQGEN**		0.00	1	n, u

Total 2 cells 0.00 2

Multibit Component : q0_reg

Cell	Reference	Library	Area	Width	Attributes
mid0/inst0/q0_reg[1]	**SEQGEN**		0.00	1	n, u
mid0/inst0/q0_reg[0]	**SEQGEN**		0.00	1	n, u

Total 2 cells 0.00 2

Total 2 Multibit Components

report_multibit_banking

Reports all multibit registers in a design and the banking ratio.

SYNTAX

```
status report_multibit_banking
  [-hierarchical]
  [-nosplit]
```

ARGUMENTS

-hierarchical

Reports all multibit registers, the total number of sequential cells, and the banking ratio in each of the submodules across the design hierarchy.

-nosplit

Prevents line splitting. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command lists information about multibit registers in the design. The report includes the total number of single-bit and multibit sequential cells, the single-bit equivalent of these sequential cells, the sequential cell and flip-flop banking ratio, and the multibit register decomposition.

The sequential cells only include leaf cells. Clock-gating latches are excluded in this report. Therefore, the sequential cell count reported here can differ from what is reported by the **report_qor** and **report_area** commands.

The multibit register decomposition section reports the information about multibit cell references used in the design. See the example section for more details.

When you specify the **-hierarchical** option, the number of single-bit and multibit sequential cells and the sequential cell banking ratio is reported for each subdesign.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example generates a multibit banking report with the **-hierarchical** option:

```
prompt> report_multibit_banking -hierarchical
Total number of sequential cells: 2422
  Number of single-bit flip-flops: 1699
  Number of single-bit latches: 10
  Number of multi-bit flip-flops: 711
  Number of multi-bit latches: 2
Total number of single-bit equivalent sequential cells: 3147
  (A) Single-bit flip-flops: 1699
  (B) Single-bit latches: 10
  (C) Multi-bit flip-flops: 1434
  (D) Multi-bit latches: 4
Sequential cells banking ratio ((C + D) / (A + B + C + D)): 45.69%
Flip-Flop cells banking ratio ((C) / (A + C)): 45.77%
```

Multi-bit Register Decomposition:

Bit-Width Reference	Number of instances	Single-bit Equivalent
2-bits	707 (29.19%)	1414 (44.93%)
MB2_DFF1	705	
MB2_LD1	2	
4-bits	6 (0.25%)	24 (0.76%)
MB4_DFF1	6	

Hierarchical multi-bit distribution:

Hierarchical cell	Num. of MB seq. cells	Num. of seq. cells	Seq. cells banking ratio
top	713	2422	45.69%
sub_design1	466	1055	61.28%

1

The **Multi-bit Register Decomposition** section reports the information about multibit cell references used in the design. The information is reported for all bit widths of multibit references. In the above example, for 2-bit width multibit cells, the report is as shown:

Bit-Width Reference	Number of instances	Single-bit Equivalent
2-bits	707 (29.19%)	1414 (44.93%)
MB2_DFF1	705	
MB2_LD1	2	

Here the number of 2-bit instances (707) corresponds to the total count of 2-bit multibit cell instances across all references (705 instances of flip-flop (MB2_DFF1) + 2 instances of latch (MB2_LD1)). The percentage of 2-bit instances (29.19%) is calculated as: $100 * \text{Number of 2-bit instances} / \text{Total number of 2-bit instances}$. The number of single-bit equivalents (1414) is calculated as: $2 * \text{Number of 2-bit instances} (707)$. The corresponding single-bit equivalent percentage (44.93%) is calculated as: $100 * \text{Number of single-bit equivalents} (1414) / \text{Total number of single-bit equivalent sequential cells} (3147)$.

The **Hierarchical multi-bit distribution** section of the report is described in the following section:

The section reports the number of single-bit and multibit sequential cells and sequential cell banking ratio for each subdesign in the hierarchy.

Hierarchical cell	Num. of MB seq. cells	Num. of seq. cells	Seq. cells banking ratio
sub_design1	466	1055	61.28%

Here the **Num. of MB seq. cells** (466) is the total count of (2-bit and 4-bit) multibit flip-flops and latches in sub_design1. The **Num. of seq. cells** (1055) is the total count of single-bit and (2-bit and 4-bit) multibit flip-flops and latches in sub_design1. The **Sequential cell**

banking_ratio (61.28%) is the sequential cell (both latches and flip-flops) banking ratio in sub_design1.

`current_design(2)`
`report_cell(2)`
`report_compile_options(2)`
`report_reference(2)`

report_mv_library_cells

Displays power management cells available in the target libraries.

SYNTAX

```
status report_mv_library_cells
  [-level_shifters]
  [-isolation_cells]
  [-retention_cells]
  [-switch_cells]
  [-always_on_cells]
  [-cell_name master_cell_name]
  [-verbose]
```

Data Types

master_cell_name string

ARGUMENTS

-level_shifters

Reports only library cells that have the level-shifter cell attribute **ls**.

-isolation_cells

Reports only library cells that have the isolation cell attribute **iso**.

-retention_cells

Reports only library cells that have the retention cell attribute **ret**.

-switch_cells

Reports only library cells that have the switch-cell attribute **switch_cg**.

-always_on_cells

Reports only library cells that have the always-on cell attribute **ao**.

-cell_name *master_cell_name*

Reports library information relative only to the given cell name.

-verbose

Reports all relevant multivoltage attributes cell by cell.

DESCRIPTION

This command reports all power management cells available in all target libraries. The output format is divided into two parts. The first is a library-based report, which prints all cells for each library available to the design. It is printed when the **-verbose** option is used.

The second is a cell-based summary, which is printed at all times. It prints the basic attributes of the cell and the library in which the cell is found.

Both reports are filtered by the available cell type options. The cell type options are not exclusive and can be combined in the command.

The report can also print one cell at the time by using **-cell_name** option. When the **-cell_name** option is used, all filtering type options are ignored.

EXAMPLES

The following example shows the output format in the default mode while reporting only isolation cells:

```
prompt> report_mv_library_cells -iso
```

```
*****
Report : report_mv_library_cells
Version: D-2010.03
Date  : Wed Aug 12 13:46:11 2009
*****
```

Cell Based Report

```
Cell: ISOHI
iso; Y=I+(!ISO); VSS(0.000,PRM); VDD(0.9,PRM); mylib1
iso; Y=I+(!ISO); VSS(0.000,PRM); VDD(1.1,PRM); mylib2
```

The following example shows the output format in verbose mode while reporting only isolation cells:

```
prompt> report_mv_library_cells -iso -verbose
```

```
*****
Report : report_mv_library_cells
Version: D-2010.03
Date  : Wed Aug 12 13:52:09 2009
*****
```

Library Based Report

```

SEE ALSO

[report_lib\(2\)](#)

report_mv_qor

Estimates and reports static power for the power domains of a design in UPF mode. This command is supported only in DC Explorer.

SYNTAX

```
status report_mv_qor
  [-verbose]
  [-domains power_domain_list]
  [-output output_file_name]
  [-html]
```

Data Types

<i>power_domain_list</i>	list
<i>output_file_name</i>	string

ARGUMENTS

-verbose

Displays additional detailed information for the power domains. Each power domain is reported separately. It breaks down area, leakage power and number of cells between isolation, level shifter, always-on, macro, I/O pad and standard cells. It also provides a total of area, leakage, and cell count for power management cells (level shifters, isolation cells, and always-on cells).

-domains *power_domain_list*

Reports estimated leakage power, area, and number of cells for the specified power domains. Each power domain is reported separately if the **-verbose** option is specified. If you do not specify the **-domains** option, all the power domains are reported.

-output *output_file_name*

Specifies a single file into which the outputs are to be written. By default, the command writes the report into ASCII format with the specified file name. If **-html** option is specified together, it writes the specified file in HTML format.

-html

Reports in HTML format. If the **-output** option is not specified, the command prints a temporary file and launches a browser specified by the Tcl variable 'web_browser' to open the temporary file. If the **-output** option is specified, the command writes the reports to the specified file in HTML format.

DESCRIPTION

The **report_mv_qor** command estimates and reports static power for the list of power domains or all the power domains of a design. It also displays the primary voltage of the domain and its switching behavior if the **-verbose** option or the **-html** option is specified.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example shows a summary report of the **report_mv_qor** command. A very low-effort analysis is performed to estimate the design's static power values.

```
prompt> report_mv_qor
```

```

report_mw_lib

Displays information about the measurement units or reference libraries of a Milkyway library.

SYNTAX

```
status report_mw_lib
  [-unit_range]
  [-mw_reference_library]
  [mw_lib]
```

Data Types

mw_lib string

ARGUMENTS

-unit_range

Displays information of about the measurement units for the Milkyway library (length, time, capacitance, and so on) and the characteristics of the routing layers. This option requires you to specify the Milkyway library name.

-mw_reference_library

Reports a list of the reference libraries for the specified Milkyway design library, or for the current Milkyway library if no library name is specified in the command. You define the association between a design library and a reference library with the **set_mw_lib_reference** command.

mw_lib

Specifies the Milkyway library to be reported.

DESCRIPTION

This command displays information about the measurement units or reference libraries of the current Milkyway library or a specified Milkyway library. Use the appropriate option, either **-unit_range** or **-mw_reference_library**, to specify the type of information to report.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example displays a list of reference libraries for the current Milkyway design library:

```
prompt> report_mw_lib -mw_reference_library
..ref/mw_lib/sc
..ref/mw_lib/io
..ref/mw/lib/ram8x64
..ref/mw/lib/ram16x128
1
```

The following example displays information about the measurement units and routing layers of a specified Milkyway design library:

```
prompt> report_mw_lib -unit_range my_mw_lib_A
```

Library: my_mw_lib_A

Tech.	Attr.	Unit	Resolution	Min. Value	Max. Value

report_name_rules

Reports the values of name rules.

SYNTAX

```
status report_name_rules  
      [name_rules]
```

Data Types

name_rules string

ARGUMENTS

name_rules

Specifies the name of the rules to be reported. If the *name_rules* option is not specified, all currently-defined name rules are reported.

DESCRIPTION

This command reports the values of a set of name rules. Name rules are created or modified by the **define_name_rules** command. "Special rules" reports the rule defined by the **-special** option. For details about **-special**, see the **define_name_rules** man page.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **report_name_rules** command to report the values of the name rules called *EXAMPLE*:

```
prompt> report_name_rules EXAMPLE
```

```
*****  
Report : name_rules  
Name Rules : EXAMPLE

```

SEE ALSO

`change_names(2)`
`define_name_rules(2)`
`report_names(2)`

report_names

Reports potential name changes of ports, cells, and nets in a design.

SYNTAX

```
status report_names
  [-rules name_rules]
  [-hierarchy]
  [-dont_touch designs_list]
  [-nosplit]
  [-original]
  [-dont_touch_collection object_list]
```

Data Types

<i>name_rules</i>	string
<i>designs_list</i>	list

ARGUMENTS

-rules *name_rules*

Specifies a set of name rules to which names must conform. The *name_rules* must be defined with the **define_name_rules** command. By default, the name rules file specified in **default_name_rules** is used.

-hierarchy

Reports all names in the design hierarchy. By default, only objects within the current design are reported.

-dont_touch *designs_list*

Specifies a list of designs to which the **changes_names** command is not applied.

-nosplit

Prevents line splitting when column fields overflow.

-original

Reports original names only, and does not report changes.

-dont_touch_collection *object_list*

Specifies the collection on which the **change_names** command is not to be applied. The collection can include designs, cells, ports, nets. You can specify a collection in the object list to ensure that the **change_names** command does not apply any changes to them.

DESCRIPTION

The **report_names** command reports the names of ports, cells, and nets that would be changed to conform to the specified name rules.

This command may not report all of the name changes that would occur by the **change_names** command.

The **report_names** is normally used before running the **change_names** command. The output of **report_names** can be redirected to a names file and used as input to **change_names**.

The *name_rules* file specifies the rules for modifying names, and must be defined with **define_name_rules**.

Use **report_name_rules** to display a list of name rules currently available. Refer to the **define_name_rules** man page for information about naming rules that can be affected when running **report_names**.

With no options specified, **report_names** operates on ports, cells, and nets in the current design. When **-hierarchy** is specified, the report is expanded to include all design objects within the current design object hierarchy.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports port, cell, and net names in the current design that do not conform to the rules defined in **default_name_rules**:

```
prompt> list default_name_rules
default_name_rules = "EXAMPLE"

prompt> report_names
*****
Report : names
    -rules EXAMPLE
Design : TOP
Version: v3.0
Date   : Tue Aug 13 14:24:23 1991
*****
```

Design	Type	Object	New Name
TOP	cell	U\$1	U_1
TOP	net	NET_NAME_IS_WAY_TOO_LONG	NET_NAME_IS_WAY_TOO
TOP	net	12345	N12345

```
prompt> change_names -names_file TOP.names
```

Information: 15 names changed using names file 'TOP.names'.

SEE ALSO

`change_names(2)`
`define_name_rules(2)`
`report_name_rules(2)`

report_net

Reports net information for the design of the current instance or for the current design.

SYNTAX

```
status report_net
[-nosplit]
[-noflat]
[-transition_times]
[-only_physical]
[-verbose]
[-cell_degradation]
[-min]
[-connections]
[-physical]
[net_list]
[-significant_digits digits]
[-max_toggle_rate]
[-max_capacitance]
[-scenarios scenario_list]
```

Data Types

<i>net_list</i>	list
<i>digits</i>	integer
<i>scenario_list</i>	list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-noflat

Allows backward compatibility to produce net reports that only trace fanin and fanout for the current level of hierarchy in a design. The **report_net** command, by default, displays fanin and fanout information throughout the hierarchy for each net, as if the net were flattened. Earlier versions of **report_net** report the fanin and fanout for a net only at the current level of hierarchy.

-transition_times

Reports the rise and fall transition times for each net at the end of the report.

-only_physical

Reports the preroutes of the physical net.

-verbose

Reports verbose connection information when used with the **-connections** option.

When used with the **-physical** or **-only_physical** options, this option displays detailed physical information.

-cell_degradation

Reports the capacitance on the net, the limit for the capacitance on the net (calculated from the cell_degradation table for the drivers of the net), and violations on the net at the end of the report.

-min

Reports the minimum value of capacitance, resistance, or transition time instead of the maximum. By default, **report_net** displays only the maximum values.

-connections

Reports information about pins connected to the nets.

-physical

Reports the total wire length of the net and preroutes of the net, if preroute information exists.

net_list

Reports only those nets specified in *net_list*. If you do not specify *net_list*, all nets in the current instance are displayed.

-significant_digits digits

Specifies the number of digits to the right of the decimal point to report. Allowed values are 0 through 13. The default value is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-max_toggle_rate

Shows the maximum toggle rate values for each net.

-max_capacitance

Shows the maximum capacitance values for each net.

-scenarios scenario_list

Reports the timing derate for the specified scenarios in a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately. If you do not specify this option, only the current scenario is reported.

DESCRIPTION

The **report_net** command displays information about the nets in the design of the current instance or in the current design. If **current_instance** is set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design.

The Load column is calculated as Load = Cell_input_cap + Wireload_cap. Attributes such as **dont_touch** and **annotated_capacitance** are displayed for each net. Note that **dont_touch** can be present on a net as an implicit attribute. This may occur when the **set_dont_touch_network** command is used. All of the nets in the transitive fanout of a port are affected, but **dont_touch** cannot be removed independently from these nets. The annotated capacitance is the value set by the **set_load** command on a net.

If you specify the **-connections** option, the leaf cell pins connected to each net are listed.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. Select different scenarios by using the **-scenarios** option.

EXAMPLES

The following is an example of a net report:

```
prompt> report_net
```

```
*****
Report : net
Design : CONTROL
Version: v3.1a
Date   : Fri 1993
*****
```

Operating Conditions: WCCOM
Wire Loading Model: 05x05

Attributes:

d - dont_touch
c - annotated capacitance

Net	Fanout	Fanin	Load	Pins	Attributes
ACCUMCL	1	1	0.39	2	
ACSEL0	1	1	0.39	2	
ACSEL1	1	1	0.39	2	
ACSEL2	1	1	0.39	2	d
BL0	0	2	0.39	2	
BL1	0	2	0.39	2	
BL2	0	2	0.39	2	
BL3	0	2	0.39	2	d
BOTCHAIN	1	1	1.39	2	
CHAININ	2	1	7.82	3	
CHAINOUT	1	1	0.39	2	
CLK	3	1	2.76	4	
DIN0	1	1	1.39	2	c
DIN2	1	1	0.00	2	
DIN3	1	1	0.00	2	
TOPCHAIN	1	1	1.39	2	
WEABLE	1	1	0.39	2	
ZEROIN	1	1	0.39	2	
n	2	2	2.32	4	
Total 50 nets	66	52	100.71	118	
Maximum	9	2	11.12	10	
Average	1.32	1.04	2.01	2.36	

The following example shows a net connection report for the net named t:

```
prompt> report_net -connections {t}
```

```
*****
Report : net
    -connections
Design : counter
Version: v3.1a
Date   : Fri 1993
*****
```

Connections for net 't':

Driver	Pins	Type
--------	------	------

```
-----  
t/Z      Output Pin (EO)
```

Load Pins	Type
t_bar/A	Input Pin (IVA)
zero/A	Input Pin (OR2)
a/C	Input Pin (AO2)

The following example shows a prerouted physical net report for the t net. It has one segment on metal m2 and a via at (900,281.70).

```
prompt> report_net -only_physical
```

```
*****
```

```
Report : net  
Design : address  
Version: 1999.10  
Date  : Tue Apr 18 22:24:57 2000  
*****
```

Net	Layer/Via	Special_Width	Start_X	Start_Y	End_X	End_Y
t	5(m2)	10.00	202.40	-279.90	202.40	281.70
t	4(via45)	*	900.00	281.70	*	*

report_default_significant_digits(3)
```

report_net_fanout

Displays net fanout or buffer-tree information for the current design.

SYNTAX

```
status report_net_fanout
  [-nosplit]
  [-high_fanout]
  [-threshold lower]
  [-bound upper]
  [-verbose]
  [-connections]
  [-physical]
  [-min]
  [-tree [-depth level]]
  [net_list]
```

Data Types

<i>lower</i>	integer
<i>upper</i>	integer
<i>level</i>	integer
<i>net_list</i>	list

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line in the same column.

-high_fanout

Specifies to show high fanout nets only. A high fanout net is a net with more fanouts than **500**. A high fanout buffer tree is a buffer tree with more leaf loads than the specified value. The fanouts cross hierarchies.

This option is mutually exclusive with the **-threshold** option.

-threshold *lower*

Specifies to only show nets with more fanout than *lower*. The fanouts cross hierarchies.

This option is mutually exclusive with the **-high_fanout** option.

-bound *upper*

Specifies to only show nets with fanout less than or equal to *upper*. The fanouts cross hierarchies.

-verbose

Displays verbose information.

-connections

Displays information about pins connected to the nets.

-physical

Displays location information when applicable.

-min

Shows the minimum conditions. By default, only maximum conditions are shown.

-tree

Indicates to treat a buffer tree as transparent. The leaf loads of the buffer tree are treated as the fanouts of the net. Hierarchical boundaries are not considered as leaf loads.

This option is mutually exclusive with the *net_list* argument.

-depth *level*

Displays only buffer trees with more levels than *level*. This option can only be used with the **-tree** option.

net_list

Specifies to process only those nets on the *net_list*. If *net_list* is not specified, all nets in the current instance are processed.

This argument is mutually exclusive with the **-tree** option.

DESCRIPTION

The **report_net_fanout** command displays net fanout or buffer-tree information in the current design. If a *net_list* is specified, the report is generated only for the specified nets.

All reports cross hierarchical boundaries as if the nets were flattened. This is consistent with the **report_net** command.

The **report_net_fanout** command can be used to find high-fanout nets, buffer trees, or long buffer chains in the current design or the current instance.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to find high-fanout nets:

```
prompt> report_net_fanout -high_fanout
```

The following example shows how to find high-fanout nets in a particular set of nets:

```
prompt> report_net_fanout -high_fanout [get_nets scan*]
```

The following example shows buffer trees with 10 leaf pins:

```
prompt> report_net_fanout -tree -threshold 9 -bound 10
```

The following example shows how to find long buffer chains:

```
prompt> report_net_fanout -tree -depth 8 -bound 1
```

SEE ALSO

`current_design(2)`
`current_instance(2)`
`remove_buffer_tree(2)`
`report_buffer_tree(2)`

report_net_routing_layer_constraints

Reports the routing layer constraints for the specified nets.

SYNTAX

```
status report_net_routing_layer_constraints
  nets
  [-output file_name]
```

Data Types

```
nets      collection
file_name string
```

ARGUMENTS

nets

Specifies the nets for which to report routing layer constraints.

This is a required option.

-output *file_name*

Generates a Tcl script that contains the **set_net_routing_layer_constraints** commands used to set the routing layer constraints for the specified nets. You can use this file to set the same constraints in another session.

DESCRIPTION

This command reports the routing layer constraints for the specified nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the routing layer constraints for a net named netA.

```
prompt> report_net_routing_layer_constraints {netA}
```

SEE ALSO

`remove_net_routing_layer_constraints(2)`
`set_net_routing_layer_constraints(2)`

report_net_routing_rules

Reports the nondefault routing rules for the specified nets.

SYNTAX

```
status report_net_routing_rules
  nets
  [-freeze]
  [-minorchange]
  [-normal]
  [-output file_name]
```

Data Types

<i>nets</i>	collection
<i>file_name</i>	string

ARGUMENTS

nets

Specifies the nets for which to report nondefault routing rules.

This is a required argument.

-freeze

Reports the specified nets with the **freeze** attribute.

This option is not supported in Design Compiler topographical mode.

-minorchange

Reports the specified nets with the **minorchange** attribute.

This option is not supported in Design Compiler topographical mode.

-normal

Reports the specified nets with the **normal** attribute.

This option is not supported in Design Compiler topographical mode.

-output *file_name*

Generates a Tcl script with the specified file name that contains **set_net_routing_rule** commands for the current net routing rule settings of the specified nets. You can use this script to set the same net routing rules in another session.

DESCRIPTION

This command lists the nondefault routing rules for the specified nets. In addition, you can generate a Tcl script that contains `set_net_routing_rule` commands for the current net routing rule settings of the specified nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the nondefault routing rules for the nets named CLK1 and CLK2.

```
prompt> report_net_routing_rules {CLK1 CLK2}
```

```
*****
```

Report : net routing rules

report_net_search_pattern

Reports the specified net search patterns.

SYNTAX

```
status report_net_search_pattern  
-pattern id | -all
```

Data Types

id integer

ARGUMENTS

-pattern *id*

Specifies the pattern ID that you want to report.

Reports the details of the search criteria used to define the specified net search pattern, such as its length, fanout, bounding box half perimeter, lower limits, and upper limits.

-all

Reports the details of all net search patterns defined for your design.

DESCRIPTION

The **report_net_search_pattern** command reports the settings of the specified net search patterns. You can specify a single net search pattern by using the **-pattern** option or all net search patterns by using the **-all** option.

Before you use this command, at least one net search pattern must exist in the design. To create a net search pattern, use the **create_net_search_pattern** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the details of the net search pattern with an ID of 42.

```
prompt> report_net_search_pattern -pattern 42
```

```
*****
Report : net_search_pattern
Design : CORE
Version: F-2011.09-ICC-SP3
Date  : Tue Nov  8 12:48:44 2011
*****
```

```
pattern id: 42
```

```
-----

set_net_search_pattern_priority(2)
report_net_search_pattern_priority(2)
get_matching_nets_for_pattern(2)
```

report_net_search_pattern_delay_estimation_options

Reports delay estimation options specified for a pattern or all net search patterns.

SYNTAX

```
status report_net_search_pattern_delay_estimation_options  
-pattern id | -all
```

Data Types

id integer

ARGUMENTS

-pattern *id*

Specifies the pattern ID you want to query. When a valid ID is entered, any pattern-based delay estimation options assigned to that ID by the **set_net_search_pattern_delay_estimation_options** command are reported.

-all

Displays all pattern-based delay estimation options defined by the **set_net_search_pattern_delay_estimation_options** command.

DESCRIPTION

The **report_net_search_pattern_delay_estimation_options** command reports pattern delay estimation options for a net pattern or all net patterns that are defined.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The **report_net_search_pattern_delay_estimation_options** command can be used as shown in the following example:

```
prompt> report_net_search_pattern_delay_estimation_options -pattern 3
```

```
*****
```

```
Report : net_search_pattern_delay_estimation_options  
Design : CORE
```

```
Version: F-2011.09-ICC-SP3
Date : Tue Nov 8 12:48:44 2011
*****
Delay estimation options for pattern: 1
-----
minimum routing layer id: METAL1
maximum routing layer id: METAL2
-----
```

SEE ALSO

```
create_net_search_pattern(2)
report_net_search_pattern(2)
remove_net_search_pattern(2)

set_net_search_pattern_priority(2)
report_net_search_pattern_priority(2)
get_matching_nets_for_pattern(2)
```

report_net_search_pattern_priority

Reports the pattern matching priority.

SYNTAX

status **report_net_search_pattern_priority**

ARGUMENTS

DESCRIPTION

The **report_net_search_pattern_priority** command reports the current prioritization of all existing net patterns. If a priority list was not specified by the **set_net_search_pattern_priority** command, the **report_net_search_pattern_priority** command returns nothing. The default behavior of the **create_net_search_pattern** command is to prioritize patterns based on the order in which they were created. For example, if 5 net patterns were created, pattern 1 will have the highest matching priority, followed by pattern 2, and then pattern 3, and so on.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a **report_net_search_pattern_priority** report:

```
prompt> report_net_search_pattern_priority
```

```
*****
```

```
Report : net_search_pattern_priority
```

```
Design : CORE
```

```

report_ocvm

Displays information about advanced on-chip variation (AOCV) and parametric on-chip variation (POCV) derating tables and coefficients, and reports derating calculation details.

SYNTAX

```
status report_ocvm
  [-min]
  [-max]
  [-early]
  [-late]
  [-rise]
  [-fall]
  [-clock]
  [-data]
  [-cell_delay]
  [-net_delay]
  [-list_annotated]
  [-list_not_annotated]
  [-nosplit]
  [-arc_details]
  -type aocvm | pocvm
  [object_list]
```

Data Types

object_list list

ARGUMENTS

-min

Reports AOCV/POCV derate tables for the minimum operating condition.

-max

Reports AOCV/POCV derate tables for the maximum operating condition.

-early

Reports early AOCV/POCV derate tables.

-late

Reports late AOCV/POCV derate tables.

-rise

Reports rise AOCV/POCV derate tables.

-fall

Reports fall AOCV/POCV derate tables.

-clock

Reports clock AOCV/POCV derate tables.

-data

Reports data AOCV/POCV derate tables.

-cell_delay

Reports cell delay AOCV/POCV derate tables.

-net_delay

Reports net delay AOCV/POCV derate tables.

-list_annotated

Generates a list of leaf cells and global nets that are annotated with AOCV/POCV derate tables.

-list_not_annotated

Generates a list of leaf cells and global nets that are not annotated with AOCV/POCV derate tables.

-nosplit

Prevents split lines when columns overflow.

-arc_details

Reports the computed depth, distance and derate values of the timing arcs that start, pass through, or end at the leaf cells listed in *object_list*; or reports the POCV sigma tables annotated on the timing arcs of the library cells listed in *object_list*.

-type aocvm | pocvm

Specifies the OCV type. The allowed values are **aocvm**, which displays AOCV-related information, or **pocvm**, which displays POCV-related information.

object_list

Specifies the design objects to be reported, on which AOCV/POCV derate tables or coefficients have been annotated. Only leaf cells or library cells should be specified when this option is used with the **arc_details** option.

DESCRIPTION

This command reports user-specified information about advanced on-chip variation (AOCV) and parametric on-chip variation (POCV) analysis. The type of information displayed depends on the type of AOCV/POCV information previously annotated with the **read_aocvm** command.

If the OCV type is specified as **aocvm**, AOCV information is displayed. If the OCV type is specified as **pocvm**, POCV information is displayed.

Note: The Design Compiler tool supports only POCV derating, which is applied with the **read_ocvm** command. The IC Compiler tool supports both AOCV and POCV derating, which are applied by the **read_aocvm** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

In the following example, the design has been annotated with AOCV derate factors using the **read_aocvm** command:

```
prompt> report_ocvm -type aocvm
*****
Report : aocvm
Design : my_design
*****
```

	Fully Total annotated	Partially annotated	Not annotated	
Leaf cells	6	0	4	2
Nets	7	0	0	7
	13	0	4	9
1				

In the following example, the design has been annotated with POCV derate factors using the **read_aocvm** command:

```
prompt> report_ocvm -type pocvm
*****
Report : pocvm
Design : my_design
*****
```

POCV coefficient:

	Fully Total annotated	Partially annotated	Not annotated	
Leaf cells	6	0	4	2
Nets	7	0	0	7
	13	0	4	9
1				

POCV distance:

	Fully Total annotated	Partially annotated	Not annotated	
Leaf cells	6	0	4	2
Nets	7	0	0	7
	13	0	4	9
1				

The following example displays metrics and AOCV derate factors for a cell specified in the *object_list*. The arc depth displayed in the report is the most pessimistic depth for all possible paths through the arc.

```
prompt> report_ocvm -type aocvm -arc_details [get_cells u4]
```

```
*****
Report : ocvm

report_opcond_inference

Reports the strategy and settings for operating condition inference.

SYNTAX

```
status report_opcond_inference  
[-object_list cells]
```

Data Types

cells collection

ARGUMENTS

-object_list *cells*

Specifies the cells on which the strategies for operating condition inference to be reported. If cells are not specified, reports the settings for the top design.

DESCRIPTION

This command reports the strategies for the operating condition inference. If cells are not specified, reports the settings for the top design.

Multicorner-Multimode Support

This command applies to all scenarios.

EXAMPLES

The following example reports the settings for the operating condition inference for the hierarchical cell **subA**.

```
prompt> report_opcond_inference -object_list [get_cells {subA}]
```

```
*****  
Report : report_opcond_inference  
Design : des_chip  
Version: F-2011.09-ICC  
Date  : Wed Apr 6 16:48:46 2011  
*****
```

Cell	Cell type	Level	Match_process_temperature
subA	macro	exact	false
	pad	exact	false
	switch	exact	false

SEE ALSO

[set_opcond_inference\(2\)](#)

report_operating_conditions

Displays a specific operating condition or all operating conditions in a library.

SYNTAX

```
status report_operating_conditions
  -library library_name
  [-name op_cond_name]
```

Data Types

library_name string
op_cond_name string

ARGUMENTS

-library *library_name*

Specifies the name of the library that stores the operating conditions.

-name *op_cond_name*

Specifies the name of the operating conditions.

DESCRIPTION

The **report_operating_conditions** command reports a specific operating condition or all operating conditions in the specified library.

To create a new operating conditions, use the **create_operating_conditions** command.

To set operating conditions on the current design, use the **set_operating_conditions** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports a specific operating condition called *BEST* in the library named *a_lib*:

```
prompt> report_operating_conditions -library a_lib -name BEST
```

The following example reports all of the operating conditions in the library named *IBM_CMOS5S6_SC*:

```
prompt> report_operating_conditions -library IBM_CMOS5S6_SC
```

SEE ALSO

`create_operating_conditions(2)`
`set_operating_conditions(2)`

report_optimize_dft_options

Reports options for physical design-for-test (DFT) optimization.

SYNTAX

status **report_optimize_dft_options**

ARGUMENTS

The **report_optimize_dft_options** command has no argument.

DESCRIPTION

This command reports the value of the physical DFT options available in command **set_optimize_dft_options**. The options are -**repartitioning_method** and **-single_dir_option**.

SEE ALSO

[remove_optimize_dft_options\(2\)](#)
[set_optimize_dft_options\(2\)](#)

report_partitions

Lists the hierarchical designs and their associated attributes and relative size (estimated in RTL).

SYNTAX

```
status report_partitions  
[-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command displays the partition-related information, including estimated relative size (or cell area, for mapped designs), number of instantiations, and which instance is the master instance.

EXAMPLES

The following is an example of a partition report:

```
prompt> report_partitions  
*****  
Report : partitions  
Design : vampire (unmapped)  
Date   : Thu Feb 8 14:47:48 2001  
*****
```

Partition attributes :

(*) - partition.
% - the percentage w.r.t total design area.
d - dont_touch.
m(n) - multiple instantiated design (number of instantiation).

Designs	Attributes
---------	------------

vampire(*)	15.6%
tap_block(*)	6.8%, m(7), u1
add(*)	1.8%, m(8), u0/u0
mult(*)	1.5%, m(8), u0/u1
first_tap(*)	6.9%
cascade	1.5%
accum(*)	4.0%

SEE ALSO

[set_compile_partitions\(2\)](#)

report_path_budget

Displays budgeting information about a design.

SYNTAX

```
status report_path_budget
  [-to to_list]
  [-from from_list]
  [-through through_list]
  [-nworst paths_per_endpoint]
  [-max_paths max_path_count]
  [-input_pins]
  [-nets]
  [-transition_time]
  [-significant_digits digits]
  [-nosplit]
  [-all]
  [-verbose]
```

Data Types

<i>to_list</i>	list
<i>from_list</i>	list
<i>through_list</i>	list
<i>paths_per_endpoint</i>	integer
<i>max_path_count</i>	integer
<i>digits</i>	integer

ARGUMENTS

-to *to_list*

Reports only the paths to pins, ports, or clocks specified by *to_list*. The default is to report the longest path to an output port, with the worst slack within each path group.

-from *from_list*

Reports only the paths from pins, ports, or clocks specified by *from_list*. The default is to report the longest path to an output port, with the worst slack within each path group.

-through *through_list*

Reports only the paths through pins specified by *through_list*. The default is to report the longest path to an output port, with the worst slack within each path group.

-nworst *paths_per_endpoint*

Specifies the number of paths per endpoint to report. The default is 1.

-max_paths *max_path_count*

Specifies the number of paths per path group to report. The default is 1.

-input_pins

Specifies that input pins are to be shown in the path report. The default is to show only output pins. This option also shows the delays of the nets connected to these pins.

-nets

Specifies that nets are to be shown in the path report. The default is not to show nets. To show the delay for the nets, use the **-input_pins** option.

-transition_time

Specifies that the net transition time for each driving pin is to be shown in the path report. The default is not to show the net transition time for each driving pin.

-significant_digits digits

Specifies the number of reported digits to be to the right of the decimal point in the report. Valid values are 0 to 13. The default value is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-all

Reports all hierarchical pins. By default, the command reports only the budget number on the hierarchical pins of the cell that have been budgeted. When the **-all** option is specified, the command reports budget numbers on all hierarchical pins on this path.

-verbose

Reports the budget number on every cell along the path.

DESCRIPTION

This command provides a report of budgeting information for the current design. The delay number shown for each block or cell shows the amount of budget allocated for that block or cell in the path. The overall budget for the path is the sum of these budgets (delays).

EXAMPLES

The following example shows a budgeting report using only the default values:

```
prompt> report_path_budget -th [get_pins i_driver/OUT]
```

```
*****
Report : budget
  -path full
  -delay max
  -max_paths 1
Design : test
Version: 2002.05
Date  : Tue Mar 19 11:20:24 2002
*****
```

report_path_group

Reports information about path groups in the current design.

SYNTAX

```
status report_path_group
  [-nosplit]
  [-expanded]
  [-scenarios scenario_list]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most design information is listed in fixed-width columns. When the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-expanded

Expands the paths when reporting.

-scenarios scenario_list

Reports path groups for the specified scenarios of a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately.

If you do not specify this option, only the current scenario is reported.

DESCRIPTION

The **report_path_group** command produces a report showing information about path groups in the current design. The report includes path groups automatically created by the **create_clock** command and groups manually created with the **group_path** command. Path groups are used to affect the calculation of maximum delay cost during optimization. You can display the cost of each group using the **report_constraint** command.

To remove all path groups in the current design, use the **reset_design** command. To remove certain paths from their current groups, use **group_path -default**.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example reports all timing attributes set on the design:

```
prompt> report_path_group
```

```
*****
Report : path_group
Design : counter
Version: 1998.01
Date  : Wed Jul 9 13:51:14 1997
*****
```

Group Name	Weight	Range
default	1.00	0.00
CLK	1.00	0.00
BLUE	1.00	5.00

Paths:	From	Through	To	Group Name
*	*	CLK	CLK	BLUE
	Red_reg[5]	*	Blue_reg[5]	BLUE

SEE ALSO

[group_path\(2\)](#)
[report_constraint\(2\)](#)
[reset_design\(2\)](#)

report_physical_constraints

Reports the physical constraint settings for the current design. This command is supported only in topographical mode.

SYNTAX

```
status report_physical_constraints  
  [-no_site_row]  
  [-pre_route]
```

ARGUMENTS

-no_site_row

Specifies that site rows are not reported. By default, the site rows are reported block by block.

-pre_route

Specifies that preroutes are reported if they exist. By default, preroutes are not reported.

DESCRIPTION

The **report_physical_constraints** command reports the physical constraints settings that are applied to the design. The command reports the following physical constraints:

- die area
- placement area
- utilization
- aspect ratio
- rectilinear outline
- port side
- port location
- cell location
- placement blockage
- wiring keepouts
- voltage area
- site rows
- bounds
- preroutes (net shapes, user shapes, vias, via arrays, and via cells)
- physical-only cells

To report the physical constraints of preroutes, specify the **-pre_route** option.

Note that because of priority considerations, the physical constraints with respect to the same type of object are not all reported by the **report_physical_constraints** command. The following two rules help determine which constraints are in effect and are reported.

1. For the core area constraints set by the commands listed below, the placement area constraint has the highest priority and

rectilinear outline has a higher priority than utilization and aspect ratio:

```
set_placement_area  
set_rectilinear_outline  
set_utilization  
set_aspect_ratio
```

2. Between the two constraints for ports, port location has a higher priority than port side. For example, assume the following constraints are set:

```
set_placement_area -coordinate { 10 10 1000 1000 }  
set_utilization 0.9  
set_port_location Clk -coordinate {100 200}  
set_port_side -side top {Clk Reset}
```

When you run the **report_physical_constraints** command, the report shows these constraints as follows:

Placement area	{ 0.000 0.000 100.000 100.000 }
PORT LOCATION 1	LOCATION
Clk	{ 100.000 200.000 }
PORt SIDE 1	SIDE
Reset	top

The utilization and the port side of the **Clk** port are omitted due to the constraint priority.

EXAMPLES

The following example shows the command usage:

```
prompt> report_physical_constraints
```

The following example shows a sample report for physical-only filler cells:

CELL2	LOCATION	ORIENTATION	FIXED
fill_1	{3100.000 700.000 }	N	Yes
fill_2	{3000.000 600.000 }	N	Yes

```

report_pin_map

Displays package pin-map information set by the **read_pin_map** command.

SYNTAX

status **report_pin_map**

ARGUMENTS

The **report_pin_map** command has no arguments.

DESCRIPTION

The **report_pin_map** command displays package pin-map information set by the **read_pin_map** command on the current design.

EXAMPLES

The following is an example of the **report_pin_map** command:

```
prompt> report_pin_map
*****
Report : BSD Pin Map
Design : M1
Version: Z-2007.03
Date   : Fri Dec 21 08:44:55 2006

report_pin_name_synonym

Reports pin-name synonym definitions.

SYNTAX

```
status report_pin_name_synonym  
      [-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_pin_name_synonym** command displays all of the currently defined pin name synonyms.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following command set shows the pin-name synonym settings and then uses the **report_pin_name_synonym** command to report pin-name synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD  
1  
prompt> set_pin_name_synonym SYN_QN QN  
1  
prompt> set_pin_name_synonym -full_name \  
    mid1/bot1/LSR0P_at_bot/SYN_R mid1/bot1/LSR0P_at_bot/R  
1  
prompt> set_pin_name_synonym -full_name this/is/a/synonym \  
    mid1/FJK2SP_at_mid/TI  
1
```

```
prompt> set_pin_name_synonym -full_name mid1/FJK2SP_at_mid/J \
           mid2/bot2/LSR0P_at_bot/Q
1

prompt> report_pin_name_synonym
*****
Report : pin name synonym
Design : top
Version: X-2005.09
Date  : Wed Jun 29 10:29:04 2005
*****

| Synonym                      | Pin Name                 | Type        |
|------------------------------|--------------------------|-------------|
| this/is/a/synonym            | mid1/FJK2SP_at_mid/T1    | full name   |
| mid1/FJK2SP_at_mid/J         | mid2/bot2/LSR0P_at_bot/Q | full name   |

report_pipeline_scan_data_configuration

Displays options specified by the **set_pipeline_scan_data_configuration** command.

SYNTAX

```
status report_pipeline_scan_data_configuration
```

ARGUMENTS

The **report_pipeline_scan_data_configuration** command has no arguments.

DESCRIPTION

This command displays options specified by the **set_pipeline_scan_data_configuration** command on the current design.

The command reports the following information:

- Head Pipeline Clock
 - Tail Pipeline Clock
 - Head Pipeline Stages
 - Tail Pipeline Stages
-

EXAMPLES

The following is an example of a pipeline scan data configuration report:

```
prompt> report_pipeline_scan_data_configuration
```

```
*****
Report : Pipeline Scan Data Configuration
Design : CORE
Version: D-2010.03-20100127
Date  : Wed Jan 27 23:12:50 2010
*****
```

Head Pipeline Clock	CLK1
Tail Pipeline Clock	CLK1
Head Pipeline Stages	3
Tail Pipeline Stages	5

1

SEE ALSO

[set_pipeline_scan_data_configuration\(2\)](#)
[reset_pipeline_scan_data_configuration\(2\)](#)

report_port

Displays information about ports of the current instance or the current design.

SYNTAX

```
status report_port
  [-drive]
  [-verbose]
  [-physical]
  [-only_physical]
  [-nosplit]
  [-significant_digits digits]
  [port_list]
```

Data Types

digits integer
port_list list

ARGUMENTS

-drive

Specifies that the port report is to include only the sections showing the drive capability of input and inout ports. By default, this option is off.

-verbose

Specifies that the port report is to include all port information. By default, only a summary section is shown that lists all ports and their direction.

-physical

Reports the physical location of the port. By default, this option is off. This option is not supported in Design Compiler topographical mode and will be ignored.

-only_physical

Reports the physical only ports. By default, this option is off. This option is not supported in Design Compiler topographical mode and will be ignored.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. By default, this option is off.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that the command reports. Using this option overrides the value set by the **report_default_significant_digits** variable. Allowed values are 0 through 13. The default is 2 for all fields except "Pin Load"

and "Wire Load," which have a default of 4. Specifying a valid value for significant digits overwrites the existing default value.

port_list

Indicates that the port report is to include only the specified ports and cannot be used if the current instance is set. By default, all ports in the current instance or current design are listed.

DESCRIPTION

This command displays information about ports in the design of the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

By default, a brief report is produced that includes all ports in the design. If you use the **-verbose** option, all types of information are included. If you use the **-drive** option, only drive information for input and inout ports is shown. If you specify a *port_list* value, the command includes only those ports in the report.

Attributes pertaining to the **set_driving_cell** command that assign the driving cells to the ports are reported in the "Attrs" column of the driving cell section of the verbose report. The letter **D** indicates that the **-dont_scale** and **-max** option of the **set_driving_cell** command are used, and the letter **d** indicates that the **-dont_scale** and **-min** option are used, the letter **N** indicates that the **-no_design_rule** and **-max** option are used, the letter **n** indicates that the **-no_design_rule** and **-min** option are used.

If the current instance has been set, the report is generated for the design of that instance. Note that attributes on these ports have no effect unless the current design is changed to that subdesign.

The "Input Delay" and "Output Delay" portions of the report list the minimum rise, minimum fall, maximum rise, and maximum fall delays. They also list the clock to which the delay is relative. If the clock name is followed by (f), the delay is relative to the falling edge of the clock. Otherwise the delay is relative to the rising edge. If the clock name is followed by (l), input delay is considered as if coming from a level-sensitive latch or output delay is considered as if going to a level-sensitive latch. By default, the delay is relative to a rising edge-triggered device.

The "Max Tran" and "Min Tran" columns list the maximum and minimum rise and fall times set by the **set_transition** command to this port.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a brief port report:

prompt> report_port

```
*****
Report : port
Design : counter
Version: v3.1
Date  : Mon 1992
*****
```

report_power

Calculates and reports dynamic and static power for the design or instance.

SYNTAX

```
status report_power
  [-net]
  [-cell]
  [-only cell_or_net_list]
  [-hierarchy]
  [-levels level_value]
  [-verbose]
  [-flat]
  [-exclude_boundary_nets]
  [-include_input_nets]
  [-analysis_effort low | medium | high]
  [-nworst number]
  [-sort_mode mode]
  [-histogram [-exclude_leq le_val
    | -exclude_geq ge_val]]
  [-nosplit]
  [-scenarios scenario_list]
  [-groups group_list]
```

Data Types

<i>cell_or_net_list</i>	object_list
<i>level_value</i>	integer
<i>number</i>	integer
<i>mode</i>	string
<i>le_val</i>	float
<i>ge_val</i>	float
<i>scenario_list</i>	list
<i>group_list</i>	list

ARGUMENTS

-net

Reports the power consumption of nets. Use the **-net** option alone, or use it with the **-cell** option. By default, only the design's summary power information is reported when neither option is specified.

-cell

Reports the power consumption of cells. If there are physical-only cells in a hierarchical module, the physical-only cells and the nonphysical-only cells are listed separately.

When you use the **-cell** option, some entries in the power report might not apply to certain cells. The column entry for such cells is annotated with N/A. Use the **-cell** option alone or with the **-net** option to report the cells and nets. By default, only the design's summary power information is reported when neither option is specified.

In Design Compiler topographical mode, when you specify the **-cell** option, the power report includes estimated clock tree power numbers, if you do not use the **-only** option and if the power prediction was turned on in the previous run of the **compile_ultra** command. This entry is marked *CLOCK_TREE_EST* in the cell column.

-only cell_or_net_list

Specifies a list of cells and nets to display with the **-net** or **-cell** options. With this option, only the cells and nets in the *cell_or_net_list* are listed in the power report. If both **-net** and **-only** options are specified, the *cell_or_net_list* must contain at least one net. Similarly, if both **-cell** and **-only** options are specified, the *cell_or_net_list* must contain at least one cell.

If the **-net**, **-cell**, and **-only** options are specified together, the *cell_or_net_list* must contain at least one net and one cell. Physical-only cells in a hierarchical module are not reported unless they are explicitly specified in the cell list as shown in the following example:

```
report_power -cell -only [get_cells hier_module/* -all]
```

-hierarchy

Specifies that the report be in a hierarchical format, with power information reported on a block-by-block basis. Use the **-levels** option to limit the number of levels of hierarchy shown in the report. The **-sort** and **-nworst** options are ignored for this report. The switching, internal, and leakage power numbers are reported for each hierarchical block. The hierarchy is shown through indentations.

In Design Compiler topographical mode, when you specify the **-hierarchy** option, the power report includes estimated clock-tree power numbers if power prediction was turned on in the last run of the **compile_ultra** command. This entry is marked *CLOCK_TREE_EST*.

-levels level_value

Specifies the number of levels of hierarchy to display, in the hierarchical report. You can specify a positive integer, greater than 1, with this option. Hierarchy levels deeper than those specified in this option are not shown in the hierarchical report. This option is only used for the hierarchical report and is ignored for all other types of reports.

-verbose

If the **-net** or **-cell** option is specified, it displays additional detailed information about the power information of the cells and nets. With the **report_power -verbose** specified, the power group summary displays the cell counts of the power groups.

-flat

Specifies that the power report traverse the hierarchy and report objects at all lower levels (assumes a flat design hierarchy). The default behavior is to report objects at only the current level of hierarchy. For cell report, if the **-flat** option is not specified, the power reported for a subdesign is the total power estimated for that subdesign, including all of its contents.

-exclude_boundary_nets

Specifies an option that is now obsolete.

-include_input_nets

Includes the switching power of primary input nets in the power report. The default is to exclude boundary input nets. This option affects the nets that are chosen to be displayed in the net-specific report as well as the value of the total switching power. This option does not affect the cell leakage and internal power values. When this option is specified, the sum of the power values of different power groups might be different with the summary report.

-analysis_effort low | medium | high

Provides a trade off between runtime and accuracy. The default is **low**. Specifying **low** effort results in the fastest runtime and the lowest accuracy of power estimates. Specifying **medium** or **high** effort results in a longer run with increased levels of accuracy. The analysis effort is considered only during the estimation of switching activity information, and therefore, has an effect only when the design is not fully annotated with switching activity.

-nworst number

Filters the report so that it displays only the highest *number* power objects. This option is valid only if either **-net** or **-cell** or both the options are specified.

-sort_mode mode

Determines the sorting mode for report order and **-nworst** selection. The valid sorting modes for the **-net** or **-cell** options are as follows:

-net option	-cell option
-----	-----
name	name
net_static_probability	cell_internal_power
net_switching_power	cell_leakage_power
net_toggle_rate	dynamic_power
total_net_load	

When using both **-net** and **-cell** and specifying a sorting mode, you must select a sorting mode that is valid for both options. The mode is used for both the cell and the net reports.

If you do not explicitly set the sorting mode, a default is chosen based on the mode of the **report_power** command:

Mode	Implicit default
-----	-----
-net	net_switching_power
-cell	cell_internal_power
-net -cell	dynamic_power

-histogram -exclude_leq le_val | -exclude_geq ge_val

Displays a histogram-style report showing the number of nets in each power range. The **-exclude_leq** and **-exclude_geq** arguments are used to exclude data values less than *le_val* or greater than *ge_val*, respectively. Useful for displaying the range and variation of power in the design. This option displays the histogram report only if either **-net** or **-cell** is specified.

-nosplit

Prevents line splitting and facilitates writing applications to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-scenarios scenario_list

Reports power for the specified scenarios of a multicorner-multimode design. Each scenario is reported separately. Inactive scenarios are skipped in the report. If you do not specify this option, only the current scenario is reported.

-groups group_list

Reports power for the specified power groups. By default all instances are placed in only 1 power group, so the sum of the predefined groups power equals the total power consumption of the design. However, if the design has multi-driven nets, then the switching power reported in the group will be smaller than the number reported in summary, since it will be divided by the number of drivers for the multi-driven nets. The valid power groups of the group_list are: io_pad, memory, black_box, clock_network, register, sequential, combinational.

io_pad	cells defined as part of the pad_cell group in the library
memory	cells defined as part of the memory group in the library
black_box	cells with no functional description in the library
clock_network	cells in the clock network excluding io_pad cells
register	latches and flip-flops driven by the clock network excluding io_pads and black_boxes
sequential	latches and flip-flops clocked by signals other than those in the clock network
combinational	nonsequential cells with a functional description

By default, `report_power` will report switching power for the groups in one column. When variable "power_report_separate_switching_power" is set to TRUE, `report_power` will report wire switching power and pin switching power in two columns.

The `power_clock_network_include_register_clock_pin_power` variables can affect internal power for `clock_network` and `register` group. For more information, see the man page.

DESCRIPTION

The `report_power` command calculates and reports power for a design. The command uses the user-annotated switching activity to calculate the net switching power, cell internal power, and cell leakage power, and displays the calculated values in a power report.

The `report_power` command needs switching activity information on all design nets, and uses a switching activity propagation mechanism to estimate switching activity information on nonannotated design objects.

The options enable you to specify cells and nets for reporting. The default operation is to display the summary of power values for only the current design. If a current instance is specified, the `report_power` command displays the summary power values for that instance. The power of an instance is estimated in the context of the higher-level design, which means using the switching activity and load of the higher-level design.

The `-verbose` option reports more details of the power information. The `-flat`, `-exclude_boundary_nets`, `-nworst`, and `-sort_mode` options enable the filtering of objects that are selected by the `report_power` command. The `-sort_mode` option also affects the formatting of the power reports by modifying the order of nets and cells that are displayed by the `report_power` command.

The `-histogram` option causes additional sections to be displayed in the power reports. The power histogram classifies the nets or cells into groups of power values, allowing for easier visual analysis of the range of power values and of the distribution of the nets and cells across that range. The `-histogram` option enables the pruning of objects in the histogram by excluding values greater than or less than specified values.

Power analysis uses the current tool's mechanism to obtain the loads. For example, for synthesis in nontopographical mode without parasitic back-annotation, the tool uses wire load models; it uses back-annotated capacitance information when available, and so on.

The standalone `report_power` command does not update extraction information, so it is recommended to use `extract_rc` before using `report_power`.

When you run the `report_power` command it checks-out a Power Compiler license. If a license is not available, the command terminates with an error message. Otherwise, the command proceeds normally. At the completion of the command, the Power Compiler license is released. To keep the license checked-out after the completion of the `report_power` command, set the `power_keep_license_after_power_commands` variable to `true`.

In topographical mode, if power prediction is enabled, `report_power` reports the correlated power. The reported power numbers include the power consumption by design components as well as the predicted power of missing components, such as clock tree. The correlated power is not reported if any option of the `report_power` is used.

When the leakage power model is set to `channel_width`, using the `set_leakage_power_model` command, the total design power reported by the `report_power` command includes the total weighted sum of the channel widths for the design.

Creation and use of scenarios is supported in Design Compiler Graphical.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the `-scenarios` option.

EXAMPLES

The following example shows a summary report of the `report_power` command. A medium-effort analysis is performed to estimate the design's power values.

```
prompt> report_power -analysis_effort medium
```

report_power_calculation

Displays the calculation of the internal power for a pin, the leakage power for a cell, or the switching power for a net.

SYNTAX

```
status report_power_calculation
  pin_cell_or_net_list
  [-state_condition boolean_eq_of_pins | default | all]
  [-path_sources pin_name | default | all]
  [-rise]
  [-fall]
  [-verbose]
  [-nosplit]
```

Data Types

<i>pin_cell_or_net_list</i>	object_list
<i>boolean_eq_of_pins</i>	string
<i>pin_name</i>	string

ARGUMENTS

pin_cell_or_net_list

Specifies the objects on which the power calculation reports. All objects in the list must be of the same type. The type of power calculation depends on the object type, as follows:

- The tool reports the internal power calculation for a pin.
- The tool reports the leakage power calculation for a cell.
- The tool reports the switching power calculation for a net.

-state_condition boolean_eq_of_pins | default | all

Reports only the tables or polynomials with matching state conditions. This option is valid only for pin or cell type objects. Use **-state_condition default** to specify the default state condition. Use **-state_condition all** to consider all states for reporting.

-path_sources pin_name | default | all

Reports only the tables or polynomials with matching path sources. This option is valid only for pin type objects. Use **-path_sources default** to specify the default path condition (no path source). Use **-path_sources all** to specify that all path sources must be considered for reporting.

-rise

Limits the report of internal power calculation to only the rise power.

-fall

Limits the report of internal power calculation to only the fall power.

-verbose

Increases the amount of information that is reported for cells or pins. For cells, the leakage power calculation report is appended by an internal power calculation report for all pins and all possible states and path sources of the cells in the object list. For pins, all of the possible states and paths are printed (equivalent to specifying **-state_condition all -path_sources all**).

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_power_calculation** command provides detailed power calculation information for the specified pin, cell, or net. Use this information for debugging or verifying power data in a logic library. Before using this command to display details of internal or leakage power calculation, read the logic library file into the system using the **read_lib** command. This command automatically compiles the library and enables the **report_power_calculation** command for internal and leakage power. Otherwise, the built-in security mechanism terminates the command when issued for pin internal power or cell leakage power calculation. This restriction does not apply to net switching power calculation.

It is considered best practice to use the **report_power** command before issuing **report_power_calculation**. This ensures the propagation of any missing switching activity. If the design is not completely annotated with switching activity when **report_power_calculation** is executed, the missing activity is propagated with the same analysis effort that was used during the last issued **report_power** command. If no power analysis is performed prior to issuing the **report_power_calculation** command, a low analysis effort is used for switching activity propagation.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the calculation of path dependent internal power from input pin *B* to output pin *Y*. The contributions for rise and fall internal power are shown separately.

```
prompt> report_power_calculation U4/Y -state_condition default -path_sources B
```

```
*****
Report : power_calculation
        U4/Y
        -state_condition default

[report_power\(2\)](#)
[set_switching_activity\(2\)](#)

report_power_derate

Reports the power derating factors for either the current design, a list of cells, or library cells in the current design.

SYNTAX

```
status report_power_derate
  [-scenarios scenario_list]
  [-include_inherited]
  [-significant_digits digits]
  [-nosplit]
  [object_list]
```

Data Types

<i>scenario_list</i>	list
<i>digits</i>	integer
<i>object_list</i>	list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

-include_inherited

Indicates that the power derating factors reported on each object should also include those set by other objects in the design.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point to report. Allowed values are from 4 to 13. The default is 4. Using this option overrides the value set by the **report_default_significant_digits** variable.

-nosplit

Prevents line-splitting and facilitates writing scripts to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line starting in the correct column.

object_list

Specifies current design or a list of cells or library cells to which the specified power derating factor is applied.

DESCRIPTION

This command is used to report the derate factors either on the design, specific cells or library cells of the design. If this command is

called without any option, a report will be invoked for the power derating factors stored on the current design and also for each cell or library cell that has power derating factors set on it.

If this command is called with option `-include_inherited` each row containing an inherited derating factor will contain a column entry indicating the object from which it was inherited. If the command is called with the `object_list` specified then derate reports will only be issued for the instances specified in the object list.

For significant digits used in power derate report, the `-significant_digits` option can be used. By default, the number of significant digits used to display values is 4.

Multicorner-Multimode Support

EXAMPLES

The following example shows a summary report of the `report_power_derate` command.

```

`set_power_derate(2)`
`get_power_derate(2)`
`reset_power_derate(2)`

report_power_domain

Reports information about the specified power domain.

SYNTAX

```
status report_power_domain
  [power_domains]
  [-hierarchy]
  [-nosplit]
  [-verbose]
  [object_list]
```

Data Types

power_domains list or collection

ARGUMENTS

power_domains

Specifies the power domains to be reported. The *power_domain* argument can be a collection of power domains or name patterns.

If this argument is not specified, the command reports all power domains in the current scope.

You cannot use this argument with the *-hierarchy* option.

-hierarchy

Reports all power domains in the current scope and all of its descendant scopes.

You cannot use this option with the *power_domain* argument.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-verbose

Reports all functions of the supply sets associated with the power domain.

DESCRIPTION

The **report_power_domain** command reports detailed information about existing power domains. If you specify the power domains, only those power domains are reported; otherwise, all power domains in the current scope are reported.

The command fails if it does not find the specified power domain.

The following information is reported for each power domain:

- The hierarchical name relative to the current scope
- The current scope
- The elements of the current scope
- The supply nets available for use (including the supply nets that are domain supply nets, used for isolation or retention strategies, and connected to switches)
- The supply sets available for use (including the supply sets that are domain supply sets, used for isolation or retention strategies, and connected to switches)
- The primary power and ground net
- The default_isolation power and ground net. Default isolation supply is reported if implicit supply handles are enabled. If suppress_iss design attribute is set on a power domain, default isolation supply will not be reported for that power domain.
- The default_retention power and ground net. Default retention supply is reported if implicit supply handles are enabled. If suppress_iss design attribute is set on a power domain, default retention supply will not be reported for that power domain.
- The isolation strategies and the isolation power and ground nets. Isolation power and ground nets are reported same as specified through **-isolation_supply_set**, **-isolation_power_net** and **-isolation_ground_net** options. If none of **-isolation_supply_set**, **-isolation_power_net** and **-isolation_ground_net** options are specified, and isolation **-location** is specified as self, domain's default_isolation.power is reported as isolation power net and domain's default_isolation.ground is reported as isolation ground net. If the isolation power net is specified but the isolation ground net is not specified then domain's primary.ground will be used as the isolation ground. If the isolation ground net is specified but the isolation power net is not specified then domain's primary.power is used as the isolation power. If the isolation **-location** is specified as parent or fanout and no power and ground nets are specified, the command does not report power and ground nets since there might be more than one power and ground nets for a given isolation strategy if parent or fanout falls in different domains for different elements used in the strategy. Instead (#) is reported. Also, in case of **-no_isolation**, no power and ground nets are reported.
- The retention strategies and its retention power and ground nets. Retention power and ground nets are reported same as specified through **-retention_supply_set**, **-retention_power_net** and **-retention_ground_net** options. If none of **-retention_supply_set**, **-retention_power_net** and **-retention_ground_net** options are specified, domain's default_retention.power is reported as retention power net and domain's default_retention.ground is reported as retention ground net.
- The power switches
- The input and output supply nets
- The maximum voltage of each supply net if it has been set by the **set_voltage** command

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports the power domains in the current scope when the supply set handles are OFF:

```
prompt> report_power_domain
```

```

report_power_gating

Reports the power-gating style of retention registers in the design.

SYNTAX

```
status report_power_gating
  [cell_or_design_list]
  [-missing]
  [-unconnected]
```

Data Types

cell_or_design_list list

ARGUMENTS

cell_or_design_list

Specifies a list of cells or designs in which the power-gating styles of cells are reported. The default is the current design.

-missing

Reports the sequential cells that do not have the power-gating style.

-unconnected

Reports only the retention registers that are not stitched.

DESCRIPTION

This command reports the power-gating style of retention registers. The retention registers in the libraries have a cell-level **power_gating_cell** attribute to specify the power-gating styles of the registers. The command only reports the cells having the **power_gating_style** attributes set by the **set_power_gating_style** command. The command requires a Power Compiler license to run.

If **-missing** is specified, the command only reports the sequential cells that do not have the power-gating style.

If **-unconnected** is specified, the command only reports the retention registers whose power gating pins have not yet been stitched.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the power-gating styles of retention registers in *my_design*:

```
prompt>report_power_gating my_design
```

SEE ALSO

[power_enable_power_gating\(3\)](#)

report_power_model

Report information of power models in the design.

SYNTAX

```
status report_power_model  
[-verbose]
```

ARGUMENTS

-verbose

Report detailed information about power models in the design.

DESCRIPTION

This command reports power model information. It includes information about power models created in the define_power_model command and applied in the apply_power_model command.

In verbose mode, it also displays detailed information about the options used in the define_power_model and apply_power_model commands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports all power models found in the design:

```
prompt> report_power_model  
*****  
Report : report_power_model  
Design : top  
*****
```

Column Header:

Elmt - Num of cells in apply_power_model -elements
SMap - Num of mappings in apply_power_model -supply_map
PMap - Num of mappings in apply_power_model -port_map

Cell - Num of cells applied with power model

Power Model	Defined In	Applied In	Elmt	SMap	PMap	Cell
model_1	User Library	macro_0	1	0	0	1
model_2	User Library	top	1	2	2	1
model_2	User Library	top	0	0	0	1

`apply_power_model(2)`

report_power_pin_info

Reports the power pin information for leaf cells in the current design.

SYNTAX

```
status report_power_pin_info
  cell_instances
  [-nosplit]
```

Data Types

cell_instances collection

ARGUMENTS

cell_instances

Specifies the leaf cells for which to report the power pin information.

This is a required argument.

DESCRIPTION

The **report_power_pin_info** command reports the power pin information for leaf cells in the current design.

The command reports the name, types, voltage specification of the power pins, as well as the supply (power and ground) nets that are connected to the power pins.

If a supply connection is marked with an asterisk (*), it is an exception (explicit) connection. Exception supply connections are connections that are established with the **connect_supply_net** command.

If a supply connection is marked with an abbreviation drv (drv), it is a derived always-on (ao) connection for the buffer cell. The connection will be considered as derived if the buffer cell comes on the always-on path but is not an always-on buffer. Hence the connection is not made to its PG pins and **connect_supply_net** command is not seen in the UPF file written out by the tool. The buffer cells with derived connections are also reported by MV-076 message during **check_mv_design -connection_rules -verbose** command.

Exception supply connections can occur in the following situations:

- Explicit specification with the **connect_supply_net** command
- Power intent specification in the UPF file
- Level-shifter cell insertion during compilation

In any of these cases you can observe the exception connections by using the **write_script** or **save_upf** command. The connections

appear as **connect_supply_net** commands in the generated files.

The best-case and worst-case voltages of the connected power net are reported, along with the name of the power net. If a voltage is not specified on the connected net, a hyphen (-) is printed in the respective voltage fields.

Hierarchical cells are ignored by this command. The tool issues the message "No power pins to report".

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports power pin information for the leaf cell instance named I0:

```
prompt> report_power_pin_info I0
```

```
*****
Report : power_pin_info
Design : top
Version: B-2008.09
Date  : Mon Mar 24 02:04:49 2008
*****
```

Note: Power connections marked by (*) are exceptional

Cell	Power Pin	Type	Best Case Power		Connected Net
			Voltage	Voltage	
Name					
I0	PWR	Primary Power	-	-	-
I0	GND	Primary Ground	-	-	-

1

The following example shows the voltage on the connected power net set:

```
prompt> report_power_pin_info [get_cells * -hier]
```

```
*****
Report : power_pin_info

```

SEE ALSO

[connect_supply_net\(2\)](#)

report_power_switch

Reports all of the specified power switches.

SYNTAX

```
status report_power_switch
  [power_switch_name]
  [-verbose]
```

Data Types

power_switch_name string or list

ARGUMENTS

power_switch_name

Specifies a list of power switch names. The individual names must be hierarchical relative to the current scope. If the switch exists in the current scope, its simple name can be used. If no power switches specified absent, the tool reports all of the power switches in the current scope.

-verbose

Reports details about the specified power switches.

DESCRIPTION

The **report_power_switch** command enables you to get the information of the specified power switches. The power switch information reported includes its relative hierarchical name that also contains the scope in which it is created, the current scope name, the name of the simple power domain of which the switch is a part, its output supply net, and its input supply net.

The command also prints out a verbose report if the **-verbose** option is used. The verbose report contains all of the information specified above along with the ctrl_port names, the ack_port names, and the on and off state names with their respective Boolean functions.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports information about all power switches within the power domain named *PD1* in the current scope:

```
prompt> report_power_switch SWA
```

```
-----  
Power Switch      : SWA  
Current Scope     : mid1  
Switch Power Domain : A  
Input port net    : SNA_2  
Output port net   : SNA_1  
-----
```

```
1
```

The following example reports the information about the same power switches as above, this time using the **-verbose** option to show more detail:

```
prompt> report_power_switch SWA -verbose
```

```
-----  
Power Switch      : SWA  
Current Scope     : mid1  
Switch Power Domain : A  
Input port net    : SNA_2  
Output port net   : SNA_1  
Control Ports     : ctrl  
Acknowledge Ports : ackport1, ackport2  
  
On States          : <on1, ctrl>, <on2, !logic1 & ctrl>,  
                     <on3, !logic1 & !ctrl>, <on4, !logic1 | ctrl>,  
                     <on5, !logic1 | !ctrl>  
Off States         : <off1, outport>, <off2, outport>  
-----
```

```
1
```

SEE ALSO

report_preferred_routing_direction

Reports the preferred routing direction for all routing layers.

SYNTAX

```
string report_preferred_routing_direction
```

ARGUMENTS

The **report_preferred_routing_direction** command has no arguments.

DESCRIPTION

The **report_preferred_routing_direction** command reports the preferred routing direction for all layers from in-memory information.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a preferred routing direction report:

```
prompt> report_preferred_routing_direction
```

```
*****
```

```
Report : Layers
```

```
Design : core_chip
```

```
Version: Y-2006.06
```

```
Date : Thu Mar 23 03:43:06 2006
```

```
*****
```

Layer Name	Library	Design	Tool understands
metal1	Horizontal	Not Set	Horizontal
metal2	Vertical	Not Set	Vertical
metal3	Horizontal	Not Set	Horizontal
metal4	Vertical	Not Set	Vertical
metal5	Horizontal	Vertical	Vertical
metal6	Vertical	Vertical	Vertical

WARNING: Consecutive layers have the same routing direction.

report_preserve_user_attribute

Reports the attribute preservation list.

SYNTAX

status **report_preserve_user_attribute**

ARGUMENTS

The **fReport_preserve_user_attribute** command has no arguments.

DESCRIPTION

This command reports the attribute preservation list previously defined by the command **define_preserve_user_attribute**.

EXAMPLES

The following example uses the **report_preserve_user_attribute** command to report the attribute preservation list:

```
prompt> define_preserve_user_attribute {my_attribute_1 my_attribute_2}
1
prompt> report_preserve_user_attribute
my_attribute_1 my_attribute_2
prompt> define_preserve_user_attribute -reset
1
prompt> report_preserve_user_attribute
prompt>
```

SEE ALSO

[define_user_attribute\(2\)](#)
[define_preserve_user_attribute\(2\)](#)

report_pst

Reports the power states in the current design previously created with the **add_pst_state** command.

SYNTAX

```
status report_pst
  [-supplies supply_list]
  [-pst_state_limit number]
  [-verbose]
  [-scope instance_name]
  [-derived]
  [-voltage_type all | nominal]
  [-reconcile]
```

Data Types

<i>supply_list</i>	list
<i>number</i>	integer
<i>instance_name</i>	string

ARGUMENTS

-supplies *supply_list*

Specifies a list of supply net or port names to be included in the report. The order of the names in this list determines their order in the report. By default, the report includes all power nets in the current design.

-pst_state_limit *number*

Specifies a limit on the number of states reported in the derived power state table, an integer between 1 and 1,000,000. The default is 100,000. The derived power state table is not reported if the number of states is over the limit. The limit applies whenever the derived power state table is reported, including when the **-supplies** option is used, or the current scope is a lower scope and the **-derived** option is not used.

-verbose

Expands the report to explicitly list all the power states. By default, the report is shortened by showing only an asterisk (*) when all states of a net or port are used. For blocks for which `enable_state_propagation_in_add_power_state` is set to false, tool will derive internal state names on functional nets for supply set states added with **add_power_state** command. In verbose mode, these internal names will be cleaned up as far as possible to state names that user has defined.

-scope *instance_name*

Specifies a design instance different from current design. The resulting power state table contains only the supply states derived from all power state tables contained in the specified design instance.

-derived

Reports the power state table at the top level, even if the current scope is a lower-level scope.

-voltage_type all | nominal

Specifies the voltage type to be included in the report. If the value is 'nominal', only the nominal voltage value of supply state(s) will be included. If the value is 'all', all defined voltage values of supply state(s) will be included. By default, voltage values are not included in the report.

-reconcile

Reports models that are marked with upf_reconcile_boundary design attribute and the threshold levels applied on all the supplies in the design using set_variation command. If option **-supplies** is used along with this option, then threshold levels are reported only for the supplies listed in option **-supplies**.

DESCRIPTION

This command reports the power state table of the current design. This table is the result of combining all user-defined power state tables in the current design and its logical hierarchy.

You create power state tables by using the **add_port_state**, **create_pst**, and **add_pst_state** commands.

If no power state table has been explicitly created with the **create_pst** command, the derived power state table is full, meaning that all combinations of power states are allowed. Just after a new power state table is explicitly created, the table is empty; you create new power states and add them to the table by using the **add_pst_state** command.

Note: You can also display the power state table in the Design Vision GUI.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following UPF script creates a power state table, and the **report_pst** command reports the resulting table.

```
## POWER STATE TABLE
add_port_state VDD -state {TOP 1.08}
add_port_state I_ALU/VDDT -state {BLOCK_1 0.7}
add_port_state I_STACK_TOP/I_STACK_TOP_sw/out \
    -state {BLOCK 1.08} -state {BLOCK_off off}
add_port_state I_REG_FILE/I_REG_FILE_sw/out \
    -state {BLOCK 1.08} -state {BLOCK_off off}
add_port_state VSS -state {GND 0.0}
create_pst risc_core_pst \
    -supplies {VDD I_ALU/VDDT I_STACK_TOP/VDDTSI_REG_FILE/VDDTS VSS}
add_pst_state s0 -pst risc_core_pst -state {TOP BLOCK_1 BLOCK BLOCK GND}
add_pst_state s1 -pst risc_core_pst -state {TOP BLOCK_1 BLOCK_off BLOCK GND}
add_pst_state s2 -pst risc_core_pst -state {TOP BLOCK_1 BLOCK BLOCK_off GND}
```

prompt> **report_pst**

...

Scope: RISC_CORE

Supply Names: I_ALU/VDDT, I_ALU/VDD, I_ALU/VSS, I_STACK_TOP/I_STACK_TOP_sw/out, I_REG_FILE/I_REG_FILE_sw/out,

Resulting Power States in this Scope:

```
I_ALU/VDDT|
  I_ALU/VDD|
    I_ALU/VSS|
I_STACK_TOP/I_STACK_TOP_sw/out|
  I_REG_FILE/I_REG_FILE_sw/out|
```

```
drv:      *| *| *| BLOCK| *
drv:      *| *| *| *| BLOCK|
```

User PST Name: risc_core_pst

Defined in Scope: RISC_CORE

Total Power States: 3

```
VDD|
I_ALU/VDDT|
I_STACK_TOP/VDDTS|
I_REG_FILE/VDDTS|
VSS|
s0: TOP| BLOCK_1| BLOCK| BLOCK| GND|
s1: TOP| BLOCK_1| BLOCK_off| BLOCK| GND|
s2: TOP| BLOCK_1| BLOCK| BLOCK_off| GND|
```

The notation "drv:" in the report indicates that the states were derived from the list of possible port states are were not explicitly defined in an **add_port_state** command.

The asterisks in the report indicate where all states of a supply can be used. To expand the asterisks to show the full list of state names, use the **-verbose** option. For example,

```
prompt> report_pst -verbose
...
Scope: RISC_CORE
Supply Names: I_ALU/VDDT, I_ALU/VDD, I_ALU/VSS, I_STACK_TOP/I_STACK_TOP_sw/out,
I_REG_FILE/I_REG_FILE_sw/out,
Resulting Power States in this Scope:
I_ALU/VDDT|
I_ALU/VDD|
I_ALU/VSS|
I_STACK_TOP/I_STACK_TOP_sw/out|
I_REG_FILE/I_REG_FILE_sw/out|
drv: BLOCK_1| TOP| GND| BLOCK| BLOCK|
drv: BLOCK_1| TOP| GND| BLOCK| BLOCK_off|
drv: BLOCK_1| TOP| GND| BLOCK_off| BLOCK|
...

```

prompt> report_pst -reconcile ... Reconciliation skipped blocks: None Reconciliation on blocks: ALU_0

User PST Name: risc_core_pst Defined in Scope: RISC_CORE Total Power States: 3 VDD| I_ALU/VDDT| I_STACK_TOP/VDDTS|
I_REG_FILE/VDDTS| VSS| s0: TOP| BLOCK_1| BLOCK| BLOCK| GND| s1: TOP| BLOCK_1| BLOCK_off| BLOCK| GND| s2: TOP|
BLOCK_1| BLOCK| BLOCK_off| GND|

In the following UPF script, power state table is created by adding power states on supply sets with **add_power_state** command. Since **enable_state_propagation_in_add_power_state** is false, the states added on supply sets and are not propagated to functional nets. Tool derives internal state names on these supply nets. These internal names are cleaned up when possible to the original state names the user has defined on supply sets. If internal names are cleaned up, the "Supply Names" list is also cleaned up to contain supply sets.

```
set_design_attributes -elements {} -attribute enable_state_propagation_in_add_power_state FALSE
## POWER STATE TABLE

set_variation(2)
```

report_qor

Displays QoR information and statistics for the current design.

SYNTAX

```
status report_qor
  [-significant_digits digits]
  [-scenarios scenario_list]
  [-summary]
  [-ignore_infeasible_paths]
  [-virtual_path_group]
```

Data Types

<i>digits</i>	integer
<i>scenario_list</i>	list

ARGUMENTS

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are from 0 through 13. The default is 2 for all sections except the Area section, which has a default of 6. Specifying a valid value for significant digits overwrites the existing default. Using this option overrides the value set by the **report_default_significant_digits** variable.

-scenarios *scenario_list*

Reports the QoR for the specified scenarios of a design containing multiple scenarios. Inactive scenarios are skipped in the report. Each scenario is reported separately.

If you do not specify this option, the command reports the QoR on all active scenarios.

-summary

Reports a QoR summary without reporting details for each timing group. This option is supported only in DC Explorer and Design Compiler topographical mode.

-ignore_infeasible_paths

Ignores all paths flagged as infeasible during the latest compilation.

-virtual_path_group

Report TNS of WNS in four virtual path groups: IN-REG REG-REG REG-OUT, IN-OUT instead of real path groups. To use this option, user needs to set timing_separate_io_group to true and run update_timing again if timer is already updated.

DESCRIPTION

This command reports timing-path group and cell count details, along with current design statistics such as combinational, noncombinational, and total area. The command also reports static power, design rule violations, and compile-time details.

Under the Cell Count section, the Leaf Cell Count report includes all leaf cells that are not constant cells. Constant cells are omitted in this count. The Combinational Cell Count and Sequential Cell Count only include leaf cells.

The design and scenario timing QoR that is reported counts an endpoint only one time when computing the total negative slack and the number of violation endpoints. This behavior is controlled by the **timing_report_union_tns** variable.

Multicorner-Multimode Support

By default, this command uses information from all active scenarios. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example shows a QoR report:

```
prompt> report_qor

report_qtm_model

Reports Quick Timing Model (QTM) data.

SYNTAX

```
string report_qtm_model
  [-global_parameters]
  [-ports]
  [-arcs]
```

ARGUMENTS

-global_parameters

Specifies that global parameters of the current QTM design be reported.

-ports

Specifies that ports of the current QTM design be reported.

-arcs

Specifies that timing arcs of the current QTM design be reported.

DESCRIPTION

The **report_qtm_model** command prints a report of the active QTM model. The information details the global parameters, ports, and arcs of the QTM model. By default, the command prints out the report of global parameters, ports, and arcs of the model.

If you want to see the global parameters in the QTM model, use the **-global_parameters** option.

If you want to see only the ports in the QTM model, use the **-ports** option.

If you want to see the arcs in the QTM model, use the **-arcs** option.

For a basic description of QTM, see the **create_qtm_model** manual page. For a more detailed description of QTM, see the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command reports all the attributes of the currently active QTM model.

```
prompt> report_qtm_model
*****
Report : qtm_model
Design : test_lib
*****

create_qtm_model test_lib
set_qtm_technology -library slow -max_transition 1.0
set_qtm_global_parameter -param clk_to_output -value 1.0
set_qtm_global_parameter -param setup -value 0.5
set_qtm_global_parameter -param hold -value 0.0
create_qtm_path_type -lib_cell AN210 -input_pin A -output_pin Y -fanout 2 path1

create_qtm_load_type -lib_cell AN210 -input_pin A load1
report_qtm_model
```

SEE ALSO

`create_qtm_model(2)`
`save_qtm_model(2)`

report_reference

Displays information about references in the current instance or in the current design.

SYNTAX

```
status report_reference
  [-nosplit]
  [-hierarchy]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-hierarchy

Displays information about references across the hierarchy in the current instance or the current design.

DESCRIPTION

This command displays information about all references in the current instance or the current design. If the current instance has been set, the report is generated for the design of that instance. Otherwise the report is generated for the current design.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following is an example of a reference report:

```
prompt> report_reference
*****
Report : reference
Design : CONTROL

SEE ALSO

[report_cell\(2\)](#)
[report_design\(2\)](#)

report_resources

Lists the resources and datapath blocks used in the design of the current instance, in the current design, or in a specific design or list of designs.

SYNTAX

```
status report_resources
  [-nosplit]
  [-hierarchy]
  [-context]
  [-minpower]
  [-html_file_name filename]
  [design_list]
```

Data Types

<i>filename</i>	string
<i>design_list</i>	string

ARGUMENTS

-nosplit

Prevents line splitting. Most design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-hierarchy

Reports information about all resources used in the hierarchy of the current design or the current instance. By default, the tool reports only the resources used in the top level of the current design or the current instance. The **-hierarchy** option is ignored if you specify a list of designs with the *design_list* argument.

-context

Reports context information in the DesignWare generator. Currently, the power context information is printed out.

-minpower

Reports only DesignWare cells that are optimized for the minpower flow.

-html_file_name *filename*

Redirects the report to a file in HTML format.

design_list

Reports resources for a specific design or list of designs. You cannot specify the *design_list* argument and the **-hierarchy** option together. In this case, the **-hierarchy** option is ignored, Design Compiler issues a warning message, and it reports only the first level of hierarchy for the specified design or designs.

DESCRIPTION

This command lists the resources and datapath blocks used in the design of the current instance, in the current design, or in a specific design or list of designs. If the current instance is set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design. To specify a specific design or a list of designs, use the *design_list* argument.

A resource is an arithmetic or comparison operator read in as part of an HDL design. Resources can be shared when compiling the design and are reported after the compile operation completes.

A datapath block contains one or more resources that are grouped together and optimized by a datapath generator.

The datapath block could be split due to different reasons. e.g. a long datapath chain could be split due to datapath depth control. If this happens, the `report_resources` will print information about the the datapath been split.

This report also has information on the parameters used to build the module, user-declared resources in each module, shared operations, and resources that are transformed into datapath blocks.

A detailed report is printed in the DC Ultra flow. The report displays the following information about the datapath blocks in the design:

- Design name
- Source file location
- Input and output connections for each datapath operand and bit width
- Operation name with source line number
- Datapath operation or expression

EXAMPLES

The following example displays resource information for the current design:

```
prompt> report_resources

```

The following example shows the datapath extraction report for the design named *mult_add*. As shown in the example, the Datapath Report has two tables for each datapath block. The first table shows the datapath block along with the contained operations. The second table shows datapath expressions for the block along with the type (Primary Input, Primary Output, or Internal FanOut), signage, and bit width of each variable in the expression.

report_retention_cell

Displays information about retention cells in the current scope.

SYNTAX

```
status report_retention_cell
  [retention_cells]
  [-domain power_domains]
  [-retention_strategy retention_strategy_names]
  [-clamps]
  [-verbose]
```

Data Types

<i>retention_cells</i>	list
<i>power_domains</i>	list
<i>retention_strategy_names</i>	string

ARGUMENTS

retention_cells

Specifies the retention cells that are to be reported. If the specified cells do not exist in the current scope, the command fails. By default, all retention cells in the current scope are reported when no other options are specified.

-domain *power_domains*

Specifies the power domains to report all retention cells in the design belonging to the power domains. If the specified power domains do not exist in the current scope, the command fails.

-retention_strategy *retention_strategy_names*

Specifies the names of the retention strategies to report all retention cells in the design that belong to the given retention strategies. When specifying the retention strategy, you must also specify a single power domain with the **-domain** option. If the specified retention strategy is not a part of the specified power domain, the command fails.

-clamps

Report clamp cells associated to zero-pin retention cells

-verbose

Reports retention strategy details in addition to information about the retention cells.

DESCRIPTION

The **report_retention_cell** command provides detailed information of all retention cells in the current scope. If the **-domain** option is specified, the tool reports on all retention cells in the specified domains. If the **-retention_strategy** option is specified, the tool reports on all retention cells under the specified strategy for the given power domain.

The report shows the instance name of the retention cell, the library reference name of the retention cell, and the retention strategy. If the **-verbose** option is specified, the report also shows the details of the retention strategy, which include the name of the retention strategy, the names of the save and restore signals, the save sense and restore sense values, and the names of the power and ground nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the information about all of the retention cells in the current scope:

```
prompt> report_retention_cell
```

Power Domain : PD1

Ret. Cell	Ret. Lib. Cell	Strategy
q2_reg	RTCLDFFPQ_F1_SNPM	retention_1
q1_reg	RTCLDFFPQ_F1_SNPM	retention_1

1

The following example reports detailed information about all of the retention cells in the current scope:

```
prompt> report_retention_cell -verbose
```

Power Domain : PD1

Ret. Cell	Ret. Lib. Cell	Strategy
regout_reg[0]	RTCLDFFPQ_F1_SNPM	retention_strategy_1
regout_reg[1]	RTCLDFFPQ_F1_SNPM	retention_strategy_1
regout_reg[2]	RTCLDFFPQ_F1_SNPM	retention_strategy_1
regout_reg[3]	RTCLDFFPQ_F1_SNPM	retention_strategy_1

Strategy	Save	Save	Restore	Restore	Power	Ground
	Signal	Sense	Signal	Sense	Net	Net
retention_strategy_1	SAVE1	High	RESTORE1	High	SN1	-

report_retention_clamp_cell

Displays information about zero-pin retention clamp cells in the current scope.

SYNTAX

```
status report_retention_clamp_cell
  [retention_clamp_cells]
  [-domain power_domains]
  [-retention_strategy retention_strategy_names]
  [-verbose]
```

Data Types

<i>retention_clamp_cells</i>	list
<i>power_domains</i>	list
<i>retention_strategy_names</i>	string

ARGUMENTS

-domain *power_domains*

Specifies the power domains to report all retention clamp cells in the design belonging to the power domains. If the specified power domains do not exist in the current scope, the command fails.

-retention_strategy *retention_strategy_names*

Specifies the names of the retention strategies to report all retention clamp cells in the design that belong to the given retention strategies. When specifying the retention strategy, you must also specify a single power domain with the **-domain** option. If the specified retention strategy is not a part of the specified power domain, the command fails.

-verbose

Reports mapping constraint details in addition to information about the retention clamp cells.

DESCRIPTION

The **report_retention_clamp_cell** command provides detailed information of all retention clamp cells in the current scope. If the **-domain** option is specified, the tool reports all retention clamp cells in the specified domains. If the **-retention_strategy** option is specified, the tool reports all retention clamp cells under the specified strategy for the given power domain.

The report shows the instance name of the retention clamp cell, the zero-pin retention registers the clamp cell is associated with, the power and ground nets and also the retention strategy. If the **-verbose** option is specified, the report also shows condition clamp pins should satisfy while in retention mode and the library reference name of the retention clamp cell. The report also shows the details of accepted mapping constraints in verbose mode.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the information about all of the retention clamp cells in the current scope:

```
prompt> report_retention_clamp_cell
```

Power Domain : PD_P1

Clamp Cell	Ret. Cell	Power Net	Ground Net	Strategy	
mid/ret_clamp_top_zprf_ret_CK	mid/freg2/regout_reg[1]	ss_p1.power (0.80)	ss_p1.ground (0.00)	top_zprf_ret	
	mid/freg2/regout_reg[2]				
	mid/freg2/regout_reg[3]				
	mid/freg2/regout_reg[0]				

1

The following example reports detailed information about all of the retention clamp cells in the current scope and also verbose information:

```
prompt> report_retention_clamp_cell -verbose
```

Power Domain : PD_P1

Clamp Cell	Ret. Cell	Lib. Cell	Clamp Val.	Power Net	Ground Net	Strategy
mid/ret_clamp_top_zprf_ret_CK	mid/freg2/regout_reg[1]	HDBSVT16_NR2B_1	!ICK	ss_p1.power (0.80)		
	mid/freg2/regout_reg[2]					
	mid/freg2/regout_reg[3]					
	mid/freg2/regout_reg[0]					

Mapping Constraint:

Strategy	lib cell (UPF GENERIC_CLOCK)	lib cell (UPF GENERIC_ASYNC_LOAD)
top_zprf_ret	HDBSVT16_NR2B_3, HDBSVT16_NR2B_1	-

report_route_zrt_common_options

Reports the settings of route options that are common among the Zroute router commands.

SYNTAX

status **report_route_zrt_common_options**

ARGUMENTS

The **report_route_zrt_common_options** command has no arguments.

DESCRIPTION

This command reports the settings of router options that have been set by the **set_route_zrt_common_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command reports the settings of the common route options.

```
prompt> report_route_zrt_common_options
```

SEE ALSO

[set_route_zrt_common_options\(2\)](#)
[get_route_zrt_common_options\(2\)](#)

report_route_zrt_global_options

Reports the settings of the global router options.

SYNTAX

status **report_route_zrt_global_options**

ARGUMENTS

The **report_route_zrt_global_options** command has no arguments.

DESCRIPTION

This command reports the settings of the global router options that have been set by the **set_route_zrt_global_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the global router settings.

```
prompt> report_route_zrt_global_options
```

SEE ALSO

[get_route_zrt_global_options\(2\)](#)
[set_route_zrt_global_options\(2\)](#)

report_routing_rules

Reports on design-specific nondefault routing rules defined by the **define_routing_rule** command.

SYNTAX

```
status report_routing_rules  
  [rule_name]  
  [-output file_name]
```

Data Types

rule_name string
file_name string

ARGUMENTS

rule_name

Specifies the name of the design-specific nondefault routing rule to report on. By default, the tool reports all design-specific nondefault routing rules.

-output *file_name*

Generates a Tcl script that contains the **define_routing_rule** commands that define the specified nondefault routing rules.

DESCRIPTION

This command reports on design-specific nondefault routing rules defined by the **define_routing_rule** command. It does not report rules defined in the physical library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports on the design-specific nondefault rule named WideMetal.

```
prompt> report_routing_rules WideMetal
```

SEE ALSO

`define_routing_rule(2)`
`set_net_routing_rule(2)`

report_rp_group_options

Reports relative placement group attributes on the specified relative placement groups.

SYNTAX

```
status report_rp_group_options  
    rp_groups
```

Data Types

rp_groups collection or list

ARGUMENTS

rp_groups

Specifies the relative placement groups for which you want to report the attributes. If relative placement groups are not specified, the attributes for all relative placement groups will be reported.

DESCRIPTION

The **report_rp_group_options** command reports the attributes of the specified relative placement groups. The attributes were set by using either the **create_rp_group** or the **set_rp_group_options** command.

This command is supported only for designs that do not contain multiply-instantiated designs.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **report_rp_group_options** to report the attributes for a relative placement group:

```
prompt> report_rp_group_options {example3::top_group example3::block2}
```

```
*****
```

Report : The RP group options.

Design : example3

Version: Y-2006.06

Date : Fri Jun 9 00:58:54 2006

```
*****
RP group: example3::top_group
utilization    : 1.000000
ignore        : FALSE
x_offset      : 0
y_offset      : 0
cts_option    : fixed_placement
RP group: example3::top_group
utilization    : 1.000000
ignore        : FALSE
1
```

SEE ALSO

[create_rp_group\(2\)](#)
[set_rp_group_options\(2\)](#)

report_safety_core_groups

Reports safety core groups of the current design.

SYNTAX

```
status report_safety_core_groups
  [group_names]
  [-all]
```

Data Types

group_names list

ARGUMENTS

group_names

Specifies the group names which need to be reported

DESCRIPTION

Prints a report of the specified safety core groups. If nothing is specified, it reports all the groups in the current design.

SEE ALSO

[create_safety_core_group\(2\)](#)
[get_safety_core_groups\(2\)](#)

report_safety_core_rules

Reports safety core rules from the current design.

SYNTAX

```
status report_safety_core_rules
  [rule_names]
  [-all]
```

Data Types

rule_names list

ARGUMENTS

rule_names

Specifies the rule names which need to be reported

DESCRIPTION

Prints a report of the specified safety core rules. If nothing is specified, it reports all the rules in the current design.

SEE ALSO

`create_safety_core_rule(2)`
`get_safety_core_rules(2)`

report_safety_error_code_groups

Reports safety error code groups of the design.

SYNTAX

```
status report_safety_error_code_groups  
[group_names]
```

Data Types

group_names collection

ARGUMENTS

group_names

Specifies the group names, which need to be reported

DESCRIPTION

Prints a report of the specified safety error code groups If nothing is specified, it reports all the safety error code groups in the design.

EXAMPLES

The following example report the specified safety_error_code_group

```
prompt> report_safety_error_code_groups group1
```

SEE ALSO

`create_safety_error_code_group(2)`
`get_safety_error_code_groups(2)`

report_safety_error_code_rules

Reports safety error code rules from the design.

SYNTAX

```
status report_safety_error_code_rules
  [rule_names]
  [-all]
```

Data Types

rule_names string

ARGUMENTS

rule_names

Specifies the rule names, which need to be reported.

DESCRIPTION

Prints a report of the specified safety error code rules. If nothing is specified, it reports all the safety error code rules in the current design.

EXAMPLES

The following example report the specified safety_error_code_rules then reports them.

```
prompt> report_safety_error_code_rules rule1*
```

SEE ALSO

`create_safety_error_code_rule(2)`
`get_safety_error_code_rules(2)`

report_safety_logic_port_map

report the port map on safety logic module.

SYNTAX

status **report_safety_logic_port_map**
-module *module* to report the port map on

Data Types

module string

ARGUMENTS

-module *module* to report the port map on

Specifies the modules that the port map is set on. If this is not specified, the command will report the port map for all modules with the map set.

EXAMPLES

The following example report port map on the specified modules

prompt> **set_safety_logic_port_map -module {VOTE2}**

SEE ALSO

`set_safety_register_rule(2)`
`set_safety_logic_port_map(2)`

report_safety_register_groups

Reports safety register groups of the current design.

SYNTAX

```
status report_safety_register_groups
  [group_names]
  [-all]
```

Data Types

group_names list

ARGUMENTS

group_names

Specifies the group names which need to be reported

DESCRIPTION

Prints a report of the specified safety register group. If nothing is specified, it reports all the groups in the current design.

EXAMPLES

The following example reports the specified safety_register_group.

```
prompt> report_safety_register_groups group1
```

SEE ALSO

`create_safety_register_group(2)`
`get_safety_register_groups(2)`
`write_safety_register_data(2)`

report_safety_register_rules

Reports safety register rules from the current design.

SYNTAX

```
status report_safety_register_rules
  [rule_names]
  [-all]
```

Data Types

rule_names list

ARGUMENTS

rule_names

Specifies the rule names which need to be reported

DESCRIPTION

Prints a report of the specified safety register rules. If nothing is specified, it reports all the rules in the current design.

EXAMPLES

The following example reports the specified safety_register_rule.

```
prompt> report_safety_register_rules rule1
```

SEE ALSO

`create_safety_register_rule(2)`
`get_safety_register_rules(2)`
`write_safety_register_data(2)`

report_safety_status

Perform and report checks related to safety_register_rules, safety_register_groups, fsm_register_rules and fsm_register_groups.

SYNTAX

```
string report_safety_status
  [-header string]
  [-safety_register_rules safety_register_rules]
  [-safety_register_groups safety_register_groups]
  [-failsafe_fsm_rules failsafe_fsm_rules]
  [-failsafe_fsm_groups failsafe_fsm_groups]
  [-safety_error_code_groups group_name_list]
  [-safety_error_code_rules rule_name_list]
  [-repelling_group_bounds]
```

Data Types

string	string
safety_register_rules	list
safety_register_groups	list
failsafe_fsm_rules	list
failsafe_fsm_groups	list

ARGUMENTS

-header *string*

Provide a custom header for the printed report.

-safety_register_rules *safety_register_rules*

Report given safety_register_rules. This option restricts the checks and reporting to the provided rules.

-safety_register_groups *safety_register_groups*

Report given safety_register_groups. This option restricts the checks and reporting to the provided groups.

-failsafe_fsm_rules *failsafe_fsm_rules*

Report given failsafe_fsm_rules. This option restricts the checks and reporting to the provided fsm rules.

-failsafe_fsm_groups *failsafe_fsm_groups*

Report given failsafe_fsm_groups. This option restricts the checks and reporting to the provided fsm groups.

DESCRIPTION

The command **report_safety_status** can be run throughout the Synopsys Automotive Flow and performs checks related to safety rules and groups defined in the top level design. It reports the number of safety register rules, groups, and redundancy registers in the design, as well as errors found during consistency checks performed on the safety register rules and groups in the design. Also, it can be run to perform checks related to failsafe_fsm_rules and groups. The following is a brief description of the various counts published in the report.

Safety register rules: Reports the number of safety register rules in the design. Safety register groups: Reports the number of safety register groups in the design. Safety critical registers: Reports the number of safety registers in the design which have a DMR/TMR safety register rule associated with them and require dual/triple modular redundancy. Safety critical register with spfm loss: Reports the number of safety registers in the design with SPFM loss attribute. Fault tolerant registers: Reports the number of safety registers in the design which have a fault tolerant safety register rule associated with them and need mapping to fault-tolerant library cells. Tree split buffers: Reports the number of tree split buffers. Tap cells: Reports the number of tap cells. Voting cells: Reports the total number of voting logic cells inserted in the design. Redundancy registers: Reports the total number of redundancy registers in the design. Failsafe FSM rules: Reports the number of Failsafe FSM rules in the design. Failsafe FSM groups: Reports the number of Failsafe FSM groups in the design. Parity_regs : Reports the number of parity regs for a particular group.

EXAMPLES

The following is an example of the textual report generated by **report_safety_status**:

```
prompt> report_safety_status
```

```
----- Safety status report -----
Design : top
-----
```

```
safety register rules: 2
safety register groups: 2
safety critical registers: 0
safety critical register with spfm loss: 0
fault tolerant registers: 0
tree split buffers: 0
tap cells: 0
voting cells: 0
redundancy registers : 6
```

```
----- Messages -----
```

SEE ALSO

report_saif

Reports the statistics of switching activity annotation, on the current design or instance.

SYNTAX

```
status report_saif
  [-only cell_or_net_list]
  [-hierarchy]
  [-missing]
  [-annotated_flag]
  [-rtl_saif]
```

Data Types

cell_or_net_list list

ARGUMENTS

-only *cell_or_net_list*

Specifies that switching activity annotation is to be reported only for the specified object list.

-hierarchy

Specifies that the command reports the switching activity on the entire design hierarchy, starting with the current instance. If the **-hierarchy** option is not used, switching activity is reported only on the design objects in the current hierarchy of the current instance.

-missing

Specifies that the report should list the design elements that do not have user specified switching activity annotation. This report does not include constant value nets (logic 1 or logic 0 nets), and pins and ports connected to such nets. These types of nets, pins, and ports are annotated with the default switching activity if they are not user-annotated.

-annotated_flag

Specifies that design elements that have user-annotated switching activity should be reported.

-rtl_saif

Specifies that switching activity annotations should be reported for objects annotated by an RTL backward SAIF file.

DESCRIPTION

The **report_saif** command reports the switching activity annotation on the nets, ports, and cells in the current design or instance.

The **report_saif** command can be used to display switching activity annotation of synthesis invariant objects by using the **-rtl_saif** flag. The percentage of user annotation of sequential cells could decrease after compile due to the registers generated from DesignWare. If this option is not used, then **report_saif** command displays information on the design ports, nets, and pins of non-hierarchical cells.

The **report_saif** command reports the percentage of objects with

switching activity that is user-annotated, default-annotated, and propagated. Switching activity can be annotated by the user by using the **set_switching_activity**, **read_saif**, and **merge_saif** commands.

During power calculations, the tool estimates the switching activity of objects that are not user-annotated by propagating the user or default annotated switching activity. Switching activity is annotated with default values on objects whose switching activity can be derived accurately, such as clocks and nets driven by constants, or on objects that cannot be annotated using the propagation mechanism, such as the primary inputs of the design and outputs of black-box cells. Switching activity is annotated by default and propagated automatically by the **report_power** command.

Propagated switching activity is less accurate than switching activity obtained by simulation. So the percentage values in the user-annotated column of the report generated by **report_saif** are an indication of the accuracy of the power reports.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following examples report switching activity for the current design.

In the following example, the **report_saif** command is used after the **read_saif** command, on a gate-level design. Because the **-missing** option is used, the report shows the nonannotated ports, nets, and pins.

```
prompt> report_saif -hierarchy -missing
```

```
*****
Report : saif
      -hierarchy
      -missing
Design : addr_con

report_scaling_lib_group

Generates a report of scaling library groups previously created by the **define_scaling_lib_group** command.

SYNTAX

```
status report_scaling_lib_group
  [-all]
  [-nosplit]
  [-show_list show_list]
  [-object_list object_list]
```

Data Types

<i>show_list</i>	list
<i>object_list</i>	list

ARGUMENTS

-all

Reports a list of all scaling library groups defined with the **define_scaling_lib_group** command, including any that are not currently being used. By default, the command reports only the scaling library groups being used in the current design.

-nosplit

Specifies not to split lines when column fields overflow.

-show_list *show_list*

Specifies the types of detailed library information to include in the report. The *show_list* can contain any one or more of the following items: **process**, **voltage**, **temperature**, and **extended_name**. The **extended_name** keyword reports the full directory path to the library name. By default, these types of information are not reported.

-object_list *object_list*

Specifies the cells for which to report the scaling library groups. Only the scaling groups that have been set on these objects are reported. By default, the command reports all scaling groups used in the current design.

DESCRIPTION

The **report_scaling_lib_group** command reports the scaling library groups defined by the **define_scaling_lib_group** command and set for usage with the **set_scaling_lib_group** command.

By default, the **report_scaling_lib_group** command reports the scaling groups for the current scenario of the current design. If you use the **-object_list** option, it reports the scaling groups for the specified objects in the current scenario.

The **-all** option reports all the scaling library groups defined by the **define_scaling_lib_group** command, either for the current design or a list of specified objects.

You can view detailed information about the libraries by using the **-show_list** option.

Multicorner-Multimode Support

This command applies to the current scenario only by default; when **-all** option is specified, this command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the scaling relationships that exist in the design.

```
prompt> report_scaling_lib_group
...
Group Library
-----
GRP_7
  RC03BTH3_max
  RC03BTH3_max
GRP_8
  RC03BTH3_max
  RC03BTH3_max
-----
1
```

The following example uses the **-show_list** option to show more detailed library information.

```
prompt> report_scaling_lib_group -show_list {voltage temperature process}
...
Group Library      Temperature   Voltage      Process
-----
GRP_10
  RC03BTH3_max  -40.000000  0.800000  1.000000
  RC03BTH3_max  125.000000  1.050000  1.000000
-----
1
```

SEE ALSO

```
define_scaling_lib_group(2)
remove_scaling_lib_group(2)
report_lib(2)
set_scaling_lib_group(2)
```

report_scan_chain

Reports the SCANDEF scan chains defined on the current design.

SYNTAX

status **report_scan_chain**

ARGUMENTS

The **report_scan_chain** command has no arguments.

DESCRIPTION

This command reports all scan chain information. The chains are defined on the current open CEL.

Using SCANDEF data, the report displays each chain's start and stop ports or pins, partition label, validation status, and all scan chain components. The scan chain components are shown in the order in which they appear in the chain of the netlist, from the start point to the stop point.

The status can be NOT YET VALIDATED, VALIDATED/V or FAILED/F.

- NOT YET VALIDATED indicates that the **check_scan_chain** command has not been run to determine the status.
- VALIDATED indicates that the SCANDEF data in the report is consistent with the netlist.
- FAILED indicates an inconsistency between the SCANDEF data and the netlist.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a scan chain report:

```
prompt> report_scan_chain
```

```
*****
```

```

SEE ALSO

report_scan_compression_configuration

Displays options specified by the **set_scan_compression_configuration** command.

SYNTAX

```
status report_scan_compression_configuration  
[-test_mode mode_name_list]
```

Data Types

mode_name_list string

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to report. If not specified, the tool reports on the current test mode, as displayed by the **current_test_mode** command. If no test modes were created, the tool reports on the default compression mode. If **all** is specified, the tool displays the configurations of all test modes.

DESCRIPTION

This command displays options specified by the **set_scan_compression_configuration** command on the current design.

The command reports the following information:

- Minimum compression
- Type of integration (if any)
- Level of X-tolerance
- Static X-chain creation
- Compression chain synchronization
- Diagnosis accuracy

- Number of decompressor inputs
- Number of compressor outputs
- Compression mode chain count
- Maximum chain length

EXAMPLES

The following is an example of a scan compression configuration report:

```
prompt> report_scan_compression_configuration
```

```
*****
Report : Scan Compression Configuration
Design : des_unit
Version: I-2013.12
Date  : Mon Oct 21 09:19:47 2013

report_scan_configuration

Displays options specified by the **set_scan_configuration** command.

SYNTAX

```
status report_scan_configuration  
[-test_mode mode_name_list]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to report. If not specified, the tool reports the scan configuration of the current test mode, as displayed by the **current_test_mode** command. If no test modes were created, the tool reports the scan configuration for the default test mode. If **all** is specified, the tool displays scan configuration information for all test modes.

DESCRIPTION

This command displays the options specified by the **set_scan_configuration** command on the current design. For more information on what is reported, see the EXAMPLES section.

EXAMPLES

The following is an example of a scan configuration report for the default test mode in a flow where no user-defined test modes are defined:

```

report_scan_group

Reports all scan groups that were specified using the **set_scan_group** command.

SYNTAX

```
status report_scan_group  
      scan_group_names
```

Data Types

scan_group_names string

ARGUMENTS

scan_group_names

Specifies the names of scan groups that you want to report. The scan groups must be previously defined using the **set_scan_group** command.

DESCRIPTION

This command reports all scan groups that were specified using the **set_scan_group** command. If no names are specified, all previously-defined scan groups are reported.

If you specify the name of a scan group to report, **report_scan_group** also reports the names of the elements within that group.

If the name you specify has not been previously defined as a scan group, the command issues a warning and exits.

EXAMPLES

The following example show how to use the **report_scan_group** command:

```
prompt> report_scan_group group1  
prompt> report_scan_group all  
prompt> report_scan_group
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`remove_scan_group(2)`
`set_scan_group(2)`

report_scan_link

Reports the scan links specified with the **set_scan_link** command.

SYNTAX

```
status report_scan_link
  -test_mode mode_name
  [link_type]
```

Data Types

mode_name string

ARGUMENTS

-test_mode *mode_name*

Specifies the name of the mode for which the specifications are reported. The default is current mode.

DESCRIPTION

The **report_scan_link** command reports scan links specified with the **set_scan_link** command. Use the **-test_mode** option to report the scan links specified in a given mode. If the **-test_mode** option is not specified, the scan links in the current mode are reported.

Scan links connect scan cells, scan segments, and scan ports within scan chains. The tool supports scan links that are implemented as wires and scan-out lock-up latches.

Use the **report_scan_link** command to view the specified scan links.

To review your scan link specifications, use the **preview_dft** command with the **-show** option set to **cells**. To create scan links and add them to the current design, use the **insert_dft** command.

EXAMPLES

The following example declares a scan-out lock-up latch named *a_lckup* and then removes it with the **remove_scan_link** command:

```
prompt> current_design WC66
prompt> set_scan_link a_lckup Lockup
prompt> report_scan_link
```

```

report_scan_path

Displays scan paths and scan cells specified by the **set_scan_path** command and displays scan paths inserted by the **insert_dft** command.

SYNTAX

```
status report_scan_path
  [-view spec | existing_dft]
  [-chain chain_name | all]
  [-cell cell_name | all]
  [-test_mode mode_name_list | all]
```

Data Types

<i>chain_name</i>	string
<i>mode_name_list</i>	list

ARGUMENTS

-view spec | existing_dft

Specifies the type of scan information to report. Valid options are **spec** and **existing_dft**. Specifying the **spec** value shows only user-defined scan path information previously specified with the **set_scan_path** command. Specifying the **existing_dft** value shows only scan paths already inserted by the **insert_dft** command. The default behavior is to show both views.

-chain *chain_name* | all

When specified, reports only the summary scan chain information for the specified scan chains, or for all scan chains if **all** is specified. By default, both summary **-chain** and detailed **-cell** reports are generated.

-cell *chain_name* | all

When specified, reports only the detailed scan cell ordering information for the specified scan chains, or for all scan chains if **all** is specified. By default, both summary **-chain** and detailed **-cell** reports are generated.

-test_mode *mode_name_list* | all

Reports only on the specified test mode(s), or on all test modes if **all** is specified. By default, the tool reports on the current test mode. If no test modes were created, the default is to report on the Internal_scan mode.

DESCRIPTION

This command displays user-specified scan paths specified by the **set_scan_path** command, as well as the actual scan paths inserted by the **insert_dft** command.

The report contains three different section types.

- **VIEW:** Specification

This section contains user-specified scan path information specified with the **set_scan_path** command. This report can contain information on scan path segments, or scan-in, scan-out, and scan-enable signals along with any hookup pin information.

- **VIEW:** Existing DFT (-chain)

This section contains summary information about scan paths that currently exist in the design. The summary contains scan-in, scan-out, scan-enable, scan-clock, scan chain name, and scan chain length information in table form, but does not print the ordered scan cell names for each scan chain.

- **VIEW:** Existing DFT (-cell)

This section contains detailed information about the scan cell ordering of the scan paths that currently exist in the design.

By default, both the summary **-chain** and detailed **-cell** reports are generated. To restrict the report to only summary information, use the corresponding option. For example, to see only summary information for all scan chains, use the **-chain all** option.

EXAMPLES

The following is an example of **report_scan_path** in the first format reporting on scan paths in the **spec** view. In this report, the *mychain1* scan path has SI (scan-in), Q (scan-out), and two scan enables SE1 and SE2, which are both hooked up to pin u5/A.

```
prompt> report_scan_path -view spec -chain mychain1 -test_mode mymodeA
```

```
*****

                           SE2 (u5/A)
```

The following is an example of **report_scan_path** in the second format reporting scan paths in the **existing_dft** view. In this report, the *mychain1* scan path is defined in the *mymodeA* test mode, and *mychain2* is defined in the *mymodeB* test mode. The *mychain2* scan chain has SI2 (scan-in), SO (scan-out), and SE2 & SE3 (scan-enable). Clocks MCLK1, MCLK2, and MCLK3 are master clocks for this scan chain, and SCLK is a slave clock.

[current_design\(2\)](#)
[insert_dft\(2\)](#)

set_scan_register_type(2)

report_scan_replacement

Displays the scan-replacement table specified by the **set_scan_replacement** command.

SYNTAX

status **report_scan_replacement**

ARGUMENTS

The **report_scan_replacement** command has no arguments.

DESCRIPTION

This command produces a report showing the complete scan-replacement table specified using the **set_scan_replacement** command. The entries in this table are used by the **compile -scan**, **compile_ultra -scan**, and **insert_dft** commands to find scan equivalents for each instance of a non-scan flip-flop in the table.

To remove this table or entries in this table, use the **remove_scan_replacement** command.

EXAMPLES

The following is an example of the **report_scan_replacement** command:

```
prompt> report_scan_replacement
*****
Report : test
         -replacements
Design : level1
Version: A-2007.12
Date   : Thu Dec 28 18:18:38 2007

report_scan_skew_group

Reports scan skew groups defined by the **set_scan_skew_group** command.

SYNTAX

```
status report_scan_skew_group  
[scan_skew_group_list]
```

Data Types

scan_skew_group_list list

ARGUMENTS

scan_skew_group_list

When you specify a list of one or more scan skew group names, the command prints a detailed list of the elements in the specified scan skew groups. Wildcards are not supported.

By default, the command reports a summary of all scan skew groups defined, but does not include the individual elements in each scan skew group.

DESCRIPTION

This command displays the user-specified scan skew groups defined by the **set_scan_skew_group** command.

EXAMPLES

To report a summary of the scan skew groups defined, issue the command with no arguments:

```
prompt> report_scan_skew_group
```

```
*****  
Report : Scan Skew Group

report_scan_state

Displays the scan state of the current design.

SYNTAX

status **report_scan_state**

ARGUMENTS

The **report_scan_state** command has no arguments.

DESCRIPTION

This command reports the current scan status description for the current design. The state of the design is either unknown, test_ready, or scan_existing.

EXAMPLES

The following example reports the scan state of the current design:

```
prompt> report_scan_state
*****
Report : test
         -state
Design : top
Version: V-2004.06-DFT
Date   : Thu Mar 25 17:42:10 2004

[insert_dft\(2\)](#)

set_scan_state(2)

report_scan_suppress_toggling

Reports on the user specifications that were provided through the **set_scan_suppress_toggling** command in terms of the list of scan flip-flops to be gated by the **insert_dft** command.

SYNTAX

```
status report_scan_suppress_toggling
```

ARGUMENTS

The **report_scan_suppress_toggling** command has no arguments.

DESCRIPTION

The **report_scan_suppress_toggling** command reports on all of the existing specifications you provide through the **set_scan_suppress_toggling** command.

EXAMPLES

The following example shows how to issue the command:

```
prompt> report_scan_suppress_toggling
```

SEE ALSO

insert_dft(2)
remove_scan_suppress_toggling(2)
set_scan_suppress_toggling(2)

report_scenario_options

Reports the scenario options set by the **set_scenario_options** command.

SYNTAX

```
status report_scenario_options  
[-scenarios scenario_list]
```

ARGUMENTS

-scenarios *scenario_list*

Specifies a list of scenarios, active or inactive, to be reported. By default, the command reports scenario options for the current scenario.

DESCRIPTION

This command reports the values of scenario options set using the **set_scenario_options** command, for the current scenario or the scenarios listed using the **-scenarios** option. This command can report scenario options for inactive scenarios as well.

EXAMPLES

The following example uses **report_scenario_options** command to check the settings for the current scenario:

```
prompt> create_scenario MODE1  
Warning: Discarding all scenario specific information previously defined in  
this session. (UID-1008)  
Current scenario is: MODE1  
1
```

```
prompt> set_scenario_options -setup false  
1
```

```
prompt> report_scenarios_options
```

```
*****  
Report : scenario options  
Design : TEST03  
Version: C-2009.06  
Date  : Wed Mar 19 14:57:08 2008  
*****
```

Scenario: MODE1 is active.

```
setup      : false
hold       : true
leakage_power : true
dynamic_power : true
```

report_scenarios

Reports scenario setup information for a multi-scenario design.

SYNTAX

status **report_scenarios**

ARGUMENTS

The **report_scenarios** command has no arguments.

DESCRIPTION

The **report_scenarios** command reports scenario setup information for a multi-scenario design. It reports all defined scenarios, all active scenarios, the current scenario, the clock tree synthesis (CTS) scenario, and the scenario option settings, as well as other scenario-specific information for active scenarios. The scenario-specific information includes the library used for linking the scenario, the design operating condition for the scenario, and the TLUPlus files for the scenario.

The creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example shows sample output of the **report_scenarios** command.

```
prompt> report_scenarios
```

```
*****

report_script_runtime

Reports the run time of the commands issued on the current session.

SYNTAX

status **report_script_runtime**

[**-simple**]
[**-reset**]
[**-legend**]
[**-cpu**]
[**-commands** *command_names*]
[**-sort** *digits*]

ARGUMENTS

-simple

Reports fewer metrics in the report.

-reset

Clears all the metrics.

-legend

Includes a legend for the metrics reported.

-cpu

Displays CPU time instead of Wall Clock time.

-commands *command_names*

Report only on the specified command list.

-sort *digits*

Sort the rows in the report using the specified column as index.

DESCRIPTION

The **report_script_runtime** command reports the wall clock or CPU time used by commands issued on the current session. It also reports on the number of times the command was executed.

SEE ALSO

[mem\(2\)](#)
[cputime\(2\)](#)

report_security_configuration

Reports the security configuration for the current design.

SYNTAX

status **report_security_configuration**

ARGUMENTS

None

DESCRIPTION

This command reports the security configuration with the following values:

Security Configuration	Status
Logic Lock:	<enable disable>
Obfuscation:	<enable disable>
Watermark:	<enable disable>
Security Lock:	<enable disable>
Input Files:	<list_of_files>

`report_security_lock(2)`
`set_security_lock(2)`

report_self_gating

Reports information about Self-Gating performed by Power Compiler. This command is supported only in topographical mode.

SYNTAX

```
status report_self_gating
  [-gated]
  [-ungated]
  [-nosplit]
```

ARGUMENTS

-gated

Reports the self-gating banks, that is, the names of all the self-gating cells of the design, along with the registers gated by each of them.

-ungated

Reports the names of all registers that are not self-gated, along with the reason for that.

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most design information is listed in fixed-width columns. If the information for a field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_self_gating** command reports information about self-gating cells and gated and ungated registers of the current design. To generate the report, **report_self_gating** uses self-gating attributes placed on the self-gating cells by the Power Compiler tool.

Any self-gating cell added by other means (for example, self-gating inferred by or instantiated in the RTL code) lacks these attributes and does not appear in the report.

Traditional clock-gating cells inserted by Power Compiler are also excluded from this report. Use **report_clock_gating** command to get information about them.

When the command is issued without options, the report lists the number of self-gating cells, the number of gated and ungated registers with percentages of the total, and the total number of registers.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows a report generated when the **report_self_gating** command is issued with no options. The report shows that out of 6 registers, 6 are self-gated and 0 are not. Also the multibit decomposition is shown when there are multibit registers in the design.

```
prompt> report_self_gating
```

```
*****
Report : self_gating
Design : top
Version: ...
Date  : ...
*****
```

Self Gating Summary

Number of self-gating cells	2	
Number of self gated registers	6 (100.00%)	
Number of registers not self-gated	0 (0.00%)	
Total number of registers	6	

Self Gating Multibit Decomposition

	Actual Count	Single-bit Equivalent	
Number of Self Gated Registers			
1-bit	3	3	
4-bit	3	12	
Total	6	15	
Number of Registers not Self-Gated			
1-bit	0	0	
4-bit	0	0	
Total	0	0	
Total Number of Registers			
1-bit	3	3	
4-bit	3	12	
Total	6	15	

The **-ungated** option displays additional information about ungated registers and the reason why they were not self-gated. Also, for some of these reasons there is a "What next" recommendation on how to fix it.

```
prompt> report_self_gating -ungated
prompt> report_self_gating -ungated
```

```
*****
Report : self_gating
    -ungated
Design : bot
Version: ...
Date  : ...

report_separate_process_options

Reports whether the tool uses separate UNIX processes for extraction, placement, and routing.

SYNTAX

```
status report_separate_process_options
```

DESCRIPTION

The **report_separate_process_options** command prints information about whether the tool uses separate UNIX processes for extraction, placement, and routing.

EXAMPLES

The following example shows a sample output of the **report_separate_process_options** command:

```
prompt> report_separate_process_options
```

```
*****
```

```
Report : separate_process_options
```

```
Version: E-2010.12-ICC

report_serialize_configuration

Displays options specified by the **set_serialize_configuration** command or the **reset_serialize_configuration** command.

SYNTAX

```
status report_serialize_configuration
```

ARGUMENTS

The **report_serialize_configuration** command has no arguments.

DESCRIPTION

This command displays options specified by the **set_serialize_configuration** command on the current design.

The command reports the following information:

- Number of deserializer inputs
- Number of deserializer outputs
- List of core instances and deserializer IP inputs
- List of core instances and serializer IP outputs
- Update stage enabled
- List of excluded clocks
- Serializer clock
- Name of the parallel mode

EXAMPLES

The following example shows a serialize configuration report:

```
prompt> report_serialize_configuration
```

```
*****
```

```
Report : Serializer Configuration

report_size_only

Reports size_only cells in the current design along with their size_only types.

SYNTAX

```
status report_size_only
  [-nosplit]
  [-summary]
  [cells]
```

Data Types

cells collection

ARGUMENTS

-nosplit

Prevents line splitting. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-summary

Displays only a summary report without detailed information about each size_only cell instance.

cells

Reports the specified size_only cells.

DESCRIPTION

The **report_size_only** command displays information about the size_only cells in the current design.

If the current instance is set, the report is generated for the design of that instance. Otherwise, the report is generated for the current design. Cells that do not have the **size_only** attribute are ignored.

You can specify a report for a collection of cells also. If you specify the **-summary** option, only the summary report is generated. If you specify both a collection of cells and **-summary**, the command generates a summary report using the cells in the collection without detailed information about each individual size_only cell in the collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following is an example of a size_only report:

```
prompt> report_size_only
```

```
*****
```

```
Report : size_only
```

```
Design : size1
```

```

report_streaming_compression_configuration

Displays options specified by the **set_streaming_compression_configuration** command.

SYNTAX

```
status report_streaming_compression_configuration  
[-test_mode mode_name_list]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to report. If not specified, the tool reports on the *current_test_mode* that can be displayed by the **current_test_mode** command. If no test modes were created, the tool defaults to the default compression mode. If **all** is specified, the tool displays the scan configurations of all streaming compression test modes, including the default test mode (**all_dft**).

DESCRIPTION

This command displays options specified by the **set_streaming_compression_configuration** command on the current design.

The command reports the following information:

- Number of decompressor inputs
 - Number of compressor outputs
 - Compressed scan chain count
 - Maximum scan chain length
 - Base mode
-

EXAMPLES

The following is an example of a streaming compression configuration report:

```
prompt> report_streaming_compression_configuration
```

```
*****
Report : Streaming Compression Configuration
Design : top

report_supply_net

Reports all supply nets in the current scope.

SYNTAX

```
status report_supply_net
  [supply_net_name]
  [-include_exception]
```

Data Types

supply_net_name string or list

ARGUMENTS

supply_net_name

Specifies the supply nets that are to be reported. If the supply net does not exist in the current scope, the command fails. If the option is not specified, all the supply nets in the current scope are reported.

-include_exception

Includes the exception connections of the supply net.

DESCRIPTION

The **report_supply_net** command reports detailed information about the supply nets in the current scope. The report for a supply net includes its full name, the scope in which it was created, its maximum and minimum voltages if set using the **set_voltage** command, its resolve type, the various supply states and the exception pins on the power net if the **-include_exception** option is specified. The names of the power domains to which the supply net belongs are also printed. The name of the power domain is suffixed with an asterisk (*) if the net is set as the domain supply net for that domain.

If the voltage of the supply net is not set, a '- U -' is printed, indicating that the voltage is undefined.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example reports information about the supply nets *SN1* in the current scope:

```
prompt> report_supply_net
```

```
*****
```

```
Report : supply_net
```

```

ARGUMENTS

supply_port_name

Specifies the supply port or list of ports to be reported. If a specified supply port does not exist in the current scope, the command fails. If this argument is not specified, the tool reports on all supply ports in the current scope.

DESCRIPTION

The **report_supply_port** command enables you to get detailed information about supply ports within the current scope. If *supply_port_name* is not specified, the tool reports on all supply ports within the current scope.

The report includes the full name of the supply port, the scope in which it is created, the direction, the supply states, and the supply net to which it is connected.

Supply ports that are present on switches can be printed by specifying the argument with the switch path name, slash (/), and supply port name as follows:

```
report_supply_port switch_full_path_name/supply_port_name
```

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports on all supply ports in the current scope:

```
prompt> report_supply_port
```

```
*****
Report : supply_port
Design : top
Version: A-2007.12-SP1
Date  : Wed Nov 21 03:14:25 2007
*****
```

```
Supply Port    : SP1
Current Scope  : top
Direction      : Input
Supply net     : S_NET_1
Supply state names : active_state off_state
```

1

The following example reports on a supply port on a power switch:

```
prompt> report_supply_port SWA/outport
```

```
*****
Report : supply_port
Design : top
Version: A-2007.12-SP3
Date  : Thu Mar 13 21:50:40 2008
*****
```

```
Supply Port    : SWA/outport
Current Scope  : mid1
Direction      : Output
Supply net     : No supply net connected to this port
Supply state names : No supply states defined for the port
```

1

SEE ALSO

[create_supply_port\(2\)](#)

report_synlib

Displays information about synthetic libraries.

SYNTAX

```
status report_synlib
  library
  [module_list]
```

Data Types

```
library      string
module_list  list
```

ARGUMENTS

library

Specifies the name of the library to be reported. This library must already be read into the tool or specified by the **search_path** variable.

module_list

Specifies a list of modules that are reported. The default is to report information about all modules in the synthetic library.

DESCRIPTION

The **report_synlib** command displays information about synthetic libraries.

The synthetic library report displays the following information in the following order:

- A list of the operators and their pins
- A list of the modules with their pins, parameters, attributes, implementations and bindings
- A list of the external implementations and bindings
- A list of DesignWare sub-blocks declared in the library

By default, all the modules are reported. If you specify the *module_list* option, the **report_synlib** command reports only the listed modules and the associated external implementations and bindings. The implementations are annotated according to the specified attributes.

If a module has external implementations in the specified library only, the **report_synlib** command searches for the definition of this module in the library list and displays the related information.

To identify the library objects that are added by the **update_lib** command, the library objects are marked with an asterisk (*). This is

because the initial library is created by using the **read_lib** command.

To generate a report, load the specified library. To see the libraries that are currently loaded, use the **list_libraries** command. You can use the **search_path** variable to locate the library.

EXAMPLES

The following report displays the *DW01_add* and *DW01_sub* modules and their implementations in the *standard.sldb* library. At the end of the report, the super and fast implementations are marked with asterisks indicating that they are added by the **update_lib** command.

```
prompt> report_synlib standard.sldb { DW01_add DW01_sub }
```

```
*****
Report : library
Library: standard.sldb
Version: v3.1
Date  : Thu Jan 28 11:46:00 1993

report_synlib_history

Displays information about the updates on **DesignWare** Datapath and Building Block (DWBB) IPs.

The command displays updates as early as P-2019.03 release. For release prior to P, user can refer to the text file located in \$SYNOPSYS/dw/doc/manuals/dwbb_history.txt for details of updates.

SYNTAX

```
status report_synlib_history
  [-modules modules]
  [-from from]
  [-nosplit]
```

ARGUMENTS

-modules *modules*

Specifies a list of modules that are reported. The default is to report information about all modules in the synthetic library. Wildcard pattern can be used in each element of the list.

-from *from*

Specifies the release version to start reporting *DesignWare* libraries change history from. The default is to report change history of the release of current loaded tool. Wildcard pattern can be used in release version.

-nosplit

Does not split lines if column overflows.

DESCRIPTION

The **report_synlib_history** command displays detailed information on Impact, Component Name, Release Name, Affected Model, and Link for the details for each update.

- Impact

Impact coding is created by Synopsys based on the type of update. The user needs to watch out for updates that are categorized as "FUNC" because the update changes existing functionality. Please refer to the following definition for each type.

- ENH: Enhance capability of the component that does not affect backward compatible functionality such as
 - Extended parameter range or addition of new parameter
 - Quality of results improvements
 - Addition of new feature

- FUNC: The update causes existing functionality changes such as
 - Correction to the result of the outputDetails can be found in "Description" or the URL link in "Link for the details".
- LOW: Low impact changes and are fully compatible with previous versions such as
 - Removal of implementation that no longer provides benefit
 - Removal/addition of constructs in the coding
 - Documentation only changes. Documentation can be datasheet, example file.
 - Enhancing design interpretation for verification tools
 - Message suppression/correction
- REG: Internal register change that does not affect functionality such as
 - Register renaming or relocating

- Component name

Displays the impacted DWBB component.

- Release name

Displays in which release the update took place.

- Affected Model

Components in the DesignWare Datapath and Building Block (DWBB) Library have a VHDL simulation model, a Verilog simulation model, and synthesis model. Since the update may not necessarily modify all three models, this column reveals which model is modified. "Documentation" means that only datasheet and/or example file are edited and there is no modification on simulation or synthesis models.

- Description

Details of change history.

- Link for the details

URL link where Synopsys publishes the detailed information about the bug for a given DWBB component.

By default, all the modules are reported. If you specify the **-modules** option, the **report_synlib_history** command reports only the listed modules and the associated implementations and bindings.

report_target_library_subset

Reports target library subsets on the design.

SYNTAX

```
status report_target_library_subset
  [-object_list cell/s]
  [-top]
  [-nosplit]
```

ARGUMENTS

-object_list *cells*

Specifies the cells on which the target library subset is to be reported.

-top

Specifies the target library subset being specified on the root design.

-nosplit

Specifies not to split lines when column fields overflow.

DESCRIPTION

This command reports the target library subset on the design based on the specified options. If neither option is specified, it reports the target library subset setting on the entire design.

Note that the command only reports the target library subset information that is explicitly set by the user. The command does not report the inherited target library subset information or the information from the **-milkyway_reflibs** option of the **set_target_library_subset** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the target library subset for the design and for block u1:

```
prompt> report_target_library_subset -top -object_list [get_cells u1]
```

SEE ALSO

`check_target_library_subset(2)`
`compile(2)`
`remove_target_library_subset(2)`
`set_operating_conditions(2)`
`set_target_library_subset(2)`
`target_library(3)`

report_test_assume

Displays the value set on the pins by the **set_test_assume** command.

SYNTAX

status **report_test_assume**

ARGUMENTS

The **report_test_assume** command has no arguments.

DESCRIPTION

This command displays the pins and the value they are set to by the **set_test_assume** command on the current design. It reports the test assume value of either 1 or 0.

EXAMPLES

The following is an example of the **report_test_assume** command:

```
prompt> report_test_assume
*****
Report : test assume
Design : sub
Version: W-2004.12
Date  : Thu Mar 31 15:48:46 2005
*****
```

PIN NAME	Test Assume Value
ff1/CD	0
ff6/Q	1
ff2/CD	1

SEE ALSO

```
remove_test_assume(2)
set_test_assume(2)
```

report_test_model

Displays the test model information attached to a design.

SYNTAX

```
status report_test_model  
[-design design_name]
```

Data Types

design_name string

ARGUMENTS

-design *design_name*

Specifies the design on which to report test model information.

DESCRIPTION

The **report_test_model** command displays the model information about a design. Specify the design with the **-design** option. If no design is specified, the model information of the current design is displayed.

Test modes are modes of operation of the scan design. The model information contains the list of test modes associated with that model and their type. If the design has no corresponding modes or model, the "No test modes" message appears.

EXAMPLES

The following example generates a test model report for the *M1* design:

```
prompt> report_test_model -design M1
```

```
*****  
Report : test model  
Design : M1  
Version: 2001.08  
Date  : Fri Oct 19 09:07:32 2001  
*****
```

Test Mode	Purpose	Spec	Impl	Model	Source
-----------	---------	------	------	-------	--------

Internal_scan	InternalTest	Yes
Mission_mode	Normal	Yes
wrp_if	InternalTest	Yes
wrp_of	ExternalTest	Yes
wrp_safe	Isolate	Yes

status report_testability_configuration  
[-type valid_type]
```

ARGUMENT

DESCRIPTION

This command displays the options specified by the **set_testability_configuration** command for the current design.

SEE ALSO

[reset_testability_configuration\(2\)](#)
[set_testability_configuration\(2\)](#)

report_threshold_voltage_group

Reports the number, area, and percentage of cells for each threshold voltage group in the design. Also shows the number, area, and percentage of cells in user-specified low threshold voltage groups. Since the threshold voltage group attribute is specified on the library cells, hierarchical cells do not have a threshold voltage group. So, their usage is reported under the "undefined" threshold voltage group category.

SYNTAX

```
status report_threshold_voltage_group
  [cell_list]
  [-lvth_groups groups]
  [-nosplit]
  [-verbose]
```

Data Types

<i>cell_list</i>	list
<i>groups</i>	list

ARGUMENTS

cell_list

Specifies a list of cells to report the threshold voltage groups. If not specified, the report is generated on all cells of the current design.

-lvth_groups *groups*

Specifies the list of threshold voltage groups to be considered as low threshold voltage. The value of the *groups* argument is a list of threshold voltage group identifiers. Each identifier is a non-empty string that can contain alphanumeric characters and the underscore character ("_"). If you do not specify this option, the low threshold voltage groups specified earlier using the **set_multi_vth_constraint** command are used; otherwise, no low threshold voltage groups are reported.

-nosplit

Prevents line splitting and facilitates writing tools to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column's width, the next field begins on a new line, starting in the correct column.

-verbose

Lists all the cells belonging to each threshold voltage group. If this option is not specified, the default summary report shows only the number and percentage of cells.

DESCRIPTION

This command reports the number, area, and percentage of cells in each threshold voltage group for the specified list of cells. The report also shows separately, the number, area, and percentage of black box and non black box cells in each group.

The threshold voltage group is defined in the logic libraries with the **threshold_voltage_group** attribute on the cell, or with the **default_threshold_voltage_group** attribute on the library. You can also set the attributes on the objects using the **set_attribute** command. The attributes can be any string values, but the values must be related to the threshold voltage of the cell to be meaningful. Any cells in the design that have no threshold voltage group attribute are included in the "undefined" group. Hierarchical cells are an example of such cells. To report the threshold voltage group for a hierarchical cell, get the list of cells it contains using [**get_cells - hierarchical hierarchical_cell/***] and pass it as the **cell_list** argument of the **report_threshold_voltage_group** command.

Use the **-lvth_groups** option to specify the list of threshold voltage groups that are to be considered as low threshold. When you specify this option, the specified low threshold voltage groups are marked by a letter "L" and it appears in the last column of the corresponding row in the report. The total number, area, and percentage of cells in all the low threshold voltage groups is also reported. Note that the low threshold voltage groups specified with the **-lvth_groups** option overrides any low threshold voltage groups specified in a previous command. Specifically, when you specify **-lvth_groups {}**, the command does not report any low threshold voltage groups even if you have previously defined low threshold voltage groups. However, if you do not specify the **-lvth_groups** option, the low threshold voltage groups that you specified by using the **set_multi_vth_constraint** command, are used to report the details of the low threshold voltage groups.

Use the **-verbose** option to list all the cells that belong to each threshold voltage group. Without this option, the command generates a summary that reports only the number, area, and percentage of cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the summary of cells in each threshold voltage group for the current design:

```
prompt> report_threshold_voltage_group -lvth_groups {lvt svt}
*****
Threshold Voltage Group Report
*****

ARGUMENTS

-to to_list

Reports only the paths to the named pins, ports, or clocks. If you do not specify the **-to** option, the default is to report the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the default is to report the path with the worst slack within each path group if the **-group** option is not present. If the **-group** option is given, the default is to report the path with the worst slack within the group specified by the **-group** option.

-rise_to rise_to_list

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by the rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

-fall_to fall_to_list

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by the falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-from from_list

Reports only the paths from the named pins, ports, or clocks. If you do not specify the **-from** option, the default is to report the longest path to an output port if the design has no timing constraints. If the design has timing constraints, the default is to report the path with the worst slack within each path group if the **-group** option is not present. If the **-group** option is given, the default is to report the path with the worst slack within the group specified by the **-group** option.

-rise_from rise_from_list

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by the rising edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-fall_from fall_from_list

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by the falling edge of the clock at the clock source, taking into account any logical inversions along the clock path.

-through through_list

Reports only paths that pass through the named pins, ports, or clocks. If you do not specify the **-through** option, the default is to report the longest path to an output port if the design has no timing constraints. If the design does have timing constraints, the default is to report the path with the worst slack within each path group if the **-group** option is not present. If the **-group** option is given, the default is to report the path with the worst slack within the group specified by the **-group** option.

If you specify the **-through** option only one time, the tool reports only the paths that travel through one or more of the objects in the list. You can specify the **-through** option more than one time in one command invocation. For a discussion of the use of multiple **-through** options, see the DESCRIPTION section.

-rise_through *rise_through_list*

Reports only paths with a rising transition at the specified objects. This option is similar to the **-through** option. You can specify the **-rise_through** option more than one time in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-fall_through *fall_through_list*

Reports only paths with a falling transition at the specified objects. This option is similar to the **-through** option. You can specify the **-fall_through** option more than one time in a single command invocation. For a discussion of multiple **-through**, **-rise_through**, and **-fall_through** options, see the DESCRIPTION section.

-exclude *exclude_list*

Prevents reporting of all data paths from/through/to the named pins, ports, nets, and cell instances. Any data path that starts from, contains, or ends on a listed object is excluded from reporting. If you specify a cell instance, data paths that include any pin of that cell instance are excluded. This option has higher precedence than the **-from**, **-through**, **-to**, and similar options.

The exclusion does not apply to clock paths, even when the **-path_type full_clock** or **-path_type full_clock_expanded** option is used. It does not apply to borrowing path from the **-trace_latch_borrow** option.

This option is not applied to clock pins.

-rise_exclude *rise_exclude_list*

Same as the **-exclude** option, but applies only to paths rising at the named pins, ports, nets, and cell instances.

-fall_exclude *fall_exclude_list*

Same as the **-exclude** option, but applies only to paths falling at the named pins, ports, nets, and cell instances.

-path_type *short* | *full* | **full_clock** | **full_clock_expanded** | *only* | *end*

Specifies how to display the timing path. By default, the full path is displayed. The following values are valid:

- If **full_clock** is specified, the report is similar to the report you get with **full** but also reports the full clock paths for propagated clocks.
- If **full_clock_expanded** is specified, the report is similar to the report you get with **full_clock** but also reports the full clock path from the primary clock to the related generated clock source.
- If **short** is specified, only startpoints and endpoints are displayed.
- If **only** is specified, only the path is displayed without the accompanying required-time and slack calculation.
- If **end** is specified, the report has a column format that shows one line for each path, showing only the endpoint path total, required-time, and slack.

-delay_type *min* | *min_rise* | *min_fall* | *max* | **max_rise** | **max_fall**

Specifies the path type at the endpoint. The default is **max**.

-nworst *paths_per_endpoint*

Specifies the maximum number of paths to report per endpoint. The default is 1, which reports only the single worst path ending at a given endpoint.

-max_paths *max_path_count*

Specifies the number of paths to report per path group by default, or the number of paths to report for the whole design if the **timing_report_fast_mode** variable is set to true. The default is 1.

-input_pins

Shows input pins in the path report. The default is to show only output pins. This option also shows the delays of the nets connected to these pins.

-nets

Shows nets in the path report. The default is not to show nets. To show the delay for the nets, use the **-input_pins** option.

-transition_time

Shows the net transition time for each driving pin in the path report. The default is not to show the net transition time for each driving pin.

-crosstalk_delta

Shows the delta delay for each input pin in the path report. The default is not to show the delta delay for each input pin.

-capacitance

Causes the total (lumped) capacitance to be shown in the path report. The default is not to show capacitance. For each driver pin, the total capacitance driven by the driver is displayed in a column preceding both incremental path delay and transition time (specified with the **-transition_time** option). When the **-nets** option is specified, the capacitance is printed on the lines with nets instead of the lines with driver pins.

-effective_capacitance

Causes the effective capacitance for nets, calculated by the Arnoldi method, to be shown in the path report. For each driver pin, the worst effective capacitance among all of the driver arcs is displayed in a column labeled "Ceff". When the **-nets** option is used, the effective capacitance is shown in the lines reporting the nets, rather than the driver pins. Only capacitance values calculated by the Arnoldi method are shown in the "Ceff" column; where capacitance is calculated by another method, the "Ceff" column is left blank.

-attributes

Shows the attributes specified in the **timing_report_attributes** variable. The supported attributes are **dont_touch**, **dont_use**, **map_only**, **infeasible_paths** (for the Design Compiler and DC Explorer tools), **size_only** for cells, **dont_touch** for cells and nets, and **ideal_net** for nets.

-physical

Shows the locations of the pins and the capacitive loads for the pins and nets in the path report. The loads are displayed as a pair of values with the first value being the wire capacitance of the net and the second value being the total capacitance driven by the driver. If the pin location cannot be determined, the cell location is displayed, with the coordinates in microns.

-slack_greater_than greater_slack_limit

Specifies that only those paths with a slack greater than *greater_slack_limit* are to be reported. This option can be combined with **-slack_lesser_than** to report only those paths inside or outside a given slack range.

-slack_lesser_than lesser_slack_limit

Specifies that only those paths with a slack less than *lesser_slack_limit* are to be reported. This option can be combined with **-slack_greater_than** to report only those paths inside or outside a given slack range.

-lesser_path max_path_delay

Selects only those paths with a delay less than *max_path_delay*. Combine this option with the **-greater_path** option to select only those paths inside or outside a given delay range.

-greater_path min_path_delay

Selects only those paths with a delay greater than *min_path_delay*. Combine this option with the **-lesser_path** option to select only those paths inside or outside a given delay range.

-loops

Reports only the timing loops in the design.

-enable_preset_clear_arcs

Enables asynchronous timing arcs for this report. By default, asynchronous timing arcs are disabled during all timing verification. This option allows you to see the timing with these arcs enabled. Only the current report is affected.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point to report. Allowed values are from 0 through 13. The default is 2. Using this option overrides the value set by the **report_default_significant_digits** variable.

-nosplit

Prevents line splitting and facilitates writing application to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-sort_by group | slack

Specifies the order in which the paths are reported. The default **-sort_by** key is **group**. By default, paths are sorted by costing groups. Within each group, the paths are ordered by slack. With **slack**, the paths are ordered by slack only.

-group *group_name*

Specifies the path group from which timing paths are selected for reporting, based on other specified options for reports. If the **-group** option is not specified, the reported paths are a subset of paths from all path groups. This option cannot be used with the **-loops** option.

-trace_latch_borrow

Controls the type of report generated for a path that starts at a transparent latch. If the path startpoint borrows from the previous stage, using this option causes the report to show the entire set of borrowing paths that lead up to the borrowing latch, starting with a nonborrowing path or a noninverting sequential loop. By default, the report shows only the last path in the sequence of borrowing stages. Each stage is reported separately, showing the time borrowed and lent and the endpoints of the stage. The cumulative amount of borrowed time along a sequence of stages is not included in the report. The **-input_pins**, **-nets**, **-transition_time**, **-capacitance**, and **-significant_digits** options apply to every stage in the sequence of borrowing paths, but the remaining options (for example, **-from**) apply only to the last stage reported.

-derate

Prints timing derate values for each path element. By default, no derate value is printed. When this option is specified, the **-input_pins** and **-nets** options are automatically turned on. Input delay and ideal clock network latency is not derated.

-normalized_slack

Paths are gathered and sorted using normalized slack instead of slack. Normalized slack divides the slack by an idealized allowed propagation delay. In order to use this option, you must run the **update_timing** command with the **timing_enable_normalized_slack** variable set to true.

-scenarios *scenario_list*

Reports each scenario in the list separately, with up to **-max_paths** paths reported for each scenario. Inactive scenarios are skipped in the report. If this option is not given, only the current scenario is reported.

-temperature

Reports the operating condition temperature for each path element for multivoltage designs.

-voltage

Reports the operating condition voltage for each path element for multivoltage designs. When the operating condition for a macro, switch, or pad cell is inferred from other library cells, a tilde character (~) is displayed next to the voltage value in the timing report.

-unique_pins

Causes only the single worst timing path through any given sequence of pins to be reported. No other paths are reported for the same sequence of pins from startpoint to endpoint. For example, if the worst path starts with a rising edge at the first pin of a pin

sequence, then paths starting with a falling edge are not reported for that sequence. For non-unate logic such as XOR gates, this greatly reduces the number of paths reported because of the large number of possible rising/falling edge combinations through the sequence of pins. Using this option can require longer runtimes when used with the **-nworst n** option because many paths must be analyzed to find the worst path through each pin sequence, but only the worst path is reported and counted toward the total number of requested paths.

-start_end_pair

Limits reporting to the single worst timing path per each combination of startpoint and endpoint found. No other paths are reported that have the same startpoint and same endpoint. For example, if the worst path starts at a register clock pin ff1/CK and ends at a register input pin ff5/D, the report omits all other less critical paths from ff1/CK to ff5/D. Using this option can require longer runtimes when used with the **-nworst n** option because many paths must be analyzed to find the worst path through each pin pair, but only the worst path in each case is reported and counted toward the total number of requested paths.

-variation

Reports the mean and standard deviation of the statistical time increment for each path element. This option works only when parametric on-chip variation (POCV) analysis has been enabled by setting the **timing_pocvm_enable_analysis** variable to true. By default, statistical parameters are not reported.

-ignore_infeasible_paths

Ignores all paths flagged as infeasible during the latest compilation.

DESCRIPTION

The **report_timing** command provides a report of timing information for the current design. By default, the **report_timing** command reports the single worst setup path in each clock group.

The command options let you specify the number of paths reported, the types of paths reported, and the amount of detail included in the report. You can restrict the scope of paths reported by startpoints, endpoints, and intermediate points by using the **-from**, **-to**, and **-through** options; and by slack or clock group by using the **-slack_lesser_than** and **-group** options.

The timing report starts by showing the primary command settings, operating conditions, path startpoint, path endpoint, path group name, and path timing check type (max for a setup check, min for a hold check, and so on).

A table in the report shows point-by-point accounting of the delays along the path from the startpoint to the endpoint. The default table has columns labeled Point, Incr, and Path. These columns list the points (cell pins) along the path, the incremental contribution to the delay at each point, and the cumulative delay up to that point, respectively. Hierarchical boundary crossings are listed as well, showing zero incremental delay at each crossing. You can optionally display net delays in the report by using the **-input_pins** option and net names by using the **-nets** option.

The symbols "r" and "f" in the Path column indicate the sense of the signal transition, either rising or falling, at that point in the path.

For a setup check, the path starts with the launch clock edge and ends at the data input of the capture device. The data arrival time shown in the table is the amount of elapsed time from the source of the launch clock edge to the arrival of data at the endpoint, taking into consideration the longest possible delays along the path.

Following this is the accounting for the required arrival time. The data required time shown in the table is the latest allowable arrival time for the data at the path endpoint, taking into account the nominal capture clock edge time, the clock network delay, the clock uncertainty, the least possible delay along the clock path, and the library setup time requirement for the capture device.

The slack value shown at the end of the report is the data required time minus the data arrival time. This represents the amount of time by which the timing constraint is met.

Back-annotations on path elements in the timing path are indicated by a character symbol in the Incr column. If the **-input_pins** option is used, each pin-to-pin delay spans either a net or cell. The symbol shown refers to the dominant annotation on each path element. (Certain annotations dominate others; for example, SDF takes precedence over back-annotated RC parasitics.)

Symbol	Annotation
-----	-----
^	Ideal network latency annotation

- * Back-annotation using SDF or preroute Elmore extraction
- & RC network back-annotation using Elmore delay calculation
- # Estimated delay for high-fanout net
- z Zero delay due to set_zero_interconnect_delay_mode
- <none> Wire-load model or none

You can use multiple **-through** options in a single command to specify paths that traverse multiple points in the design. The following example specifies paths beginning at A1, passing through B1, then through C1, and ending at D1:

```
prompt> report_timing -from A1 -through B1 -through C1 -to D1
```

If more than one object is specified within one **-through** option, the path can pass through any of the objects. The following example specifies paths beginning at A1, passing through either B1 or B2, then passing through either C1 or C2, and ending at D1:

```
prompt> report_timing -from A1 -through {B1 B2} -through {C1 C2} -to D1
```

Creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option. The only exception is the clock object, which only comes from current scenario.

EXAMPLES

The following example shows a timing report using only the default values:

```
prompt> report_timing
```

```
*****
Report : timing
  -path full
  -delay max
  -max_paths 1
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:23:02 1992
*****
```

Operating Conditions:

Wire Loading Model Mode: top

Startpoint: c (input port)

Endpoint: z2 (output port)

Path Group: default

Path Type: max

Point	Incr	Path
input external delay	0.00	0.00 r
c (in)	0.00	0.00 r
u1/Z (IVA)	0.54	0.54 f
u0/Z (NR2)	1.20	1.74 r
u8/Z (IVA)	0.43	2.17 f
u7/Z (OR3)	1.24	3.41 f
z2 (out)	0.00	3.41 f
data arrival time		3.41
max_delay	0.00	0.00
output external delay	0.00	0.00
		0.00

```
-----
data required time          0.00
data arrival time           -3.41
-----
slack (VIOLATED)          -3.41
```

The following example reports the longest path to Z1, without required-time and slack calculation:

```
prompt> report_timing -to z1 -nworst 2 -path_type only
```

```
*****
```

```
Report : timing
  -path only
  -delay max
  -nworst 2
  -max_paths 2
```

```
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:52:43 1992
*****
```

Operating Conditions:

Wire Loading Model Mode: top

Startpoint: c (input port)
 Endpoint: z1 (output port)
 Path Group: default
 Path Type: max

Point	Incr	Path
input external delay	0.00	0.00 f
c (in)	0.00	0.00 f
u1/Z (IVA)	0.60	0.60 r
u17/Z (AO7)	0.53	1.13 f
u18/Z (OR3)	1.24	2.37 f
z1 (out)	0.00	2.37 f
data arrival time		2.37

Startpoint: d (input port)
 Endpoint: z1 (output port)
 Path Group: default
 Path Type: max

Point	Incr	Path
input external delay	0.00	0.00 f
d (in)	0.00	0.00 f
u20/Z (IVA)	0.53	0.53 r
u17/Z (AO7)	0.53	1.06 f
u18/Z (OR3)	1.24	2.30 f
z1 (out)	0.00	2.30 f
data arrival time		2.30

The following example reports the endpoint path delay, required time, and slack for each path:

```
prompt> report_timing -path_type end
```

```
*****
```

```
Report : timing
  -path end
  -delay max
```

```
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:28:07 1992
*****
```

Operating Conditions:
Wire Loading Model Mode: top

Endpoint	Path Delay	Path Required	Slack
z2	3.41 f	0.00	-3.41
z3	3.03 f	0.00	-3.03
z4	2.77 f	0.00	-2.77
z6	2.69 r	0.00	-2.69
z0	2.59 f	0.00	-2.59
z1	2.37 f	0.00	-2.37
z5	2.26 f	0.00	-2.26

The following example reports the startpoints and endpoints of the path from a to z2:

```
prompt> report_timing -from a -to z2 -path_type short
```

```
*****
Report : timing
  -path short
  -delay max
  -max_paths 1
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:29:40 1992
*****
```

Operating Conditions:
Wire Loading Model Mode: top

Startpoint: a (input port)
Endpoint: z2 (output port)
Path Group: default
Path Type: max

Point	Incr	Path
input external delay	0.00	0.00 f
a (in)	0.00	0.00 f
...		
z2 (out)	1.24	1.24 f
data arrival time		1.24
max_delay	0.00	0.00
output external delay	0.00	0.00
data required time		0.00
data required time	0.00	
data arrival time		-1.24
slack (VIOLATED)		-1.24

The following example shows input pins in the report, in addition to the default values:

```
prompt> report_timing -input_pins
```

```
*****
Report : timing
  -path full
  -delay max
```

```
-input_pins
-max_paths 1
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:32:28 1992
*****
```

Operating Conditions:
Wire Loading Model Mode: top

Startpoint: c (input port)
Endpoint: z2 (output port)
Path Group: default
Path Type: max

Point	Incr	Path
input external delay	0.00	0.00 r
c (in)	0.00	0.00 r
u1/A (IVA)	0.00	0.00 r
u1/Z (IVA)	0.54	0.54 f
u0/A (NR2)	0.00	0.54 f
u0/Z (NR2)	1.20	1.74 r
u8/A (IVA)	0.00	1.74 r
u8/Z (IVA)	0.43	2.17 f
u7/B (OR3)	0.00	2.17 f
u7/Z (OR3)	1.24	3.41 f
z2 (out)	0.00	3.41 f
data arrival time		3.41
max_delay	0.00	0.00
output external delay	0.00	0.00
data required time		0.00
data required time		0.00
data arrival time		-3.41
slack (VIOLATED)		-3.41

The following example shows input pins and nets in the report, and does not show required time and slack calculation:

prompt> report_timing -input_pins -nets -path_type only

```
*****
Report : timing
  -path only
  -delay max
  -input_pins
  -nets
  -max_paths 1
Design : led
Version: v3.1a
Date  : Tue Apr  7 16:34:20 1992
*****
```

Operating Conditions:
Wire Loading Model Mode: top

Startpoint: c (input port)
Endpoint: z2 (output port)
Path Group: default
Path Type: max

Point	Incr	Path
-------	------	------

```
-----

[**-nosplit**]
[**-scenarios scenario_list**]
[**-increment**]
[**-multiply**]

Data Types

object_list list
scenario_list list

ARGUMENTS

-include_inherited

Includes inherited derating factors in the report. The derating values reported are the ones used in the delay calculation. The name of the cell or design from which the derating is inherited is shown in the "Inherited" column of the report. When this option is not used, only the values set directly on the object are reported.

-pocvm_guardband

Reports the POCV guardband derating factors.

-pocvm_coefficient_scale_factor

Reports the POCV coefficient scale factors.

No more than one of the following three options can be used in the command: **-aocvm_guardband**, **-pocvm_guardband**, or - **pocvm_coefficient_scale_factor**.

object_list

Specifies the list of objects whose derating factors are to be reported. The objects in the list can be leaf cells, instances, library cells, and designs. If this option is not used in the command, it reports all objects in the current design with user-defined derating applied.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-scenarios scenario_list

Reports timing derating factors for the specified scenarios of a multi-scenario design. Inactive scenarios are skipped in the report. Each scenario is reported separately.

If you do not use this option, only the current scenario is reported.

DESCRIPTION

The **report_timing_derate** command reports timing derating factors previously set for the design or for specified objects using the **set_timing_derate** command.

When the **-include_inherited** option is used, the command reports all derating factors that are used in delay calculation, including those inherited from other objects. By default, only the derating factors set directly on the object are reported.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

In the following example, the first **report_timing_derate** command reports the derating factors that were set on the design; the second one reports the guardband derating factors that were set on the design.

```
prompt> set_timing_derate -early 0.95
prompt> set_timing_derate -late 1.05
prompt> set_timing_derate -early -aocvm_guardband 0.96
prompt> set_timing_derate -late -aocvm_guardband 1.06
prompt> report_timing_derate
*****
```

prompt> report_timing_derate s1 -include_inherited

SEE ALSO

`report_timing(2)`
`reset_timing_derate(2)`
`set_timing_derate(2)`

report_timing_requirements

Reports timing path requirements (user attributes) and related information.

SYNTAX

```
status report_timing_requirements
  [-attributes]
  [-ignored]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
  [-expanded]
  [-nosplit]
```

Data Types

<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list

ARGUMENTS

-attributes

Lists the path delay attributes set on the design. If used with the **-from** or **-to** option, **-attributes** limits the report to the specified from and to objects. This option reports on attributes set by the **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay** commands.

The **-attributes** option is the default when no other options are specified. Any **max_time_borrow** attributes on objects are printed.

-ignored

Lists path timing attributes set on the current design that are ignored. For example, a false path might be specified from port A to port Z1, but there is no timing path between those points. Use **-from** or **-to** to limit the report to certain paths. Ignored attributes on objects are printed, such as **max_time_borrow** on a cell other than a level-sensitive latch.

-from *from_list*

Specifies a list of clocks, ports, cells, and pins in the current design. The **-from** option limits the report to information that was set with **-from** to a path-based command, such as **set_multicycle_path**. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-rise_from *rise_from_list*

Specifies a list of clocks, ports, cells, and pins in the current design, similar to the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Specifies a list of clocks, ports, cells, and pins in the current design, similar to the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of ports, cells, and pins in the current design. The **-through** option limits the report to information that was set with **-through** to a path-based command, such as **set_multicycle_path**.

-rise_through *rise_through_list*

Specifies a list of ports, cells, and pins in the current design, similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Specifies a list of ports, cells, and pins in the current design, similar to the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies a list of clocks, ports, cells, and pins in the current design. The **-to** option limits the report to information that was set with **-to** to a path-based command, such as **set_multicycle_path**. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-rise_to *rise_to_list*

Specifies a list of clocks, ports, cells, and pins in the current design, similar to the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Specifies a list of clocks, ports, cells, and pins in the current design, similar to the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-expanded

Expands compressed timing exceptions on the design. Compressed timing exceptions applied on the design are reported as compressed exceptions by the **report_timing_requirements** command. Although every object in the from, to, and through list gets enumerated, the exception is still a compressed exception. With the **-expanded** switch, these exceptions are expanded so that each of the from, to, and through list references at the most one element.

It is considered best practice not to use this option, since it can create a very large report.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_timing_requirements** command produces a report showing information about timing requirements of the design.

Use the **reset_design** command to remove all timing attributes on the current design. To remove timing attributes from specified paths, use the **reset_path** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists all timing attributes set on the design:

```
prompt> report_timing_requirements
```

```
*****
Report : timing_requirements
    -attributes
Design : counter

report_tlu_plus_files

Reports the files used for TLUPlus extraction. This command is supported only in topographical mode.

SYNTAX

```
status report_tlu_plus_files  
[-scenarios scenario_list]
```

Data Types

scenario_list list

ARGUMENTS

-scenarios *scenario_list*

Reports the TLUPlus files for the specified scenarios of a multi-scenario design. Non-existing scenarios are skipped in the report. Each scenario is reported separately. If you do not specify this option, only the current scenario is reported.

DESCRIPTION

This command reports the files used for virtual route and postroute extraction using TLUPlus.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example runs the **report_tlu_plus_files** command:

```
prompt> report_tlu_plus_files
```

SEE ALSO

[extract_rc\(2\)](#)

set_tlu_plus_files(2)

report_top_implementation_options

Reports the top-level design options for the linking and optimization of a block's interface logic using transparent interface optimization.

SYNTAX

status **report_top_implementation_options**

DESCRIPTION

The **report_top_implementation_options** command reports the top-level implementation options that are specified by using the **set_top_implementation_options** command for the blocks that belong to the current top-level design. The report is generated in a tabular form.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the top-level implementation options.

```
prompt> set_top_implementation_options -block_references blk1
prompt> set_top_implementation_options -block_references blk2 \
    -optimize_block_interface true
prompt> report_top_implementation_options
```

```

SEE ALSO

`set_top_implementation_options(2)`

report_track

Reports the routing tracks for a specified layer or for all layers.

SYNTAX

```
int report_track
  [-layer layer]
  [-dir X | Y]
```

Data Types

layer string

ARGUMENTS

-layer *layer*

Specifies the routing layer to use the routing tracks. You can use layer name, layer number, or a collection containing one layer object.

The default is to report the routing tracks on all layers.

-dir X | Y

Specifies the direction how routing tracks are placed. The valid values are **X** and **Y**; specify either. The default is to report routing tracks in both direction.

DESCRIPTION

This command reports a group of routing tracks for the routing layer.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports routing tracks on the floorplan.

```
prompt> report_track
*****
```

```

report_transitive_fanin

Reports logic in the transitive fanin of specified sinks.

SYNTAX

```
status report_transitive_fanin
  -to sink_list
  [-nosplit]
```

Data Types

sink_list list

ARGUMENTS

-to *sink_list*

Specifies a list of sink pins, ports, or nets in the design. The transitive fanin of each sink in the *sink_list* is reported. If a net is specified, the effect is the same as listing all driver pins on the net. This argument is required.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanin** command produces a report showing the transitive fanin of specified sink pins, ports, or nets in the design. A pin is considered to be in the transitive fanin of a sink if there is a timing path through combinational logic from the pin to that sink. The fanin report stops at the clock pins of registers (sequential cells).

Use the **report_timing** command to show path delays in the design. Use the **report_transitive_fanout** command to see the fanout of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanin within the current instance. The report stops at the boundaries of the current instance, and paths outside the current instance are not reported. The report shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example shows the transitive fanin of two internal pins in the design:

```
prompt> report_transitive_fanin -to {u5/A u5/B}
```

```
*****
Report : transitive_fanin
Design : counter
Version: v3.1
Date  : Thu 1992
*****
```

The fanin network of sink u5/A is as follows:

Driver Pin	Load Pin	Type	Sense
u2/Z	u5/A	(net arc)	same

Load Pin	Driver Pin	Type	Sense
u2/A	u2/Z	IV/A	opposite

Driver Pin	Load Pin	Type	Sense
b	u2/A	(net arc)	opposite

The fanin network of sink u5/B is as follows:

Driver Pin	Load Pin	Type	Sense
c	u5/B	(net arc)	same

SEE ALSO

[current_design\(2\)](#)
[current_instance\(2\)](#)
[report_clock\(2\)](#)
[report_timing\(2\)](#)
[report_transitive_fanout\(2\)](#)

report_transitive_fanout

Reports logic in the transitive fanout of specified sources.

SYNTAX

```
status report_transitive_fanout
    -clock_tree | -from source_list
    [-nosplit]
```

Data Types

source_list list

ARGUMENTS

-clock_tree

Indicates that all clock source pins and ports in the design are to be used as the list of sources. Clock sources are specified using the **create_clock** command. If there are no clocks, or if the clocks do not have sources, the report is empty. Use the **report_clock** command to list the sources for all clocks in the design. The **-clock_tree** option is a special form of the report that displays the clock trees (or "networks") in the design.

Either the **-clock_tree** or the **-from** option must be specified. The options are mutually exclusive, so specify only one.

-from *source_list*

Specifies a list of source pins, ports, and nets in the design. The transitive fanout of each source in the *source_list* is reported. If a net is specified, the effect is the same as listing all load pins on the net.

Either the **-clock_tree** or the **-from** option must be specified. The options are mutually exclusive, so specify only one.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_transitive_fanout** command produces a report showing the transitive fanout of specified source pins or ports in the design. A pin is considered to be in the transitive fanout of a source if there is a timing path through combinational logic from the source to that pin. The fanout report stops at the inputs to registers (sequential cells). The source pins or ports are specified with either **-clock_tree** or **-from source_list**.

Use the **report_timing** command to show path delays in the design. Use the **report_transitive_fanin** command to see the fanin of a pin, port, or net.

If the *current_instance* is set, the report focuses on the fanout within the current instance. The report stops at the boundaries of the current instance, and does not report paths outside the current instance. The report also shows the hierarchical boundary pins on the current instance.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example lists the transitive fanout for all clock sources in the design:

```
prompt> report_transitive_fanout -clock_tree
```

```
*****
Report : transitive_fanout
      -clock_tree
Design : counter
Version: v3.0
Date   : Thu 1992
*****
```

The fanout network of source CLK is as follows:

Driver Pin	Load Pin	Type	Sense
CLK	ffd/CP	(net arc)	same
CLK	ffc/CP	(net arc)	same
CLK	ffb/CP	(net arc)	same
CLK	ffa/CP	(net arc)	same

The following example shows the transitive fanout of two internal pins in the design:

```
prompt> report_transitive_fanout -from {ffa/Q ffb/Q}
```

```
*****
Report : transitive_fanout
Design : counter
Version: F-2011.09
Date   : Wed Jul 27 17:21:06 2011
*****
```

The fanout network of source ffa/Q is as follows:

Driver Pin	Load Pin	Type	Sense
ffa/Q	QA/A	(net arc)	same

Load Pin	Driver Pin	Type	Sense
QA/A	QA/Z	IV	opposite

Driver Pin	Load Pin	Type	Sense
QA/Z	QA	(net arc)	opposite

The fanout network of source ffb/Q is as follows:

Driver Pin	Load Pin	Type	Sense
------------	----------	------	-------

ffb/Q	QB/A	(net arc)	same
Load Pin	Driver Pin	Type	Sense

QB/A	QB/Z	IV	opposite
Driver Pin	Load Pin	Type	Sense

QB/Z	QB	(net arc)	opposite

report_units

Reports the units used for resistance, capacitance, timing, leakage power, current, and voltage in the flow. The units must be consistent with the main library units.

SYNTAX

string **report_units**

ARGUMENTS

The **report_units** command has no arguments.

DESCRIPTION

The **report_units** command displays the units used by the current design. To generate the report, the design should be loaded and linked to a library. The units are always reported in reference to the MKS units such as farad, amp, ohm, second, volt, and watt.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the **report_units** output:

```
*****
Report : units
Design : labf.mw
Version: Z-2007.03-ICC
Date : Tue Aug 22 10:32:44 2006
*****
Units
-----
Time_unit      : 1e-09 Second(nS)
Capacitive_load_unit : 1e-12 Farad(pF)
Resistance_unit   : 1000 Ohm(kohm)
Voltage_unit     : 1 Volt
Power_unit       : 1e-06 Watt(uW)
Current_unit     : 1 Amp
```

SEE ALSO

`set_units(2)`

report_upf_cell_mismatch

Reports PM cells which are dirtily mapped by violating TLS, PVT or UPF constraint by using set_upf_cell_mismatch command.

SYNTAX

```
status report_upf_cell_mismatch
  -tlsViolation
  -pvtMismatch
  -noUnmapped
  [-cells cells]
  [-nosplit]
```

ARGUMENTS

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

This command reports power management cells present in the netlist which were mapped by relaxations specified by the set_upf_cell_mismatch command ie. relaxations on target_library_subset, PVT matching and UPF constraint allowing for no unmapped power management cells in the final netlist.

All the options are optional. If just report_upf_cell_mismatch is specified without any options, then power management cells mapped by allowing any of the relaxations are reported.

EXAMPLES

The following example shows how to specify relaxations using report_upf_cell_mismatch command.

```
prompt> report_upf_cell_mismatch -nosplit
```

User specified command: set_upf_cell_mismatch -allow_pvt_mismatch

Violation:

 tls - TLS violation
 pvt - PVT mismatch
 nu - No unmapped

Cell	Reference	PM Type	Violation
mid/snps_PD1_ISO_snps_q2_UPF_ISO	HS45_LS_ISOAND2X9	iso	pvt
mid/snps_PD1_ISO_snps_q1_UPF_ISO	HS45_LS_ISOAND2X9	iso	pvt

1

SEE ALSO

[set_upf_cell_mismatch\(2\)](#)

report_use_test_model

Reports test model usage for each subdesign under the current design.

SYNTAX

status **report_use_test_model**

ARGUMENTS

The **report_use_test_model** command has no arguments.

DESCRIPTION

This command displays the list of subdesigns currently in dc_shell that are instantiated within the current design. For each subdesign, it indicates whether a test model or gates are used.

EXAMPLES

The following is an example of the **report_use_test_model** command:

```
prompt> report_use_test_model
```

SEE ALSO

[use_test_model\(2\)](#)

report_via_ladder_candidates

Reports via ladder candidates set by the **set_via_ladder_candidate** command.

SYNTAX

```
status report_via_ladder_candidates  
    lib_pin_list
```

Data Types

lib_pin_list collection

ARGUMENTS

DESCRIPTION

This command reports via ladder candidates on library pins.

EXAMPLES

The following example reports existing via ladder candidates on library pin "slow/TBUFIXL/Y"

```
prompt> report_via_ladder_candidates  
report_via_ladder_candidates  
library pin: slow/TBUFIXL/Y  
via ladder candidate: VL1_1_2 (400.000 220.000)  
                           VL1_2 (500.000 220.000)
```

1

SEE ALSO

report_via_ladder_constraints

Reports via ladder constraints.

SYNTAX

```
status report_via_ladder_constraints
  -pins pins
  -output file_name
```

Data Types

<i>pins</i>	collection
<i>file_name</i>	string

ARGUMENTS

-pins *pins*

Collection of pins specified to report via ladder constraints.

-output *file_name*

Output file specified to writes the report.

DESCRIPTION

This command reports via ladder lists that were previously set by the **set_via_ladder_constraints** command.

A via ladder is a physical structure of connected vias and wires that is placed on top of a standard cell pin as a special connecting device. A via ladder can have, for example, two rows of via1, four columns of via2, and one row of via3 connected with a metal4 wire.

A named via ladder is defined by set of rules in the technology file.

This command also reports the via ladder added on pins during optimization.

EXAMPLES

The following command will report via ladders on all pins:

```
prompt> report_via_ladder_constraints
```

SEE ALSO

`set_via_ladder_constraints(2)`
`remove_via_ladder_constraints(2)`

report_via_ladder_rules

Reports via ladder rules set by the **set_via_ladder_rules** command.

SYNTAX

status **report_via_ladder_rules**

ARGUMENTS

The **report_via_ladder_rules** command has no arguments.

DESCRIPTION

This command reports existing via ladder rules.

This command returns 1 if succeeded, 0 otherwise.

EXAMPLES

The following example reports all via ladder constraints from the block.

```
prompt> report_via_ladder_rules
report_via_ladder_rules
master pin: lib/INVD8/ZN via ladder:{ VP2 }
master pin: lib/BUFFD10/Z via ladder:{ VP1 }
1
```

SEE ALSO

set_via_ladder_rules(2)
remove_via_ladder_rules(2)

report_via_rules

Displays via_rule's information from the current library.

SYNTAX

```
string report_via_rules
  [-verbose]
  [-nosplit]
  -all
  via_rule_list
```

Data Types

via_rule_list string or collection

ARGUMENTS

-verbose

Outputs the various set properties names and their values for each of the via rule along with default information. Name of the properties displayed is same as used in the technology file.

-nosplit

Prevents line splitting if the column overflows. Most information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column. This option prevents line-splitting and facilitates writing software to extract information from the report output.

via_rule_list

Displays information only on the specified via_rule objects. *via_rule_list* contains either a collection of via_rules or a pattern that matches the via_rule names.

This option is mutually exclusive with the -all option, but you must specify one.

DESCRIPTION

This command displays information about via_rules in the current library. By default, the command produces a brief report containing via_rule's name and if they are via_ladder.

EXAMPLES

Below example outputs the report for all via_rule objects.

```
prompt> report_via_rules -all
*****
Report : report_via_rules
Version:
Date  :
*****
Name      Via ladder
-----
VR1       No
VL1       Yes
1
```

Below example outputs the verbose report for via_rule named VL1.

```
prompt> report_via_rules VL1 -verbose
*****
Report : report_via_rules
Version: L-2016.03-SP5-1-BETA
Date  : Sun Oct 23 23:27:33 2016
*****
Name      Via ladder Property name          Value
-----
VL1       Yes    cutLayerNameTblSize        2
            cutLayerNameTbl                VIA1, VIA2
            cutNameTbl                   cut1, cut2
            numCutRowsTbl              2, 2
            numCutsPerRowTbl           2, 2
1
```

SEE ALSO

```
get_via_rules(2)
remove_via_rules(2)
create_via_rule(2)
```

report_voltage_area

Reports the voltage areas in the design. This command is supported only in topographical mode.

SYNTAX

```
status report_voltage_area
  [-name list]
  [-nosplit]
  [-verbose]
  -all | patterns
```

Data Types

```
list      patterns
patterns  list
```

ARGUMENTS

-name *list*

Specifies the names of voltage areas to be reported.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

-verbose

Reports both maximum and minimum operating conditions.

-all

Reports all voltage areas in the design. Voltage areas are created by using the **create_voltage_area** command for the hierarchical blocks.

This option is mutually exclusive with the *patterns* argument.

patterns

Specifies the list of hierarchical cells that each represent a voltage area.

This argument is mutually exclusive with the **-all** option.

DESCRIPTION

This command reports the user-specified voltage area constraints in the design, as specified by the **create_voltage_area** command. If you use the **-all** option, all voltage areas in the design are reported.

The report includes voltage area name, hierarchical blocks associated with voltage area, voltage area geometry, area of the voltage area, and utilization for the voltage area. The area is reported in square microns.

Voltage areas can physically be completely nested, that is, one voltage area lies completely inside another voltage area. When considering the area or utilization of the outside voltage area, the area of the inner voltage area is excluded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example reports the voltage area va1:

```
prompt> report_voltage_area -name va1
*****
Voltage area name va1
Block(s) :PPL_LBUS_CORE
Voltage area geometry : { 19.87 29.86 576.47 1148.89 }
Voltage area region Area : 622854.88
Voltage area Utilization : 0.66
Voltage Area Guard-band (X, Y) : (1, 1)
Voltage Area Max Operating Conditions : 1.16
Voltage Area Min Operating Conditions : 1.16
Voltage Area Max Operating Voltage : 1.160
Voltage Area Min Operating Voltage : 1.160
Voltage Area Max Operating Temperature : 125.000
Voltage Area Min Operating Temperature : -40.000
*****
```

report_wire_load

Displays the characteristics of the wire-load models set on a design or in a library.

SYNTAX

```
status report_wire_load
  [-design design_name]
  [-name model_name]
  [-libraries]
  [-nosplit]
```

Data Types

<i>design_name</i>	string
<i>model_name</i>	string

ARGUMENTS

-design *design_name*

Specifies the design name for which to report wire-load models. The default is to report wire-load models set on the current design.

-name *model_name*

Specifies the name of the wire-load model to report. By default, the tool reports all of the wire-load models set on the specified design.

-libraries

Specifies to also report on wire-load models in the libraries used to link the current design.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the wire load model information is listed in fixed-width columns. If the information for a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

DESCRIPTION

The **report_wire_load** command displays characteristics of wire-load models set on a design, a cluster, or stored in a library. Wire-load models are set on a design or cluster with the **set_wire_load_model** command. Wire-loads models are created for designs and clusters with the **create_wire_load** command.

The wire-load report displays where the model is stored under the Location field. This can be the current design, one of its subdesigns or clusters, or a library linking the current design. The Location is a design, subdesign, or cluster if the model was created with **create_wire_load**, otherwise the Location is a library.

If the wire-load model is in the wire_load format, a wire-load report displays the coefficients to calculate net resistance, capacitance, and area from the net length. The report displays the statistics on how the model was generated. Points indicates how many nets were used to calculate the average capacitance. Standard Deviation is the standard deviation indicating the accuracy of the length and average capacitance. A standard deviation close to zero indicates that all data points reside very close to the average. The standard deviation is the average delta between the model's capacitance for a fanout and each annotated capacitance for the same fanout. The weighted standard deviation is the average percentage of all standard deviation weighted with the number of points for each fanout. This measure characterizes the accuracy of the model created. The wire_load format is generated with the **create_wire_load** command when the **compile_create_wire_load_tablevariable is set to true**.

If **create_wire_load** is used to generate the wire load, and the **compile_create_wire_load_table** variable is set to **true**, the report for the wire-load table does not have the statistics information. The report has the length, capacitance, resistance, and area value listed for each fanout.

EXAMPLES

The following is an example of a wire-load report for the current design. The design has the wire_load format model. The **compile_create_wire_load_table** variable was set to **false** when the **create_wire_load** command was executed.

```
prompt> report_wire_load

report_wrapper_configuration

Reports the wrapper configuration of the current design.

SYNTAX

```
status report_wrapper_configuration  
[-test_mode mode_name_list]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to report. If not specified, the tool reports on the *current_test_mode* that can be displayed by the **current_test_mode** command. If no test modes were created, the tool defaults to the default compression mode. If **all** is specified, the tool displays the global wrapper configuration.

DESCRIPTION

This command reports the wrapper configuration in the following format:

Wrapper Structures	Status
Class:	<class_name>
Style:	<style_name>
Dedicated Cell Type:	<cell_type>
Shared Cell Type:	<cell_type>
Dedicated Cell Design Name:	<design_name>
Shared Cell Design Name:	<design_name>
Register IO Implementation:	<impl_name>
Use Dedicated Wrapper Clock:	<boolean>
Safe State:	<state>
Delay Test:	<boolean>

EXAMPLES

The following example reports the wrapper configuration with a dedicated cell type *WC_D1_S* and safe state 1:

```
prompt> set_wrapper_configuration class core_wrapper \
           -dedicated_cell_type WC_D1_S -safe_state 1

report_write_lib_mode

Reports the **write_lib** mode of the tool, either enabled or disabled.

SYNTAX

status **report_write_lib_mode**

ARGUMENTS

None

DESCRIPTION

This command tells whether the **write_lib** mode of the tool is enabled or disabled. By default, the **write_lib** command is disabled. It can be enabled by using the **enable_write_lib_mode** command.

SEE ALSO

[enable_write_lib_mode\(2\)](#)
[write_lib\(2\)](#)

reset_app_options

Resets previously set values of one or more application options to the unset status.

SYNTAX

Boolean **reset_app_options**
 names

ARGUMENTS

DESCRIPTION

This command resets the values of the specified application options to unset status. The argument of name is mandatory. If the application option is unspecified previously, it will print a warning message.

EXAMPLES

The following example unsets the value of the shell.tmp_dir_path option and the time.enable_preset_clear_arcs option.

```
prompt> reset_app_options {shell.tmp_dir_path time.enable_preset_clear_arcs}
```

The following example produces an error, because there is no 'name' argument.

```
prompt> reset_app_options  
Error: Required 'name' argument was not found. (DCT-300)
```

SEE ALSO

[report_app_options\(2\)](#)
[set_app_options\(2\)](#)

reset_autofix_configuration

Resets the global AutoFix configuration applied to the design for the specified fixing type.

SYNTAX

```
status reset_autofix_configuration  
-type fix_type
```

Data Types

fix_type string

ARGUMENTS

-type *fix_type*

Specifies the fixing type to report. The valid *fix_type* values are:

```
all  
clock  
set  
reset  
xpropagation  
internal_bus  
external_bus  
bidirectional
```

DESCRIPTION

The **reset_autofix_configuration** command resets the global AutoFix configuration applied to the current design for the specified fixing type.

Note that this command only resets the specified fixing type to its default behavior. To disable an AutoFix fixing type completely, use the **set_dft_configuration** command.

EXAMPLES

The following example resets the global clock-fixing specification to the default behavior:

```
prompt> reset_autofix_configuration -type clock
```

SEE ALSO

`insert_dft(2)`
`report_ autofix_configuration(2)`
`set_ autofix_configuration(2)`

reset_autofix_element

Resets a local AutoFix configuration applied to design objects for the specified fixing type.

SYNTAX

```
status reset_autofix_element
      list_of_design_objects
      -type fix_type
```

Data Types

<i>list_of_design_objects</i>	list
<i>fix_type</i>	string

ARGUMENTS

list_of_design_objects

Specifies the list of design objects to reset local fixing configurations for. Wildcards and collections are not supported.

Valid object types depend on the fixing type, as follows:

- clock - cell** (hierarchical and leaf)
- set - cell** (hierarchical and leaf)
- reset - cell** (hierarchical and leaf)
- xpropagation - cell** (hierarchical and leaf)
- internal_bus - net**
- external_bus - net**
- bidirectional - port**

-type *fix_type*

Specifies the fixing type to report. The valid *fix_type* values are:

- all**
- clock**
- set**
- reset**
- xpropagation**
- internal_bus**
- external_bus**
- bidirectional**

DESCRIPTION

The **reset_autofix_element** command resets a local AutoFix configuration applied to design objects for the specified fixing type.

Note that this command only resets the specified fixing type to its default behavior. To disable an AutoFix fixing type completely, use the **set_dft_configuration** command.

EXAMPLES

The following example resets local clock-fixing specifications from cells *u0* and *u1*:

```
prompt> reset_ autofix_ configuration [list u0 u1] -type clock
```

SEE ALSO

`insert_dft(2)`
`report_ autofix_ element(2)`
`set_ autofix_ element(2)`

reset_bsd_configuration

Removes the IEEE 1149.1 or 1149.6 specifications from a boundary-scan design.

SYNTAX

status **reset_bsd_configuration**

ARGUMENTS

The **reset_bsd_configuration** command has no arguments.

DESCRIPTION

The **reset_bsd_configuration** command removes the IEEE 1149.1 or 1149.6 specifications from the current design.

EXAMPLES

The following is an example of the **reset_bsd_configuration** command:

```
prompt> reset_bsd_configuration
```

SEE ALSO

`define_dft_design(2)`
`set_boundary_cell(2)`
`set_bsd_compliance(2)`
`set_bsd_instruction(2)`
`set_bsd_linkage_port(2)`
`set_scan_path(2)`

reset_cell_mode

Resets the modes of the specified instances.

SYNTAX

```
status reset_cell_mode  
    [instance_list]
```

Data Types

instance_list list

ARGUMENTS

instance_list

Specifies a list of instances for which modes are to be reset, which cancels the effects of any previous **set_cell_mode** commands for those instances. This enables all modes for the instances.

DESCRIPTION

The **reset_cell_mode** command resets the modes of the specified instances. If no instances are specified, all instances have their modes reset.

Applying this command to a cell that has no modes has no effect and does not generate any error or warning message.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example resets the modes of all instances whose name matches the description RAM*. You can use the **report_cell_mode** command to report the active mode of each instance that has modes. After executing **reset_cell_mode**, the read and write modes are active for both instances, as shown by the **report_cell_mode** command.

```
prompt> report_cell_mode Uram*
```

```
*****
```

```
Report : mode
```

```
Design : top_design
```

```
*****
```

```
*****
```

SEE ALSO

[report_cell_mode\(2\)](#)
[set_cell_mode\(2\)](#)

reset_clock_gate_latency

Resets all clock-latency values previously specified for or applied to clock-gating cells.

SYNTAX

```
status reset_clock_gate_latency
      [-clock clock_list]
```

Data Types

clock_list list

ARGUMENTS

-clock *clock_list*

Removes latency values only with respect to the specified clocks. If *clock_list* is not specified, latency is removed from all clocks that are currently defined.

DESCRIPTION

This command resets all clock-latency values previously specified for or applied to clock-gating cells. The following three effects are produced by issuing this command:

- Removes the attributes from the source ports of clocks where some clock-latency values may have been previously specified by using **set_clock_gate_latency** command.
- Removes all clock-latency information from clock-gating cells that already have annotated latency values. In this case, it does not differentiate between latencies set using the **set_clock_latency** command and those specified using the **set_clock_gate_latency** command.
- Removes the current fanout mode that was defined by using or not using the **-transitive_fanout** option from **set_clock_gate_latency** command.

Multicorner-Multimode Support

This command is scenario dependent and will affect the current scenario only. You must use this command on each scenario that already had a clock-gate latency setting to remove the settings. This is necessary if you wish to change the fanout mode of your **set_clock_gate_latency** constraint.

EXAMPLES

The following command removes clock-latency values from all clocks currently defined:

```
prompt> reset_clock_gate_latency
```

The following example shows how to reset the clock-gate latency constraint across different scenarios.

```
prompt> current_scenario sc1 \
reset_clock_gate_latency\
current_scenario sc2 \
reset_clock_gate_latency
```

SEE ALSO

[apply_clock_gate_latency\(2\)](#)
[remove_clock_latency\(2\)](#)
[report_clock_gating\(2\)](#)
[set_clock_gate_latency\(2\)](#)

reset_design

Removes all user-specified objects and attributes from the current design, except those defined by using the **set_attribute** command and **UPF** commands.

SYNTAX

status **reset_design**

ARGUMENTS

The **reset_design** command has no arguments.

DESCRIPTION

The **reset_design** command removes all user-specified clocks, path groups, and attributes from the current design, except those defined by using the **set_attribute** command and **UPF** commands. This command returns zero if there is no current design.

WARNING: Executing the **reset_design** has wide-ranging consequences. This command removes all user-specified attributes on the design, with a result that is often equivalent to starting the design process from the beginning. If you want to reset only a few attributes, consider using the **remove_attribute** command. Alternatively, you might be able to remove selected attributes by using the commands that set them. Many attribute-setting commands, such as **set_cost_priority**, have a **-default** option that removes all attributes previously set by that command. See the appropriate man page to determine whether a specific **set_*** command has the **-default** option.

Note that when the **reset_design** command removes user-specified objects such as clocks, collections that contain those objects are implicitly deleted. For more information about collections, see the **collections** man page.

If any generated clocks derived from the library cell have been deleted by the **remove_generated_clock** command, the **reset_design** command restores them to their original undeleted state.

The **reset_design** command does not remove UPF constraints. To remove UPF constraints, use the **remove_upf** command instead.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example resets the current design:

```
prompt> reset_design
1
```

The following example illustrates how the **reset_design** command can implicitly delete collections:

```
prompt> set a [get_clocks]
{clk}
prompt> query_objects $a
{clk}
prompt> reset_design
1
prompt> query_objects $a
Error: No such collection '_sel126' (SEL-001)
```

reset_dft_clock_controller

Resets the on-chip clocking controller specification for the current design.

SYNTAX

```
status reset_dft_clock_controller
      [-test_mode mode_name_list]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to which the **reset_dft_clock_controller** command applies.

DESCRIPTION

This command resets the on-chip clocking controller specification for the current design.

Use the **set_dft_clock_controller** command to specify an on-chip clocking controller specification. Use the **report_dft_clock_controller** command to report the current on-chip clocking controller specification.

For more information, see the man page for the **set_dft_clock_controller** command.

EXAMPLES

In the following example, the current on-chip clocking controller specification is reset:

```
prompt> reset_dft_clock_controller
```

SEE ALSO

report_dft_clock_controller(2)
set_dft_clock_controller(2)

reset_dft_clock_gating_configuration

Resets the DFT clock-gating configuration for the current design.

SYNTAX

```
status reset_dft_clock_gating_configuration
```

ARGUMENTS

The **reset_dft_clock_gating_configuration** command takes no arguments.

DESCRIPTION

The **reset_dft_clock_gating_configuration** command resets the DFT clock-gating configuration for the current design.

EXAMPLES

In the following example, the command resets the DFT clock-gating configuration for the current design:

```
prompt> reset_dft_clock_gating_configuration
```

SEE ALSO

```
set_dft_clock_gating_configuration(2)  
report_dft_clock_gating_configuration(2)
```

reset_dft_configuration

Resets the DFT configuration for the current design specified by the **set_dft_configuration** command.

SYNTAX

status **reset_dft_configuration**

ARGUMENTS

The **reset_dft_configuration** command has no arguments.

DESCRIPTION

The **reset_dft_configuration** command resets the DFT configuration for the current design.

EXAMPLES

In the following example, the command resets the current design to the default configuration:

```
prompt> reset_dft_configuration
```

SEE ALSO

insert_dft(2)
report_dft_configuration(2)
set_dft_configuration(2)

reset_dft_drc_rules

Resets the DFT DRC rule specifications to their default behaviors.

SYNTAX

```
status reset_dft_drc_rules
  [-violation drc_list]
  [-cell cell_list]
```

Data Types

drc_list string
cell_list string

ARGUMENTS

-violation *drc_list*

Restricts the reset to the specified DRC violations.

-cell *cell_list*

Restricts the reset to the specified cells.

DESCRIPTION

The **reset_dft_drc_rules** command resets any modifications to how certain DRC rule violations affect DFT insertion that were applied by the **set_dft_drc_rules** command. The list of violation IDs supported by this command is:

- TEST-504 (warning) Cell %s has constant 0 value.
- TEST-505 (warning) Cell %s has constant 1 value.
- D17 (warning) D17 Clock input I of <type> S couldn't capture data.

By default, the command resets all DFT DRC specifications applied by the **set_dft_drc_rules** command. You can use the **-violation** and **-cell** options to restrict the scope of the reset.

Use the **set_dft_drc_rules** command to apply DFT DRC rule specifications. Use the **report_dft_drc_rules** command to display the DFT DRC rule specifications that have been applied.

EXAMPLES

The following example removes all DFT DRC specifications that apply to the TEST-504 and TEST-505 violations:

```
prompt> reset_dft_drc_rules -violation {TEST-504 TEST-505}
```

SEE ALSO

`dft_drc(2)`

`preview_dft(2)`
`report_dft_drc_rules(2)`
`set_dft_drc_rules(2)`

reset_dft_insertion_configuration

Resets the DFT insertion configuration for the current design.

SYNTAX

```
status reset_dft_insertion_configuration
```

ARGUMENTS

The **reset_dft_insertion_configuration** command has no arguments.

DESCRIPTION

This command resets the existing insertion configuration to its defaults. The map effort default is medium, synthesis optimization is all, route_scan_enable is TRUE, route_scan_clock is TRUE, route_scan_serial is TRUE, preserve_design_name is FALSE, and the unscan option is FALSE. Use the **report_dft_insertion_configuration** command to display the current DFT insertion configuration of the design.

Use the **reset_dft_insertion_configuration** command to remove the current DFT insert configuration from the design.

EXAMPLES

The following example shows how to reset the insert DFT configuration:

```
prompt> reset_dft_insertion_configuration
```

SEE ALSO

`insert_dft(2)`
`report_dft_insertion_configuration(2)`
`set_dft_insertion_configuration(2)`

reset_ieee_1500_configuration

Resets the IEEE 1500 configuration for the current design.

SYNTAX

status **reset_ieee_1500_configuration**

ARGUMENTS

The **reset_ieee_1500_configuration** command has no arguments.

DESCRIPTION

The **reset_ieee_1500_configuration** command resets the IEEE 1500 configuration for the current design.

EXAMPLES

In the following example, the command resets the current design to the default IEEE 1500 insertion configuration:

```
prompt> reset_ieee_1500_configuration
```

SEE ALSO

`report_ieee_1500_configuration(2)`
`set_ieee_1500_configuration(2)`

reset_logic_lock_configuration

Resets the logic_lock configuration for the current design.

SYNTAX

status **reset_logic_lock_configuration**

ARGUMENTS

None

DESCRIPTION

This command resets the logic_lock configuration with the following values:

Logic Lock Configuration	Status

reset_logicbist_configuration

Resets the LogicBIST compression configuration to the default configuration values for the current design.

SYNTAX

status **reset_logicbist_configuration**

ARGUMENT

The **reset_logicbist_configuration** command has no arguments.

DESCRIPTION

Use the **reset_logicbist_configuration** command to reset the LogicBIST compression configuration to the default configuration values for the design.

EXAMPLES

```
prompt> reset_logicbist_configuration
Accepted LogicBIST specification for design 'CORE'.
1
```

SEE ALSO

`set_logicbist_configuration(2)`
`report_logicbist_configuration(2)`

`preview_dft(2)`

reset_mode

Resets the modes of the specified instances.

SYNTAX

```
status reset_mode
      [instance_list]
```

Data Types

instance_list list

ARGUMENTS

instance_list

Specifies a list of instances for which modes are to be reset. If using DCL, all modes except for the default are disabled. If using .lib, all modes of these instances are enabled. No error occurs if you specify to reset the modes on a cell that has no modes.

DESCRIPTION

The **reset_mode** command resets the modes of the specified instances. If no instances are specified, all instances have their modes reset. If using DCL, all modes except for the default are disabled. If using .lib, all modes of these instances are enabled. This is the default behavior when no modes are specified with the **set_mode** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example resets the modes of all instances whose name matches the description RAM*. You can use the **report_mode** command to report the active mode of each instance that have modes. Before executing **reset_mode**, instance *Uram1/core* was only in read mode, and instance *Uram2/core* was only in write mode. After executing **reset_mode**, the read and write modes are active for both instances, as shown by the **report_mode** command.

```
prompt> report_mode Uram*
*****
Report : mode
Design : top_design
```

```
*****
```

Cell	Mode(Group)	Status
Uram1/core(RAM2_core)	read(rw)	ENABLED
write(rw)	disabled	

Uram2/core(RAM2_core)	read(rw)	disabled
write(rw)	ENABLED	

```
*****
```

prompt> **reset_mode RAM***

prompt> **report_mode RAM***

```
*****
```

Report : mode

Design : top_design

```
*****
```

Cell	Mode(Group)	Status

reset_path

Resets the specified paths to single cycle timing.

SYNTAX

```
status reset_path
  [-setup | -hold]
  [-rise | -fall]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
```

Data Types

<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list

ARGUMENTS

-setup

Specifies that the setup checking (maximum delay) is reset to single cycle behavior.

-hold

Specifies that the hold checking (minimum delay) is reset to single cycle behavior.

-rise

Specifies that the rising path delays are reset to single cycle behavior. The default is that both rising and falling delays are affected.

-fall

Specifies that falling path delays are set to single cycle behavior. The default is that both rising and falling delays are affected.

-from *from_list*

Specifies the names of clocks, pins, or cells to use to find path startpoints. If a specified object is a clock, all flip-flops, latches, and

primary inputs related to that clock are used as path startpoints.

-rise_from *rise_from_list*

Specifies the names of clocks, pins, or cells to use to find path startpoints. This option is similar to the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Specifies the names of clocks, pins, or cells to use to find path startpoints. This option is similar to the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Specifies a list of path throughpoints (port, pin, or leaf cell names) of the current design. The **reset_path** applies only to paths that pass through one of the points in the *through_list*. If more than one object is included, the objects must be enclosed either in quotation marks ("") or in braces ({}). If you specify the **-through** option multiple times, the **reset_path** applies to paths that pass through a member of each *through_list* in the order the lists are given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the **reset_path** applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Specifies a list of path throughpoints (port, pin, or leaf cell names) of the current design. This option is similar to the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Specifies a list of path throughpoints (port, pin, or leaf cell names) of the current design. This option is similar to the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies the names of clocks, pins, or cells to use to find path endpoints. If a specified object is a clock, all flip-flops, latches, and primary outputs related to that clock are used as path endpoints.

-rise_to *rise_to_list*

Specifies the names of clocks, pins, or cells to use to find path endpoints. This option is similar to the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Specifies the names of clocks, pins, or cells to use to find path endpoints. This option is similar to the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

DESCRIPTION

This command specifies that designated timing paths in the current design are restored to the default single cycle behavior. The **reset_path** command is used to undo the effect of the **set_multicycle_path**, **set_false_path**, **set_max_delay**, and **set_min_delay** commands. Remove the attributes set by those commands with **reset_path**. Note that a general **reset_path** command removes the

effect of matching general or specific point-to-point exception commands.

If you do not specify **-setup** or **-hold**, both are restored to the default behavior. The default is a setup relation of one cycle and a hold relation of 0 cycles. A hold value of 0 means that hold is checked one active edge before the setup data at the destination register.

If you specify **-setup**, only setup (maximum delay) checking is reset to the default behavior. If you specify **-hold**, only hold (minimum delay) checking is reset to the default behavior.

There is separate setup and hold information for rise and fall. In most cases, these are reset together. The **-rise** or **-fall** options are used to reset only one or the other.

To disable setup or hold calculations for paths, use the **set_false_path** command.

To see the nondefault path requirements on the design, use the **report_timing_requirements** command.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example resets the timing relation between *ff1/CP* and *ff2/D* to the default single cycle:

```
prompt> reset_path -from {ff1/CP} -to {ff2/D}
```

This example resets the rising delay to single cycle for all paths ending at *latch2d*:

```
prompt> reset_path -rise -to {latch2d}
```

This example shows how a specific and general point-to-point exception is set and then removed:

```
prompt> set_false_path 2 -from A -to Z
```

```
prompt> set_max_delay 15 -to Z
```

```
prompt> reset_path -to Z /* removes all exceptions to Z */
```

reset_physical_constraints

Resets all current physical constraints.

SYNTAX

status **reset_physical_constraints**

ARGUMENTS

The **reset_physical_constraints** command has no arguments.

DESCRIPTION

The **reset_physical_constraints** command resets the physical constraints settings that were previously applied to the design. After this command is executed, the netlist does not have any physical information.

EXAMPLES

The following command resets the physical constraints:

```
prompt> reset_physical_constraints
```

SEE ALSO

`extract_physical_constraints(2)`
`report_physical_constraints(2)`
`write_physical_constraints(2)`

reset_pipeline_scan_data_configuration

Resets the pipeline scan data configuration specified by the **set_pipeline_scan_data_configuration** command.

SYNTAX

```
status reset_pipeline_scan_data_configuration
```

ARGUMENTS

The **reset_pipeline_scan_data_configuration** command has no arguments.

DESCRIPTION

This command resets the the pipeline scan data configuration for the current design.

EXAMPLES

The following example resets the pipeline scan data configuration of the current design to the default:

```
prompt> reset_pipeline_scan_data_configuration
```

SEE ALSO

[set_pipeline_scan_data_configuration\(2\)](#)

reset_power_derate

Resets the power derating factors for either the current design, a list of cells, library cells or all cells in a power group in the current design.

SYNTAX

```
status reset_power_derate
  [-scenarios scenario_list]
  [-groups group_names]
  [object_list]
```

Data Types

<i>scenario_list</i>	list
<i>group_names</i>	list
<i>object_list</i>	list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is to be reset. If no scenario is specified the current_scenario is used.

-groups *group_names*

Specifies the power group for which the derate factor is to be reset. The derate factors are reset for each cell object in the power group. Note groups and object_list are mutually exclusive option.

object_list

Specifies the list of cells or library cells on which the power derating factors are reset. Note groups and object_list are mutually exclusive option.

DESCRIPTION

Invoke this command with no arguments to reset all derate (to the default of 1.0). This includes both derating factors set globally on the design and those set on specific instances in the current design. If the command is called with a list of objects, only the power derating factors on the specified objects are reset. After a reset_power_derate command is applied to an object, the power derating factors of all power components, including leakage, internal and switching power are reset.

Note that power derating factors set specifically on an object are not overwritten by a set or reset command on its parent hierarchical cell. To reset the power derating factors set specifically on the child cells, include them in the object list of the command.

The -groups options allows to reset the derate factors of cells only in the specified group.

Heterogeneous collections of objects can be combined and passed to this command.

Multicorner-Multimode Support

EXAMPLES

The following command resets both power derating factors set globally and those set on specific instances in the design for the scenario SCN1.

```
prompt> reset_power_derate -scenario SCN1
```

The following example resets the power derating factors set on cell U1 for the current scenario.

```
prompt> reset_power_derate [get_cell U1]
```

The following command resets the power derating factors set on all cells matching "***"

```
prompt> reset_power_derate [get_cells *]
```

The following example resets the power derating factors set on all instances of library cell IV in the library MY_LIB.

```
prompt> reset_power_derate [get_lib_cells MY_LIB/IV]
```

Assuming that the hierarchical cell H1 contains a cell U1, then the following command resets the derate factors set on U1. As a result, U1 inherits the derate factors that are set on H1.

```
prompt> reset_power_derate [get_cells H1/U1]
```

SEE ALSO

`set_power_derate(2)`
`get_power_derate(2)`

reset_scan_compression_configuration

Resets the scan compression configuration for the current design.

SYNTAX

```
status reset_scan_compression_configuration
```

ARGUMENTS

The **reset_scan_compression_configuration** command has no arguments.

DESCRIPTION

This command resets the current scan compression configuration on the design.

EXAMPLES

The following example shows the **reset_scan_compression_configuration** command:

```
prompt> reset_scan_compression_configuration
Accepted scan compression specification for design 'des_unit'.
1
```

SEE ALSO

`preview_dft(2)`
`report_scan_compression_configuration(2)`
`set_scan_compression_configuration(2)`

reset_scan_configuration

Resets the scan configuration for the current design.

SYNTAX

```
status reset_scan_configuration  
[-test_mode mode_name_list]
```

Data Types

mode_name_list list

ARGUMENTS

-test_mode *mode_name_list*

Specifies the test mode(s) to which the **reset_scan_configuration** command applies. If this option is not specified, the default is to reset the current test mode. If you specify **all**, the global configuration is reset, but any mode-specific configurations are retained.

DESCRIPTION

The **reset_scan_configuration** command resets the current scan configuration from the design.

EXAMPLES

The following example shows how to reset the scan configuration:

```
prompt> reset_scan_configuration
```

SEE ALSO

insert_dft(2)
report_scan_configuration(2)
set_scan_configuration(2)

reset_security_configuration

Resets the security configuration for the current design.

SYNTAX

status **reset_security_configuration**

ARGUMENTS

None

DESCRIPTION

This command resets the security configuration with the following values:

Security Configuration	Status
Logic Lock:	Disable
Obfuscation:	Disable
Watermark:	Disable
Security Lock:	Disable
Input Files:	
Output Files:	
Top Module:	

EXAMPLES

The following example resets the security configuration for the current design. A report command follows that shows the security configuration values after the reset.

```
prompt> reset_security_configuration

reset_switching_activity

Removes switching activity information from all objects in the current design.

SYNTAX

```
status reset_switching_activity
  [-verbose]
  [cell_list]
```

Data Types

cell_list list

ARGUMENTS

-verbose

Prints more information messages than are printed by default.

cell_list

Removes the switching activity information from all objects except top-level pins within the specified hierarchical cells.

DESCRIPTION

By default, this command enables you to remove the annotated switching activity throughout the entire design. However, if the *cell_list* option is provided, then this command removes the annotated switching activity of all objects within the specified cells except for their top-level pins.

To remove the annotated switching activity for specific nets, ports, and pins, use the **set_switching_activity** command. See the **set_switching_activity** man page for additional details.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes the switching activity information from the *TOP_MULT* design:

```
prompt> current_design TOP_MULT
```

```
prompt> reset_switching_activity
```

SEE ALSO

`read_saif(2)`
`set_switching_activity(2)`

reset_test_mode

Resets the test mode for the current design.

SYNTAX

status **reset_test_mode**

ARGUMENTS

The **reset_test_mode** command has no arguments.

DESCRIPTION

The **reset_test_mode** command resets the current test mode of the current design to the default test mode.

EXAMPLES

The following example resets the current test mode:

```
prompt> reset_test_mode
Current test mode is reset to default
1
```

SEE ALSO

`current_test_mode(2)`
`define_test_mode(2)`
`remove_test_mode(2)`

reset_test_point_configuration

Resets the automatic test point insertion configuration for the current design.

SYNTAX

```
status reset_test_point_configuration
```

ARGUMENTS

The **reset_test_point_configuration** command has no arguments.

DESCRIPTION

The **reset_test_point_configuration** command resets all automatic test point configuration options, set by the **set_test_point_configuration** command, to their default values.

If automatic test point insertion is enabled with the **set_dft_configuration -test_points enable** command, the default is to perform pattern reduction test point insertion. The **reset_test_point_configuration** command does not disable automatic test point insertion. To disable automatic test point insertion, use the following command:

```
prompt> set_dft_configuration -test_points disable
```

EXAMPLES

The following example shows how to reset the test point configuration to the default specifications:

```
prompt> reset_test_point_configuration
```

SEE ALSO

`insert_dft(2)`
`report_test_point_configuration(2)`
`set_test_point_configuration(2)`

reset_testability_configuration

Resets the testability configuration for the current design.

SYNTAX

```
status reset_testability_configuration
      [-type type]
```

ARGUMENTS

DESCRIPTION

The **reset_testability_configuration** command resets the current testability configuration for the current design.

SEE ALSO

[insert_dft\(2\)](#)
[report_testability_configuration\(2\)](#)
[set_testability_configuration\(2\)](#)

reset_timing_derate

Removes all derating factors set on the current design and libraries.

SYNTAX

```
string reset_timing_derate
      [-pocvm_guardband]
      [-pocvm_coefficient_scale_factor]
      [-increment]
      [-multiply]
```

ARGUMENTS

-pocvm_guardband

Removes only the POCV guardband derating factors previously set with the **-pocvm_guardband** option of the **set_timing_derate** command.

-pocvm_coefficient_scale_factor

Removes only the POCV coefficient scaling factors previously set with the **-pocvm_coefficient_scale_factor** option of the **set_timing_derate** command.

DESCRIPTION

This command removes all timing derating factors from the current design or libraries previously set with the **set_timing_derate** command. After the command has been run, the result is the same as if timing derating factors had never been set.

Use the **-aocvm_guardband** option to remove only the AOCV guardband derating factors.

Use the **-pocvm_guardband** or **-pocvm_coefficient_scale_factor** option to remove only those specific types of POCV derating factors.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example removes derating factors for all of the objects in the current design or libraries.

```
prompt> reset_timing_derate
```

The following example removes only the guardband derating factors from the objects in the current design and libraries. After that, the **report_timing_derate -aocvm_guardband** command shows no guardband derating values.

```
prompt> reset_timing_derate -aocvm_guardband
prompt> report_timing_derate -aocvm_guardband
```

```
*****
```

```
Report : timing derate
-aocvm_guardband
```

```
Design : top

reset_watermark_configuration

Resets the watermark configuration for the current design.

SYNTAX

status **reset_watermark_configuration**

ARGUMENTS

None

DESCRIPTION

This command resets the watermark configuration with the following values:

Watermark Configuration	Status
-----	-----
Exec Name:	
Parameters:	
Level:	
Location:	
Exclude Cells:	

EXAMPLES

The following example resets the watermark configuration for the current design. A report command follows that shows the watermark configuration values after the reset.

```
prompt> reset_watermark_configuration
1
```

```
prompt> report_watermark_configuration
```

```

reset_wrapper_configuration

Resets the wrapper configuration for the current design.

SYNTAX

```
status reset_wrapper_configuration
      [-test_mode mode_name]
```

Data Types

mode_name string

ARGUMENTS

-test_mode *mode_name*

Specifies the test mode to which the **reset_wrapper_configuration** command applies. The default is **all**, which resets the global wrapper configuration, but keeps any mode-specific configurations.

DESCRIPTION

This command resets the wrapper configuration with the following values:

Wrapper Structures	Status
Class:	Core Wrapper
Style:	Dedicated Wrapper
Dedicated Cell Type:	WC_D1
Shared Cell Type:	WC_S1
Dedicated Cell Design Name:	
Shared Cell Design Name:	
Register IO Implementation:	Swap
Use Dedicated Wrapper Clock:	False
Safe State:	None
Delay Test:	False

EXAMPLES

The following example resets the wrapper configuration for the current design. A report command follows that shows the wrapper configuration values after the reset.

```
prompt> reset_wrapper_configuration

resize_polygon

Pushes the edges of the specified polygon inward or outward by the specified direction and distance.

SYNTAX

```
list resize_polygon
  polygons
  -size size
  -size_left size
  -size_right size
  -size_bottom size
  -size_top size
```

Data Types

polygons polygon list or collection
size double

ARGUMENTS

polygons

Specifies the list or collection of input polygons whose edges are pushed inward or outward by the specified direction and distance. You can specify a single polygon or multiple polygons.

To specify a polygon as a list, enter a sequence of X-Y coordinate pairs that represent the successive vertices of the polygon, using the following format:

$\{\{x_1\ y_1\}\ \{x_2\ y_2\}\ \dots\ \{x_N\ y_N\}\ \{x_1\ y_1\}\}$

The coordinate unit size is specified in the technology file; typically it is microns.

Polygons must be rectilinear, so the X coordinate of each data point must match the X coordinate of a neighboring data point, and the Y coordinate must match the Y coordinate of the other neighboring data point. The last point in the list must be the same as the first.

Instead of specifying lists of coordinates, you can specify a polygon collection. In that case, the output of the command is also a collection.

-size *size*

Specifies the distance that the edges of the polygon are moved. Enter a negative value to push the edges inward or a positive number to push the edges outward. The coordinate unit is specified in the technology file; typically it is microns.

-size_left *size*

Specifies the distance that the left-facing edges are moved. Enter a negative value to push these edges inward or a positive number to push these edges outward.

-size_right *size*

Specifies the distance that the right-facing edges are moved.

-size_bottom size

Specifies the distance that the bottom-facing edges are moved.

-size_top size

Specifies the distance that the top-facing edges are moved.

DESCRIPTION

This command pushes the edges of the specified polygon inward or outward by the specified distance and returns the list of polygons whose edges have been moved. Polygons can be represented as lists of coordinates or as a collection. Before using this command, the Milkyway design library must be open.

The **-size** option resize each polygon in all four directions, whereas the **-size_left**, **-size_right**, **-size_bottom**, and **-size_top** options resize each polygon only in the specified direction. You can use any combination of these four options together at the same time, but not with **-size** option.

If you specify a positive size value, the edges of the polygon are pushed outward to increase the size of the polygon, which is called oversizing the polygon. For example, if you use **-size_left 10** to size a polygon, the left edges of the polygon are moved outward (left) by 10 units. Oversizing fills any gaps that are less than two times the distance unit.

When you oversize a polygon, the command returns a single polygon. You can directly pass this result to another polygon command such as **convert_from_polygons**, **get_polygon_area**, **resize_polygon**, or **compute_polygons**.

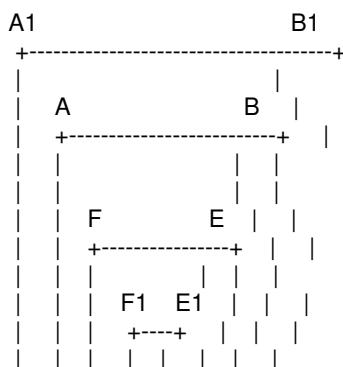

If you specify a negative size value, the edges of the polygon are pushed inward and the size of the polygon is reduced, which is called undersizing the polygon. For example, if you use **-size_left -10** to size a polygon, the left edges of the polygon are moved inward (right) by 10 units.

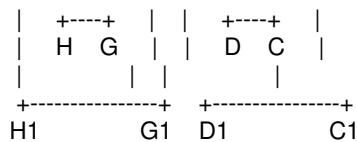

When you undersize a polygon, the result can be a disjoint rectilinear region that is represented by more than one polygon. Because the polygon commands take a single polygon as input, you cannot directly pass the result as a parameter to another polygon command. Instead, you must use a Tcl list command, such as the **foreach** or **lindex** command, to extract each polygon from the returned list, and then pass each polygon to the polygon command.

If you use more than one of the **-size_left**, **-size_right**, **-size_bottom**, or **-size_top** options at the same time, the size values should be consistently all positive or all negative, so that either oversizing or undersizing is performed in all directions that are being modified.

EXAMPLES

The following example oversizes the polygon A-B-C-D-E-F-G-H-A polygon by 10 units, producing the new polygon B1-C1-D1-E1-F1-G1-H1-A1-B1.

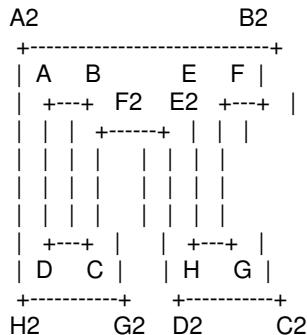

```

prompt> resize_polygon {{10 40} {60 40} {60 10} {50 10} {50 30} \
{20 30} {20 10} {10 10} {10 40}} -size 10
{{70.000 50.000} {70.000 0.000} {40.000 0.000} {40.000 20.000} {30.000 20.000} \
{30.000 0.000} {0.000 0.000} {0.000 50.000} {70.000 50.000}}

```

The following example undersizes the polygon A2-B2-C2-D2-E2-F2-G2-H2-A2 polygon by 10 units, producing two polygons, A-B-C-D-A and E-F-G-H-E.

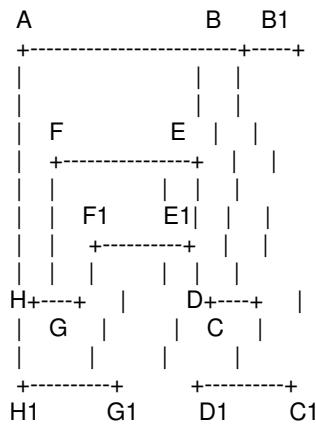

```

prompt> resize_polygon {{0 45} {80 45} {80 0} {50 0} {50 30} \
{30 30} {30 0} {0 0} {0 45}} -size -10
{{10.000 35.000} {20.000 35.000} {20.000 10.000} {10.000 10.000} {10.000 35.000} \
{60.000 35.000} {70.000 35.000} {70.000 10.000} {60.000 10.000} {60.000 35.000}}

```

The following example oversizes the polygon A-B-C-D-E-F-G-H-A polygon on the right by 10 units and on the bottom by 10 units, producing the new polygon B1-A-H1-G1-F1-E1-D1-C1-B1

```

prompt> resize_polygon {{10 40} {60 40} {60 10} {50 10} {50 30} \
{20 30} {20 10} {10 10} {10 40}} -size_right 10 -size_bottom 10
{{70.000 40.000} {10.000 40.000} {10.000 0.000} {30.000 0.000} {30.000 20.000} \
{50.000 20.000} {50.000 0.000} {70.000 0.000} {70.000 40.000}}

```

The following example passes the result of the **resize_polygon** command to another **resize_polygon** command. Note that undersizing by 10 and then oversizing by 10 does not restore the original polygon because of gap filling performed during undersizing.

```

prompt> resize_polygon -size -10 \
[resize_polygon {{10 40} {50 40} {50 10} \
{40 10} {40 30} {20 30} {20 10} {10 10} {10 40}} -size 10]
{{10.000 40.000} {50.000 40.000} {50.000 10.000} {10.000 10.000} {10.000 40.000}}

```

SEE ALSO

rewire_clock_gating

Changes the clock-gating cell implemented by the tool for a particular gated cell.

SYNTAX

```
status rewire_clock_gating
  [-gating_cell new_clock_gating_cell]
  [-gated_objects gated_objects_list]
  [-balance_fanout]
  [-undo]
  [-verbose]
```

Data Types

new_clock_gating_cell string
gated_objects_list list

ARGUMENTS

-gating_cell *new_clock_gating_cell*

Specifies a new clock-gating cell to be used to gate the cells or pins on the *gated_objects_list*.

-gated_objects *gated_objects_list*

Specifies that all registers, clock gates, and clock pins of gated modules in the *gated_objects_list* are gated by the *new_clock_gating_cell*.

-balance_fanout

Specifies that the clock gates and registers must be rewired to meet the minimum and maximum fanout constraints specified with the **set_clock_gating_style** command.

-undo

Indicates that directives specified by previously-executed **rewire_clock_gating** commands are to be removed.

-verbose

Specifies that additional information is to be displayed as the command executes.

DESCRIPTION

This command changes the clock-gating cell for the specified gated cell. The cell can be a register, a clock gate, or a gated module.

The tool performs clock gating at the RTL level with the use of the **compile_ultra -gate_clock** command. If you use the

set_clock_gating_style command with the **-max_fanout** option, the tool limits the fanout of individual clock-gating elements created by **compile_ultra-gate_clock**. The tool duplicates clock-gating logic to ensure that the fanout of each element is bound by the constraint specified with the **-max_fanout** option. The clock-gating cells created to satisfy the **-max_fanout** constraint are logically equivalent. The **rewire_clock_gating** command directs the tool to move a clock-gated cell from one clock-gating cell to another logically-equivalent clock-gating cell.

The **rewire_clock_gating** command directs the tool to perform the actual circuit modifications to rewire clock gating in the design. You can undo the effect of any prior **rewire_clock_gating** command by using the **-undo** option. The **-undo** option deletes the directives previously specified by the **rewire_clock_gating** command.

In some cases, the tool could delete or add registers. This might alter the balanced fanout of clock gates. When invoked with the **-balance_fanout** option, **rewire_clock_gating** attempts to reinstate the clock gate fanout limits by splitting, merging or rewiring.

If multibit registers have to be rewired, fanout is computed by adding the total bit-width of each multibit register. For instance, if a clock gate is gating a 4-bit register and a 2-bit register, the total fanout of this clock gate is NOT 2, but 6.

When using this option, running **compile-incremental** might not be necessary. Under some circumstances, a few GTECH cells might be introduced. In this case, the **rewire_clock_gating** command prints a message that running **compile-incremental** is necessary. When the command is going to be invoked from a script (non-interactive mode) it is best to add **compile-incremental** after **rewire_clock_gating -balance_fanout**. This option can also be used if you require the clock-gate fanout limits to be changed after the **compile_ultra-gate_clock** command. Invoke this command after the **compile** command. Note that this command has no effect on multilevel and module clock gates.

Because rewiring gated registers alters the connections of the clock-gating cell that gates the registers, any path-based timing exception that passes through the old clock-gating cell to a gated register is no longer relevant and is lost.

If either the *new_clock_gating_cell* or any of the *gated_register_list* is marked for removal of clock gating with the **remove_clock_gating** command, the rewiring directive is not honored.

This command has no effect on a clock-gating cell or its gated registers if the clock gate or its parent hierarchical cell is marked as **dont_touch** with the **set_dont_touch** command.

EXAMPLES

The following example provides a directive to change the clock-gating cell gating the *pipeline_reg_A[0]* and *pipeline_reg_A[3]* registers to the *clk_gate_pipeline_reg_A_0* clock-gating cell:

```
prompt> rewire_clock_gating -gating_cell \
    clk_gate_pipeline_reg_A_0 -gated_registers \
    {pipeline_reg_A[0], pipeline_reg_A[3]}
```

The following example provides a directive to remove the previous directive and to change the clock-gating cell gating the *pipeline_reg_A[0]* and *pipeline_reg_A[3]* registers:

```
prompt> rewire_clock_gating -undo \
    -gated_registers {pipeline_reg_A[0] pipeline_reg_A[3]}
```

The following example directs the **rewire_clock_gating** command to change the minimum and maximum fanout limits to new values:

```
prompt> set_clock_gating_style -min 2 -max 128
prompt> rewire_clock_gating -balance_fanout
```

```

rp_group_inclusions

Returns a collection of relative placement groups that are directly included in the specified relative placement groups.

SYNTAX

```
collection rp_group_inclusions  
  [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups in which to search for directly-included relative placement groups.

If you do not specify this argument, the tool searches all relative placement groups for directly-included relative placement groups.

DESCRIPTION

The **rp_group_inclusions** command returns a collection containing all relative placement groups that are directly included in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all included relative placement groups. This command is supported only for designs that do not contain multiply-instantiated designs.

A group directly includes another group if the group was added by using the **add_to_rp_group -hierarchy** command without also using the **-instance** option.

If no groups are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_inclusions** command:

```
prompt> get_rp_groups  
{b::top a0::a0_group b::u_top/a1_group
```

```
b::u_top/a1_group_include b::u_nxt/a1_group  
b::a1_group_include a1::a1_group}
```

```
prompt> rp_group_inclusions  
{b::u_top/a1_group b::u_nxt/a1_group}
```

```
prompt> rp_group_inclusions a0::a0_group
```

```
prompt> rp_group_inclusions top  
{b::u_top/a1_group b::u_nxt/a1_group}
```

```
prompt> remove_rp_groups -all -quiet  
1
```

```
prompt> rp_group_inclusions
```

rp_group_instantiations

Returns a collection of relative placement groups that are instantiated in any of the specified relative placement groups.

SYNTAX

```
collection rp_group_instantiations  
  [rp_groups]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups in which to search for instantiated relative placement groups.

If you do not specify this argument, the tool searches all relative placement groups for instantiated relative placement groups.

DESCRIPTION

The **rp_group_instantiations** command returns a collection containing all relative placement groups that are instantiated in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all instantiated relative placement groups.

This command is supported only for designs that do not contain multiply-instantiated designs.

A group instantiates another group if the group was added by using the **add_to_rp_group -hierarchy -instance** command.

If no groups are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_instantiations** command:

```
prompt> get_rp_groups
```

```
{b::top a0::a0_group b::u_top/a1_group  
b::u_top/a1_group_include b::u_nxt/a1_group  
b::a1_group_include a1::a1_group}  
  
prompt> rp_group_instantiations  
{a0::a0_group}  
  
prompt> rp_group_instantiations b::a1_group_include  
{a1::a1_group}  
  
prompt> remove_rp_groups -all -quiet  
1  
  
prompt> rp_group_instantiations
```

rp_group_references

Returns a collection of cells that are directly included in the specified relative placement groups.

SYNTAX

```
collection rp_group_references
  [rp_groups]
  [-leaf | -instance | -all_leaf]
```

Data Types

rp_groups list or collection

ARGUMENTS

rp_groups

Specifies the relative placement groups in which to find directly-included cells.

-leaf | -instance | -all_leaf

Specifies to return only leaf cells, only hierarchical cells, or all leaf cells in the group and down the hierarchy. By default, both leaf and hierarchical cells are returned.

DESCRIPTION

The **rp_group_references** command returns a collection containing all cells that are directly included in the relative placement groups specified in *rp_groups*. If you do not specify *rp_groups*, the command returns a collection containing all cells that are directly included in any relative placement group.

This command is supported only for designs that do not contain multiply-instantiated designs.

When you specify the **-leaf** option, only leaf cells that are contained in the specified relative placement groups are returned. When you specify the **-instance** option, only hierarchical cells are returned. When you specify the **-all_leaf** option, all cells that are in the specified relative placement groups and their hierarchical relative placement groups are returned.

An included relative placement group, unlike an instantiated relative placement group, does not have a hierarchical cell associated with it, so the **rp_group_references** command does not report included hierarchical relative placement groups.

A group directly includes a leaf cell if the cell was added to that group using the **add_to_rp_group -leaf** command.

A group directly includes a hierarchical cell if the cell was used to hierarchically instantiate another group using the **add_to_rp_group -instance** command.

If no cells are found, an empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **rp_group_references** command:

```
prompt> get_rp_groups
{b::top a0::a0_group b::u_top/a1_group
 b::u_top/a1_group_include b::u_nxt/a1_group
 b::a1_group_include a1::a1_group}

prompt> rp_group_references
{u_mid u_bot}

prompt> all_rp_references u_0 -design a0
{a0::a0_group}

prompt> rp_group_references a0::a0_group
{u_bot/u_1 u_bot/u_0}

prompt> remove_rp_groups -all -quiet
1

prompt> rp_group_references
```

The following examples show the difference between the **-leaf** and **-all_leaf** options. The top relative placement group D::top directly includes leaf cells *U1*, *U2*, *U3*, *U4*, and relative placement group D::mid. The D::mid relative placement group directly includes leaf cells *U11*, *U12*, *U15*, and *U16*.

```
prompt> rp_group_references -leaf D::top
{ U1, U2, U3, U4}

prompt> rp_group_references -all_leaf D::top
{ U1, U2, U3, U4, U11, U12, U15, U16}
```

run_test_point_analysis

Runs SpyGlass DFT testability analysis.

SYNTAX

status **run_test_point_analysis**

ARGUMENTS

This command has no arguments.

DESCRIPTION

The **run_test_point_analysis** command performs SpyGlass DFT analysis to determine the test points to be inserted by the **testability** DFT client.

Testability analysis is configured by the **set_testability_configuration** command. For details, see that man page.

This command is run after pre-DFT DRC, but before DFT preview and insertion.

Before running this command, the SPYGLASS_HOME environmental variable (not Tcl application variable) must be set so the tool can find the **spyglass** binary. You can check this as follows:

```
prompt> echo $env(SPYGLASS_HOME)
/global/apps/spyglass_2016.06-SP2
```

When you run this command, it reports information about the SpyGlass DFT analysis as it runs, such as coverage values and number of test points found.

The analysis is performed inside a SpyGlass DFT project directory whose name is unqualified using the current process ID and username. This directory name is reported when analysis starts:

```
Information: Test point analysis directory is '/proj/chip/_snpDft_user3.25145.0'.
```

The following testability targets do not require you to run testability analysis (although doing so is harmless):

- The **core_wrapper** target
- The **user** target
- Any target that has the **-only_from_file true** option set

EXAMPLES

The following example configures testability analysis, then reports the resulting test points:

```
# enable and configure testability analysis
set_dft_configuration -testability enable
set_testability_configuration -target {random_resistant}
set_testability_configuration -target {untestable_logic}

# perform pre-DFT DRC
create_test_protocol
dft_drc

# perform testability analysis
run_test_point_analysis

# preview the resulting test points
preview_dft -test_points all
```

SEE ALSO

[set_dft_configuration\(2\)](#)
[set_testability_configuration\(2\)](#)

saif_map

Manages the SAIF name-mapping mechanism for reading SAIF files.

SYNTAX

```
string saif_map
[-start]
[-end]
[-reset]
[-report]
[-get_name]
[-set_name names]
[-add_name names]
[-remove_name names]
[-clear_name]
[-get_object_names name]
[-create_map]
[-write_map filename]
[-read_map filename]
[-type type]
[-inverted]
[-instances objects]
[-no_hierarchical]
[-columns columns]
[-sort columns]
[-rtl_summary]
[-missing_rtl]
[-input SAIF_file]
[-source_instance SAIF_instance_name]
[-target_instance target_instance_name]
[-review]
[-preview]
[-hsep character]
[object_list]
[-nosplit]
```

Data Types

<i>names</i>	string
<i>name</i>	string
<i>filename</i>	string
<i>objects</i>	list
<i>columns</i>	string
<i>SAIF_file</i>	string
<i>SAIF_instance_name</i>	string
<i>target_instance_name</i>	cell
<i>character</i>	string
<i>object_list</i>	list

ARGUMENTS

-start

Initializes the name-mapping database. The features of the name-mapping mechanism are not available unless it is initialized. Use the **saif_map -start** command before reading the RTL source files when you need to use the SAIFname-mapping mechanism.

-end

Reverses the initialization of the name-mapping database.

-reset

Resets the name-mapping information by clearing all SAIF names from the name-mapping database and sets all the original names to an initial value depending on the object's name and scope.

-report

Outputs a report of the name-mapping information. By default, the report lists the design objects and their SAIF names. You can use the **-columns** option to include more information, such as the object's original name. You can use the **sort** option to specify sorting criteria. By default, all objects in the current instance hierarchy are considered for the report. You can specify a list of objects explicitly as the *object_list* argument or implicitly by using the **-instances**, and **-no_hierarchical** options.

-get_name

Returns the name of the specified object in the name-mapping database. The name returned depends on the value of the optional **-type** option.

- If the **-type** option is **saif_names** (the default value), a list of SAIF names on that object is returned.
- If the **-type** option is **orig_name**, the original name is returned.
- If the **-type** option is **extended_orig_name**, the original name is returned in the extended syntax.

-set_name names

Sets the name of the specified object in the name-mapping database. The name to be set depends on the value of the optional **-type** option.

- If the **-type** option is **saif_names** (the default value), the SAIF names on that object are set.
- If the **-type** option is **orig_name**, the original name is set.
- If the **-type** option is **extended_orig_name**, the original name is set and the *names* argument is expected to be in extended syntax.

-add_name names

Adds the specified SAIF names to the specified object in the name-mapping database.

-remove_name names

Removes the specified SAIF names from the specified object in the name-mapping database.

-clear_name

Clears the names of the specified object in the name-mapping database. The name that is cleared depends on the value of the optional **-type** option.

- If the **-type** option is **saif_names** (the default value), the SAIF names on that object are cleared.
- If the **-type** option is **orig_name** or **extended_orig_name**, the original name is cleared.

- If the **-type** option is **all_names**, both, the SAIF names and the original name are cleared.

You can specify the objects explicitly as the *object_list* argument or implicitly by using the optional **-instances**, and **-no_hierarchical** options. If you do not specify the **-instances** option, the current instance is used.

-get_object_names name

Returns the object names of the design objects that have the specified name in the name-mapping database. The name used for finding the design objects in the name-mapping database depends on the value of the **-type** option.

- If the **-type** option is **saif_names** (the default value), the *name* argument is assumed to be a SAIF name.
- If the value of the **-type** option is **orig_name**, the *name* argument is assumed to be an original name.
- If the value of the **-type** option is **extended_orig_name**, the *name* argument is assumed to be an original name in extended syntax.

-create_map

Updates the name-mapping database automatically with new SAIF names by reading a SAIF file and matching design objects with the names in the SAIF file. The SAIF file must be specified by using the **-input** option, and the instance name of the current design in the SAIF file must be specified by using the **-source_instance** option.

-write_map filename

Outputs the name-mapping database into the specified name-mapping file. You can read the name-mapping file back into Power Compiler by using the **-read_map** option of the **saif_map** command. If the **-type primepower** option or **-type ptx** option is used, the SAIF names in the name-mapping database are output into a file with a list of **set_rtl_to_gate_name** commands that can be read by PrimePower or PrimeTime PX.

-read_map filename

Reads the name-mapping information stored in a name-mapping file generated by using the **-write_map** option of **saif_map**.

-type type

Specifies an optional type argument with some of the **saif_map** command features. When used with the **-get_name**, **-set_name**, or **-get_object_names** options, the following values are the valid type keywords:

- **saif_names** (the default) specifies that SAIF names are used.
- **orig_name** specifies that original names are used.
- **extended_orig_name** specifies that original names in extended syntax format are used.

In addition to these values, you can use the **all_names** keyword with the **-clear_name** option to specify that both SAIF names and original names are cleared.

When used with the **-write_map** option, the following values are the valid type keywords:

- **name_map** (the default) specifies that a name-mapping file is created.
- **ptpx** specifies that a set of PrimeTime PX instructions is generated.
- **primepower** specifies that a set of PrimePower instructions is generated.

-inverted

Specifies that the name to be set, maps to a logically inverted object. This option is valid only with the **-set_name** option. For example, you can use the **-inverted** option when specifying that the object *A_reg/QN* maps to the SAIF named *A*, but its logical value is inverted. However, note that for such a simple example, it is generally sufficient to specify that the register cell *A_reg* maps to the SAIF named *A*, and the fact that *A_reg/QN* is logically inverted to *A* is deduced automatically when the SAIF file is read.

-instances objects

Restricts the effect of some of the **saif_map** command features to the specified instances. Some **saif_map** options (including **-report** and **-clear**) act on a number of objects that can be specified explicitly as the *object_list* argument or implicitly by using the optional **-instances**, or **-no_hierarchical** options. The *objects* argument is a list of hierarchical cells, and the default value is the

current instance. If you do not explicitly specify the list of objects, all the objects in the current instance are used (if you use **-no_hierarchical**, only the top-level objects are used).

-no_hierarchical

Specifies that all objects in the top-level of the current instance or the instances specified with the **-instance** option are used by the **saif_map** command. Some **saif_map** options (including **-report** and **-clear**) act on a number of objects that can be specified explicitly as the *object_list* argument or implicitly by using the optional **-instances**, or **-no_hierarchical** options.

-columns columns

Specifies a list of column names that are used when reporting the name-mapping database information. The possible values of the elements in the *columns* argument are

- **type** specifies the type (pin, port, cell, or net) of the object.
- **object_names** specifies the name of the design object.
- **saif_names** specifies that SAIF names are included in the report.
- **orig_names** specifies that original names are included in the report.
- **extended_orig_names** specifies that original names in extended format are included in the report.
- **attributes** specifies that attributes, or flags, are included in the report.

The default value of *columns* is {**type object_names saif_names attributes**}.

-sort columns

Specifies the sorting criteria that is used when reporting the name-mapping database information. The *columns|P* argument is a list of column names as specified under the **-columns** description above.

-rtl_summary

Specifies that a summary report of which RTL or synthesis invariant objects have SAIF name-mapping information. This option is valid only when you also use the **-report** option. The report contains the number of synthesis invariant design objects that have SAIF name information obtained automatically or set by you. It also contains the number of design objects that do not have the SAIF name information annotated directly on them, but annotated to some of the object's connecting nets, pins, or ports. The synthesis invariant objects included in the report are design ports, hierarchical cell pins, sequential cells, and tristate cells.

-missing_rtl

Displays a list of RTL or synthesis invariant objects that do not have SAIF name-mapping information. This option is valid only when you also use the **-report** and **-rtl_summary** options.

-input SAIF_file

Specifies the name of the SAIF file that is used to create the name-mapping information when used with the **-create_map** option.

-source_instance SAIF_instance_name

Specifies the name of the current design instance in the SAIF file that is used to create the name-mapping information when used with the **-create_map** option.

-target_instance target_instance_name

Specifies the instance in the current design for which the name-mapping information is created when used with the **-create_map** option. The default target instance is the current instance.

-review

Displays a SAIF match report showing which design objects are matched with which SAIF file objects after the SAIF name-mapping information is created from a SAIF file. This option is valid only with the **-create_map** option.

-preview

Displays a SAIF match report without creating the actual SAIF name mapping. The report shows which design objects would be

matched with which SAIF file objects when the name mapping is created. This option is valid only when used with the **-create_map** option.

-hsep *character*

Specifies the hierarchical separator when parsing or reporting SAIF names and original names. The default value is slash (/). Other possible values are dot (.) and double quotation marks (""). The **-hsep " "** argument can be useful when the slash (/) character is part of the identifier names of the design objects.

object_list

Specifies the list of objects used by the **saif_map** command.

-nosplit

Prevents line splitting and facilitates writing software to extract information from the report output. Most of the design information is listed in fixed-width columns. If the information for a given field exceeds its column-width, the next field begins on a new line, starting in the correct column.

OBSOLETE ARGUMENTS

-hierarchical

When selecting objects implicitly, the **-hierarchical** flag is assumed by default, so it is never required.

DESCRIPTION

The **saif_map** command manages and uses a SAIF name-mapping database that provides a mapping between design objects and the names in SAIF files. The name-mapping database can be created automatically and you can query and modify the information in the database. You can use the name-mapping database when reading SAIF files generated by RTL simulation, where the names in the SAIF file do not exactly match the names of the design objects.

The information stored in the name-mapping database consists of the following possible information on design ports, nets, pins, and cells:

- A list of SAIF names, representing the possible names in the SAIF file that match the design object.
- An original name, representing the original name of the design object as created by the synthesis RTL reader.
- A number of flags that specify, for example, whether the SAIF and original names have been created automatically or set by the user.

When the name-mapping mechanism is active (the **saif_map -start** command activates the name-mapping mechanism), the original names are automatically created when the design RTL source is read and linked. The SAIF names and original names are full instance names.

The SAIF names can be created automatically when processing an RTL SAIF file by using the **saif_map -create_map** command, which matches the original names of the design objects with the names in the SAIF file. The SAIF names information can then be used when reading the SAIF file by using the **-map_names** option of the **read_saif** command. Also, the name-mapping mechanism can be created automatically and used to read a SAIF file by using the **-auto_map_names** option of the **read_saif** command.

The **saif_map** command provides several options for reporting, querying, and modifying the SAIF name-mapping database information (see the list of arguments above). You might need to set the SAIF names of design objects explicitly by using the **-create_map** option in cases where they cannot be created automatically. You can report, query, and modify the original names of the design objects that can be represented in a simple format by using the **-type orig_name** option or in an extended syntax format by using the **-type extended_orig_name** option, which is close to the internal representation of the original names information and provides more information on the scope of the design objects.

You can write the name-mapping database information to a file by using the **-write_map** option. You can read the information back into the design by using the **-read_map** option. Note that the name-mapping database is stored on the design and is therefore automatically stored in the .ddc files. If you read the design as a gate-level source file, you might need to read the name-mapping information read back into the design.

EXAMPLES

The following example shows how you can automatically create and use the name-mapping mechanism when reading an RTL SAIF file into a compiled design.

```
saif_map -start  
prompt> read_verilog ex.v  
prompt> current_design ex  
prompt> link  
prompt> compile  
prompt> read_saif -input ex.rtl.saif -instance tb/u1 -auto_map_names
```

The following example shows how you can create the name-mapping mechanism, report it, modify it slightly, and use it to read an RTL SAIF file.

```
prompt> saif_map -start  
prompt> read_verilog ex.v  
prompt> current_design ex  
prompt> link  
prompt> compile  
prompt> saif_map -create_map -input ex.rtl.saif -source tb/u1  
prompt> saif_map -report  
prompt> saif_map -get_name [get_port clk_1]  
prompt> saif_map -set_name "clk1" [get_port clk_1]  
prompt> read_saif -input ex.rtl.saif -instance tb/u1 -map_names
```

The following example shows how the SAIF name-mapping information can be stored to a file and used later. Because the **saif_map -write** command is used before the SAIF name mapping is created by using **saif_map -create_map**, there are no SAIF names in the database and only the original names are stored in the name-mapping file.

```
prompt> saif_map -start  
prompt> read_verilog ex.v  
prompt> current_design ex  
prompt> link  
prompt> compile  
prompt> change_name -rules verilog  
prompt> write -f verilog -hier -out ex.gate.v  
prompt> saif_map -write_map ex.namemap  
  
...  
  
prompt> read_verilog ex.gate.v  
prompt> saif_map -read_map ex.namemap  
prompt> read_saif -input ex.rtl.saif -instance tb/u1 -auto_map_names
```

SEE ALSO

[read_saif\(2\)](#)
[report_saif\(2\)](#)
[merge_saif\(2\)](#)

save_lib

Saves a library and its changed blocks to disk.

SYNTAX

```
status save_lib
  [-as library_name [-version release_version]]
  [-all]
  [-compress]
  [library]
```

Data Types

<i>library_name</i>	string
<i>release_version</i>	string
<i>library</i>	collection

ARGUMENTS

-as *library_name*

Specifies the name of the saved library.

If you do not specify this option, the library is saved with the same name.

This option is mutually exclusive with the *-all* option; you can specify only one of these options.

-version *release_version*

Specifies the version of the saved library.

To see the valid version strings, use the *report_versions* command.

This option is valid only with the *-as* option.

-all

Saves all open libraries that have changed blocks. Note that in an implementation tool, the command saves only design libraries and not reference libraries that contain library cells.

This option is mutually exclusive with the *-fl-as* option and *library* argument; you can specify only one of these arguments.

-compress

Saves libraries in compressed format. This option is applicable to design libraries only. lib-cell libraries cannot be compressed. Once a library has been saved with "-compress", the "is_compressed" attribute on the library is set to true. All future *save_lib* or *save_block* on this library or its blocks will be in compressed format, even if the "-compress" option isn't specified. If the "is_compressed" attribute is set to false, future *save_lib* on this library will be in uncompressed format.

DESCRIPTION

This command saves the library data to disk. Library data includes the design catalog, library attributes, technology data, and parasitic data. The command also saves all blocks in the library that have been modified but not saved.

In an implementation tool, the command saves only design libraries in edit mode. It does not save read-only libraries or reference libraries that contain library cells.

If the command successfully saves one or more libraries, it returns 1. Otherwise, it returns 0. If you try to save a library with an illegal name, such as a name that contains a slash, the command raises a Tcl error.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

This example saves the contents of the MyDesign design library.

```
prompt> save_lib MyDesign
1
```

This example saves the contents of the Top library to a library named Top.1.0 using the database schema revision for version J-2014.06.

```
prompt> save_lib Top -as Top.1.0 -version J-2014.06
Saving library 'Top' as 'Top.1.0' in version 'J-2014.06'
1
```

save_qtm_model

Saves the current quick timing model (QTM) description.

SYNTAX

```
string save_qtm_model  
  [-format db | lib | script]
```

ARGUMENTS

-format db | lib | script

Specifies the output format to be used.

Valid output formats are

- db - The .db version of the QTM model. By default, the .db format is used.
- lib - The .lib version of the QTM model.
- script - A script containing QTM commands. The command writes out a script file that contains the QTM commands to describe the QTM model.

DESCRIPTION

This command creates an in-memory .db timing model for the QTM model and indicates that the model being defined is completed. All QTM commands must be placed between a **create_qtm_model** command and a **save_qtm_model** command.

This command creates an in-memory Synopsys .db representation to be used by the tool's timing engine. This command runs faster than the obsolete **write_qtm_model** command and does not require disk I/O. You can call this command multiple times in a session if you need to modify the QTM model.

To display information about the current QTM model, use the **report_qtm_model** command.

For a basic description of QTM models, see the **create_qtm_model** man page. For a more detailed description about QTM models, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example saves the QTM model in .db and .lib format.

```
prompt> save_qtm_model -format {db lib}
```

The following example save the QTM model with a script of QTM commands.

```
prompt> save_qtm_model -format {script}
```

SEE ALSO

`create_qtm_model(2)`
`report_qtm_model(2)`

save_ssF

Writes out the design's SSF commands into the specified file.

SYNTAX

status **save_ssF**
[*file_name*]

Data Types

file_name string

ARGUMENTS

Specifies the name of the file to which SSF commands are to be written out.

DESCRIPTION

This command writes out an ASCII file in the SSF format. It interprets the safety registers related objects present in the design into Functional Safety (FuSa) intent, maps them into SSF commands and writes them out in the specified file. Currently safety registers are supported, therefore the output file will contain only the commands related to these objects. This is a read-only command since it does not modify the database.

EXAMPLES

The following is an example of the **save_ssF** command:

```
prompt> save_ssF design.ssf
```

SEE ALSO

[report_safety_status\(2\)](#)

save_upf

Writes out the design's UPF power intent as a UPF command script.

SYNTAX

```
collection save_upf
  [upf_file_name]
  [-supplemental supf_file_name]
  [-include_supply_exceptions]
  [-full_upf]
```

Data Types

<i>upf_file_name</i>	string
<i>supf_file_name</i>	string

ARGUMENTS

upf_file_name

Specifies the name of the UPF script file written by the command.

This option can be used only in the UPF-prime mode, not the golden UPF mode.

-supplemental *supf_file_name*

Specifies the name of the supplemental UPF file written by the command.

This option can be used only in the golden UPF mode, not the UPF-prime mode.

-include_supply_exceptions

Specifies whether the supplemental UPF file written by the command contains exception power connections derived by the tool. Use this option when the Verilog netlist file does not contain any PG connection information.

This option can be used only in the golden UPF mode, not the UPF-prime mode.

-full_upf

In the hierarchical flow mode, **save_upf** excludes UPF commands that are defined in abstract hierarchies, or refer to elements in these hierarchies. This option specifies that **save_upf** should write all commands.

This option can be used only in the UPF-prime mode, not the golden UPF mode.

DESCRIPTION

In the UPF-prime (not golden) mode, the **save_upf** command writes out design's complete power intent infrastructure as a UPF save_upf

command script. The script consists of commands previously loaded with the **load_upf** command, UPF commands entered at the tool prompt during the session, and UPF power intent changes derived by the tool during the session.

For example, if optimization has changed the name of the cell that drives an isolation signal, it modifies the **set_isolation_control** command to reflect the new isolation signal name. The script written by the **save_upf** command reflects the change made by the tool.

In the golden UPF mode, this command writes out a supplemental UPF file that reflects only the UPF changes made by the tool. The original "golden" UPF file and the supplemental UPF file together fully specify the UPF power intent of the design.

In the golden UPF mode, you can use the **-include_supply_exceptions** option to specify whether the supplemental UPF file contains supply connection information. You should use this option whenever you write the Verilog netlist without power supply connection information.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following examples saves the full UPF power intent of the design in a file called my_design_power.upf:

```
prompt> save_upf my_design_power.upf
```

In the following example, the tool is operating in the golden UPF mode. The command saves the supplemental UPF into a file called my_supp_power.upf.

```
prompt> save_upf -supplemental my_supp_power.upf
```

SEE ALSO

`check_upf(2)`
`write_file(2)`
`enable_golden_upf(3)`

scale_floorplan

Scales the given user floorplan.

SYNTAX

```
status scale_floorplan
      -scale_ratio {scale_ratio | scale_ratio_x scale_ratio_y}
      -output output_def_name
      [-script script_name]
      [-apply]
```

ARGUMENTS

-scale_ratio {scale_ratio | scale_ratio_x scale_ratio_y}

Specifies the scale ratio constraint for the core area; If only one value is specified, the square-root of the value is used to scale both width and height of a given core. If two values are specified, the first value is applied to the width and second value is applied to the height of the core. The values can be positive float numbers. This is a required argument.

-output *output_def_name*

Specifies the name of the DEF file written by the *scale_floorplan* command. This is a required argument.

-script *script_name*

Specifies the script to be sourced after the scaled floorplan is generated.

-apply

Specifies the scaled floorplan DEF to be sourced automatically after the scaled floorplan is generated.

DESCRIPTION

This command **scale_floorplan** scales the user floorplan based on given **scale_ratio**, generates a new scaled floorplan. If option **-apply** is specified, the command reads the generated scaled floorplan in non-incremental mode in the current session. The command leverages IC Compiler II link capabilities to scale the floorplan.

The command does not support block abstractions.

Use command **set_auto_floorplan_constraints** to provide the **site_def** to generate uni-row floorplan or the **row_pattern** to generate hybrid-row floorplan. In the absense of this, the **scale_floorplan** command errors out.

In DCNXT Milkyway mode, it's required to provide **set_icc2_options** command.

This command is supported only in Design Compiler NXT topographical mode.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to scale a floorplan to hybrid row floorplan in DCNXT NDM mode:

```
prompt> create_lib -technology tech.tf -ref_libs std_ref.nlib design_nlib
prompt> open_lib design_nlib
prompt> read_ddc risc_core.ddc
prompt> current_design RISC_CORE
prompt> link
prompt> extract_physical_constraints risc_core.def
prompt> set_auto_floorplan_constraints -row_pattern H169_H221_H221_H169
prompt> scale_floorplan -scale_ratio 0.9 -output scaled_fp.def
```

The following example shows how to scale a floorplan to hybrid row floorplan in DCNXT Milkyway mode:

```
prompt> create_mw_lib -technology tech.tf -mw_reference_library std_ref.mw design_mw
prompt> open_mw_lib design_nlib
prompt> read_ddc risc_core.ddc
prompt> current_design RISC_CORE
prompt> link
prompt> extract_physical_constraints risc_core.def
prompt> set_icc2_options -ref $ref_ndm_files -tech $mw_tech_file
prompt> set_auto_floorplan_constraints -row_pattern H169_H221_H221_H169
prompt> scale_floorplan -scale_ratio 0.9 -output scaled_fp.def
```

SEE ALSO

[set_auto_floorplan_constraints\(2\)](#)
[report_auto_floorplan_constraints\(2\)](#)

select_block_scenario

Performs scenario mapping between the top-level design and interface logic models (ILMs) or block abstractions.

SYNTAX

```
status select_block_scenario
  [-scenarios top_scenario_list]
  [-block_references block_list]
  -block_scenario block_scenario | -reset
```

Data Types

<i>top_scenario_list</i>	list
<i>block_list</i>	collection
<i>block_scenario</i>	string

ARGUMENTS

-scenarios *top_scenario_list*

Specifies a list of top-level scenarios to which this mapping applies. The default is the current scenario. In a non-multicorner multimode top-level design, you must not specify this option because the top-level design does not have any scenarios.

-block_references *block_list*

Specifies a list of block references for which the mapping is specified. The value can be a collection of block references or name patterns.

If this option is not specified, the command sets or resets the mapping for all the block references in the current design.

-block_scenario *block_scenario*

Specifies the scenario name in the specified blocks to which the top-level scenarios are mapped.

This option and the **-reset** option are mutually exclusive.

-reset

Resets the user-specified scenario mapping to name-based matching.

This option and the **-block_scenario** option are mutually exclusive.

DESCRIPTION

The **select_block_scenario** command enables you to select the ILM or block abstraction scenario from which the data is to be loaded.

Use this command to map the scenarios in the top-level design with the block-level scenarios in the following situations:

- When the names of the scenarios at the top-level and the block-level do not match
- To use a multicorner-multimode block in a non multicorner-multimode top-level design
- When you have additional modes in the top-level design than in the block

You do not need to use the **select_block_scenario** command with a non multicorner-multimode block and a multicorner-multimode top-level design. If the block is not multicorner-multimode, the tool automatically detects it and assumes that every top scenario is mapped to the block's operating conditions.

If you specify multiple top-level scenarios and multiple block references, the mapping applies to all specified top-level scenarios and for all specified blocks.

These settings are stored in the database when the top-level design is saved. The settings are restored when the design is later reopened. You need not specify these settings in every session.

You should set these mappings before applying constraints and avoid changing them later.

The tool expects the TLUPlus settings and temperature to be the same for the top-level scenario and the corresponding ILM or block abstraction scenario.

See the report generated by the **report_ilm** command or **report_block_abstraction** command to verify the scenario mappings that are specified.

You can reset the specified scenario mapping to name-based matching by using the **-reset** option.

Multicorner-Multimode Support

By default, this command uses information from the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example maps the top-level scenario top_scen to the block scenario blk_scen:

```
prompt> select_block_scenario -scenarios top_scen \
    -block_references blk -block_scenario blk_scen
1
```

The following example shows the command usage when the top-level design does not have scenarios and the block has a scenario named blk_scen. In this case, you must not specify the **-scenarios** option:

```
prompt> select_block_scenario \
    -block_references blk -block_scenario blk_scen
1
```

The following example resets the user-specified scenario mapping for the top-level scenario top_scen and blk block reference:

```
prompt> select_block_scenario -scenarios top_scen \
    -block_references blk -reset
1
```

SEE ALSO

[all_scenarios\(2\)](#)
[current_scenario\(2\)](#)
[report_block_abstraction\(2\)](#)

set_active_scenarios

Specifies which scenarios are to be active.

SYNTAX

status **set_active_scenarios**
 scenario_list | -all

Data Types

scenario_list list of strings

ARGUMENTS

scenario_list

Specifies which scenarios are active.

This argument and the **-all** option are mutually exclusive. You must specify one, but not both.

-all

Makes all scenarios active.

This option and the *scenario_list* argument are mutually exclusive. You must specify one, but not both.

DESCRIPTION

This command specifies the scenarios that are to be active.

To report timing results with back-annotated delays for newly-activated scenarios, run the **extract_rc -estimate** command before issuing the **report_timing** command. Creation and usage of scenarios is available with Design Compiler Graphical.

Multicorner-Multimode Support

This command uses information from both active and inactive scenarios.

EXAMPLES

The following example uses **set_active_scenarios** to set only the *MODE1* scenario as active:

```
prompt> create_scenario MODE1
```

```
prompt> create_scenario MODE2  
prompt> set_active_scenarios {MODE1}  
prompt> all_scenarios  
MODE1 MODE2  
prompt> all_active_scenarios  
MODE1
```

SEE ALSO

[all_active_scenarios\(2\)](#)
[all_scenarios\(2\)](#)
[create_scenario\(2\)](#)
[current_scenario\(2\)](#)
[extract_rc\(2\)](#)
[remove_scenario\(2\)](#)

set_ahfs_options

Specifies the options to use when running automatic high-fanout synthesis (AHFS).

SYNTAX

```
status set_ahfs_options
[-enable_port_punching true | false]
[-no_port_punching cells]
[-default_reference references]
[-port_map_file file_name]
[-preserve_boundary_phase true | false]
[-constant_nets true | false]
[-global_route true | false]
[-default]
```

Data Types

<i>cells</i>	string
<i>references</i>	string
<i>file_name</i>	string

ARGUMENTS

-enable_port_punching true | false

Enables or disables port punching in automatic high-fanout synthesis optimization. The default is **true**.

When this option is **true**, automatic high-fanout synthesis can insert buffers or inverters across hierarchy boundaries to get better QoR.

Port punching is turned off in **compile_ultra** if the **-no_boundary_optimization** option is defined for **compile_ultra**.

You can use the **-no_port_punching** option to prevent port punching on specific hierarchical cells, even when **-enable_port_punching** is **true**.

-no_port_punching *cells*

Specifies the hierarchical cells for which automatic high-fanout synthesis cannot add or remove any ports. The cells are specified as a string of hierarchical cell instance names separated by commands, such as "sub/mod1 sub/block2".

Use this option to limit the port punching on specific hierarchical cell instances when **-enable_port_punching** is **true** (the default). If **-enable_port_punching** is **false**, there is no need for this option.

During the removal phase of automatic high-fanout synthesis, inverters might be moved across hierarchical boundaries to cancel "inverter chains" for better QoR. If you do not want to allow any phase changes on hierarchical boundaries, use the **-preserve_boundary_phase true** option instead of using this option.

-default_reference *references*

Specifies a list of buffers or a list of inverters for automatic high-fanout synthesis to use when constructing new buffer or inverter trees.

You can specify the reference cells with or without the library prefix.

If you do not specify this option, or if the specified references are not active buffer cells, automatic high-fanout synthesis tries to use all active buffer or inverter cells defined in the library.

This option is not supported by the **place_opt** command.

-port_map_file file_name

Specifies the name of the port-mapping file. This option is used only when **-enable_port_punching** is set to **true**.

If you do not specify this option and **-enable_port_punching** is set to **true**, the default name of the port-mapping file is *design_name_port_map.version*. The initial file is created with a version of 0. If the specified port-mapping file already exists, a new version of the file is created with the version number increased by one, such as *design_name_port_map.1*.

-preserve_boundary_phase true | false

Specifies whether automatic high-fanout synthesis is allowed to move inverters across hierarchical boundaries so that the logical phase of the boundary changes.

The default is **false**, meaning that automatic high-fanout synthesis can freely move inverters across hierarchical boundaries. This default behavior often leads to better QoR because automatic high-fanout synthesis can move inverters and cancel inverter chains as needed.

-constant_nets true | false

Specifies that automatic high-fanout synthesis works on constant nets as well as signal nets.

By default, automatic high-fanout synthesis ignores constant nets.

-global_route true | false

Specifies whether to enable Zroute-based global buffering during automatic high-fanout synthesis. This feature is deprecated and will be removed in a future release.

When this option is set to **true** before compile, Zroute-based global buffering takes effect during the compile and incremental compile stages. You must specify the **-spg** option with the **compile_ultra** command to enable it. For best results, if you enable Zroute-based global buffering in Design Compiler Graphical, enable it also in IC Compiler. Zroute-based global buffering might increase runtime and affect area and timing; therefore, use it only on macro-intensive designs with narrow channels.

-default

Resets all of the options set by previous **set_ahfs_options** commands to their default values.

DESCRIPTION

This command defines the constraints used when performing automatic high-fanout optimization. You can report the settings by running the **report_ahfs_options** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to set automatic high-fanout synthesis options for the current design. It enables port punching and uses cells of type BUFX3M or ss_0v80_125c/DLY4X4M during high-fanout synthesis. The **-preserve_boundary_phase false** option indicates that inverters should not move across hierarchical boundaries. The **-no_port_punching "sub/mod1 sub/mod2"** option

indicates that the *sub/mod1* and *sub/mod2* hierarchical cells should not have changes to their ports during automatic high-fanout synthesis.

```
prompt> set_ahfs_options \
    -enable_port_punching true \
    -no_port_punching "sub/mod1 sub/mod2" \
    -preserve_boundary_phase false \
    -default_reference "BUFX3M ss_0v80_125c/DLY4X4M"
```

```
prompt> report_ahfs_options
```

Report AHFS options:

```
*****
```

AHFS options for the design:

Enable port punching: ON

Default Reference : BUFX3M ss_0v80_125c/DLY4X4M

Port Map File :

Preserve Boundary Phase : OFF

No Port Punching on these hier cells : "sub/mod1 sub/mod2"

Constant Nets allowed during AHFS optimization : OFF

SEE ALSO

[report_ahfs_options\(2\)](#)

set_always_on_cell

Sets on-the-fly specification for an always-on library cell.

SYNTAX

```
status set_always_on_cell  
    cell_name
```

Data Types

cell_name string

ARGUMENTS

cell_name

Specifies that the library cell is an always-on cell.

DESCRIPTION

The **set_always_on_cell** command sets all cells in the library whose name matches the specified cell name as always-on cells. Only buffer or inverter cells in the library can be specified as always-on cells.

EXAMPLES

The following example uses the **set_always_on_cell** command to set the library cell named *INV_AO* as an always-on cell:

```
prompt> set_always_on_cell INV_AO
```

SEE ALSO

`check_library(2)`
`report_lib(2)`

set_always_on_strategy

Sets the always-on strategy for specified shutdown power domains.

SYNTAX

```
status set_always_on_strategy
      -object_list list_of_domains
      -cell_type single_power | dual_power
```

Data Types

list_of_domains collection

ARGUMENTS

-object_list *list_of_domains*

Specifies one or more power domains for which to define the always-on strategy.

-cell_type **single_power** | **dual_power**

Specifies the type of always-on cells to be used, either single-power cells or dual-power cells with backup power. The default is **dual_power**.

DESCRIPTION

This command sets the always-on strategy for specified shutdown power domains. The strategy indicates the type of cells to be used for always-on buffering. You can choose to use standard cells with single-power cells, or dual-power cells with a backup supply. This information drives cell selection during optimization.

The dual-power strategy uses special-purpose, always-on cells. Each of these cells has two power pins: a primary pin connected to the primary supply and a backup pin connected to a backup supply net. The cell also has an attribute called `always_on` which is set to true at the cell level. This type of cell is known as a dual-rail, always-on cell.

The single-power strategy uses standard, single-power cells that are placed in dedicated always-on site rows of the power domain's corresponding voltage area. These always-on sites are powered by the backup power supply. During optimization, the tool does not make any changes to these always-on site rows, so it leaves these cells on the always-on paths.

The dual-power strategy does not require always-on site rows and the cells can be placed anywhere in the voltage area.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example sets the always-on strategy on *switchable_domain* to use single-power standard cells:

```
prompt> set_always_on_strategy \
           -object_list switchable_domain \
           -cell_type single_power
1
```

SEE ALSO

`create_power_domain(2)`
`remove_power_domain(2)`
`report_power_domain(2)`
`set_power_guide(2)`
`unset_power_guide(2)`

set_analyze_rtl_logic_level_threshold

Specifies the logic level threshold value to be used by report_logic_levels command. Also used to remove the previously set value.

SYNTAX

```
status set_analyze_rtl_logic_level_threshold
      [-group group_name]
      [-reset]
      [threshold]
```

Data Types

group_name string
threshold integer

ARGUMENTS

-group *group_name*

Specifies a name for the path group for which threshold value is being set or reset. The group name should be one of the group names reported by report_path_group command. When this option is not used, the threshold setting is applied at global level.

-reset

Specifies that the previously specified threshold value be reset. If -group option is specified, then reset applies only to the specified path group. If -group option is not specified, then the threshold value is reset for all path groups and global level.

threshold

Specifies the threshold integer value to be used by report_logic_levels command.

DESCRIPTION

This command is used to specify the threshold value to be used by report_logic_levels command. The value can be specified at each path group level or at global level. When threshold is specified both at global level and path group level, path group threshold setting is used for the paths belonging to that path group.

Not using this command will result in tool computing the threshold automatically based on the required time for the path and the delay of average size NAND2 cell in the target library.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the logic level threshold to 10 at global level.

```
prompt> set_analyze_rtl_logic_level_threshold 10
```

The following example sets the logic level threshold to 5 only for the paths in the path group CLOCK while setting 6 for all other paths.

```
prompt> set_analyze_rtl_logic_level_threshold 6
prompt> set_analyze_rtl_logic_level_threshold -group CLOCK 5
```

The following example re-sets the logic level threshold for path group CLOCK.

```
prompt> set_analyze_rtl_logic_level_threshold -group CLOCK -reset
```

The following example re-sets the logic level threshold for all paths (all path groups).

```
prompt> set_analyze_rtl_logic_level_threshold -reset
```

SEE ALSO

[report_logic_levels\(2\)](#)
[report_path_group\(2\)](#)

set_annotated_check

Sets the setup, hold, recovery, or removal timing check value between two pins.

SYNTAX

```
status set_annotated_check
  check_value
  -from from_pins
  -to to_pins
  -setup
    | -hold
    | -recovery
    | -removal
    | -nochange_high
    | -nochange_low
  [-rise | -fall]
  [-clock rise | fall]
  [-worst]
  [-increment]
```

Data Types

check_value	float
from_pins	list
to_pins	list

ARGUMENTS

check_value

Specifies the timing check value between pins on the same cell, which can be positive or negative. You must express the *check_value* argument in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, the *check_value* argument must be expressed in nanoseconds.

-from *from_pins*

Specifies the leaf-cell clock pins that are the startpoints of the timing arcs for which checks are to be annotated.

-to *to_pins*

Specifies the leaf-cell data pins that are the endpoints of the timing arcs for which checks are to be annotated.

-setup | -hold | -recovery | -removal | -nochange_high | -nochange_low

Specifies the type of the timing check. There must be a corresponding timing arc between the from and to pins.

- The **-setup** option specifies that data must be stable for the amount of time specified by *check_value* before the closing clock edge.
- The **-hold** option specifies that data must be stable for the amount of time specified by *check_value* after the closing clock edge.

- The **-recovery** option specifies that an asynchronous set or clear inactive edge cannot occur within the amount of time specified by *check_value* before the closing clock edge. This is essentially a setup requirement on an asynchronous pin, but only the inactive transition is considered.
- The **-removal** option specifies that an asynchronous set or clear inactive edge cannot occur until the amount of time specified by *check_value* after the closing clock edge. This is essentially a hold requirement on an asynchronous pin, but only the inactive transition is considered.
- The **-nochange_high** option provides a timing check that specifies that the data must not rise within the amount of time specified by *check_value* before the clock becomes active and must not fall until the amount of time specified by *check_value* after the clock becomes inactive.
- The **-nochange_low** option provides a timing check that specifies that the data must not fall within the amount of time specified by *check_value* before the clock becomes active and must not rise until the amount of time specified by *check_value* after the clock becomes inactive.

-rise | -fall

Specifies whether the check is for the data rise or fall transition. If you do not specify either **-rise** or **-fall**, both values are set.

The **-rise** option specifies a rise data transition that corresponds to the check before the activating clock edge. A rise data transition corresponds to the check after the deactivating clock edge. A rise clock transition indicates that the clock is active-high.

The **-fall** option specifies a fall data transition that corresponds to the check after the deactivating clock edge. A fall data transition corresponds to the check before the activating clock edge. A fall clock transition indicates that the clock is active-low.

-clock rise | fall

Specifies whether the check is for clock rising or falling. By default, checks for both clock rise and fall are set.

-worst

Specifies that the check is to overwrite the previously annotated check only if the *check_value* specified is worse than the check value previously annotated. By default, *check_value* overwrites any previously annotated value.

-increment

Adds the specified check value to the existing default check value. Without this option, the check value replaces the default check value. If you use the **set_annotated_check** command multiple times with the **-increment** option, the last **-increment** setting is used and earlier ones are ignored. If you use a **set_annotated_check** command without the **-increment** option, that check value is used, and any **-increment** setting is ignored.

DESCRIPTION

This command annotates a timing check between two or more pins on a cell or a net in the current design. This might be appropriate after place and route for technologies where the timing check value varies for different instances and the library timing check values do not provide sufficient accuracy.

If the design is not already linked, the **set_annotated_check** command links it automatically.

The command can be used for pins at lower levels of the design hierarchy. Pins are specified as "INSTANCE1/INSTANCE2/PIN_NAME."

To list annotated timing check values, use the **report_annotated_check** command. To remove annotated timing check values from a design, use the **remove_annotated_check** or **reset_design** command. To see the affect of **set_annotated_check** for a specific instance, use the **report_timing** command.

Multicorner-Multimode Support

This command applies to current scenario only.

EXAMPLES

The following example annotates a setup time of 2.1 units between the CP clock pin and the D data pin of the u1/ff12 cell instance:

```
prompt> set_annotated_check -setup 2.1 \
    -from u1/ff12/CP -to u1/ff12/D
```

The following example annotates a nochange check between data low and clock low. The nochange margin before the clock is 1.3 units and the nochange margin after the clock is 2.4 units.

```
prompt> set_annotated_check -nochange_low 1.3 \
    -clock fall -fall -from u1/CP -to u1/EN
```

```
prompt> set_annotated_check -nochange_low 2.4 \
    -clock fall -rise -from u1/CP -to u1/EN
```

SEE ALSO

[report_annotated_check\(2\)](#)
[report_timing\(2\)](#)
[reset_design\(2\)](#)

set_annotated_delay

Sets the net or cell delay value between two pins.

SYNTAX

```
status set_annotated_delay
  -net | -cell
  [-dont_touch]
  [-load_delay load_delay_type]
  [-rise | -fall]
  [-min]
  [-max]
  delay_value
  [-from from_pins]
  [-to to_pins]
  [-worst]
```

Data Types

<i>load_delay_type</i>	string
<i>delay_value</i>	float
<i>from_pins</i>	list
<i>to_pins</i>	list

ARGUMENTS

-net

Specifies a net delay, between a driver and a receiver.

-cell

Specifies a cell delay, from an input to an output of a cell.

You must specify either **-net** or **-cell**, and not both.

-dont_touch

Sets the **dont_touch** attribute to **true** for the specified net. By default, this attribute is set to **false**, allowing optimization to change the net and remove the annotated delay constraint. If you use the **-dont_touch** option, the net cannot be changed by optimization. This option works only with the **-net** option, not with the **-cell** option. You can report the **dont_touch** attribute setting with the **report_dont_touch -class net** command.

-load_delay *load_delay_type*

Specifies whether to include load delay as part of annotated net delays or as part of annotated cell delays. The *load_delay_type* must be either **net** or **cell**. Load delay is the portion of cell delay arising from the capacitive load of the net the cell is driving. All timing arcs of the same net or same cell must be annotated with the same *load_delay_type*.

-rise

Applies the delay to rising transitions.

-fall

Applies the delay to falling transitions.

If you specify neither **-rise** nor **-fall**, the delay value applies to both rising and falling transitions.

-min

Specifies that the *delay_value* is to be used for minimum delay analysis.

-max

Specifies that the *delay_value* is to be used for maximum delay analysis.

By default, the *delay_value* is used for both maximum and minimum delay analysis.

delay_value

Specifies the delay value between pins on the same cell or net. The *delay_value* must be expressed in units consistent with the logic library used during optimization. For example, if the logic library specifies delay values in nanoseconds, *delay_value* must also be in nanoseconds.

-from from_pins

Specifies a list of leaf-cell pins or top-level ports that are the startpoints of the timing arcs for which delays are to be annotated.

If you omit the **-from** option, all arcs to the *to_pins* are annotated.

-to to_pins

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs for which delays are to be annotated.

If you omit the **-to** option, all arcs from the *from_pins* are annotated.

-worst

Overwrites the previously annotated delay only if the *delay_value* specified is worse than the delay value previously annotated. By default, the *delay_value* overwrites any previously annotated value.

DESCRIPTION

This command annotates cell or net delays in the design.

Cell delays exist between pins of the same leaf cell. With the **-cell** option, pins in *from_pins* must be cell input or inout pins, and pins in *to_pins* must be cell output or inout pins.

Net delays exist between leaf-cell pins or top-level ports connected by a net. With the **-net** option, pins in *from_pins* must be cell output or inout pins or top-level input ports, and pins in *to_pins* must be cell input or inout pins or top-level output ports.

To verify the accuracy of the back-annotation done by the **set_annotated_delay** command, run the **update_timing** command.

Delays annotated with this command affect both timing analysis and optimization.

Load delay, also known as extra source gate delay, is the portion of cell delay caused by the capacitive load of the net being driven. Some delay calculators consider load delay part of the net delay and others consider it part of the cell delay. If your annotated delay value (for either cell or net) assumes that load delay is part of the cell delay, use **-load_delay cell**. If your delay value assumes that load delay is included in the net delay, use **-load_delay net**. By default, load delays are assumed to be in cell delays, so they appear in **report_timing** path listings.

The specified delay value overrides the internally estimated cell and net delay value. If the specified pins are not in the same cell or on the same net, when the timing is updated, the tool issues an error message and *delay_value* is discarded for those pins.

You can use **set_annotated_delay** for pins at lower levels of the design hierarchy by specifying them as "INSTANCE1/INSTANCE2/PIN_NAME."

To list annotated delay values, use the **report_annotated_delay** command. To remove the annotated cell or net delay values from a design, use the **remove_annotated_delay** or **reset_design** command.

Multicorner-Multimode Support

This command applies to current scenario only.

EXAMPLES

The following example annotates a cell delay of 20.0 time units between input pin A of cell instance U1/U2/U3 and output pin Z of the same cell instance. The delay value of 20.0 includes the load delay.

```
prompt> set_annotated_delay -cell -load_delay cell 20.0 \
           -from U1/U2/U3/A -to U1/U2/U3/Z
```

The following example annotates a rise net delay of 1.4 between output pin U1/Z and input pin U2/A. The delay value for this net does not include load delay.

```
prompt> set_annotated_delay -net -rise -load_delay cell 1.4 \
           -from U1/Z -to U2/A
```

The following example annotates a rise net delay of 12.3 for minimum delay analysis between output pin U1/Z and input pin U2/A. In this case, the net delay value does include load delay.

```
prompt> set_annotated_delay -net -rise -min -load_delay net 12.3 \
           -from U1/Z -to U2/A
```

target_library(3)

set_annotated_transition

Sets the transition time at a given pin.

SYNTAX

```
status set_annotated_transition
  [-rise | -fall]
  [-min]
  [-max]
  transition
  port_pin_list
```

Data Types

```
transition      float
port_pin_list  list
```

ARGUMENTS

-rise | -fall

Specifies whether the transition time is for a data rise or data fall transition. If you do not specify **-rise** or **-fall**, both values are set.

-min

Specifies that the transition is to be used for minimum delay analysis. By default, the transition value is used for maximum and minimum delay analysis. If a transition value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different transition values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

-max

Specifies that the transition is to be used for maximum delay analysis. By default, the transition value is used for maximum and minimum delay analysis. If a transition value is annotated for only minimum or maximum delay analysis, that value is used for both maximum and minimum delays. It is possible to annotate different transition values for minimum and maximum analysis, but it is not possible to annotate only for minimum or annotate only for maximum.

transition

Specifies the transition value at the pins supplied with the *port_pin_list* argument. The transition value must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies transition values in nanoseconds, the transition values must be expressed in nanoseconds.

port_pin_list

Specifies a list of leaf-cell pins or top-level ports that are the endpoints of the timing arcs for which delays are to be annotated.

DESCRIPTION

This command sets the transition time at a given pin.

To list annotated transition values, use the **report_annotated_transition** command. To remove the annotated transition values from a design, use the **remove_annotated_transition** or **reset_design** command.

Multicorner-Multimode Support

This command applies to current scenario only.

EXAMPLES

The following example annotates a transition time of 20 units at input pin A of cell instance U1/U2/U3:

```
prompt> set_annotated_transition 20 U1/U2/U3/A
```

The following example annotates a rise transition of 1.4 units at the input pin U5/A:

```
prompt> set_annotated_transition -rise 1.4 U5/A
```

The following example annotates a rise transition of 12.3 units for minimum delay analysis at U5/A:

```
prompt> set_annotated_transition -rise -min 12.3 U5/A
```

SEE ALSO

set_input_transition(2)
target_library(3)

set_app_options

Sets application options to the specified value.

SYNTAX

Boolean **set_app_options**

[-block *block*]
[-category *category*]
[-name *name*]
[-value *value*]
[-list *name_value_list*]

Data Types

<i>block</i>	block
<i>category</i>	string
<i>name</i>	string
<i>value</i>	string
<i>name_value_list</i>	list

ARGUMENTS

-block *block*

The name of the block on which to set the option values.

-category *category*

Specifies the category of the application options to follow with the -list option. When setting multiple application options that belong to the same category, this option enables you to provide the category one time, instead of multiple times with the option name. This option is not required. If this option is not specified, then the application option name should have the complete category information.

-name *name*

Specifies the name of the application option which to modify. The -name and -value options go together and are mutually exclusive with the -list option, but you must specify either -name and -value, or specify -list.

-value *value*

Specifies the new value of the application option. The -name and -value options go together and are mutually exclusive with the -list option, but you must specify either -name and -value, or specify -list.

-list *name_value_list*

Specifies a list of option name and value pairs which to set. The list must have an even number of tokens to be valid. The -name and -value options go together and are mutually exclusive with the -list option, but you must specify either -name and -value, or specify -list.

DESCRIPTION

This **set_app_options** command sets the values of the specified application options in the global scope.

The name of application option is not verified. If the application option is invalid, the command fails and prints an error message during the run.

Many application options have a value that must be expressed in units of time, voltage, and so on. In this case, the value must include a multiplier character (such as 'p', 'n', or 'k') and/or a units specifier character (such as 'F', 'V', or 's'). The units specifier character must be in correct upper or lower case, for example, uppercase 'V' for volts and lowercase 's' for seconds. If the units character does not specify the correct type of unit, this command will fail with no effect. Note that the user input units currently in effect are not used by this command.

User must set all app options every time the design is loaded into Design Compiler. The app options can be saved to a file using Design Compiler NXT command **report_app_options**. The app options can be read back by sourcing later the saved file.

EXAMPLES

The following example sets the value of the time.enable_preset_clear_arcs application option to true.

```
prompt> set_app_options -name time.enable_preset_clear_arcs -value true
```

The following example uses the -category option to modify multiple application options of the same category.

```
prompt> set_app_options -category signoff.create_metal_fill -list \
{flat true run_dir /tmp}
```

The following example uses the -list option to modify multiple application options.

```
prompt> set_app_options -list {shell.tmp_dir_path "/tmp" \
time.enable_preset_clear_arcs true}
```

The following example produces an error, because the list does not have an even number of tokens.

```
prompt> set_app_options -list {name1 value1 name2 value2 name3}
Error: set_app_options -list must contain an even number of tokens. (DCT-296)
```

The following example sets the np.high_fanout_net_pin_capacitance application option with units of capacitance to a value of 1.5 picofarads.

```
prompt> set_app_options -name time.high_fanout_net_pin_capacitance -value 1.5p
```

SEE ALSO

[report_app_options\(2\)](#)
[reset_app_options\(2\)](#)

set_app_var

Sets the value of an application variable.

SYNTAX

```
string set_app_var
  -default
    var
      value
```

Data Types

```
var   string
value string
```

ARGUMENTS

-default

Resets the variable to its default value.

var

Specifies the application variable to set.

value

Specifies the value to which the variable is to be set.

DESCRIPTION

The **set_app_var** command sets the specified application variable. This command sets the variable to its default value or to a new value you specify.

This command returns the new value of the variable if setting the variable was successful. If the application variable could not be set, then an error is returned indicating the reason for the failure.

Reasons for failure include:

- The specified variable name is not an application variable, unless the application variable **sh_allow_tcl_with_set_app_var** is set to true See the **sh_allow_tcl_with_set_app_var** man page for details.
- The specified application variable is read only.
- The value specified is not a legal value for this application variable

EXAMPLES

The following example attempts to set a read-only application variable:

```
prompt> set_app_var synopsys_root /tmp
Error: can't set "synopsys_root": variable is read-only
      Use error_info for more info. (CMD-013)
```

In this example, the application variable name is entered incorrectly, which generates an error message:

```
prompt> set_app_var sh_enable_page_mode 1
Error: "sh_enable_page_mode" is not an application variable
      Use error_info for more info. (CMD-013)
```

This example shows the variable name entered correctly:

```
prompt> set_app_var sh_enable_page_mode 1
1
```

This example resets the variable to its default value:

```
prompt> set_app_var sh_enable_page_mode -default
0
```

SEE ALSO

[get_app_var\(2\)](#)
[report_app_var\(2\)](#)
[write_app_var\(2\)](#)

set_aspect_ratio

Specifies the placement aspect ratio for the core area. This command is supported only in topographical mode.

SYNTAX

```
status set_aspect_ratio  
      y_x_ratio
```

Data Types

y_x_ratio float

ARGUMENTS

y_x_ratio

Specifies the aspect ratio constraint for the core area; it is defined as *y:x* ratio. For example, specifying 1.2 as the aspect ratio results in a core area whose *y* dimension is 1.2 times the *x* dimension. The default value for the aspect ratio is 1.0.

DESCRIPTION

The **set_aspect_ratio** command specifies the design-level physical constraint for the aspect ratio, which is used to generate the coarse floorplan during synthesis. Use this command before running synthesis commands, and after loading the physical library and the design.

The other commands that set constraints on the core area, are **set_placement_area**, **set_rectilinear_outline**, and **set_aspect_ratio**. Among the four commands, **set_placement_area** has the highest priority, while **set_rectilinear_outline** has higher priority than **set_utilization** and **set_aspect_ratio**. This means if the placement area constraint is set by **set_placement_area** or if the rectilinear outline constraint is set by **set_rectilinear_outline** on the current design, then the aspect ratio constraint will not be used during synthesis. Furthermore, in this case, the aspect ratio will neither be reported by the command **report_physical_constraints**, nor written out by the **write_physical_constraints** command.

EXAMPLES

The following example shows how to set the aspect ratio to 2.0:

```
prompt> set_aspect_ratio 2.0
```

SEE ALSO

`report_physical_constraints(2)`
`set_placement_area(2)`
`write_physical_constraints(2)`

set_attribute

Sets an attribute to a specified value on the specified list of objects.

SYNTAX

```
collection set_attribute
  objects
  attribute_name
  attribute_value
  [-type boolean | integer | float | string]
  [-bus]
  [-quiet]
```

Data Types

<i>objects</i>	collection
<i>attribute_name</i>	string
<i>attribute_value</i>	string

ARGUMENTS

objects

Specifies the objects on which the attribute is to be set.

attribute_name

Specifies the name of the attribute to be set.

attribute_value

Specifies the value of the attribute. The data type must be the same as that of the attribute.

-type boolean | integer | float | string

Specifies the data type of the *attribute_value* argument. This argument is required when creating new attributes; otherwise, it is optional. If the attribute data type is not specified, the tool uses either the specified *attribute_value* argument or the data type of the existing attribute.

-bus

Sets attributes on the bus instead of bus members.

-quiet

Turns off the warning message that would otherwise be issued if the attribute or objects are not found.

DESCRIPTION

This command sets the value of an attribute on an object. For a complete list of attributes, see the **attributes** man page.

This command returns a collection of objects that have the specified attribute value set. If the attribute is not set on any objects, the command returns an empty string.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the attributes. However, for attributes such as **max_leakage_power**, which are scenario dependent, this command uses information from the current scenario only.

EXAMPLES

The following example defines an integer cell attribute named X, and then sets this attribute to 30 on all cells in this level of the hierarchy:

```
prompt> define_user_attribute -type int -classes cell X  
cell  
prompt> set_attribute [get_cells *] X 30  
{U1}
```

SEE ALSO

[collections\(2\)](#)
[define_user_attribute\(2\)](#)
[get_attribute\(2\)](#)
[list_attributes\(2\)](#)
[remove_attribute\(2\)](#)
[attributes\(3\)](#)

set_auto_disable_drc_nets

Sets the **auto_disable_drc_net** attribute on the current design, causing the specified nets to have DRC disabled. This command was previously called by the **set_auto_ideal_nets** command.

SYNTAX

```
status set_auto_disable_drc_nets
  [-default]
  [-none]
  [-all]
  [-clock true | false]
  [-constant true | false]
  [-scan true | false]
  [-on_clock_network true | false]
```

ARGUMENTS

-default

Disables design rule checking (DRC) on nets connected to clocks and constant nets in the current design. This option is equivalent to **-clock true** and **-constant true**. This is also the default behavior if no option is selected or if the command is not executed. You cannot use **-default** with any other option.

-none

Enables DRC for all nets in the current design, including nets connected to clocks. You cannot use **-none** with any other option.

-all

Disables DRC on all applicable nets in the current design. It is equivalent to setting **-clock true**, **-constant true**, and **-scan true**.

-clock true | false

Disables or enables DRC on nets that are connected to clock pins of sequential cells for ideal clocks with a user-specified clock transition time. When set to **false**, DRC is enabled on these nets. This option is supported for backward compatibility. However, it is recommended that you use the **-on_clock_network** option instead to enable or disable DRC for the clock network.

-constant true | false

Disables or enables DRC on constant nets in the current design. When set to **true** (the default), it automatically disables DRC on constant nets. When set to **false**, it enables DRC on constant nets.

-scan true | false

Disables or enables DRC on scan clock and scan enable nets in the current design. When set to **true**, it automatically disables DRC on scan clock and scan enable nets. When **false** (the default), it enables DRC on scan clock and scan enable nets. This option does not prevent the tool from automatically disabling DRC on nets connected to clocks and constant nets, unless **-clock false** and **-constant false** is also used. Scan data nets (those specified in the SCANDEF) are not affected by this option.

-on_clock_network true | false

Disables or enables DRC on clock networks in the current design. When set to **true**, DRC is disabled on clock networks. The default is **false**. It is recommended that you use this option instead of the **-clock** option.

DESCRIPTION

This command disables design rule checking (DRC) for specified nets in the current design. If the command is executed without options, or if the command is not executed at all, by default, the tool disables DRC for all nets connected to clocks and constant nets. The command options are additive each time a new **set_auto_disable_drc_nets** command is executed.

To disable DRC for clock networks, use the **-on_clock_network true** option. The **-clock true** option is kept only for backward compatibility.

To prevent constant nets from having DRC disabled, use the **-constant false** or **-none** options.

DRC disabled nets are those nets that are free from the max_capacitance, max_fanout, and max_transition design rule constraints. They are useful for reducing DRC violations caused by clock trees, because these nets usually have high max_capacitance and max_fanout violations.

You can add the **dont_touch** attribute to the DRC disabled nets by using the **set_dont_touch_network** or the **set_dont_touch** command.

Note that nets with the **auto_disable_drc_nets** attribute are different from nets with the **ideal_nets** and **ideal_networks** attributes because the nets with the **ideal_nets** and **ideal_networks** attributes use ideal timing and the **dont_touch** attribute.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example disables DRC on nets connected to clocks and constant nets in the current design:

```
prompt> set_auto_disable_drc_nets -clock true -constant true
```

The following example disables DRC on only the constant nets in the current design:

```
prompt> set_auto_disable_drc_nets -constant true
```

The following example re-enables DRC for all relevant nets, including those on clock nets, in the current design:

```
prompt> set_auto_disable_drc_nets -none
```

set_auto_floorplan_constraints

Sets constraints for implicit floorplan initialization.

SYNTAX

```
status set_auto_floorplan_constraints
[-control_type core | die]
[-side_length {side_a side_b [side_c side_d side_e side_f]}]
[-side_ratio {side_a side_b [side_c side_d side_e side_f]}]
[-core_utilization utilization]
[-boundary {{x y} {x y} {x y} {x y} ...}]
[-orientation N | W | S | E]
[-coincident_boundary true | false]
[-core_offset {value | vertical_value horizontal_value | side_1 ... side_N}]
[-row_core_ratio row_core_ratio]
[-flip_first_row true | false]
[-honor_pad_limit]
[-site_def site_def_name]
[-use_site_row]
[-origin_offset {x, y}]
[-row_pattern {row_pattern_name}]
[-reset]
```

Data Types

<i>utilization</i>	float
<i>row_core_ratio</i>	float
<i>site_def_name</i>	string

ARGUMENTS

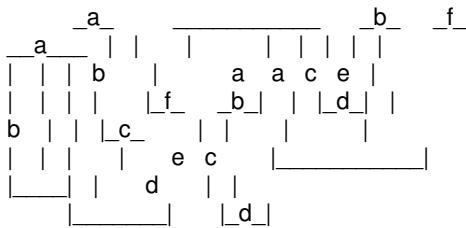

-control_type core | die

Specifies whether the side_length and side_ratio options apply to the core or the die boundary. If set to die, then the dimensions (side_length and side_ratio) are applied to the die boundary and the core_offset values are subtracted from the dimensions to determine the core boundary. If set to core (default), the dimensions are applied to the core boundary and the core_offset values are added to the dimensions to determine the final die boundary. By default, the control_type is core.

-side_length { *side_a side_b side_c side_d side_e side_f* }

Specifies the side length used by the command. If the control_type is die, then it applies to the die boundary side settings. Each dimension in the side_length list represents the length of the edge. If you provide more values than required to describe the specified shape, the extra values are ignored. If you do not provide all of the values required to describe the specified shape, the tool issues an error message. There are only two dimensions for **shape Rect**: width and height. This option is mutually exclusive with the -side_ratio option.

The following diagram shows the definition of the edges and the orientation of the R-, L-, T-, and U- rectilinear blocks. By default, the core shape is R (rectangular).

-side_ratio { side_a side_b side_c side_d side_e side_f }

Specifies the side ratio used by the command. If the control_type is die, then it applies the side_ratio to the die boundary side settings. Each dimension in the list represents the relative proportion of the dimension of the edge to the sum of all the dimensions listed. For example, if the list of dimensions of an L-shaped block is {1 2 1 1}, the tool calculates the dimension of side a, c, or d (where the value is 1) as 20% ($1/(1+2+1+1)$) of the sum of the dimensions listed, and the dimension of side b is 40% of the summation.

-core_utilization utilization

Specifies the utilization of the core area. The utilization is the total area of the core occupied by all standard cells and macro cells divided by the total core area. You can specify a value between 0 and 1. The cell area includes all standard and macro cells. For example, a core utilization of 0.8 specifies that 80 percent of the core area is used for cell placement at this stage. Later, the tool might add more cell area, with the remaining area available for routing. By default, the core utilization is 0.7.

-boundary {{x y} {x y} {x y} {x y} ...}

Specifies the shape to be used by the command. If the control_type is core, then the boundary defines the core area and the core_offsets should be added to create the die. If control_type is die, then the core_offset should be subtracted from the die boundary to create the core area. The format is { {x1 y1} {x2 y2} {x3 y3} {x4 y4} }.

-orientation N | W | S | E

Specifies one of four possible orientations for the specified rectilinear shape. The orientations are North (N), West (W), South (S), and East (E). The tool repositions the block to the specified orientation by rotating it in a clockwise direction. For **shape R**, the orientation is always N.

-coincident_boundary true | false

Specifies whether the die boundary follows the shape of the core. If true, the die boundary assumes the same shape as the core and requires a **-core_offset** setting with the same number of sides as the core. If false, the die boundary is rectangular and the **-core_offset** option requires only four values. When the die boundary is rectangular it is created with **-core_offset** values such that the offset value is honored to the closest core edge on a per side basis. In this case, the bounding box of the die boundary is the minimum size that meets all four **-core_offset** values. By default, this option is true.

-core_offset {value | vertical_value horizontal_value | side_1 ... side_N}

Specifies the distance between the side of the core and the side of the die boundary. If only one value is specified, the value is used for all sides. If two values are specified, the first value is applied to all vertical edges and the second value is applied to all horizontal edges. Side numbers are based on the standard rectilinear numbering and do not correlate to the numbering scheme used to define the size of each edge (side_a, side_b, etc). By default, the core offset is equal to the minimum I/O cell height. If there are no I/O cells, the core offset is 0.

-row_core_ratio row_core_ratio

Specifies the amount of channel area between cell rows in the core area to reserve for routing. The *ratio* is a number between 0 and 1.0. A smaller row-to-core ratio creates more space for routing channels. A value of 1.0 creates no routing channel space. By default, the ratio is 1.0. Note that this ratio should be greater than or equal to the core utilization value.

-flip_first_row true | false

Specifies whether the command flips the first row at the bottom of the core area for horizontally-placed cell rows, or flips the leftmost row for vertically-placed cell rows. By default, this option is true.

-honor_pad_limit

Adjusts the core and die size to honor pad-limited designs. If this option is not specified, the core area is created based on the default core utilization ratio 0.7.

-site_def site_def_name

Specifies the site def to be used in floorplanning when there are multiple site defs in the technology file. The default is to use default site def. If there is no default site def, the command uses the site def with the smallest site width.

-use_site_row

Specifies that the tool creates site rows.

-origin_offset {x, y}

Specifies the location of the lower-left corner of the die boundary bbox with respect to the origin of the block.

-row_pattern {row_pattern_name}

Specifies the name of row_pattern to be used for floorplan when there are row patterns specification in the physical rule section of technology file.

-reset

Reset all the constraints to their defaults.

DESCRIPTION

This command invokes the auto floorplan feature during **compile_ultra** and creates a floorplan with a boundary, core, site array (or rows), and wire tracks, if die outline or rows are not provided by user. The command takes effect only during **compile_ultra**.

In order to invoke auto floorplan feature in Design Compile NXT Milkyway mode, it's required to provide **set_icc2_options** command as well.

This command is supported only in Design Compiler NXT topographical mode.

EXAMPLES

The following example sets the constraint of utilization to be 0.8.

```
prompt> set_auto_floorplan_constraints -core_utilization 0.8  
1
```

The following example sets the preferred core length to create the floorplan.

```
prompt> set_auto_floorplan_constraints -side_length {200 200}  
1
```

SEE ALSO

[report_auto_floorplan_constraints\(2\)](#)

set_auto_ideal_nets

This command is obsolete. It has been replaced by the **set_auto_disable_drc_nets** command, which works in the same way. The change was made to correctly distinguish between DRC disabled nets and ideal nets, which additionally have ideal timing and dont_touch.

SEE ALSO

set_auto_disable_drc_nets(2)
set_ideal_net(2)
set_ideal_network(2)

set_autofix_configuration

Configures automatic fixing of violations (AutoFix), performed by DFT insertion, globally for the current design.

SYNTAX

```
status set_autofix_configuration
[-type fix_type]
[-control_signal control_name]
[-test_data test_data_name]
[-method method]
[-fix_data enable | disable]
[-fix_latch enable | disable]
[-include_elements list_of_design_objects]
[-exclude_elements list_of_design_objects]
```

Data Types

<i>fix_type</i>	string
<i>control_name</i>	string
<i>test_data_name</i>	string
<i>method</i>	string
<i>list_of_design_objects</i>	list

ARGUMENTS

-type *fix_type*

Specifies the type of fixing to configure. For multiple fixing types, specify a configuration command for each type. The valid *fix_type* values are:

```
clock
set
reset
xpropagation
internal_bus
external_bus
bidirectional
```

-control_signal *control_name*

Specifies the name of the control signal that activates the fixing logic. The specified signal must be predefined as either a **TestMode** or **ScanEnable** signal. The **ScanEnable** signal type is valid only for the **set** and **reset** fixing types when using the **gate\gP** fixing method. If no control signal is specified, the AutoFix test points are controlled by any signal with the **TestMode** signal type. If no **TestMode** signal is found, Autofix creates a new test mode port.

-test_data *test_data_name*

Specifies the name of the test data signal used for fixing violations. This signal is used as a controllable source signal by the AutoFix test points. The signal must be predefined using the **set_dft_signal** command as a **TestData** signal. In addition, the signal must also be predefined as a **ScanClock** signal type for the **clock** fixing type, or as a **Reset** signal type for the **set** and **reset** fixing

types. If no test data signal is specified, Autofix creates a new **ScanClock** or **Reset** port depending on the fixing type.

-method method

Specifies the fixing method to use for the fixing type specified with the **-type** option. Valid methods depend on the fixing type, as follows:

```

clock - mux
set - mux | gate (default is mux)
reset - mux | gate (default is mux)
xpropagation - mux
internal_bus - no_disabling | enable_one | disable_all (default is enable_one)
external_bus - no_disabling | enable_one | disable_all (default is disable_all)
bidirectional - input | output | no_disabling (default is input)

```

-fix_data enable | disable

Enables or disables fixing of clock-used-as-data and reset-as-data violations. This option is only valid for the **clock**, **set**, and **reset** fixing types. The default is **disable**.

-fix_latch enable | disable

Enables or disables fixing of uncontrollable set and reset pins on latches. The default is **disable**. This option is only valid for the **set** and **reset** fixing types. This option does not affect the enable signal of the latch.

-include_elements list_of_design_objects

Specifies the list of design objects to which the global fixing configuration applies. Wildcards and collections are supported.

If this option is used, only the specified design objects are fixed. By default, all violated design objects are AutoFixed.

Valid object types depend on the fixing type, as follows:

```

clock - cell (hierarchical and leaf)
set - cell (hierarchical and leaf)
reset - cell (hierarchical and leaf)
xpropagation - cell (hierarchical and leaf)
internal_bus - net
external_bus - net
bidirectional - port

```

-exclude_elements list_of_design_objects

Specifies the list of design objects to exclude from global fixing. Wildcards and collections are supported. By default, the list of excluded design objects is empty.

Valid object types are the same as for the **-include_elements** option.

DESCRIPTION

The **set_ autofix_configuration** command allows you to specify details about how different DFT violation types should be AutoFixed. This command specifies a global fixing configuration for the current design. To specify different fixing configurations for different parts of the design, use the **set_ autofix_element** command instead.

Note that this command does not enable or disable AutoFix fixing types. Before configuring fixing with this command, you must enable AutoFix by using the **-fix_clock**, **-fix_set**, **-fix_reset**, **-fix_xpropagation**, **-fix_bus**, or **-fix_bidirectional** options of the **set_dft_configuration** command. See that man page for more details.

A separate configuration is maintained for each fixing type. If multiple **set_ autofix_configuration** commands are issued for the same fixing type, the most recent fixing specification for that type replaces previous specifications.

The AutoFix configuration is applied to the current design. If you apply an Autofix configuration and then change the current design,

your settings are no longer visible.

Use the **report_autofix_configuration** command to display the current Autofix configuration for the design. Use the **reset_autofix_configuration** command to reset the Autofix configuration for the design.

EXAMPLES

In the following example, AutoFix is configured to fix uncontrollable clock violations using the TESTCLK signal as the new Autofix clock signal, and the TM_FIX signal as the AutoFix fixing logic enable pin. Note that the test mode and controllable clock pin signals are defined with the **set_dft_signal** command.

```
prompt> set_dft_signal -view existing_dft -type ScanClock \
           -timing {45 55} -port TESTCLK

prompt> set_dft_signal -view spec -type TestMode -port TM_FIX

prompt> set_dft_configuration -fix_clock enable

prompt> set_dft_signal -view spec -type TestData -port TESTCLK

prompt> set_autofix_configuration -type clock \
           -include_elements [get_object_name [get_cells -hierarchical *]] \
           -control_signal TM_FIX \
           -test_data TESTCLK
```

SEE ALSO

`set_dft_configuration(2)`
`report_autofix_configuration(2)`
`reset_autofix_configuration(2)`
`preview_dft(2)`
`insert_dft(2)`
`set_dft_signal(2)`

set_autofix_element

Configures automatic fixing of violations (AutoFix), performed by DFT insertion, locally for a particular part of the design.

SYNTAX

```
status set_autofix_element
  list_of_design_objects
  [-type fix_type]
  [-control_signal control_name]
  [-test_data test_data_name]
  [-method method]
  [-fix_data enable | disable]
  [-fix_latch enable | disable]
```

Data Types

<i>list_of_design_objects</i>	list
<i>fix_type</i>	string
<i>control_name</i>	string
<i>test_data_name</i>	string
<i>method</i>	string

ARGUMENTS

list_of_design_objects

Specifies the list of design objects to which the local fixing configuration applies. Wildcards and collections are not supported.

Valid object types depend on the fixing type, as follows:

- clock - cell** (hierarchical and leaf)
- set - cell** (hierarchical and leaf)
- reset - cell** (hierarchical and leaf)
- xpropagation - cell** (hierarchical and leaf)
- internal_bus - net**
- external_bus - net**
- bidirectional - port**

-type *fix_type*

Specifies the type of fixing to configure. For multiple fixing types, specify a configuration command for each type. The valid *fix_type* values are:

- clock**
- set**
- reset**
- xpropagation**
- internal_bus**
- external_bus**
- bidirectional**

-control_signal control_name

Specifies the name of the control signal that activates the fixing logic. The specified signal must be predefined as either a **TestMode** or **ScanEnable** signal. The **ScanEnable** signal type is valid only for the **set** and **reset** fixing types. If no control signal is specified, the AutoFix test points are controlled by any signal with the **TestMode** signal type. If no **TestMode** signal is found, Autofix creates a new test mode port.

-test_data test_data_name

Specifies the name of the test data signal used for fixing violations. This signal is used as a controllable source signal by the AutoFix test points. The signal must be predefined using the **set_dft_signal** command as a **TestData** signal. In addition, the signal must also be predefined as a **ScanClock** signal type for the **clock** fixing type, or as a **Reset** signal type for the **set** and **reset** fixing types. If no test data signal is specified, Autofix creates a new **ScanClock** or **Reset** port depending on the fixing type.

-method method

Specifies the fixing method to use for the fixing type specified with the **-type** option. Valid methods depend on the fixing type, as follows:

clock - mux
set - mux | gate (default is **mux**)
reset - mux | gate (default is **mux**)
xpropagation - mux
internal_bus - no_disabling | enable_one | disable_all (default is **enable_one**)
external_bus - no_disabling | enable_one | disable_all (default is **disable_all**)
bidirectional - input | output | no_disabling (default is **input**)

-fix_data enable | disable

Enables or disables fixing of clock-used-as-data and reset-as-data violations. This option is only valid for the **clock**, **set**, and **reset** fixing types. The default is **disable**.

-fix_latch enable | disable

Enables or disables fixing of uncontrollable set and reset pins on latches. The default is **disable**. This option is only valid for the **set** and **reset** fixing types. This option does not affect the enable signal of the latch.

DESCRIPTION

The **set_ autofix_element** command allows you to specify details about how different DFT violation types should be AutoFixed in a particular part of the design. This command specifies a local fixing configuration that overrides the global fixing configuration specified by the **set_ autofix_configuration** command.

Note that this command does not enable or disable AutoFix fixing types. Before configuring fixing with this command, you must enable AutoFix by using the **-fix_clock**, **-fix_set**, **-fix_reset**, **-fix_xpropagation**, **-fix_bus**, or **-fix_bidirectional** options of the **set_dft_configuration** command. See that man page for more details.

Separate configurations are maintained for each fixing type. If multiple **set_ autofix_element** commands are issued for the same fixing type on the same design object, the most recent fixing specification for that type replaces previous specifications.

The AutoFix configuration is applied to the current design. If you apply an Autofix configuration and then change the current design, your settings are no longer visible.

Use the **report_ autofix_element** command to display the current Autofix configuration for the design. Use the **reset_ autofix_element** command to reset the Autofix configuration for the design.

EXAMPLES

The following example configures clock-fixing globally for the design using CLK, then configures clock-fixing locally in hierarchical cells U_RX_BLK and U_TX_BLK:

```
prompt> set_ autofix_configuration -type clock -test_data CLK  
prompt> set_ autofix_element -type clock -test_data RXCLK {U_RX_BLK}  
prompt> set_ autofix_element -type clock -test_data TXCLK {U_TX_BLK}
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`report_ autofix_configuration(2)`
`report_ autofix_element(2)`
`set_ autofix_configuration(2)`

set_autoungroup_options

Specifies the options to control autoungrouping.

SYNTAX

```
status set_autoungroup_options
  [-start_level level]
  [-keep_parent_hierarchies constraints]
  [-reset]
```

Data Types

level integer
constraints string

ARGUMENTS

-start_level *level*

Specifies the level from which ungrouping should start. Default value is 1.

-keep_parent_hierarchies *constraints*

Preserve parent hierarchies depending on constraints. Constraints can be UPF, SDC, bigger_hier. By setting the -keep_parent_hierarchies option to SDC, preserve all the hierarchy and its parents with leaf/hierarchical cells or pins having timing constraints. By setting -keep_parent_hierarchies option to UPF, preserve all the hierarchy and its parents with leaf/hierarchical cells or pins having UPF constraints. By setting -keep_parent_hierarchies option to bigger_hier, preserve all the parents of the big hierarchies which are not ungrouped by the auto_ungroupfeature

-reset

Resets the controls to default values.

DESCRIPTION

You can use this command to specify the controls for autoungrouping. Before compile, you should set the configuration by using this command.

If the command is called multiple times, the new options will be added to the previous ones. To completely use new set of options, "-reset" should be called.

If set_ungroup command is also used, then set_ungroup will have preference over this command.

EXAMPLES

The following example shows how to use set_autoungroup_options .

```
prompt> set_autoungroup_options -start_level 3
```

This will prevent the ungrouping of hier alts at level 1 and 2.

```
prompt> set_autoungroup_options -start_level 3 -keep_parent_hierarchies SDC|UPF
```

This will prevent the ungrouping of hier alts at level 1 and 2 and also, all those alts and parent alts of those alts which have any sdc or upf constraints.

```
prompt> set_autoungroup_options -keep_parent_hierarchies SDC
```

If there is a hierarchical structure “top/mid/bot1/bot2”. The hierarchy “bot2” has SDC constraints on the pins. This command will prevent ungrouping of hierarchy bot1,mid and top also. But if user has used “set_ungroup top/mid true”,then the hierarchy “mid” will be ungrouped irrespective of set_autoungroup_options command.

set_balance_registers

Sets the **balance_registers** attribute on the specified designs or on the current design, so that the design is retimed during compile.

SYNTAX

```
status set_balance_registers
  [-design]
  [true | false]
  [design_list]
```

Data Types

design_list list

ARGUMENTS

-design

Specifies a design on which to set the **balance_registers** attribute.

true | false

Specifies the value with which to set the **balance_registers** attribute. The default value is **true**, which allows the **compile** command to automatically invoke the **balance_registers** command. When the value is set to **false**, **balance_registers** is not invoked.

design_list

Specifies a list of designs to retime. The default is the current design.

DESCRIPTION

This command sets the **balance_registers** attribute on the specified designs or on the current design, so that the design is retimed during compile. If the **balance_registers** attribute is set to **true** (the default) on a design, the **compile** command automatically invokes the **balance_registers** command, which moves registers to minimize the maximum register-to-register delay. Subdesigns in the hierarchy are ungrouped into the design, unless the **dont_touch** attribute is set.

It is an error to invoke **balance_registers** on a design that contains generic logic. If the **balance_registers** attribute is set, **compile** attempts to optimize the design by invoking **balance_registers**. Ensure that your design contains no generic logic at the instant **balance_registers** is called during **compile**.

For more details on retiming during optimization, see the Design Compiler documentation.

To remove **balance_registers**, use the **remove_attribute** or **reset_design** command. You can achieve the same effect by setting the **balance_registers** attribute to **false** by running **set_balance_registers false**.

Licensing during compile when using the **balance_registers** attribute can be controlled by using the

compile_retime_license_behavior shell variable.

EXAMPLES

In the following example, **balance_registers** is enabled on the design named TEST:

```
prompt> set_balance_registers -design TEST
```

In the following example, **balance_registers** is enabled on the current design and **balance_registers** is disabled on the design named OLD:

```
prompt> read TEST
```

```
prompt> set_balance_registers
```

```
prompt> set_balance_registers false -design OLD
```

set_boundary_cell

Sets the boundary-cell configuration for the specified ports and core cells.

SYNTAX

```
status set_boundary_cell
  -class core_wrapper | shadow_wrapper | bsd
  [-function function]
  [-ports port_list]
  [-core_cells core_list]
  [-type type]
  [-design design_name]
  [-register_io_implementation swap | in_place]
  [-use_dedicated_wrapper_clock true | false]
  [-safe_state 0 | 1 | none]
  [-share true | false]
  [-name bcell_name]
  [-shift_clk bcell_shift_clk]
  [-instance hier_cell_list]
  [-include cell_list]
  [-exclude cell_list]
  [-reuse_threshold threshold_value]
  [-hookup_pin hookup_pin_name]
  [-add_shared_wrapper_cell_only true | false]
  [-pins list_of_pins]
  [-scan_en atpg_shift_port_or_hookup_pin]
  [-internal_pins list_of_pins]
```

Data Types

<i>function</i>	string
<i>port_list</i>	list
<i>core_list</i>	list
<i>type</i>	string
<i>design_name</i>	string
<i>bcell_name</i>	string
<i>bcell_shift_clk</i>	string
<i>hier_cell_list</i>	list
<i>cell_list</i>	list
<i>threshold_value</i>	integer
<i>hookup_pin_name</i>	string

ARGUMENTS

-class core_wrapper | shadow_wrapper | bsd

Specifies the name of the class for which the configuration applies. Valid values are **core_wrapper**, **shadow_wrapper**, and **bsd**.

This argument is required.

-function function

Specifies the function of the specified ports to which the local configuration applies. There is no default value for this option. The following values are valid for *function*:

```
input
output
control
bidir
observe
input_inverted
output_inverted
bidir_inverted
receiver_p
receiver_n
ac_select
```

This option is only supported when "-class bsd" is specified.

-ports port_list

Specifies the list of ports for which the configuration applies. There is no default value for this option. You must specify either the **-ports** option or the **-core** option.

-core_cells core_list

Specifies a list of core cells to which the boundary configuration applies.

-type type

Specifies the cell type to be used for the boundary cell in DFT insertion. There is no default value for this option. If this option is not specified, the tool uses the **set_wrapper_configuration** command to get the type of DFT design to use for the specified ports. The following values are valid for *type*:

```
WC_D1
WC_D1_S
WC_S1
WC_S1_S
BC_1
BC_2
BC_4
BC_7
BC_8
BC_9
AC_1
AC_2
AC_7
AC_SELU
AC_SELX
none
```

-design design_name

Specifies the name of the user-defined DFT design as specified by the **define_dft_design** command to be used for the boundary cell.

There is no default value for this option. By default, the tool uses a DesignWare cell for DFT insertion.

This option is mutually exclusive with the **-type** option. You must specify either the **-type** option or the **-design** option.

-register_io_implementation swap | in_place

Specifies the implementation to use for synthesizing shared wrapper cells in core wrapping the current design.

When the option is set to **swap**, registers connected to the specified ports of the design are replaced with equivalent shared wrapper cells. When the option is set to **in_place**, additional glue logic is added to registers attached to the specified ports of the design to reuse them in core wrapper chains.

There is no default value for this option. If the option is not specified, the tool uses the **set_wrapper_configuration** command to get the implementation style to use for the specified ports.

-use_dedicated_wrapper_clock true | false

Specifies whether the dedicated wrapper clock is used for shared wrapper. When the option is set to **true**, core wrapper application uses the dedicated wrapper clock for all shared wrapper cells of the specified ports of the design. When the option is set to **false**, functional clocks are used for shared wrapper cells connected to the specified ports of the design.

-safe_state 0 | 1 | none

Specifies the safe state to be used for wrapper cells added by core wrapping. Valid values for this option are **0**, **1**, and **none**.

There is no default value for this option. If the option is not specified, the tool uses the **set_wrapper_configuration** command to get the safe state to use for the specified ports.

-share true | false

Specifies whether the boundary cells should be shared. Sharing boundary cells is allowed only for control boundary cells. If the value of the option is set to **true**, the boundary cells for the specified ports are shared. If the value of the option is set to **false**, the boundary cells for the specified ports are not shared.

The default value of this option is **true** for function value control and **false** for all other types of boundary cells.

-name bcell_name

Specifies the name of the boundary cell. The name can be subsequently referenced in a **set_scan_path** specification to control the boundary cell ordering.

This option is mandatory if the **-share** option is set to **true** or if the **-function** option is set to **control** or **ac_select**.

-shift_clk bcell_shift_clk

Specifies the shift clock to be used for the boundary cell.

This option is applicable only with the **-class core_wrapper** and either of the **-type WC_D1** or **-type WC_D1_S** options.

The value of this option must be a port or an internal pin. The specified port or pin is connected to the shift clock pin of the dedicated boundary cell.

The timing information of the specified clock is obtained from DRC.

There is no default value for this option.

-instance hier_cell_list

This option is applicable only when the **-class** option is set to **core_wrapper** and the **-maximize_reuse** option of the **set_wrapper_configuration** command is enabled.

This option specifies a list of hierarchical cells. If a port is connected to a register inside one of these hierarchical cells, the tool adds the specified type of boundary cell to the port.

The valid types of boundary cells supported with this option are **none** or **WC_D1**.

If the type of the boundary cell is chosen as **none**, no wrapper cell is added to the port.

If the type of the boundary cell is chosen as **WC_D1**, a dedicated wrapper cell is added to the port.

This option is mutually exclusive with the **-port** option.

There is no default value for this option.

-include cell_list

Applies only when the **-class** option is set to **core_wrapper** and the **-maximize_reuse** option of the **set_wrapper_configuration** command is enabled.

This option specifies the list of I/O register cells to be included for the specified port.

There is no default value for this option.

-exclude *cell_list*

Applies only when the class option is set to **core_wrapper** and the **-maximize_reuse** option of the **set_wrapper_configuration** command is enabled.

This option specifies the list of I/O register cells to be excluded for the specified port.

To specify a list of cells to be excluded from all the ports, do not specify the port names with the command.

There is no default value for this option.

-reuse_threshold *threshold_value*

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells for the specified ports.

This option is applicable only when the **-class** option is set to **core_wrapper**.

This option is applicable only when the **-maximize_reuse** option of the **set_wrapper_configuration** command is enabled.

When the number of I/O registers detected for the specified ports exceeds the specified threshold value, a dedicated wrapper cell is added to the ports.

The default value of this option is -1; that is, the reuse threshold value specified with wrapper configuration is applicable to the specified ports.

If the value of the option is set to 0, all I/O registers associated with the specified ports are reused as shared wrapper cells.

-hookup_pin *hookup_pin_name*

Specifies the name of the hookup pin to be used to stitch custom BSR cells. When the **-hookup_pin** option is not specified, the BSR cells are hooked up at pad pins.

This option is applicable only when the **-class** option is set to **bsd** and the **-function** option is set to **input**, **output**, or **control**.

DESCRIPTION

The **set_boundary_cell** command overrides the default configuration for the specified ports and core cells of the current design. The ports and core cells must exist in the current design.

To set the default core wrapper configuration, use the **set_wrapper_configuration -class core_wrapper** command.

To set the default shadow wrapper configuration, use the **set_wrapper_configuration -class shadow_wrapper** command.

To set the default BSD configuration, use the **set_bsd_configuration** command.

EXAMPLES

The following example specifies that the DesignWare WC_D1 cell is to be used with safe value of 1 on *port1* and *port2* in core wrapping:

```
prompt> set_boundary_cell -class core_wrapper -type WC_D1 \
    -safe_state 1 -port_list {port1 port2}
```

The following example specifies that the DesignWare BC_1 cell is to be used for ports *port1* and *port2* in BSD insertion:

```
prompt> set_boundary_cell -class bsd -type BC_1 \
    -function output -port_list {port1 port2}
```

The following example specifies that the DesignWare BC_2 cell is to be used as a control BSR cell for ports *port1* and *port2* in BSD insertion: The control BSR cells for these ports are not shared.

```
prompt> set_boundary_cell -class bsd -type BC_2 \
    -function control -port_list {port1 port2} \
    -name CTRL1 -share false
```

The following example specifies that the DesignWare BC_2 cell is to be used as a control BSR cell for ports *port1* and *port2* in BSD insertion. The control BSR cell is shared for these ports.

```
prompt> set_boundary_cell -class bsd -type BC_2 \
    -function control -port_list {port1 port2} \
    -name CTRL1 -share true
```

The following example specifies that the DesignWare AC_SELU cell is to be used as the AC selection BSR cell for ports *ac_port1* and *ac_port2* in BSD insertion. The AC selection BSR cell is shared for these ports.

```
prompt> set_boundary_cell -class bsd -type AC_SELU \
    -function ac_select -port_list {ac_port1, ac_port2} \
    -name SELECT1
```

The following example specifies a user defined implementation of BC_1 BSR cell to be used for ports *port1* and *port2* in BSD insertion:

```
prompt> define_dft_design -type BC_1 -design my_bc_1 \
    -interface { capture_clk cclk h \
    update_clk uclk h shift_dr se h mode tm h si si h \
    data_in di h data_out do h so so h }

set_boundary_cell -class bsd -design my_bc_1 -port_list {port1 port2}
```

The following example specifies that no boundary cell to be added to the ports connected to hierarchical cell *core1_inst/core_inst*:

```
prompt> set_boundary_cell -class core_wrapper -type none \
    -instance core1_inst/core2_inst
```

The following example specifies that a dedicated boundary cell to be added to the ports connected to hierarchical cell *core1_inst/core_inst*.

```
prompt> set_boundary_cell -class core_wrapper -type WC_D1 \
    -instance core1_inst/core2_inst
```

The following example specifies that I2_reg, I2_1_reg to be included as boundary cells for the port /I2:

```
prompt> set_boundary_cell -class core_wrapper -port { I2 } \
    -include { I2_reg I2_1_reg }
```

The following example specifies that I2_reg, I2_1_reg to be excluded as boundary cells for the port /I2:

```
prompt> set_boundary_cell -class core_wrapper -port { I2 } \
    -exclude { I2_reg I2_1_reg }
```

The following example specifies that the custom BSR minimp_o_bc1, minimp_bc4 and minimp_e_bc1 should be stitched to the specified hookup pins.

```
prompt> set_boundary_cell -class bsd -design minimp_o_bc1 \
    -function output -port DDR_UDQS -hookup_pin i_phy_64b_bs_dqs[1]
prompt> set_boundary_cell -class bsd -design minimp_bc4 \
    -function input -port DDR_UDQS -hookup_pin i_phy_64b_bs_dqs_in_observe[1]
prompt> set_boundary_cell -class bsd -design minimp_e_bc1 \
    -function control -port DDR_UDQS -name bc_e_DDR_UDQS \
    -hookup_pin i_phy_64b_bs_dqsoe[1]
```

The following example specifies that I2_reg, I2_1_reg to be excluded as boundary cells for the design:

```
prompt> set_boundary_cell -class core_wrapper \
    -include { I2_reg I2_1_reg }
```

SEE ALSO

`report_boundary_cell(2)`
`set_bsd_configuration(2)`
`set_wrapper_configuration(2)`

set_boundary_cell_io

Specifies the primary inputs (PIs) and primary outputs (POs) of a boundary cell in the current design.

SYNTAX

```
status set_boundary_cell_io
  -access {pin_type pin_name}
  -type boundary | wrapper
  -cell shift_flop_name
```

Data Types

<i>pin_type</i>	string
<i>pin_name</i>	string
<i>shift_flop_name</i>	string

ARGUMENTS

-access {*pin_type* *pin_name*}

Specifies a list of pairs, with each pair consisting of the pin type and the hierarchical pin name. Valid values for *pin_type* are **in_pi**, **in_po**, **out_pi**, **out_po**.

-type boundary | wrapper

Specifies the type of cell as either **boundary** or **wrapper**.

-cell *shift_flop_name*

Specifies the names of the shift flop of the boundary cell.

DESCRIPTION

The **set_boundary_cell_io** command specifies the primary inputs (PIs) and primary outputs (POs) of boundary cells. For input cells, specify only **in_pi** and **in_po**. For output and control cells, specify **out_pi** and **out_po**. For merged cells, specify all four values (**in_pi**, **in_po**, **out_pi**, **out_po**). The cell name indicates the name of the shift flop of the cell.

EXAMPLES

The following example instructs **check_bsd** to use the specified primary inputs and primary outputs for the BSR cell *bs_d_oe2/q2bscan/inst1/inst4*:

```
prompt> set_boundary_cell_io -type boundary \
    -access {out_pi bs_d_oe2/U1/**logic_0** out_po U8/U1/A} \
    -cell bs_d_oe2/q2bscan/inst1/inst4/q_reg \
```

SEE ALSO

[check_bsd\(2\)](#)
[write_bsdl\(2\)](#)

set_boundary_optimization

Sets the **boundary_optimization** attribute on specified cells, references, or designs, thus allowing for optimization across hierarchical boundaries.

SYNTAX

```
status set_boundary_optimization  
    object_list  
    [true | false]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cell, reference, or design names for which to enable boundary optimization. Cell or reference names in *object_list* must be from the current design. If more than one object is specified, they must be enclosed in quotation marks ("") or braces ({}).

true | false

Specifies the value with which to set the **boundary_optimization** attribute. When this option is set to **true** (the default), boundary optimization is enabled.

DESCRIPTION

This command sets the **boundary_optimization** attribute on *object_list*. This attribute is used to specify the cells, references, or designs to be optimized across hierarchical boundaries. The compile commands use this information to create smaller designs. This might change the function of the object, so the object must not be used in any other context.

If a cell with a specified name is found in the current design, the **boundary_optimization** attribute is set to the specified value in the cell. If no cell with a specified name is found, the tool searches for a reference. If a reference is found, the attribute is set for the reference. Otherwise, the tool searches for a design and the attribute is set for the design.

By default, setting the **boundary_optimization** attribute to **false** does not disable constant propagation across hierarchical boundaries of the specified object. To disable constant propagation with the **boundary_optimization false** attribute, set the **compile_enable_constant_propagation_with_no_boundary_opt** variable to **false**.

Occasionally, cells use an input signal only in its complemented form. In this case, it is best to invert the signal and its ports. The **set_boundary_optimization** command considers these optimizations. When this occurs, port names are changed according to the **port_complement_naming_style** variable.

To remove this attribute, use the **remove_attribute** command.

EXAMPLES

The following example shows how to ignore hierarchical boundaries during optimization for cells named U0 and U1 and how to preserve them for a cell named U2:

```
prompt> set_boundary_optimization { U0 U1 }
prompt> set_boundary_optimization U2 false
```

set_bsd_ac_port

Identifies the AC ports in your design.

SYNTAX

```
status set_bsd_ac_port  
-port_list list_of_ports
```

Data Types

list_of_ports list

ARGUMENTS

-port_list *list_of_ports*

Specifies the ports of the current design to be considered as AC ports.

DESCRIPTION

The **set_bsd_ac_port** command identifies the ports of the current design to be considered as AC ports. Boundary Scan Insertion adds AC BSR cells for such ports if the IEEE1149.6_2003 standard mode is enabled.

This specification is honored only by Boundary Scan Synthesis.

To report the defined AC ports, use the **report_bsd_ac_port** command. To delete AC port specifications, use the **remove_bsd_ac_port** command.

EXAMPLES

The following example shows how the ports *A_1*, *A_2*, and *A_3* are identified as AC ports:

```
prompt> set_bsd_ac_port -port_list {A_1 A_2 A_3}
```

SEE ALSO

[insert_dft\(2\)](#)

```
preview_dft(2)
remove_bsd_ac_port(2)
report_bsd_ac_port(2)
```

set_bsd_compliance

Specifies an IEEE 1149.1 compliant pattern for a boundary-scan design.

SYNTAX

```
status set_bsd_compliance
  -name pattern_name
  -pattern signal_port_bit_value_pairs
```

Data Types

<i>pattern_name</i>	string
<i>signal_port_bit_value_pairs</i>	list

ARGUMENTS

-name *pattern_name*

Specifies the name of the pattern. Patterns having the same name merge and overwrite earlier versions.

-pattern *signal_port_bit_value_pairs*

Lists signal port and binary value pairs that specify the compliance-enable pattern. The specified signal ports must be input ports and cannot include IEEE 1149.1 test access ports. Valid bit values specified at each signal port are **0** or **1**.

DESCRIPTION

The **set_bsd_compliance** command specifies the compliance-enable ports and patterns that enable the IEEE 1149.1 boundary-scan functionality for a design.

The functionality of the IEEE 1149.1 boundary-scan logic in certain designs depends on the logic values at the compliance-enable ports for the designs. Compliance-enable ports are defined in ANSI/IEEE Std. 1149.1, section 3-8.

The **set_bsd_compliance** command is mandatory for all IEEE 1149.1 designs that contain at least one compliance-enable port.

EXAMPLES

The following example specifies one compliance-enable pattern named *p1* for the current design:

```
prompt> set_bsd_compliance -name p1 \
  -pattern [get_ports c_en*, 1, ntest, 0]
```

SEE ALSO

`reset_bsd_configuration(2)`

set_bsd_configuration

Specifies the boundary-scan configuration for a design.

SYNTAX

```
status set_bsd_configuration
  [-asynchronous_reset true | false]
  [-default_package package_name]
  [-instruction_encoding binary | one_hot]
  [-ir_width instruction_register_length]
  [-style synchronous | asynchronous]
  [-check_pad_designs none | all | pad_design_list]
  [-control_cell_max_fanout max_fanout]
  [-ieee1149.1_1993 enable | disable]
  [-std std_version_name_list]
  [-rtl enable | disable]
```

Data Types

<i>package_name</i>	string
<i>instruction_register_length</i>	integer
<i>max_fanout</i>	integer
<i>std_version_name_list</i>	list of strings

ARGUMENTS

-asynchronous_reset true | false

Specifies whether or not the boundary-scan circuitry synthesized by the **insert_dft** command is to have an asynchronous test logic reset port. When set to **true** (the default), an asynchronous test logic reset port is used. When set to **false**, there is no asynchronous test logic reset port.

-default_package *package_name*

Specifies the default package for a boundary-scan design. The *package_name* value must correspond to one of the packages for the design read in using the **read_pin_map** command.

-instruction_encoding binary | one_hot

Specifies the instruction encoding scheme to use to generate the decoding logic for the instruction register and the instruction code assignment.

Setting the value to **binary** (the default) causes the **insert_dft** command to use binary coding for the instruction opcodes. This method uses a minimum number of register bits for the instruction register.

Setting the value to **one_hot** causes the **insert_dft** command to use opcodes that have only one bit set to logic 1 with all other bits set to logic 0. The exception is the BYPASS instruction, which has all encoding bits set to logic 1. This encoding method uses more instruction register bits, but it simplifies the decoding logic.

-ir_width *instruction_register_length*

Specifies the length of the instruction register, in bits, for the boundary-scan design. Allowed values are the integers **2** through **63**, inclusive. The default is the minimum value calculated by BSD Compiler to fit the set of instructions specified and encoding method to be used.

-style synchronous | asynchronous

Specifies the style of boundary-scan to implement. Valid values are **asynchronous** and **synchronous**. The default style is **synchronous**.

-check_pad_designs none | all | pad_design_list

Specifies the pad designs to check. When set to **none**, the **preview_dft** command does not validate any pad design.

When set to **all** (the default), the **preview_dft** command validates all pad designs instantiated in the design.

When given a *pad_designs_list*, the **preview_dft** command validates all pad designs specified in the list.

The signal type **port** must be specified in the access list of all pad designs that are to be validated. See the man page for the **set_bsd_pad_design** command for details.

-control_cell_max_fanout max_fanout

Specifies the maximum number of fanouts allowed for the control cell when the **-share true** option is specified in the **set_boundary_cell** command.

-ieee1149.1_1993 enable | disable

Specifies the mode in which BSD Compiler performs. This option is disabled by default, so BSD Compiler runs in the IEEE1149.1-2001 standard mode. When set to **enable**, BSD Compiler runs in the old IEEE1149.1-1993 standard mode.

This option is obsolete. Use **-std {ieee1149.1_1993}** to enable IEEE1149.1-1993 standard mode.

-std std_version_name_list

Specifies the modes in which BSD Compiler performs. You can specify one or more of the following values: **ieee1149.1_1993**, **ieee1149.1_2001**, and **ieee1149.6_2003**.

- When set to **-std ieee1149.1_1993**, BSD Compiler runs in the old IEEE1149.1-1993 standard mode.
- When set to **-std ieee1149.6_2003**, BSD Compiler runs in the IEEE1149.6-2003 standard mode.
- When set to **-std {ieee1149.1_1993 ieee1149.6_2003}**, BSD Compiler runs in the IEEE1149.1-1993 and IEEE1149.6-2003 standard modes.

By default, BSD Compiler runs in the IEEE1149.1-2001 standard mode.

-rtl enable | disable

Specifies the flow in which BSD Compiler should run. This option is disabled by default, so BSD Compiler runs in the default netlist flow.

When set to **enable**, BSD Compiler runs in the new RTL generation flow and generates RTL output. The **write_bsd_rtl** command should be used to generate RTL output file.

DESCRIPTION

The **set_bsd_configuration** command specifies the boundary-scan configuration for a design. Customize the implementation by selecting the synchronization style, the instruction register length, the reset mechanism, and the port-to-pin mapping.

When the **asynchronous** style is selected, the asynchronous signals coming from the TAP controller cell, `capture_dr` and `update_dr`, are connected to the boundary-scan register cells. The asynchronous version of the TAP controller is used.

When the **synchronous** style is selected, the synchronous signals coming from the TAP controller cell, `capture_en`, `update_en`, and

TCK are connected to the boundary-scan register cells. The synchronous version of the TAP controller is used. By default, BSD Compiler generates a synchronous boundary scan design.

By specifying the instruction length, you can control the opcode length of the implemented instruction register. By default, BSD Compiler calculates the minimum length of the instruction register needed to encode both the mandatory instruction and those instructions specified using the **set_bsd_instruction** command. This also depends on the encoding scheme selected with the **-instruction_encoding** option.

To reset the TAP controller, you can hold the TMS signal high for a minimum of five TCK clock cycles. You can also specify the implementation of an asynchronous test reset signal (TRST) with the **-asynchronous_reset true** option. In this case, you must either configure a TRST port with the **set_dft_signal -type trst** command, or you must configure an on-chip power-up reset (PUR) cell with the **set_bsd_power_up_reset** command.

The mapping of logical signals onto the physical pins of a component package is described through a port-to-pin map file. Multiple packages for a design can be read in, using the **read_pin_map** command. The sequence of ports listed in the pin mapping file after the line declaring the package name drives the order of the corresponding cells in the boundary-scan register. The default package name specified with the **set_bsd_configuration -default_package** command appears in the generic parameter statement of the BSDL file produced by the **write_bsd** command.

By specifying the **rtl** option, BSD Compiler can be used to generate RTL boundary scan output for a given design.

Use the **report_test -bsd_configuration** command to display the current default package for the design.

Use the **reset_bsd_configuration** command to remove the settings for the design.

EXAMPLES

The following example enables ieee1149.1_1993:

```
prompt> set_bsd_configuration -std ieee1149.1_1993
```

The following example specifies a bypass model for BSR cell insertion. It also specifies that a buffer chain should be inserted for the shift_dr, clock_dr, update_dr and mode control signals, placed every 10 BSR cells:

```
prompt> set_bsd_configuration -cross_hierarchy { u_CORE/u_model } \
    -bsr_buffer_fanout 10
```

The following example enables the RTL generation flow:

```
prompt> set_bsd_configuration -rtl enable
```

Data Types

instruction_list	list
inst_code_list	list
register_name	string
clock_conditioning	string
pin_name	string
capture_value_list	list
clock_cycle_list	list
pattern	string
pin_name_list	list
real_time	float

ARGUMENTS

-view existing_dft | spec

Specifies the view to which the specification applies. Valid views are **existing_dft** and **spec**.

Set the view to **existing_dft** to refer to the existing instructions in the design. Use the **existing_dft** value when working with BSD-inserted designs. For example, use the following command to specify the instruction for the tool to implement:

```
prompt> set_bsd_instruction bypass -view existing_dft \
```

-register BYPASS -code 1111

Set the view to **spec**, the default, to refer to instructions that the tool must use when running **check_bsd**. Use this view when boundary-scan synthesis is not performed by **insert_dft** (in the verification flow). For example, to direct the tool that the *my_instr* instruction must be implemented as targeted for the register BOUNDARY, use the following command:

```
prompt> set_bsd_instruction my_instr -view spec |
    -register BYPASS -code 1001
```

instruction_list

Specifies a set of boundary instructions.

-code *inst_code_list*

Specifies the list of binary codes corresponding to the instructions specified by *instruction_list*. A single instruction can be associated with an opcode. This means that the *instruction_list* must contain a single identifier if **-code *inst_code_list*** is used. The opcode must have a length equal to the number set by **set_bsd_configuration -ir_width**. By default, the opcode is assigned automatically by BSD Compiler.

When using this option with the **check_bsd** command in the verification flow, opcodes should be specified. Only BYPASS and EXTEST reserved opcodes are inferred automatically.

-register *register_name*

Selects a standard data register or a user-defined register, previously declared with the **set_dft_signal** and the **set_scan_path** commands, to be connected for serial access between TDI and TDO when the instruction is active. Valid standard data registers are **BOUNDARY** and **BYPASS**. The **BOUNDARY** value is automatically selected for EXTEST, SAMPLE, PRELOAD and INTEST. The **BYPASS** value is automatically selected for BYPASS, CLAMP and HIGHZ. User-defined instructions must specify a register. You cannot specify **BOUNDARY** as a data register for the BYPASS, HIGHZ, CLAMP, IDCODE, and USERCODE standard instructions. Similarly, **BYPASS** cannot be specified as the data register for the EXTEST, INTEST, SAMPLE_PRELOAD, SAMPLE, PRELOAD, IDCODE, and USERCODE standard instructions.

-input_clock_condition *clock_conditioning*

Specifies the value that drives the clock signal going into the system when the instruction is active. If you are clocking the TDR with the system clock, set the value to **PI**. If you are using TCK clock, set the value to **TCK**. Valid values are **PI** or **TCK**. The default is **PI**.

-output_condition BSR | HIGHZ | NONE

Specifies how the system outputs are driven when the instruction is active. Valid conditions are as follows:

- **BSR** puts the boundary scan register into EXTEST mode.
- **HIGHZ** puts the output pins into high impedance mode.
- **NONE** puts the boundary scan register into transparent mode (the default).

-internal_scan *pin_name*

Specifies a hierarchical pin in the design to which the TAP controller's shift-dr signal gated with the decoded instruction is connected.

-capture_value *capture_value_list*

Defines the capture value of the DEVICE-ID register for the IDCODE instruction. The capture value contains 32 digits. Ensure that the least significant bit (LSB) of the capture value is set to 1 for the IDCODE capture value.

-private

Specifies that the instructions are considered private. Private instructions have the **INSTRUCTION_PRIVATE** attribute in the BSDL file generated by the tool. The data registers of private instructions are not shown in the BSDL file. No test patterns are generated for private instructions. By default, the instructions are not considered private.

-clock_cycles *clock_cycle_list*

Lists the clock port and integer pairs that specify the minimum number of clock cycles on the clock port required for the design to stay in the Run-Test/Idle TAP controller state to ensure completion of the INTEST or the RUNBIST instruction.

-signature *pattern*

Specifies the state of the boundary-scan register after execution of the RUNBIST instruction. The *pattern* argument correlates to the <det pattern> argument defined in section B.8.15 of the Supplement to IEEE Std. 1149.1.

-high *pin_name_list*

Specifies a list of pins to be asserted high when the specified instructions are selected. The *pin_name_list* contains the hierarchical names of the pins. There is no default for this option. This option can be used with any instruction, including standard instructions.

-low *pin_name_list*

Specifies a list of pins to be asserted low when the specified instructions are selected. The *pin_name_list* contains the hierarchical names of the pins. There is no default for this option. This option can be used with any instruction, including standard instructions.

-sequential_high *pin_name_list*

Specifies a list of pins to be glitchlessly asserted high when the specified instructions are selected. This option is similar to the **-high** option, except that the combinational decode logic is registered to prevent glitches at the specified pins.

-sequential_low *pin_name_list*

Specifies a list of pins to be glitchlessly asserted low when the specified instructions are selected. This option is similar to the **-low** option, except that the combinational decode logic is registered to prevent glitches at the specified pins.

-time *real_time*

Specifies a real number that indicates the time duration in nanoseconds for the EXTEST_TRAIN and EXTEST_PULSE instructions in the Run-Test-Idle (RTI) state, as well as for INTEST and RUNBIST. The tool returns an error if this option is used with other instructions.

-excluded_bsr_condition CLAMP | NONE

Specifies the condition of BSR cells excluded from the specified short BSR chain. The following values are valid for this option:

- **CLAMP** indicates that all BSR cells that are not part of the specified BSR chain are conditioned as if CLAMP instruction is active.
- **NONE** indicates that all BSR cells that are not part of the specified BSR chain are kept transparent while the user instruction is active.

Note: The following error occurs when a value other than CLAMP or NONE is used with this option:

Invalid value '%s' specified for option '-excluded_bsr_condition'.

-bsd_init_data *init_value*

Specifies an optional initialization value to be loaded into the test data register associated with this instruction at the beginning of the test program created by the **create_bsd_patterns -setup_instructions** command.

By default, no initialization value is loaded at the beginning of the test program.

DESCRIPTION

The **set_bsd_instruction** command specifies one or more boundary-scan instructions that the **insert_dft** command implements for the current design. The **check_bsd** command infers these instructions in the verification flow when the **-infer_instructions** switch is set to **true** or if the **insert_dft** command does not perform boundary-scan synthesis. Alternatively, all boundary-scan synthesis decoded opcodes need to be listed. The default value for the **-infer_instructions** switch is **false**, in which case, it checks compliance of the instructions specified in the run script. You can specify a list of IEEE Std 1149.1 instructions. The keywords for the standard instructions are BYPASS, EXTEST, SAMPLE, PRELOAD, IDCODE, CLAMP, HIGHZ, and USERCODE.

For all other standard and private instructions, including INTEST and RUNBIST, you can specify their corresponding binary code, input clock conditioning, user-defined register, and output conditioning.

If you do not specify any binary code, the **insert_dft** command selects one automatically in the design flow. However, you must specify opcodes in the Verification flow for the BYPASS, SAMPLE, PRELOAD, and EXTEST instructions when the **set_bsd_instruction** command is used with the **check_bsd** command and the **-infer_instructions** switch is set to **true**. The input clock conditioning and output conditioning (BSR or HIGHZ) specifications are required for the standard instructions INTEST and RUNBIST.

By default, the capture and update clock pins of the Test Data Register (TDR) specified with instructions are not gated, that is, the pins are always driven by TCK. To gate the clock pins of a TDR with a MUX so that the pins are driven by TCK when the instruction that selects the TDR is active and driven by system logic when the instruction is not active, set the following variable to **true** prior to BSD insertion:

```
prompt> set test_bsd_synthesis_gated_tck true
```

You can use the **-high**, **-low**, **-sequential_high**, and **-sequential_low** options to specify one or more design pins to be asserted high or low when an instruction in the *instruction_list* is loaded. The **-high** and **-low** options create a combinational decode of the instruction register Q pins, which provides a minimal-area decode but can produce glitches in the assertion signal. If you are asserting glitch-sensitive design pins such as asynchronous set/reset pins, use the **-sequential_high** and **-sequential_low** options instead. These options create a registered decode of the instruction register D pins, which increases sequential area but produces a glitch-free assertion signal.

Note that registered decodes cannot be mixed with combinational decodes. If you specify the **-sequential_high** or **-sequential_low** option for any pin, then all **-high** and **-low** pin assertions (for all instructions) also become registered.

The **-clock_cycle** option specifies a list of clock port and integer pairs, and each pair specifies the minimum number of clock cycles on the specified clock port that the design needs to stay in the Run-Test or the Idle TAP controller state to ensure completion of the RUNBIST, INTEST, EXTEST_PULSE, and EXTEST_TRAIN instructions.

The **-time** option applies to EXTEST_PULSE and EXTEST instructions. For the EXTEST_PULSE instruction, the *real_time* value specifies the minimum wait time in nanoseconds in the Run-Test or the Idle TAP controller state. Note that you can specify only one of the **-clock_cycles** or **-time** options for this instruction.

For the EXTEST_TRAIN instruction, the *real_time* value specifies the maximum time in nanoseconds prior to the exit of the Run-Test or the Idle TAP controller state within which the specified minimum number of pulses specified with the **-clock_cycles** option should occur for EXTEST_TRAIN instruction. Note that the **-time** option must always be used along with **-clock_cycles** for this instruction.

The **-signature** option specifies a binary string that represents the signature produced by the RUNBIST instruction.

The **-capture_value** option allows you to specify a 32-bit binary or hexadecimal value and pins in the design, that provide the capture value, to be connected to the DIR register. This option also allows you to specify a mix of bits and design pins.

Specify a valid user code value for the USERCODE instruction. The user code value can only be specified for the USERCODE instruction. Specify binary or hexadecimal bit-patterns using the size-constant Verilog syntax as shown in the following example:

```
<number of binary bits>'[b|h|B|H]<binary or hex value>
```

Specify pin names with the full hierarchical pin name. Specify a bus representing a collection of pins using the following syntax:

```
<name of the bus>[<upper bit>:< lower bit>]
```

To review your boundary-scan instruction specifications, use the **preview_dft -bsd all** command. To implement the boundary-scan instruction set, use the **insert_dft** command. To delete boundary-scan instruction specifications, use the **remove_bsd_instruction** command.

EXAMPLES

The following example directs **insert_dft** to implement the HIGHZ and CLAMP instructions as a part of the synthesized boundary-scan circuitry:

```
prompt> set_bsd_instruction -view spec {HIGHZ CLAMP}
```

The following example directs **insert_dft** to implement the user-defined instruction named *UDI1*, whose binary code is 1010, and to select the boundary-scan register to be connected for serial access between TDI and TDO. This puts the outputs in high-impedance

instructions as a part of the synthesized boundary-scan circuitry.

```
prompt> set_bsd_instruction -view spec UDI1 -register BOUNDARY \
           -code {1010} -output_conditioning HIGHZ
```

The following example directs **insert_dft** to implement the INTEST instructions, and to drive the system clock by **TCK**:

```
prompt> set_bsd_instruction -view spec INTEST \
           -input_clock_condition TCK
```

The following example directs **insert_dft** to implement the USERCODE instruction:

```
prompt> set_bsd_instruction -view spec USERCODE -code {0110} \
           -user_code_val {version_reg/v3 version_reg/v2 \
           version_reg/v1 version_reg/v0 16'b1111111100000000 12'h2ab}
```

set_bsd_linkage_port

Identifies the linkage ports in your design.

SYNTAX

```
status set_bsd_linkage_port  
-port_list list_of_ports
```

Data Types

list_of_ports list

ARGUMENTS

-port_list *list_of_ports*

Specifies the ports of the current design to be considered as linkage ports.

DESCRIPTION

The **set_bsd_linkage_port** command identifies the ports of the current design to be considered as linkage ports. Such ports may be analog ports, power or ground ports, or any port driven by a black-box cell that you do not want to consider for boundary-scan insertion.

The following actions are not performed for ports declared as linkage ports by the **set_bsd_linkage_port** command:

- Checking for pad cells connected to the port during boundary-scan insertion.
- Insertion of a boundary-scan cell to be connected to the port.
- Compliance checking on the port.
- Toggling of the port in test vector generation.

The linkage ports are listed as linkage bits in the BSDL.

To preview the boundary-scan implementation, use the **preview_dft** command with the **-bsd all** option. To implement the boundary-scan logic, use the **insert_dft** command. To delete boundary-scan linkage port specifications, use the **remove_bsd_specification** command with the **-linkage_port** option.

EXAMPLES

The following example shows how the PLL_1, PLL_2, and PLL_3 ports are identified as linkage bits:

```
prompt> set_bsd_linkage_port -port_list {PLL_1, PLL_2, PLL_3}
```

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`

set_bsd_power_up_reset

Specifies and characterizes the power-up reset cell for the current design.

SYNTAX

```
status set_bsd_power_up_reset
  -cell_name cell_name
  -reset_pin_name reset_pin_name
  -active high | low
  [-delay power_up_reset_delay]
```

Data Types

<i>cell_name</i>	string
<i>reset_pin_name</i>	string
<i>power_up_reset_delay</i>	integer

ARGUMENTS

-cell_name *cell_name*

Specifies the instance name of the power-up reset cell.

-reset_pin_name *reset_pin_name*

Specifies the pin name of the power-up reset cell which generates a reset pulse upon power-on.

-active high | low

Specifies whether the power-up reset pulse is active **high** or active **low**.

-delay *power_up_reset_delay*

Specifies the initial power-up reset delay, which is measured from the time power is switched on to the time the TAP controller resets to the test-logic-reset state, in library time units.

DESCRIPTION

This command specifies and characterizes the power-up reset cell instance for the design. You must use the **-delay** option with the *power_up_reset_delay* value if the design does not have the (optional) TRST test access port.

EXAMPLES

The following example shows how to specify the *PUR* instance as the power-up reset with a pin named *reset_out* as the pin at which an active-high reset pulse is generated upon power-up with a delay of 1300 library time units:

```
prompt> set_bsd_power_up_reset -cell_name PUR \
           -reset_pin_name reset_out -active high -delay 1300
```

set_case_analysis

Specifies that a port or pin is at a constant 1 or 0 logic value or has only a rising or only a falling transition applied to it.

SYNTAX

```
status set_case_analysis  
    value  
    port_or_pin_list
```

Data Types

<i>value</i>	integer or string
<i>port_or_pin_list</i>	list

ARGUMENTS

value

Specifies the constant logic value or the transition assigned to the specified port or pin. The valid constant values are **0**, **1**, **zero**, and **one**. The valid transition values are **rising**, **falling**, **rise**, and **fall**.

port_or_pin_list

Lists the ports or pins to which the *value* applies.

DESCRIPTION

This command specifies that a port or pin is at a constant 1 or 0 logic value or has only a rising or only a falling transition applied to it.

Case analysis is a way to specify a given mode of the design without altering the netlist structure. For the current timing analysis session, you can specify that certain signals are at a constant value (1 or 0) or that only one type of transition (rising or falling) is to be applied. When you specify case analysis as a constant value, that value is propagated forward through the network as long as a controlling value for the traversed logic is at the constant value.

For example, if you specify that one of the inputs of a NAND gate is a constant logic 0, that condition is propagated to the NAND output, which is then considered a constant logic 1 value. This constant value is in turn propagated to the inputs of all cells driven by this signal, and so on.

In the event of case analysis set as a transition (such as rising), the specified pin or port is only considered for timing analysis with that type of transition. The other transition (such as falling) is not considered.

You can use case analysis (in addition to the mode commands) to fully specify the operating mode of a design. For example, you can use the **set_mode** command to specify a design that instantiates models with a TESTMODE signal that is disabled during timing analysis. In addition, if a TESTMODE signal exists in the design, you can set it to a constant logic value so that all test logic that the TESTMODE signal controls is disabled.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies that a port named IN1 is at a constant 0 logic value.

```
prompt> set_case_analysis 0 IN1
```

The following example specifies that the U1/U2/A pin is considered only for a rising transition. The falling transition on this pin is not considered.

```
prompt> set_case_analysis rising U1/U2/A
```

SEE ALSO

```
remove_case_analysis(2)
report_case_analysis(2)
set_mode(2)
reset_mode(2)
```

set_cell_degradation

Sets the **cell_degradation** attribute to a specified value on the specified ports or designs.

SYNTAX

```
status set_cell_degradation
    cell_degradation_value
    object_list
```

Data Types

<i>cell_degradation_value</i>	float
<i>object_list</i>	list

ARGUMENTS

cell_degradation_value

Specifies a capacitance value for setting the **cell_degradation** attribute. You must enter the *cell_degradation_value* argument in capacitance units consistent with those used by the technology library during optimization. For example, if the library specifies capacitance values in picofarads, you must express the *cell_degradation_value* argument in picofarads.

object_list

Specifies the input ports on which to set the **cell_degradation** attribute.

DESCRIPTION

This command sets the **cell_degradation** attribute on the specified ports or designs to the value specified in the *cell_degradation_value* argument.

During optimization, the tool attempts to ensure that the capacitance value for a net is less than the *cell_degradation_value* if the value of the **compile_fix_cell_degradation** variable is **true**.

If cell degradation tables are specified in the technology library (implicit constraints), the tool automatically tries to meet them if the value of the **compile_fix_cell_degradation** variable is **true**. The cell degradation tables give the maximum capacitance that can be driven by a cell as a function of the transition times at the inputs of the cell.

By default, a port has no cell degradation constraint.

The **cell_degradation** attribute and the **max_capacitance**, **max_fanout**, and **max_transition** attributes are design rule constraints; the **max_delay** and **max_area** attributes are optimization constraints. Design rule constraints reflect those technology-specific restrictions that must be met for a design to function correctly. Optimization constraints reflect desirable, but not crucial, goals and restrictions for the operation of a design. The tool attempts to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process. Therefore, optimization gives preference to **cell_degradation** and other design rule constraints, even if they adversely affect the optimization constraints on a design.

To get information about optimization and design rule constraints, use the **report_constraint** command. To remove the **cell_degradation** attribute from a port, use the **remove_attribute** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a maximum capacitance value of 2.0 units on the port named late_riser:

```
prompt> set_cell_degradation 2.0 late_riser
```

SEE ALSO

all_inputs(2)

remove_attribute(2)
report_constraint(2)
set_max_capacitance(2)
compile_fix_cell_degradation(3)

set_cell_internal_power

Sets or removes the **power_value** attribute on the specified pins. The value represents the power consumption for a single toggle of each pin.

SYNTAX

```
status set_cell_internal_power
  pin_list [power_value [unit]]
  | -delete_all
```

Data Types

<i>pin_list</i>	collection
<i>power_value</i>	float
<i>unit</i>	string

ARGUMENTS

pin_list

Specifies the pins on which to either set the **power_value** attribute or remove previously-annotated **power_value** attributes.

This option cannot be used with the **-delete_all** option.

power_value

Specifies the value with which to set the **power_value** attribute on the specified pins. This value represents the power consumption for a single toggle of the pin.

If you do not specify the *power_value* argument, any existing **power_value** attributes are removed from the specified pins.

This option cannot be used with the **-delete_all** option.

unit

Specifies the unit of the power value. Allowed values for *unit* are as follows:

GW	MW	KW	W	mW
uW	nW	pW	fW	aW

If you do not specify the *unit* argument, the tool uses the library power unit. If the library does not have any units, the tool displays an error message.

This option cannot be used with the **-delete_all** option.

-delete_all

Deletes all of the internal power annotations from all of the pins in the design.

This option cannot be used with the *pin_list*, *power_value*, or *unit* arguments.

DESCRIPTION

This command sets or removes the **power_value** attribute on the specified pins.

If a cell has at least one pin with a **power_value** attribute, its internal power is calculated as the sum of the pin power values, where each pin power value is calculated by multiplying the annotated power value on that pin by the pin toggle rate.

You can use this command to override a cell's library power characterization in situations where that characterization does not apply. A common use is when you manually replace an entire cloud of logic with a single cell and you want the single cell's power consumption to represent that of the cloud of logic. For example, if you replace a clock tree by a single buffer cell, you can set the **power_value** attribute on the output pin of the buffer cell with the value of the power consumption for one clock toggle of the entire clock tree. Although the buffer cell might have been power-characterized in the library, its power consumption is now calculated by using the value of the **power_value** attribute set by the **set_cell_internal_power** command.

Do not use this command as a routine part of the power characterization flow. It is considered a best practice to use a cell's library power characterization unless there is a reason to override it, as described above.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example shows how an instance-specific cell is power-characterized by using the **set_cell_internal_power** command:

```
prompt> set_cell_internal_power [get_pins U123/A] 1.234 uW
prompt> set_cell_internal_power [get_pins U123/B] 1.567 uW
prompt> set_cell_internal_power [get_pins U123/*] -1.000 nW
prompt> set_cell_internal_power -delete_all
```

SEE ALSO

[report_power\(2\)](#)

set_cell_location

Specifies the physical location, orientation, and dont_touch status for leaf cells. This command is supported in Design Compiler topographical mode only.

SYNTAX

```
status set_cell_location
  -coordinates {x y}
  [-orientation target_orient]
  [-fixed]
  object_list
```

Data Types

x	float
y	float
target_orient	string
object_list	collection

ARGUMENTS

-coordinates {x y}

Specifies the lower-left coordinates of the specified cells. The numbers are in microns relative to the chip origin.

-orientation target_orient

Specifies the target orientation.

Valid values are

N or 0: Nominal orientation (north)

S or 180: 180-degree rotation (south)

E or 270: 270-degree counterclockwise rotation (east)

W or 90: 90-degree counterclockwise rotation (west)

FN or 0-mirror: reflection in the y-axis (flipped north)

FS or 180-mirror: 180-degree rotation followed by reflection in the y-axis (flipped south)

FE or 90-mirror: 90-degree counterclockwise rotation followed by reflection in the y-axis (flipped east)

FW or 270-mirror: 270-degree counterclockwise rotation followed by reflection in the y-axis (flipped west)

-fixed

Sets the **dont_touch** attribute on the specified cells to prevent modification or replacement of these cells during optimization.

object_list

Specifies the leaf cells on which to set the physical location, orientation, and dont_touch status for leaf cells. Typically, this command uses a single leaf cell as the argument.

DESCRIPTION

The **set_cell_location** command specifies the physical location, orientation, and dont_touch status for leaf cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the location of the lower-left corner of the cell named INST_1 to (100 100):

```
prompt> set_cell_location -coordinates { 100 100 } INST_1
```

set_cell_mode

Selects the mode of a component.

SYNTAX

```
status set_cell_mode
      [mode_list]
      [instance_list]
```

Data Types

<i>mode_list</i>	list
<i>instance_list</i>	list

ARGUMENTS

mode_list

Specifies the active modes for timing analysis. All other modes of the same mode group are implicitly inactive. The specified modes are active on the given instance list. If multiple modes are selected they must be in separate mode groups.

instance_list

Specifies the cells for which the specified modes are active.

DESCRIPTION

The **set_cell_mode** command is used to select the active mode of a cell that has several functional modes. The other modes in the same mode group that are not selected become disabled.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command selects the READ mode for the RAM instance Uram1.

```
prompt> set_cell_mode READ Uram1
```

The following example applies the **set_cell_mode** command to a cell that has two mode groups, rw0 and rw1, and then shows the

output of **report_cell_mode**. In this example mode group rw0 is set to mode read0, and mode group rw1 is set to mode write1.

```
prompt> set_cell_mode [list read0 write1] U11/core
```

```
prompt> report_cell_mode
```

```
*****
```

```
Report : mode
```

```
Design : top_ram2
```

```
Version: 2013.03-ICC-SP
```

```
Date : Wed Feb 13 14:12:56 2013
```

```
*****
```

Cell	Mode(Group)	Status
U11/core	read0 (rw0)	ENABLED
	write0 (rw0)	DISABLED
	read1 (rw1)	DISABLED
	write1 (rw1)	ENABLED

<i>absolute_tolerance</i>	float

```
criteria_spec      list
groups_or_attributes  list
format_spec        list
```

ARGUMENTS

-cell_area

Compares the cell area defined by the area attribute in the logic library with the area determined by the cell place-and-route boundary in the physical library.

In a FRAM view, the rectangular area covered by the place-and-route boundary for a standard cell, or the area enclosed by the cell boundary of a macro in a polygon, is compared with the cell area in the .db file. This comparison determines an area ratio for each cell in the .db file. If the ratio is found to be the same for all the cells in the logic library, the cell areas are considered consistent. However, if the ratio for a cell deviates from the normal or average ratio for this library by a margin of 5 percent or more, the cell areas are considered inconsistent.

There is no area check for the pad cells because they are special cells located at the chip boundary, and are not used as internal gates. They are considered to have zero area, and are therefore not checked for area.

This option also enables the default logic-versus-physical checks.

-cell_footprint

Checks that the cell place-and-route boundary in the physical library is consistent among a set of cells when the **cell_footprint** attribute is specified in the logic library. This option reports cell names and their place-and-route boundaries.

This option also enables default logic versus physical checks.

-bus_delimiter

Reports bus delimiters in the logic and physical libraries. If the library does not contain a bus delimiter, the field remains blank in the report.

This option also enables default logic versus physical checks.

-tech_consistency

Checks for consistency of technology data between the main library or design library and each associated reference library. The option checks the physical libraries for missing layer data and mismatched technology data. This option is not supported in NDM mode.

-view_comparison

Checks for existence of the CEL and FRAM views in the library, and for mismatched time stamps between these views. In the report table for missing views, the CEL and FRAM columns list the cell name and version number. The missing views are marked by an X.

In the report table for the mismatched views, the CEL version and FRAM version columns list the version numbers. The CEL and FRAM "modified time" column shows the time when each view was last modified. If the FRAM view's "modified time" is earlier than that of the CEL view, it is marked as mismatched.

The internal view creation or modification time in the Milkyway database is checked. No check is performed on the cell content. If the FRAM views were read from a library exchange format (LEF) database, and CEL views were streamed in later, the views are reported as mismatched. You can ignore the report in such cases. This option is not supported in NDM mode.

-same_name_cell

Checks for cells with identical names among the specified main or design library and all physical reference libraries linked to the specified library. If there are cells with the same name in multiple reference libraries, the first cell in the reference control file is used. The remaining cells are ignored. This option does not check naming among the logic libraries.

-signal_em

Checks the signal electromigration rule for the current model and the model type in each routing layer.

-antenna

Checks for missing antenna properties of cells and antenna rules in the layers of the specified main library.

An antenna property report table lists the names of the cells and pins that are missing an antenna property and shows the missing property type. For example, the following conditions are reported:

- * An input pin is missing the gate size.
- * An output pin is missing diode protection information.
- * A macro is missing the hierarchical antenna property.

This option reports the mode, diode mode, default metal ratio, default cut ratio, and maximum ratio for each antenna rule.

-rectilinear_cell

Checks and reports the cell names, types, and coordinates of cells with rectilinear boundaries. This option is not supported in NDM mode.

-physical_only_cell

Checks and reports the cell names, types, and properties of physical-only cells. Physical-only cells are corner pad cells, tap cells, chip cells, I/O pad cells, cover cells, cells that only have power and ground pins, and filler cells with or without metal. This option is not supported in NDM mode.

-phys_property {property_list}

Specifies a list of physical properties to check. You can specify one or more of the following values: **place**, **route**, **cell**, or **metal_density**.

- **place** reports the following placement properties of each standard cell:
 - * Place-and-route boundary as represented by its lower-left and upper-right coordinates.
 - * Cell height relative to the unit-tile height, such as 2xH for a cell with twice the tile height.
 - * Coordinate, the bottom-left location of a cell with unit-tile height, or for a multiple-height cell, the left locations at each unit-tile height.
 - * Tile pattern representing possible cell orientations that have combinations of R0, R90, R160, R0_MX, R0_MY, 90_MX, and R90_MY.
 - * Remarks reporting the place-and-route boundary mismatch with the tile pattern. If there is a mismatch, use the **cmSetMultiHeightProperty** command in the Milkyway Environment tool to set the tile patterns of multiple-height cells.
 - * Macros report the cell boundary and height.

When you specify the **place** option, it also lists the main library and its reference library names with paths, if any, and the unit tiles, names, and sizes. The unit-tile size is reported in the width x height format. If the library does not have a unit-tile, the unit-tile size is not reported. In this case, the unit-tile of the main library is used in the design.

- **route** checks and reports the routing properties of each routing layer, including the preferred direction, track direction, offset, pitch, and remarks. The remarks column is marked "OK" for zero or half-pitch offset. Otherwise, it shows "pitch!=0" or "offset!=0.5*pitch".
- **cell** reports the cell and pin properties for each cell, including the pin name, direction, and type. It also reports the number of cells with multiple power and ground pins.
- **metal_density** checks the macro metal density data for the cells specified by the **check_library** command with the **-cells** option. The option checks if a cell has at least one of the following errors:
 - * The metal density data in the CEL view and the FRAM view are inconsistent.
 - * The metal density windows do not cover the entire area on a layer.

The option lists all the cells with metal density errors in a table with columns for the cell name, data inconsistency between the CEL view and the FRAM view, and the layer where the density windows do not cover the entire cell area.

This option is not supported in NDM mode.

-rail view_data

Checks the rail data consistency between the FRAM and CONN views, and between the FRAM and PARA views. The view_data includes FRAM, CONN and PARA views. If the PG port type, net type, or number does not match in the CONN and FRAM views, the **check_library** command generates a warning message. This option is not supported in NDM mode.

-routeability

-routability

Checks the physical pin on-track accessibility and quality of the defined wire tracks. The option reports the total number of pins without optimal on-track routability and lists the pin names, directions, layers, and tracks for each cell with this issue.

In the track column, an H denotes that the pin is not accessible on a horizontal track, a V denotes that the pin is not accessible on a vertical track, and H&V denotes that the pin is not accessible on both horizontal and vertical tracks.

If a pin is reported as not accessible on-track, the pin might be routed by an off-track wire during detail routing. However, if too many pins do not have on-track routability, adjust the offset values of the wire track preferably to zero or half-pitch. Rerun the **create_lib_track** command to reduce the number of pins that lack optimal accessibility. For NDM mode, use -routability.

-min_pin_layer layer_name

Specifies the minimum layer name. Pins on layers lower than this layer are checked for existence. This option goes with -routability.

-tech

Checks for technology data consistency within a single specified library. This is different from the **-tech_consistency** option, which checks the consistency between different libraries. The messages resulting from using the **-tech** option are similar to those generated during library creation or technology data replacement.

This option requires write permission for the directory where the library resides. If the directory does not have the write permission, the command copies the library to a local directory and checks the copy there.

-placement

Checks cell placement constraint, layers, and sites. This option is supported only in NDM mode.

-pattern_must_join_pin

Checks pattern must-join related items. This option goes with -routability. This option is supported only in NDM mode.

-pattern_must_join_pin_exclusion_list lib_pin_list

Specifies a collection of lib_pins that don't need the pattern must-join check. This option goes with -pattern_must_join_pin.

-drc

Enables DRC checking of the FRAM views in the specified library. Milkyway based DRC check has 2 modes: normal/native mode and advanced mode. In dc_shell/dcnxt_shell/icc_shell, both modes require Milkyway-Interface license, and the advanced mode requires PSYN, PNR and DFY as well as Hercules(ev_engine) licenses. dc_shell/dcnxt_shell/lc_shell only has normal mode. It checks the following design rules in normal mode:

```
wire minWidth
minEdgeLength
minEnclosedArea
minSpacing
cutWidth
cutSpacing
minEnclosure
sameNetMinSpacing
maxStackLevel
```

fatTblSpacing
metal-via spacing (minSpacing in DesignRule section of technology file)

This option lists the cells with DRC violations in a table with columns for showing the cell name, type, and error cell. Check the error cells for detailed information about the DRC violations if the check is done in advanced mode. This option requires write permission for the directory where the library resides. This option is hidden in NDM mode and not included in -physical option.

-scaling {scaling_types}

Specifies a list of logic library consistency checks for various types of scaling.

You can specify one or more of the following strings:

- **timing** specifies logic library consistency checking for composite current source (CCS) timing scaling.
- **noise** specifies logic library consistency checking for CCS noise scaling.
- **power** specifies logic library consistency checking for CCS or nonlinear delay model (NLDM) power scaling, including driver and receiver models, load indexes, base curve_x, waveform, noise, and power models.

-mcmm

Specifies logic library consistency checking for multicorner-multimode, including the power_down_function attribute and power data.

-upf

Specifies logic library consistency checking for multivoltage and IEEE 1801, also known as Unified Power Format (UPF), and includes power special cells, the pg_pin, voltage_names, and power_down_function attributes, and power data.

-optimization {power}

Checks the libraries for various types of optimization. The **power** option checks for power optimization related issues in the libraries, namely, missing high threshold_voltage_group cells specified by the **target_library** variable or **check_library -logic_library_name** option (the latter having higher priority). When you use the **-optimization** option, use the **-criteria** option to specify the low threshold_voltage_group names. With optimization power checking, the tool checks for the presence of high-threshold-voltage library cells having the same logic functions as the low-threshold-voltage library cells.

-compare {construct | attribute | value}

Specifies the type or types of information compared between logic libraries, which can be one or more of the keywords **construct**, **attribute**, or **value**. For **attribute** or **value** comparison, only two libraries are compared; if more than two libraries are specified, only the first two are compared.

- **-compare {construct}** checks to see if constructs or attributes are missing.
- **-compare {attribute}** checks to see if constructs and attributes are missing and if the attribute values are inconsistent. This option checks all groups, subgroups, and attribute values except characterization values. It is a superset of the **-compare {construct}** option.
- **-compare {value}** compares values of each group and attribute between the libraries. This option is a superset of the **-compare {attribute}** option.

In comparing characterization values, if the source is not from the .lib library files, the values are not reported, such as vector and capacitance values.

The comparison of the characterization values is controlled by the tolerances specified by the **-tolerance** option, or by the default values if the **-tolerance** option is not used. For minimum and maximum library checking and scaling group library checking, you should use the **-compare {attribute}** option to check all the library contents except for characterization values.

When you specify this option, the following default checks are also performed: missing cells, missing and mismatched pins, and timing arcs.

-tolerance {type relative_tolerance absolute_tolerance}

Specifies a relative tolerance and an absolute tolerance for characterization value comparison, such as delay values. The format is

-tolerance {type rel_tol abs_tol}

The valid values for the *type* argument are delay, slew, delay_ocv, slew_ocv, delay_ccsn, slew_ccsn, delay_sensitivity, slew_sensitivity, constraint, slew_index, load_index, time, power, current, energy, and capacitance. If the type is not specified, the values are for the output load capacitance. When you specify an absolute tolerance, do not include the unit. The units are fixed and can be reported by the **set_check_library_options** command. For example, specify the tolerance values for delay and slew as shown below:

-tolerance {delay 0.1 0.2 slew 0.3 0.4}

If you do not specify tolerance values for a type, the default values are used. The default values that are set as follows, in compliance with PrimeTime and the Library Quality Assurance System:

```
Relative tolerance for load index : 0.01
Absolute tolerance for load index : 0.001pF
Relative tolerance for time : 0.04
Absolute tolerance for time : 0.015ns
Relative tolerance for power : 0.04
Absolute tolerance for power : 5pW
Relative tolerance for delay : 0.02
Absolute tolerance for delay : 0.005ns
Relative tolerance for slew : 0.03
Absolute tolerance for slew : 0.0075ns
Relative tolerance for ocv delay : 0.02
Absolute tolerance for ocv delay : 0.005ns
Relative tolerance for ocv slew : 0.03
Absolute tolerance for ocv slew : 0.0075ns
Relative tolerance for ccsn delay : 0.03
Absolute tolerance for ccsn delay : 0.003ns
Relative tolerance for ccsn slew : 0.05
Absolute tolerance for ccsn slew : 0.005ns
Relative tolerance for sensitivity delay : 0.1
Absolute tolerance for sensitivity delay : 0.01ns
Relative tolerance for sensitivity slew : 0.15
Absolute tolerance for sensitivity slew : 0.015ns
```

-validate {timing noise value}

Specifies logic library consistency checking for library characterization between different models. The **{timing}** option is for validation between different timing models (NLDM versus CCS). The optional **value** is for validation of the characterization value between models of different dimensions, such as a one-dimensional NLDM and a two-dimensional CCS model. The **{noise}** option is for validation of delay/slew between CCSN and NLDM.

-analyze {nominal_vs_sigma | table_trend | table_bound | table_slope | table_index | sensitivity | voltage_range}

Specifies what is analyzed. You can specify any of the following values:

- **nominal_vs_sigma** analyzes multiple characterization tables. In the case of variation-aware models, analyze nominal, - sigma, and +sigma tables to see the trend and standard deviation for each slew and load index grid of a linear model. The linear model is modeled by the va_parameters option. Specify the va_parameters in the **-group_attribute** option. If you do not specify the va_parameters, the variation-aware models for all va_parameters are analyzed. Wildcards apply to va_parameters.
- **table_trend** analyzes a characterization table for trend. It analyzes the trend within the table to check if the values change monotonically in terms of slew or load indexes.
- **table_bound** analyzes a characterization table for bounds. It analyzes the values of the table to check if the values exceed the upper or lower bound.
- **table_slope** analyzes a characterization table for slope. It analyzes the slope formed by two adjacent grid points within the table to check if the slope value exceeds the maximum or minimum slope criteria. The slope calculation uses normalized values to eliminate the effect of the unit and table types.
- **table_index** analyzes the table index accuracy by calculating the ratio of each pair of adjacent indexes (next index to current index) and reports the index tables if at least one ratio meets the condition specified by the **-criteria {table_type xfactor>min_ratio}** option.
- **sensitivity** analyzes a cell's sensitivity. It reports the condition that the CCSN model response to the clamped waveform has

an output delay or output slew that deviates from the CCSN model response to the original or normal non-clamped version of the waveform.

- **voltage_range** analyzes output waveform's voltage swing to see if it reaches 95% of VDD.

-criteria {*criteria_spec*}

Specifies analysis criteria for variation analysis (multiple tables), non-variation analysis (single table), or low threshold_voltage_group for power optimization. This option is used with the **-analyze** or **-optimization** option. It is specified in the following format:

```
{std_error>m.m slope>n.n trend=trend_symbol |
  table_type upper_bound=upper_bound_value lower_bound=lower_bound_val |
  table_type[table_sub_index] min_slope=min_value max_slope=max_value |
  table_type xfactor>min_ratio clamping_ratio=ratio_val}
```

The std_error and slope are used by the linear regression models. The **trend_symbol** includes the following eight symbols:

/	monotonically increasing
\	monotonically decreasing
^	non-monotonically up
V	non-monotonically down
-	flat
M	Multiple peaks
W	Multiple troughs
N	>=2 peaks with 2nd not turning low

To specify the monotonically decreasing trend, use {trend = '\'}, {trend = '\\'}, or "trend = \\ ". Do not use {trend = \'}. To specify the inequality trend, use {trend!= }. For the std_error and slope expressions, you can also use the less-than sign (<).

The variation-aware analysis reports the results that meet any of the specified criteria.

This option is used with the **-analyze** option.

You can also set criteria for table bounds and slope analysis in this field.

```
{table_type lower_bound=lower_value upper_bound=upper_value |
  table_type[table_sub_index] min_slope=min_value max_slope=max_value}
```

The table type, table sub_index, and associated group names are:

Type Name	Index Type	Related Group Names
delay	slew_index	cell_rise
	load_index	cell_fall
transition	slew_index	rise_transition
	load_index	fall_transition
constraint	constrained_index	rise_constraint
	related_index	fall_constraint
energy	slew_index	rise_power
	load_index	fall_power
current	time	output_current_rise
		output_current_fall
capacitance	slew_index	receiver_capacitance1_rise
	load_index	receiver_capacitance1_fall
		receiver_capacitance2_rise
		receiver_capacitance2_fall
dc_current	input_voltage	dc_current
	output_voltage	

```

ccsn      time          output_voltage_rise
          output_voltage_fall
          propagated_noise_low
          propagated_noise_high
-----
pg_current time          pg_current
-----

```

{lvth_groups=*vt_name_list*} Specifies a list of low threshold_voltage_group strings for power optimization, such as {lvth_groups="lvt svt"}. lvth_groups is equivalent to the **-lvth_groups** option of the **set_multi_vth_constraint** command.

{clamping_ratio=*ratio_value*} Specifies a percentage for sensitivity analysis. By default clamping_ratio=0.95. This is used with -analyze {sensitivity} option.

-group_attribute {groups_or_attributes}

Checks or compares specific groups and attributes only.

You can specify one or more groups or attributes. An item can be a group, an attribute, a group and an attribute together with a value, or a group and an attribute together without a value. Use a space to separate each item in the list.

Use a forward slash (/) to combine a group name and an attribute name that you are specifying together. For example, the **{pin/direction}** option combines the pin group and the direction attribute under the pin group. In this case, the command checks the direction only in the pin group.

Use curly braces ({{}}) or double quotation marks ("") to enclose an expression delimited by spaces. The following example checks only the pin group whose name is A:

-group_attribute {"pin = A"}

The following wildcard characters are available for pattern matching:

- An asterisk (*) matches any string, including a null string.
- A question mark (?) matches any single character.

For example:

- **-group_attribute {pin}** checks the pin group only.
- **-group_attribute {direction}** checks the direction attribute only.
- **-group_attribute {pin/direction}** checks the pin's direction only.
- **-group_attribute {pin/direction=input}** checks the pin direction only when it is an input pin.
- **-group_attribute {cell_rise cell_fall output_current_*}** checks and validates the NLDM and CCS timing models only.
- **-group_attribute {va_* compact_ccs_*}** checks and validates the variation-aware timing models only.

If you do not specify the **-group_attribute** option, the **check_library** command checks all groups and attributes that apply to the specified mode.

-report_format {format_spec}

Specifies the format for the generated report. The syntax of the specification is as follows:

[csv[=csv_dir]] [nosplit] [html] [display] [sort_by_cell | sort_by_group_type]

You must include at least one of the following values in the specification:

- **csv[=csv_dir]**
Selects comma-separated values (CSV) as the report format, which is compatible with spreadsheet programs. By default, the CSV

files are stored in the current working directory. Specify the directory to store the CSV files by using the *csv_dir* argument.

If you perform multiple runs with the same settings, the directory for the previous run is saved to a directory named *csv_dir_bak*.

If you do not specify this value, the **check_library** command generates a plain ASCII report.

- **nosplit**

Prevents line-splitting, and facilitates writing scripts to extract information from the report output. Most of the information is listed in fixed-width columns. If the information in a given field exceeds the column width, the next field begins on a new line, starting in the correct column.

- **html[=html_dir]**

Selects HTML as the report format. Optionally specify the directory in which to store the HTML files by using the *html_dir* argument. By default, it is the current directory.

- **display**

Launches a browser to view the check results in HTML. This should be used only with the **html** report format.

- **sort_by_cell | sort_by_group_type**

Specifies the sorting method. Use **sort_by_cell** to sort the validation and analysis tables by cell names. Use **sort_by_group_type** (the default) to sort the validation and analysis tables by group types, such as delay, slew, constraints, and receiver capacitance.

If you do not specify this option, the **check_library** command generates an ASCII report that is sorted by the group type.

-leq

Checks the logical equivalence for "when" conditions. For example, if you set the **-leq** option, the following expressions are reported as identical:

```
when : A+B  
when : B+A
```

By default, logical equivalence is disabled and string comparisons are used.

-by_group_order

Compares or checks libraries by the order of library groups for non-unique groups and groups without a name, such as *leakage_power*. This is for concurrent checking of multiple libraries.

-char_integrity

Checks the following options for CCSN accuracy:

```
-validate { timing noise }  
-analyze { sensitivity voltage_range }
```

-significant_digits digits

Specifies the number of significant digits displayed for floating-point numbers. Allowed values are from 0 through 13. The default value is 6.

-physical

Includes the following physical checking options:

```
-tech_consistency  
-view_comparison  
-same_name_cell  
-signal_em  
-antenna  
-rectilinear_cell  
-physical_only_cell  
-phys_property {place route}  
-rail view_data  
-routeability  
-tech
```

-drc**-logic_vs_physical**

Checks all logic versus physical library checking, including the default checks for missing cells, missing or mismatched pins in the logic or physical library, and the following checks:

- cell_area**
- cell_footprint**
- bus_delimiter**

-logic

Checks the following options for the logic library:

- scaling**
- mcm**
- upf**
- optimization {power}**

-reset

Resets the options of the command to their default. Missing cells and missing or mismatched pins are checked between logic and physical libraries. All other options are ignored if used with the **-reset** option.

-all

Checks the following options for the library:

- tech_consistency**
- view_comparison**
- same_name_cell**
- signal_em**
- antenna**
- rectilinear_cell**
- physical_only_cell**
- phys_property {place route cell metal_density}**
- rail view_data**
- routeability**
- tech**
- drc**
- logic_vs_physical**
- logic**

DESCRIPTION

The **set_check_library_options** command sets specific options for the **check_library** command for logic library versus logic library checking, logic library versus physical library checking, and for checks between physical libraries.

Run the **set_check_library_options** command before you run the **check_library** command. If you do not specify any option with the **set_check_library_options** command, by default the command checks missing cells, missing and mismatched pins, including pg_pins versus power and ground pins.

The command returns the status, indicating success or failure of the option settings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the **-cell_footprint** and **-bus_delimiter** options are set, the lib1.db and lib2.db logic libraries are checked against the phys_lib physical libraries for missing cells and pins and mismatched pins. The cell footprints are compared, and the bus delimiters are checked:

```
prompt> set_check_library_options -cell_footprint \
           -bus_delimiter
1
prompt> check_library -mw_library_name {phys_lib} \
           -logic_library_name {lib1.db lib2.db}
1
```

```
#BEGIN_XCHECK_LIBRARY
```

```
Logic Library: lib1.db
               lib2.db
```

```
Physical Library: phys_lib
```

```
check_library options: -cell_footprint -bus_delimiter
```

```
Version: A-2007.12

set_cle_options

Sets command line editor settings.

SYNTAX

```
int set_cle_options [-mode vi / emacs] [-beep on / off] [-defaults]
```

ARGUMENTS

-mode "vi | emacs"

Sets the command line editor mode to either vi or emacs. Valid values are **vi** or **emacs**.

-beep "on | off"

Sets the command line editor beep sound to on or off. Valid values are **on** or **off**.

-defaults

Sets command line editor default settings. This option will override other options. Default edit mode is **emacs** and terminal beep is **off**.

DESCRIPTION

The **set_cle_options** command can be used to set command line editor settings.

If used without any options, it will display the current editor settings.

EXAMPLES

The following example sets command line editor to vi mode.

```
dc_shell-t> set_cle_options -mode vi
Information: Command line editor mode is set to vi successfully. (CLE-01)
1
```

The following example enables terminal beep.

```
dc_shell-t> set_cle_options -beep on
1
```

The following example sets command line editor default settings.

```
dc_shell-t> set_cle_options -defaults  
1
```

The following example displays current command line editor settings.

```
dc_shell-t> set_cle_options
```

```
*****

set_clock_gate_latency

Specifies clock network latency values to be used for clock-gating cells, as a function of clock domain, clock-gating stage and fanout.

SYNTAX

```
status set_clock_gate_latency
  [-clock clock_list]
  [-overwrite]
  -stage cg_stage
  -fanout_latency cg_fanout_list
  [-transitive_fanout]
```

Data Types

<i>clock_list</i>	list
<i>cg_stage</i>	integer
<i>cg_fanout_list</i>	string

ARGUMENTS

-clock *clock_list*

Specifies that the latency must be applied with respect to the specified clocks. If the **-clock** option is not specified, the latency is applied with respect to all clock domains to which the clock-gating cell belongs.

-overwrite

Specifies that clock latency values previously set on clock-gating cells should be overwritten.

-stage *cg_stage*

Specifies the clock-gating stage to which the clock latency data from the fanout range is applied. Registers are considered as stage 0.

-fanout_latency *cg_fanout_list*

Specifies the list of clock-gating cells fanout and clock latency values; for example, {1-5 0.9, 6-20 0.5, 21-inf 0.3}. A fanout of 1 to 5 has a latency of 0.9; a fanout of 21 or larger has a latency of 0.3. If the same latency value is wanted for the entire fanout range, it can be specified as {1-inf 0.9}.

-transitive_fanout

Specifies that transitive fanout should be used instead of direct fanout when annotating clock gate latency. Direct fanout is the default.

DESCRIPTION

The **set_clock_gate_latency** command allows you to specify clock network latency values for clock-gating cells, as a function of clock domain, clock-gating stage, and fanout. These latency values are annotated on the clock pins of clock-gating cells when running the **compile_ultra** command, or when running the **apply_clock_gate_latency** command.

The clock-gate latency settings specified using the **set_clock_gate_latency** command are stored as an attribute on the source port of each specified clock. Invoke this command after defining all clocks of the design. These stored latency values are annotated on the clock pins of clock-gating cells by means of one of the following processes:

- Using the **apply_clock_gate_latency** command, which applies latency on any existing clock-gating cells
- During **compile_ultra** command, which applies latency on any existing clock-gating cells or those inserted or modified during the compile

NOTE: The stages of the clock gating network are numbered from 0 for the register stage number and increasing toward the clock source. For example, in a four stage clock gating tree, Stage 0 drives register clocks directly, and Stage 3 is the clock gating cell with its input directly connected to the clock source.

Use the **set_clock_gate_latency** command to specify the latency for gated registers by specifying the command for stage 0. By definition stage 0 has no fanout, so use the following syntax:

```
prompt> set_clock_gate_latency -stage 0 -fanout_latency \
{ 1-inf value }
```

When clock latency settings are provided for stage 0, the values are annotated on the output pin (enabled clock pin) of each clock-gating cell that is directly driving gated registers. If no clock latency is set for stage 0, but a clock latency has been set on the clock object by using **set_clock_latency** command, then this value is used for clock latency. For ungated registers, the latency is propagated by the timer from the clock object latency.

You can use the **-clock** and **-overwrite** options with the **-stage 0** option.

Use the **-transitive_fanout** option to calculate latency value based upon the transitive fanout of a clock-gating cell instead of the direct fanout. The transitive fanout of a clock-gating cell is defined as the total number of all driven leaf registers. The registers driven by a stage 1 clock-gating cell, ICG_1, are counted as part of the transitive fanout of the stage 2 clock-gating cell, ICG_2, that drives ICG_1. By definition:

stage 2 transitive fanout >= stage 1 transitive fanout

NOTE: Transitive fanout only counts registers, unlike the direct fanout which counts both registers and driven clock-gating cells.

When the **-transitive_fanout** option is used for the first time, a *fanout mode* is set, and this is indicated by the PWR-916 information message. You cannot mix fanout modes of the **set_clock_gate_latency** command, where some instances use the **-transitive_fanout** option and others do not. If you want to switch between fanout modes, use the **reset_clock_gate_latency** command.

If you specify fanout ranges in the *cg_fanout_list* and you do not cover all values from 1 to inf, the fanout ranges with missing latency information are filled by the tool with the smallest latency value from the adjacent ranges.

In a clock tree, latency values are lowest for cells closest to the top of the tree (clock source). Transitive fanout values are highest for cells at the source and decrease toward the registers. Therefore, specified clock latency values must decrease with respect to fanout ranges otherwise a PWR-742 warning message is generated.

If clock latency settings are not specified for a certain clock-gating stage and a clock-gating cell within this stage exists, the latency is propagated from the driving clock-gating cell or from clock object latency, and a warning message is issued. These actions are performed during the annotation process:

apply_clock_gate_latency or **compile_ultra** command.

If specified clock latency values do not decrease with respect to clock gating stages, the PWR-744 warning message is generated. This check is disabled if the **-transitive_fanout** option is used. In addition, if an inconsistent clock latency annotation is detected when running the **apply_clock_gate_latency** or **compile_ultra** command, the tool attempts to fix it by assuming the smallest value from the clock latencies annotated on gated clock-gating cells or registers. This ensures that clock latencies are monotonically increasing values in the path going from the clock source to the gated registers. The following actions can be performed by the tool to achieve this:

- If clock-gating cell A is directly driving one or more registers, and some clock latency settings have been provided for the timing of these gated registers (by using value 0 for the **-stage** option of **set_clock_gate_latency** command or by propagation of latency specified for clock object), and the latency annotated on cell A is higher than the latency provided for gated registers, then the latency on clock-gating cell A is overwritten with the latency provided for gated registers. If this fix is done, the PWR-746

warning message is generated.

- If clock-gating cell A is driving another clock-gating cell B, and the clock latency set on A is higher than the one set on B, the tool resolves it by overwriting the clock latency on A with the value set on B. If this fix is done, the PWR-746 warning message is generated.

To remove the settings specified using **set_clock_gate_latency**, use the **reset_clock_gate_latency** command.

If the variable **power_cg_physically_aware_cg** is enabled, then the annotation of latency values from **set_clock_gate_latency** is disabled.

Multicorner-Multimode Support

This command is scenario dependent and affects the current scenario only.

The actual clock latency annotation performed during the execution of the **compile_ultra** or **apply_clock_gate_latency** commands is done for all the scenarios for which a clock latency value is available.

EXAMPLES

The following example specifies the clock latency values for the complete fanout range of clock-gating cells for stages 1, 2, and 3. This latency data applies to the clock-gating cells whose clock pins belongs to clock *clk1*.

```
prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 1 \
    -fanout_latency {1-30 2.1, 31-100 1.7, 101-inf 1.1}

prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 2 \
    -fanout_latency {1-5 0.9, 6-20 0.5, 21-inf 0.3}

prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 3 \
    -fanout_latency {1-10 0.28, 11-inf 0.11}
```

In the following example, fanout ranges specified in the **-fanout_latency** *cg_fanout_list* do not cover all values from 1 to inf. In this case, the tool assumes a clock latency value of 1.7 to be applied to fanout range 11-30 and a clock latency of 1.1 for fanouts higher than 80.

```
prompt> set_clock_gate_latency -stage 1 \
    -fanout_latency {1-10 2.1, 31-80 1.7, 101-300 1.1}
```

The following example shows how to specify and annotate different clock latency values using the transitive fanout.

```
prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 1 \
    -fanout_latency {1-30 2.1, 31-100 1.7, 101-inf 1.1} \
    -transitive_fanout

prompt> set_clock_gate_latency -clock [get_clocks clk1] -stage 2 \
    -fanout_latency {1-5 0.9, 6-20 0.5, 21-inf 0.3} \
    -transitive_fanout
```

The following example shows how to specify and annotate different clock latency values for different multicorner-multimode scenarios.

```
prompt> current_scenario sc1
prompt> set_clock_gate_latency -stage 1 \
    -fanout_latency {1-inf 0.11}

prompt> current_scenario sc2
prompt> set_clock_gate_latency -stage 1 \
    -fanout_latency {1-inf 0.15}

prompt> compile_ultra -gate_clock
```

set_clock_gating_check

Puts setup and hold checks on clock-gating cells.

SYNTAX

```
status set_clock_gating_check
  [-setup setup_margin]
  [-hold hold_margin]
  [-rise]
  [-fall]
  [-high | -low]
  [object_list]
```

Data Types

<i>setup_margin</i>	float
<i>hold_margin</i>	float
<i>object_list</i>	collection

ARGUMENTS

-setup *setup_margin*

Specifies the setup margin for the clock-gating signal. For AND and NAND clock-gating elements, the setup time is checked relative to the 0->1 transition of the clock input. For OR and NOR clock-gating elements, the setup time is checked against the 1->0 transition of the clock input. For more complicated clock-gating elements, the setup check is against the clock transition where the clock input goes from a controlling value to a noncontrolling value for the clock-gating element.

-hold *hold_margin*

Specifies the hold margin for the clock-gating signal. For AND and NAND clock-gating elements, the hold time is checked relative to the 1->0 transition of the clock input. For OR and NOR clock-gating elements, the hold time is checked against the 0->1 transition of the clock input. For more complicated clock-gating elements, the hold check is against the clock transition where the clock input goes from a noncontrolling value to a controlling value for the clock-gating element.

-rise

Specifies if rising delays are constrained for clock-gating checks. If you do not specify the **-rise** or **-fall** option, both rising and falling delays are constrained.

-fall

Specifies if falling delays are constrained for clock-gating checks. If you do not specify the **-rise** or **-fall** option, both rising and falling delays are constrained.

-high

Indicates that the check is to be performed on the high level of the clock. By default, timing analysis determines whether to use the high or low level of the clock using information from the cell's logic. That is, for AND and NAND gates, the check is performed on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX, OR-AND) it cannot be determined which level to use, and so no check is performed unless either **-high** or **-low** is specified. This option can be used only

when the object list contains cells or pins.

-low

Indicates that the check is to be performed on the low level of the clock. By default, timing analysis determines whether to use the high or low level of the clock using information from the cell's logic. That is, for AND and NAND gates, the check is performed on the high level; for OR and NOR gates, on the low level. For some complex cells (for example, MUX, OR-AND) it cannot be determined which level to use, and so no check is performed unless either **-high** or **-low** is specified. This option can be used only when the object list contains cells or pins.

object_list

Specifies the cells, pins, or clock objects where the clock-gating setup or hold margins are to be checked.

If you do not specify the *object_list* argument, the clock-gating check is applied to the current design.

To enable clock-gating checks only for specific clock-gating cells, specify the names of the cells in the object list. Clock-gating checks for specific cells override any clock-gating checks that have been specified for the design.

To enable clock-gating checks only for specific pins, specify the pins in the object list.

To enable clock-gating checks on all clock-gating cells driven by specific clocks, specify the clock objects in the object list.

DESCRIPTION

The **set_clock_gating_check** command provides the ability to check setup or hold margins for control inputs of clock-gating cells. The setup check ensures that the clock-gating input stabilizes for a given amount of time before the clock input of the gating cell makes a transition to a noncontrolling value. The hold check ensures that the clock-gating signal stabilizes for a given amount of time after the clock input has gone back to a controlling value. Together, the two checks ensure that the clock-gating signal stabilizes for the entire period of time when the gated clock input has a noncontrolling value. This is so that the gating signal cannot "clip" a clock edge or generate spurious clock pulses by changing when the clock input is noncontrolling.

You can specify in which interval of the clock the clock-gating checks are made by using the **-high** and **-low** options.

The clock-gating checks created by **set_clock_gating_check** act as optimization constraints; the tool tries to adjust the delays of the logic driving the clock-gating inputs to avoid setup or hold violations.

Be aware that the presence of clock-gating checks on a clock-gating cell disables certain logic transformations that otherwise might be applied to the cell. The tool can adjust only the size of the cell by replacing it with other cells with the same logic function but with different drive capacity. No other logic transformations involving the clock-gating cell are permitted.

The **set_clock_gating_check** command can create setup and hold checks only against a clock signal. The command cannot introduce setup or hold checks between two nonclock signals.

To undo **set_clock_gating_check**, use the **remove_clock_gating_check** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example creates setup checks with a 0.75 margin and hold checks with a 0.5 margin for all clock-gating inputs in the current design:

```
prompt> set_clock_gating_check -setup 0.75 -hold 0.5
```

The following example creates setup checks with a 0.58 rise margin for all clock-gating cells driven by the CLK1 clock:

```
prompt> set_clock_gating_check -setup 0.58 -rise [get_clocks CLK1]
```

The following example creates hold checks with a margin of 0.64 on all gating inputs of the CLK_GATE1 cell:

```
prompt> set_clock_gating_check -hold 0.64 CLK_GATE1
```

The following example creates a setup check with a margin of 0.44 and a hold check with a margin of 0.64 on all gating inputs of the CLK_GATE1 cell and specifies that the clock is noncontrolling when it is low:

```
prompt> set_clock_gating_check -setup 0.44 -hold 0.64 -low CLK_GATE1
```

`current_design(2)`
`remove_clock_gating_check(2)`
`report_clock(2)`

set_clock_gating_enable

Controls the signals to be used as the clock gating enable in the execution of the **compile_ultra -gate_clock** command.

SYNTAX

```
status set_clock_gating_enable  
  [-exclude objects_to_exclude]  
  [-undo objects_to_remove_exclusion]
```

Data Types

objects_to_exclude collection
objects_to_remove_exclusion collection

ARGUMENTS

-exclude *objects_to_exclude*

Specifies a collection of objects in the current design that are considered the source of a signal that must be excluded (if logically possible) from the enable logic for clock gating. Objects can be of following types:

- Primary input ports
- Sequential cells, black boxes, or macros
- Output pins of sequential cells, black boxes, or macros

-undo *objects_to_remove_exclusion*

Removes from the given objects the directives specified by a previously executed **set_clock_gating_enable -exclude** command. Objects can be of following types:

- Primary input ports
- Sequential cells, black boxes, or macros
- Output pins of sequential cells, black boxes, or macros

DESCRIPTION

This command provides a mechanism to tell the tool that a given signal should not be used as an enable condition for clock gating.

During the execution of the **compile_ultra -gate_clock** command, the tool looks at the transitive fanin of the logic cone driving the enable signal for clock gating (for both preexisting clock gates and candidate registers). If any object is found with the exclusion constraint, the tool tries to compute a modified enable expression without dependency of this excluded signal. The clock-gating enable signal and register's enable pin signal are modified for this purpose. If it is feasible to compute those signals, the enable logic is

modified accordingly. If signal exclusion is logically infeasible, the candidate registers are not clock gated and the preexisting clock gates are removed.

A register is also not clock gated if the synthesis of the modified enable signal requires modifying the boundary of a constrained hierarchy.

The registers that are not clock gated because of this inability of excluding a certain signal are reported with the message **Suitable enable signal has been excluded** by the **report_clock_gating -ungated** command.

The Tcl variable **power_cg_all_registers** or the use of **set_clock_gating_objects -force_include** command does not prevent the removal of clock gates with infeasible signal exclusions. In both cases, the registers are gated by an always-enabled clock gate.

The presence of enable exclusion directives on any object has no impact in the computation of enable signals for XOR Self Gating.

You must run the **set_clock_gating_enable** command before running the **compile_ultra -gate_clock** command. The specifications persist during the subsequent executions of **compile_ultra -gate_clock**. The directives are also stored in the .ddc file and written by the **write_script** command (unless **-no_cg** option is used) for ASCII flow support.

One and only one of the two arguments must be used for the command to succeed.

This command can be used as part of a Design Compiler Embedded Tcl script on the RTL.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example excludes input port **en** as a valid enable signal for clock gating:

```
prompt> set_clock_gating_enable -exclude [get_pots en]
```

In the following example, all the output pins of register **reg** are discarded as potential drivers of an enable signal for clock gating:

```
prompt> set_clock_gating_enable -exclude [get_cells reg]
```

The following example restores input port **en** as a valid driver of enable signal for clock gating:

```
prompt> set_clock_gating_enable -undo [get_pots en]
```

set_clock_gating_objects

Forces the enabling or disabling of clock gating for specified objects in the current design, overriding all conditions necessary for automatic RTL clock gating, by the **compile_ultra -gate_clock** command. Objects can be of type register, hierarchical cell, power domain, or design.

SYNTAX

```
status set_clock_gating_objects
  [-force_include object_list]
  [-exclude object_list]
  [-include object_list]
  [-undo object_list]
```

Data Types

object_list list

ARGUMENTS

-force_include *object_list*

Specifies a list of objects in the current design that to be clock gated, overriding the conditions set by the clock-gating style. The *object_lists* is mutually exclusive, that is, an object cannot be specified with more than one of the following options: **-force_include**, **-exclude**, **-include** and **-undo**.

-exclude *object_list*

Specifies a list of objects in the current design to be excluded from clock gating. The *object_lists* are mutually exclusive, that is, an object cannot be specified with more than one of the following options: **-force_include**, **-exclude**, **-include** and **-undo**.

-include *object_list*

Specifies a list of objects in the current design for which clock gating should be done as per the style specified by the **set_clock_gating_style** command. This is the default for all objects in the design. An object cannot be specified with more than one of the following options: **-force_include**, **-exclude**, **-include** or **-undo**.

-undo *object_list*

Specifies a list of objects in the current design for which the inclusion or exclusion criteria for clock gating should be removed. The *object_lists* are mutually exclusive. An object cannot be included on more than one of the following options: **-force_include**, **-exclude**, **-include** and **-undo**.

DESCRIPTION

This command specifies the objects on which clock gating is to be either enabled or disabled on its registers, overriding all conditions necessary for automatic clock gating by the **compile_ultra -gate_clock** command.

For objects specified with the **-force_include** option, clock gating is performed regardless of the previous specification. Objects specified with the **-exclude** option are excluded from clock gating regardless of the previous specification.

Use the **-include** option to specify that regular clock gating criteria should be used on the specified objects.

Use the **-undo** option to remove a previously specified criteria on the specified objects.

You must run the **set_clock_gating_objects** command before running the **compile_ultra -gate_clock** command. The specifications persists during the subsequent executions of the **compile_ultra -gate_clock**.

This command can be used as part of a DC Embedded Tcl script on the RTL.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example excludes the register bank A_reg in the current design, from clock gating:

```
prompt> set_clock_gating_objects -exclude A_reg[*]
```

In the following example, the register bank D_OUT_reg in the MID subdesign, is clock-gated, ignoring the previous specification.

```
prompt> set_clock_gating_objects -force_include MID/D_OUT_reg[*]
```

The following example includes and excludes certain registers from clock gating in the ADDER subdesign:

```
prompt> set_clock_gating_objects \
    -force_include ADDER/out1_reg[*] \
    -exclude ADDER/out2_reg[*]
```

The following example removes the directive to include and exclude clock gating for the registers in the ADDER subdesign:

```
prompt> set_clock_gating_objects \
    -undo {ADDER/out1_reg[*] ADDER/out2_reg[*]}
```

The following example excludes every register present in the ADDER subdesign, except for the out1_reg bank, which is clock gated according to the specified style.

```
prompt> set_clock_gating_objects \
    -exclude ADDER \
    -include ADDER/out1_reg[*]
```

set_clock_gating_registers

Forces the enabling or disabling of clock gating for the specified registers in the current design, overriding all conditions necessary for automatic RTL clock gating, performed by the **compile_ultra -gate_clock** command.

SYNTAX

```
status set_clock_gating_registers
  [-include_instances register_list]
  [-exclude_instances register_list]
  [-undo register_list]
```

Data Types

register_list list

ARGUMENTS

-include_instances *register_list*

Specifies a list of registers in the current design to be included for clock gating. A register cannot be specified with more than one of the **-include_instances**, **-exclude_instances**, and **-undo** options.

-exclude_instances *register_list*

Specifies a list of registers in the current design to be excluded from clock gating. A register cannot be specified with more than one of the **-include_instances**, **-exclude_instances**, and **-undo** options.

-undo *register_list*

Specifies a list of registers in the current design for which the previous specification of the **set_clock_gating_registers** command is to be undone. A register cannot be specified with more than one of the **-include_instances**, **-exclude_instances**, and **-undo** options.

DESCRIPTION

The **set_clock_gating_registers** command will be obsolete in a future release. Use the **set_clock_gating_objects** command instead, to specify inclusion criteria for different registers.

This command specifies registers for which clock gating is to be either enabled or disabled, overriding all conditions necessary for automatic clock gating by the **compile_ultra -gate_clock** command. Registers specified with the **-include_instances** and **-exclude_instances** options are clock-gated or excluded from clock-gating respectively, regardless of any previous specifications.

Use the **-undo** option to remove the specification already set by the **set_clock_gating_registers** command.

You must run the **set_clock_gating_registers** command before running the **compile_ultra -gate_clock** command. The specification is used during all subsequent executions of **compile_ultra -gate_clock** command.

The **set_clock_gating_registers** command directs the **compile_ultra -gate_clock** command to implement synchronous load enable flip-flops with gated clocks instead of data feedback through multiplexers, if certain conditions (for example, minimum register bank size) are satisfied. This command overrides these conditions for the specified registers; thus, registers specified by the **-include_instances** option are clock gated, and registers specified by the **-exclude_instances** option are not clock gated, regardless of any previously-specified conditions necessary for automatic clock gating.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example excludes the register bank named *A_reg* in the current design, so that these registers are not clock gated:

```
prompt> set_clock_gating_registers -exclude_instances A_reg[*]
```

The following example includes the register bank named *D_OUT_reg* in the *MID* subdesign, so that this register is always clock gated:

```
prompt> set_clock_gating_registers -include_instances MID/D_OUT_reg[*]
```

The following example includes and excludes clock gating for registers in the *ADDER* subdesign:

```
prompt> set_clock_gating_registers \
    -include_instances ADDER/out1_reg[*] \
    -exclude_instances ADDER/out2_reg[*]
```

The following example removes the directive to include and exclude clock gating to and from the registers in the *ADDER* subdesign:

```
prompt> set_clock_gating_registers \
    -undo {ADDER/out1_reg[*] ADDER/out2_reg[*]}
```

[-power_domains {power_domain_list}]
[-designs {designs_list}]
```

Data Types

<i>minsize_value</i>	integer
<i>setup_value</i>	float
<i>hold_value</i>	float
<i>depth_value</i>	integer
<i>max_fanout_count</i>	integer
<i>num_stages_count</i>	integer
<i>instances_list</i>	list
<i>power_domain_list</i>	list
<i>designs_list</i>	list

ARGUMENTS

-sequential_cell none | latch

Specifies the cell that is used to delay the enable signal gating the clock. By default, the tool selects a latch cell. To select a latch-free style, use **none**. You can specify a specific latch cell by using the following syntax:

latch:lib_cell

The latch style must be compatible with the clock-gating circuitry as chosen by the **-positive_edge_logic** and **-negative_edge_logic** options. If you need to use different latches for positive-edge logic and negative-edge logic, use the **-positive_edge_logic** and **-negative_edge_logic** options, instead of the **-sequential_cell** option. If you specify either of the following, the tool infers a latch-based clock-gating style:

-sequential_cell none -positive_edge_logic {latch and}

-sequential_cell none -negative_edge_logic {latch or}

-minimum_bitwidth *minsize_value*

Specifies the minimum size of a register bank for which the clock can be gated.

-setup *setup_value*

Specifies the setup time constraint at the enable input of the 2-input clock gate in the clock-gating circuitry.

-hold *hold_value*

Specifies the hold time constraint at the enable input of the 2-input clock gate in the clock-gating circuitry.

-positive_edge_logic {*cell_list* | integrated active_low_enable invert_gclk}

Specifies the circuitry used to gate the clock of a flip-flop that is inferred by a positive edge clock construct in the HDL code. You can specify the circuitry in one of the following ways:

- *cell_list*

Specifies a list of 1 to 4 strings that describe the gates inserted in the clock network. The circuitry must be compatible with the latch style specified by the **-sequential_cell** option. For example, AND or NAND functionality for alatch-based style and OR or NOR functionality for a latch-free style.

If the circuitry inverts the clock signal, an additional inverter is inferred between the clock output pin of the clock-gating circuitry and the clock input pin of the register. You can map this inverter with the generic sequential cell to a negative-edge triggered flip-flop.

- {integrated [active_low_enable] [invert_gclk]}

Uses a single special integrated cell instead of the clock-gating circuitry.

-negative_edge_logic {*cell_list* | integrated active_low_enable invert_gclk}

Specifies the circuitry used, to gate the clock of a flip-flop that is inferred by a negative-edge clock construct in the HDL code. You can specify the circuitry in one of the following ways:

- *cell_list*

Specifies a list of 1 to 4 strings that describe the gates inserted in the clock network. The circuitry must be compatible with the latch style specified by the **-sequential_cell** option. For example, OR, NOR functionality for alatch-based style and AND, NAND functionality for a latch-free style.

If the circuitry does not invert the clock signal, an additional inverter is inferred between the clock output pin of the clock-gating circuitry and the clock input pin of the register. In contrast to an inverter specified in the clock-gating circuitry, you can map this inverter with the generic sequential cell to a negative-edge triggered library flip-flop.

- {integrated [active_low_enable] [invert_gclk]}

Uses a single special integrated cell instead of the clock-gating circuitry.

-control_point none | before | after

Specifies where to insert a control point in the clock gating circuitry. With **before** or **after** control styles, the tool implements an OR gate with the original register enable signal and a test control signal as inputs. If you specify a latch-based style, the **before** or **after** control styles determine the location of the OR gate with respect to the latch. If you specify a latch-free style, the **before** and **after** control styles are equivalent. The tool creates a new input port to provide the test signal. The control points must be hooked up to the design level **test_mode** or **scan_enable** port using the **insert_dft** command.

-control_signal scan_enable | test_mode

Specifies the test control signal. If an input port is created and the argument of the **-control_signal** option is **scan_enable**, the name of the port is determined by the **test_scan_enable_port_naming_style** variable, and a **test_scan_enable** signal_type attribute is put on the new port. If an input port is created and the argument of the **-control_signal** option is **test_mode**, the name of the port is determined by the **test_mode_port_naming_style** variable, and a **test_hold** attribute is set on the new port.

-observation_point true | false

Specifies whether or not to implement observability logic. The observed signals are the enable signal inputs to the control point OR gates. A new input port is created to provide the test signal, which blocks activity to the observability logic during mission mode.

-observation_logic_depth *depth_value*

Specifies the maximum depth of an XOR tree built in the observability circuitry.

-max_fanout *max_fanout_count*

Specifies the maximum size of a register bank which can be gated with a clock gate.

-num_stages *num_stages_count*

Specifies the maximum number of stages for multistage clock gating.

-no_sharing

Limits the registers gated by a clock-gating cell to a single register bank.

-instances {*instances_list*}

Specifies that the clock-gating style should be applied over the given list of hierarchical cells.

-power_domains {*power_domain_list*}

Specifies that the clock-gating style should be applied over the given list of power domains.

-designs {*designs_list*}

Specifies that the clock-gating style should be applied over the given list of designs.

DESCRIPTION

This command sets the clock-gating style to be used for clock gating with the **compile_ultra -gate_clock** and **replace_clock_gates** commands, as well as gate-level clock gating enabled by specifying the **-gate_clock** option to the **compile** or **compile_ultra** command.

Clock gating of register banks is an alternative implementation of load-enable registers. In comparison to the traditional implementation using recirculating feedback and multiplexers, power consumption is reduced on the clock tree, in the registers, and in the combinational logic (multiplexers). Clock gating has implications on testability and physical design.

The clock-gating style specifies three aspects of clock gating:

- The conditions when clock gating is applied
- The clock-gating circuitry that is implemented
- Additional circuitry to improve testability.

Clock-gating Conditions

A number of conditions must be satisfied to gate a register clock in a latch-based style. First, the register must be a load enable flip-flop. Second, the register belongs to a bank with a bit width equal to or larger than the value specified by the **-minimum_bitwidth** option. Because clock-gating circuitry, and possibly some testability-improving gates, is implemented for each register bank, a register bank should be a reasonable size to be considered for clock gating. The default is 3. An additional condition (known as the setup condition) must be satisfied for latch-free clock gating. All of the inputs to the combinational logic generating the load enable signal of a register bank must be flip-flops that are triggered by the same clock, and on the same clock edge as the register bank. For hierarchical designs, it might be necessary to derive the related clock for the inputs to the combinational logic from the clock connectivity in parent hierarchies. This is enabled by setting the **power_cg_derive_related_clock** variable to **true**. Use the **set_clock_gating_objects** command to force clock gating of registers that do not satisfy these conditions, or disable the setup condition for all registers by setting the **power_cg_ignore_setup_condition** variable to **true**.

Specifying the Clock-Gating Circuitry

The clock-gating circuitry is a hierarchical cell. The cell is attributed such that its structure is maintained during compilation, which

means you have tight control over the structure of the clock-gating circuitry. There are several options to determine the clock-gating circuitry. The most important option is **-sequential_cell**, which determines latch-based or latch-free clock gating. The basic effect of latch-based clock gating is to prevent a leading clock edge by maintaining the value of the clock signal after the trailing edge. For example, for positive-edge triggered flip-flops, the clock signal is forced and kept to Logic0 after the negative edge, preventing a rising edge that loads new data into the register. To achieve this, the clock-gating circuitry must have AND or NAND functionality for positive-edge triggered flip-flops, and OR or NOR functionality for negative-edge triggered flip-flops. To prevent problems on the gated clock signal, the load enable signal is delayed by a latch that is transparent and it is between the trailing and the leading clock edge. Additionally, setup and hold time constraints are set at the enable input of the clock gate. The **-setup** option specifies the setup time value; the **-hold** option specifies the hold time value. The **-sequential_cell** option can also be used to specify a particular D-latch from a particular library:

```
string seq_cell = none / latch[:library_name/]cell_name]
string library_name
string cell_name
```

Latch-free clock gating prevents a leading clock edge by maintaining the value of the clock signal before the trailing edge. For example, for positive-edge triggered flip-flops, the clock signal is forced and kept to Logic1 before the negative edge. To achieve this, the clock-gating circuitry must have OR or NOR functionality for positive-edge triggered flip-flops, and AND or NAND functionality for negative-edge triggered flip-flops. Because the load enable signal must arrive before the trailing edge of the clock, there is no latch. Additionally, setup and hold time constraints are set at the enable input of the clock gate. The setup time value is specified by the **-setup** option; the hold time value is specified by the **-hold** option.

Before compilation, you must propagate the setup and hold timing constraints to the current design using the **propagate_constraints -gate_clock** command.

Note that the term "positive-edge triggered flip-flop" here means that the register is inferred by a positive edge clock construct in the HDL code. Because the clock-gating circuitry for positive-edge triggered flip-flops differs from that for negative-edge triggered flip-flops, you have two options for specifying the clock gating circuitry: **-positive_edge_logic**, for flip-flops inferred by a positive edge construct in the HDL code and **-negative_edge_logic**, for flip-flops inferred by a negative edge construct in the HDL code. With each of these options, you can specify a list of one to four strings that describe the gates inserted in the clock network. If you specify four strings, the first string specifies the latch, the second string specifies a 1-input gate (inverter or buffer) in the fanin of the clock gate on the clock network, the third string specifies the 2-input clock gate (AND/NAND/OR/NOR gate), and the fourth string specifies a 1-input gate (inverter or buffer) in the fanout of the clock gate. The specification of the 1-input gates in the fanin and fanout of the clock gate is optional. There can be four strings, each of which can contain the specification of a library cell:

```
string gate = gate_type[:library_name/]cell_name]
string gate_type = latch | and | nand | or | nor | buf | inv
string library_name
string cell_name
```

Note that the **-positive_edge_logic** and **-negative_edge_logic** options must be compatible with the latch style as specified by the **-sequential_cell** option or in the gate-level list. For latch-based clock gating, the **-positive_edge_logic** option must specify AND or NAND functionality, and the **-negative_edge_logic** option must specify OR or NOR functionality. For latch-free clock gating, the **-positive_edge_logic** option must specify OR or NOR functionality, and the **-negative_edge_logic** option must specify AND or NAND functionality.

The AND functionality is given by one of the following lists:

```
{and}
{buf and}
{and buf}
{buf and buf}
{nand inv}
{buf nand inv}
{inv or inv}
{inv nor}
{inv nor buf}
```

The NAND functionality is given by one of the following lists:

```
{and inv}
{buf and inv}
{nand}
{buf nand}
{nand buf}
{buf nand buf}
```

```
{inv or}
{inv or buf}
{inv nor inv}
```

The OR functionality is given by one of the following lists:

```
{or}
{buf or}
{or buf}
{buf or buf}
{nor inv}
{buf nor inv}
{inv and inv}
{inv nand}
{inv nand buf}
```

The NOR functionality is given by one of the following lists:

```
{or inv}
{buf or inv}
{nor}
{buf nor}
{nor buf}
{buf nor buf}
{inv and}
{inv and buf}
{inv nand inv}
```

You can designate certain library cells to be used exclusively or preferentially for gating the clocks. Such cells can be used for the 2-input clock gate, inverters, buffers, or D-latches in the clock-gating circuitry. To use a specific cell for clock gating and to prevent its use in other areas of the design, set the **dont_use** and the **is_clock_gating_cell** attributes to **true** in the library description. To preferentially use a specific cell in the clock-gating circuitry, set only the **is_clock_gating_cell** attribute to **true**. The **is_clock_gating_cell** attribute is a user-defined attribute of type Boolean for the cell group.

You can also designate a specific input pin of the 2-input clock gate as the enable input. If the **clock** attribute is set on one of the input pins of the 2-input clock gate, the other input is recognized as the enable pin. Otherwise, if the **clock_gate_enable_pin** attribute is set to **true** on an input, this pin is recognized as the enable pin. The **clock_gate_enable_pin** attribute is a user-defined attribute of type Boolean for the pin group.

Besides specifying simple 2-input gates, you also have the option to specify that a single complex clock-gating cell be used for the clock-gating logic. This is done by specifying **integrated** for the gate list to the **-positive_edge_logic** or **-negative_edge_logic** options. Note that if these options are specified as **integrated**, the strings after it are of integrated clock-gating cell types. No inverters or buffers are allowed before or after the integrated cell. This string can contain the specification of a library cell:

```
string gate = {integrated[:library_name]/cell_name] |
  [active_low_enable] [invert_gclk]}
string library_name
string cell_name
```

If a library cell is specified for use as an integrated clock-gating cell, the cell must have the **clock_gating_integrated_cell** attribute. Specify the attribute value as **generic**. The Library Compiler tool infers the functionality of the library cell based on the logic functions of the pins of the library cell. For backward compatibility, this string attribute can still have the value and specifies the functionality of the cell as a clock-gating cell. Based on the presence or absence of a latch, whether it is to be used as **positive_edge_logic** or **negative_edge_logic**, whether the control point is present and whether the observability port is present, the **clock_gating_integrated_cell** can have the following values:

```
latch_posedge
latch_posedge_precontrol
latch_posedge_postcontrol
latch_posedge_precontrol_obs
latch_posedge_postcontrol_obs
latch_negedge
latch_negedge_precontrol
latch_negedge_postcontrol
latch_negedge_precontrol_obs
latch_negedge_postcontrol_obs
```

```
none_posedge
none_posedge_control
none_negedge
none_negedge_control
```

Also, the pins of the integrated cell must have appropriate attributes, which include,

```
clock_gate_enable_pin attribute on the enable input pin
clock_gate_clock_pin attribute on the clock input pin
clock_gate_out_pin attribute on the gated-clock output pin
clock_gate_test_pin attribute on the scan-enable or test-mode pin
clock_gate_obs_pin attribute on the observability output pin
```

Specifying Additional Circuitry to Improve Testability

The next sections describe the specification of additional circuitry to improve testability of designs with gated clocks. The last four options specify circuitry that is introduced to improve testability. The impact of clock gating on testability is twofold. First, due to the clock gate, the control of the gated clock signal is reduced. Therefore, the clock-gating style allows the insertion of an OR gate, which forces the enable signal to logic 1 during testing. The **-control_point** option specifies if and where the OR gate is implemented. The **-control_signal** option specifies if a scan enable or a test mode signal is used to drive the OR gate. The test mode signal is held constant during testing. The scan enable signal is guaranteed to be logic 1 only during scan-in and scan-out. A port is created in the design according to the chosen test control signal.

Second, due to the control point OR gate, the enable signal is not observable if a test mode signal has been chosen as input to the control point OR gate. To improve the observability, the **-observation_point** option enables the insertion of observation points on the enable signals. The enable signals are grouped according to the clock signal and the clock edge of the register with which they are associated. An XOR gate tree fed by enable signals and providing input to an observability register is implemented for each group. The maximum depth of the XOR tree is determined by the **-observation_logic_depth** option. To minimize power consumption in the observability circuitry, the enable signals and the observability register's clock signal are gated by the test control signal.

The **-max_fanout** option enables you to specify a number for the maximum fanout of clock-gating cell at the RTL level. Based on the **max_fanout_count**, the Power Compiler tool splits the register banks that are to be clock-gated, and creates as many clock-gating cells that is required to drive them.

This option does not override the maximum fanout design rule constraint during the **compile_ultra** command. The value specified with the **-max_fanout** option is an integer, greater than 0. It should not be less than the **minimum_bitwidth** value. The default is a huge number (unlimited for all practical purposes).

The **-num_stages** option enables multistage clock gating with the **compile_ultra -gate_clock** command. The **num_stages_count** value is an integer greater than 0. It determines the maximum number of stages that are introduced by factoring of the inserted clock gates. The default is 1, so no factoring is performed. The number of stages are counted from the register to the clock source. Any multiple-input combinational cell in the clock path will stop the stage count.

The **-no_sharing** option can be used only with the **-max_fanout** option. When you use this option, Power Compiler does not share any clock-gating cell between register banks. When you do not use this option, Power Compiler enables you to share clock-gating cells between register banks with similar control logic to meet the **max_fanout_count** value.

If **compile_ultra -gate_clock** or **replace_clock_gates** is issued without explicitly setting the clock-gating style beforehand (such as when the **set_clock_gating_style** command is not issued) a default style is applied.

The default style is derived from the **target_library** that is set when the **compile_ultra -gate_clock** or **replace_clock_gates** command is issued. The style is chosen such that the best available clock gating configuration is used with the current **target_library**. The "best available" style corresponds to the first legal style in context of the current **target_library** of the following combinations:

- (a) **set_clock_gating_style -pos integrated -neg integrated \ -control_point before -control_signal scan_enable**
- (b) **set_clock_gating_style -pos integrated -neg integrated \ -control_point after -control_signal scan_enable**
- (c) **set_clock_gating_style -pos integrated -neg integrated \ -control_point before -control_signal test_mode \ -observation_point true**

- (d) `set_clock_gating_style -pos integrated -neg integrated \ -control_point after -control_signal test_mode \ -observation_point true`
- (e) `set_clock_gating_style -pos integrated -neg integrated`
- (f) `set_clock_gating_style -pos integrated -neg or \ -control_point before -control_signal scan_enable`
- (g) `set_clock_gating_style -pos integrated -neg or \ -control_point after -control_signal scan_enable`
- (h) `set_clock_gating_style -pos integrated -neg or \ -control_point before -control_signal test_mode \ -observation_point true`
- (i) `set_clock_gating_style -pos integrated -neg or \ -control_point after -control_signal test_mode \ -observation_point true`
- (j) `set_clock_gating_style -pos integrated -neg or`
- (k) `set_clock_gating_style -pos and -neg integrated \ -control_point before -control_signal scan_enable`
- (l) `set_clock_gating_style -pos and -neg integrated \ -control_point after -control_signal scan_enable`
- (m) `set_clock_gating_style -pos and -neg integrated \ -control_point before -control_signal test_mode \ -observation_point true`
- (n) `set_clock_gating_style -pos and -neg integrated \ -control_point after -control_signal test_mode \ -observation_point true`
- (o) `set_clock_gating_style -pos and -neg integrated`
- (p) `set_clock_gating_style -pos and -neg or`

Instance specific Clock-gating Style

Instance specific clock-gating style refers to the possibility of setting a clock gating style on a specific instances of the design. The **-instances**, **-power_domains** and **-designs** options allow you to specify the set of hierarchical cells, power domains and designs on which a given clock gating style should be applied.

To enable instance specific clock gating style, set the **power_cg_iscgs_enable** variable to **true**.

When instance specific clock gating style is disabled, the use of the **-instances**, **-power_domains** and **-designs** options is not allowed, and **set_clock_gating_style** command errors out. If **-instances**, **-power_domains** and **-designs** are not used, the clock gating style is associated with the current design.

The following method is used to set the style on a hierarchical instance:

1. Look for a style set on that instance.
2. If no style has been found and the instance was used to define a power_domain, try to find a style set on the power_domain.
3. If no style has been found, look for a style set on the design it is referencing.
4. If no style has been found, it inherits the style from the hierarchical cell containing it.

Note that instances that have a specific clock gating style set are not automatically ungrouped.

EXAMPLES

Default values are assumed for all unspecified options. In particular, option values from previous clock-gating style settings are not stored.

The following example sets the clock-gating style such that banks with two or more flip-flops are implemented with gated clocks:

```
prompt> set_clock_gating_style -minimum_bitwidth 2
```

The following example specifies the clock-gating circuitry, including the library cells for gating the clock of registers inferred by a positive edge clock HDL code construct. Note that for the negative-edge registers, the default is used. The latch-based style is chosen, therefore, the circuitry must have AND functionality. A particular latch LD2 is chosen from the target library.

```
prompt> set_clock_gating_style -sequential_cell latch:LD2 \
    -positive_edge_logic {nand:NAND2 inv:IV3}
```

The following example specifies the clock-gating circuitry for registers inferred by positive and negative edge clock HDL code constructs. By default, latch-based clock gating is assumed. Three gates are specified on the clock network. The mapping to library cells happens automatically during compilation. A hold time constraint of 0.5 is specified. By default, the setup time constraint is 0.

```
prompt> set_clock_gating_style -pos {buf nand inv} \
    -neg {buf or inv} -hold 0.5
```

The following example specifies the clock-gating circuitry for registers inferred by positive and negative edge clock HDL code constructs (latch-free clock gating). Note that an inverter is inferred for those registers that are inferred by a negative-edge clock construct to obtain an inverted clock signal at the flip-flops clock pin.

```
prompt> set_clock_gating_style -sequential_cell none \
    -pos {or} -neg {and}
```

The following example specifies that clock gating is performed with the insertion of control point OR gates:

```
prompt> set_clock_gating_style -control_point after \
    -control_signal scan_enable
```

The following example specifies that clock gating is performed with the insertion of control point OR gates, as well as the insertion of observation points:

```
prompt> set_clock_gating_style -control_point before \
    -control_signal test_mode -observation_point true \
    -observation_logic_depth 4
```

The following example specifies a latch based clock-gating style and limits the fanout of individual clock-gating cells to 8. The **-no_sharing** option ensures that a single clock-gating cell gates registers from only one register bank.

```
prompt> set_clock_gating_style -sequential_latch \
    -max_fanout 8 -no_sharing
```

The following example specifies the clock-gating circuitry for registers inferred by positive and negative edge clock HDL code constructs. Note that an active low enabled and inverting gclk output integrated clock-gating cell is chosen for registers that are inferred by a positive-edge clock construct. An inverting gclk output integrated clock-gating cell is chosen for registers that are inferred by a negative-edge clock construct.

```
prompt> set_clock_gating_style \
    -pos {integrated active_low_enable invert_gclk} \
    -neg {integrated invert_gclk}
```

The following example specifies two different latches for positive and negative-edge logic:

```
prompt> set_clock_gating_style \
    -positive_edge_logic {latch:lsi_10k/LD2 and} \
    -negative_edge_logic {latch:lsi_10k/LD1 or}
```

The following example specifies a clock gating style with minimum bitwidth and maximum fanout of 1 on instances m1/b1 and m2:

```
prompt> set_clock_gating_style -minimum_bitwidth 1 \
           -max_fanout 1 -instances {m1/b1 m2}
```

The following example specifies a clock-gating style with integrated cells on instances m1 and power domain PD0:

```
prompt> set_clock_gating_style -positive_edge_logic {integrated} -instances m1 \
           -power_domains PD0
```

The following example specifies a clock-gating style with integrated cells set on instances m1, power domain PD0 and all instances of design adder16:

```
prompt> set_clock_gating_style -positive_edge_logic {integrated} -instances m1 \
           -power_domains PD0 -designs adder16
```

set_clock_groups

Specifies clock groups that are mutually exclusive or asynchronous with each other in a design so that the paths between these clocks are not considered during timing analysis.

SYNTAX

```
status set_clock_groups
  -physically_exclusive
  | -logically_exclusive
  | -asynchronous [-allow_paths]
  [-name clock_group_name]
  -group clock_list
  [-comment comment_string]
```

Data Types

<i>clock_group_name</i>	string
<i>clock_list</i>	collection
<i>comment_string</i>	string

ARGUMENTS

-physically_exclusive

Specifies that the clock groups are physically exclusive with each other. Physically-exclusive clocks cannot coexist in the design physically. An example of this is multiple clocks that are defined on the same source pin. The **-physically_exclusive**, **-logically_exclusive**, and **-asynchronous** options are mutually exclusive; you must choose only one.

-logically_exclusive

Specifies that the clock groups are logically exclusive with each other. An example of logically-exclusive clocks is multiple clocks that are selected by a multiplexer but might have coupling with each other in the design. However, you should not set these multiplexed clocks to be exclusive if some physical paths exist among them somewhere in the design. The **-physically_exclusive**, **-logically_exclusive**, and **-asynchronous** options are mutually exclusive; you must choose only one.

-asynchronous

Specifies that the clock groups are asynchronous to each other. Two clocks are asynchronous with respect to each other if they have no phase relationship at all. Signal integrity analysis uses an infinite arrival window on the aggressor unless all the arrival windows on the victim net and the aggressor net are defined by synchronous clocks. The **-physically_exclusive**, **-logically_exclusive**, and **-asynchronous** options are mutually exclusive; you must choose only one.

-allow_paths

Enables timing analysis between the specified clock groups. If this option is not specified, timing analysis among the defined clock groups are disabled. This option can be used with only with asynchronous clock groups.

-name *clock_group_name*

Specifies a name for the clock grouping. Each command must specify a unique name that identifies the exclusive or asynchronous relationship among the specified clock groups. This name is used later to easily remove the clock grouping defined here. By default,

the command creates a unique name.

-group *clock_list*

Specifies the clocks in a group. You can use the **-group** option more than once in a single command execution. However, you can include a clock only in one group in a single command execution. To include a clock in multiple groups, you must execute the **set_clock_groups** command multiple times.

By default, a generated clock and its master clock are not in the same group when the exclusive or asynchronous clock groups are defined. Put these clocks explicitly in the same group if needed.

Each **-group** instance specifies a group of clocks, which are exclusive or asynchronous with the clocks in all other groups. If you specify only one group, it means that the clocks in that group are exclusive or asynchronous with all other clocks in the design. A default other group is created for this single group. Whenever a new clock is created, it is automatically included in this group.

-comment *comment_string*

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

DESCRIPTION

This command specifies clock groups that are mutually exclusive, either physically or logically, or asynchronous with each other in a design.

If multiple clock group relationships are defined for the same pair of clocks, physically exclusive has the highest precedence, followed by asynchronous, and logically exclusive has the lowest precedence.

By default, the timing paths between these clocks are not considered during timing analysis. This is similar to declaring false paths between these clocks. Thus, you do not have to manually set a false path if you have already specified two clocks as exclusive or asynchronous. If a false path is already set between two clocks when you specify that they are exclusive or asynchronous, the false path is overwritten by the **set_clock_groups** command. Other exceptions are unaffected.

Note that for asynchronous clock groups, you can consider the timing paths between these clocks by using the **-allow_paths** option.

The two types of exclusive clocks are not treated differently for simple timing analysis. However, signal integrity analysis treats logically-exclusive clocks as synchronous for timing windows. Physically-exclusive clocks are not considered for timing window analysis with each other.

When the clocks are asynchronous to each other, crosstalk analysis ignores the timing relationship between them during the timing window overlap analysis. This case is also referred to as infinite window overlap. The results can be optimistic without infinite window overlap for the synchronous clocks. It is important to use the **set_clock_groups -asynchronous** command when the clocks are not synchronous to each other.

To undo the **set_clock_groups** command, use the **remove_clock_groups** command. To report the clock groups defined in a design, use the **report_clock** command with the **-groups** option.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example defines two asynchronous clock domains:

```
prompt> set_clock_groups -asynchronous -name g1 \
```

```
-group CLK1 -group CLK2
```

The following example defines a clock named CLK1 as asynchronous with all other clocks in the design:

```
prompt> set_clock_groups -asynchronous -group CLK1
```

The following example shows how to simultaneously analyze multiple clocks per register without manually specifying false paths.

Assume that a design contains two pairs of mutually-exclusive clocks that are multiplexed: CLK1 and CLK2, and CLK3 and CLK4.

If each pair of clocks is selected by a different signal, you must execute two **set_clock_groups** commands to simultaneously analyze all four clocks:

```
prompt> set_clock_groups -logically_exclusive \
    -group CLK1 -group CLK2
prompt> set_clock_groups -logically_exclusive \
    -group CLK3 -group CLK4
```

If each pair of clocks is selected by the same signal, you must execute only one **set_clock_groups** command to simultaneously analyze all four clocks:

```
prompt> set_clock_groups -logically_exclusive \
    -group {CLK1 CLK3} -group {CLK2 CLK4}
```

The following example shows how to define clocks CLK1 and CLK2 as physically exclusive:

```
prompt> set_clock_groups -physically_exclusive \
    -group {CLK1} -group {CLK2}
```

`set_false_path(2)`

set_clock_latency

Specifies the clock latency for clocks, ports, or pins.

SYNTAX

```
status set_clock_latency
  [-rise]
  [-fall]
  [-min]
  [-max]
  [-source]
  [-early]
  [-late]
  [-dynamic jitter]
  [-clock clock_list]
  delay
  object_list
```

Data Types

<i>jitter</i>	float
<i>clock_list</i>	list
<i>delay</i>	float
<i>object_list</i>	collection

ARGUMENTS

-rise

Applies the specified latency value only to rising transitions at register clock pins. By default, the latency value applies to both rising and falling transitions at register clock pins.

-fall

Applies the specified latency value only to falling transitions at register clock pins.

-min

Applies the specified latency value only to the minimum operating condition. By default, the latency value applies to both the minimum and maximum operating conditions.

-max

Applies the specified latency value only to the maximum operating condition.

-source

Specifies the source (instead of network) latency. Source latency is the amount of delay from the ideal waveform to the source object in the design, as defined by the **create_clock** command.

By default, the delay value applies to the network latency, the amount of delay from the source object in the design to the register

clock pin of the sequential device. The total latency is source latency plus network latency.

-early

Applies the specified delay value only to early source latency, for example, to calculate the clock delay to the capture register in a setup check. This option can be used only with the **-source** option. By default, when you use the **-source** option, the specified delay value applies to both early and late source latency.

-late

Applies the specified delay value only to late source latency, for example, to calculate the clock delay to the capture register in a hold check. This option can be used only with the **-source** option.

-dynamic jitter

Specifies the dynamic component of the clock latency, which represents the amount of jitter in the original clock source. This option can be used only with the **-source** option.

-clock *clock_list*

Applies the latency value with respect to the specified clock. This option lets you specify the relevant clock when you set the latency on a port or pin, and multiple clocks pass through the port or pin.

delay

Specifies the clock latency value, either network latency by default, or source latency if you use the **-source** option.

object_list

Specifies the clocks, ports, and pins on which to set the delay value.

DESCRIPTION

This command specifies clock latency, which is the amount of delay for a clock signal reaching the clock pin of a sequential device. You can specify two types of clock latency: network latency (the default) and source latency (by using the **-source** option).

Clock network latency is the time it takes a clock signal to propagate from the clock definition point (as defined by the **create_clock** command) to a register clock pin. The rise and fall latencies are the latencies for rising and falling transitions at the register clock pin, respectively. The tool considers inversion of the clock waveform, if present in the clock network, to determine the rising or falling sense at the register clock pin .

Clock source latency (also called insertion delay) is the time it takes for a clock signal to propagate from its actual ideal waveform origin point to the clock definition point in the design. You can use it to model off-chip clock latency when a clock generation circuit is not part of the current design. For generated clocks, you can use clock source latency to model the delay from the master clock to the generated clock definition point. You can use the **-early** and **-late** options to specify early and late clock source latencies, respectively.

The dynamic component of clock latency is the amount of jitter in the original clock source, which leads to a reduction in timing slack equal to the specified amount of time. You specify this amount by using the **-dynamic** option, which can be used only with the **-source** option. In the case of a zero-cycle path, in which the same clock edge both launches and captures data in the path, jitter does not reduce the slack; the tool takes this into account in any clock reconvergence pessimism removal adjustment performed on the path.

If multiple clocks are allowed per object, you can specify the clock latency with respect to specific clocks by using the **-clock** option. By using multiple **set_clock_latency** commands, you can specify different latency values for different clocks that pass through the same ports or pins.

By default, the tool assumes ideal clocking, which means clocks have a specified network latency (from the **set_clock_latency** command) or zero network latency by default. Propagated clock network latency (from the **set_propagated_clock** command) is normally used after layout and final clock tree generation. Specifying the ideal clock network latency provides an estimate of the clock tree delay for before layout.

You can specify clock source latency using the **-source** option for both ideal and propagated clocks. The total clock latency at a register clock pin is the sum of the source latency and network latency.

When you apply the **set_clock_latency** command to pins or ports, it affects all register clock pins in the transitive fanout of the specified pins or ports. You can apply source latency only to clocks and clock source pins.

To undo the effects of the **set_clock_latency** command, use the **remove_clock_latency** command.

To report the clock network latency and clock source latency information, use the **report_clock-skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies a rise latency of 1.2 and a fall latency of 0.9 for the clock named CLK1:

```
prompt> set_clock_latency 1.2 -rise [get_clocks CLK1]
prompt> set_clock_latency 0.9 -fall [get_clocks CLK1]
```

The next example specifies an early rise and an early fall source latency of 0.8, and a late rise and a late fall source latency of 0.9 for the clock named CLK1:

```
prompt> set_clock_latency 0.8 -source -early [get_clocks CLK1]
prompt> set_clock_latency 0.9 -source -late [get_clocks CLK1]
```

The next example specifies an early and late source latency of 3 and 5 respectively with dynamic components of 0.5.

```
prompt> set_clock_latency 3 -source -early -dynamic 0.5 [get_clocks CLK1]
prompt> set_clock_latency 5 -source -late -dynamic 0.5 [get_clocks CLK1]
```

set_clock_sense

Specifies the clock sense (with respect to the clock source) propagating forward from the specified pins.

SYNTAX

```
status set_clock_sense
  -stop_propagation
  | -logical_stop_propagation
  | -positive
  | -negative
  | -pulse pulse_type
  [-clocks clocks]
  pins
```

Data Types

<i>pulse_type</i>	string
<i>clocks</i>	collection
<i>pins</i>	collection

ARGUMENTS

-stop_propagation

Stops propagation of the specified clocks at the specified pins along the clock paths only.

The **-stop_propagation** option is mutually exclusive with the **-positive**, **-negative**, **-logical_stop_propagation**, and **-pulse** options. You must specify one of these options.

-logical_stop_propagation

Stops propagation of the specified clocks at the specified pins along the clock paths only.

The **-logical_stop_propagation** option is mutually exclusive with the **-positive**, **-negative**, **-stop_propagation**, and **-pulse** options. You must specify one of these options.

-positive

Propagates only the positive unate paths forward from the specified pins.

The **-positive** option is mutually exclusive with the **-negative**, **-pulse**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-negative

Propagates only the negative unate paths forward from the specified pins.

The **-negative** option is mutually exclusive with the **-positive**, **-pulse**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-pulse *pulse_type*

Specifies the type of pulse clock that is generated from the specified pins. You must specify one of the following values: **rise_triggered_high_pulse**, **rise_triggered_low_pulse**, **fall_triggered_high_pulse**, or **fall_triggered_low_pulse**.

The **-pulse** option is mutually exclusive with the **-positive**, **-negative**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-clocks *clocks*

Specifies the clocks to which the specified clock sense applies.

If you do not specify this option, the clock sense setting applies to any clock that passes through the specified pins.

pins

Specifies the pins on which to set the clock sense.

DESCRIPTION

This command provides the capability to define the clock sense at nonunate points in the clock network. The command is ignored if it is used on a unate point in the clock network. The specified clock sense propagates forward from the specified pins.

If the **-clocks** option is used, only the specified clocks are considered. Otherwise, all clocks passing through the specified pins are considered.

Warning messages are issued if the specified sense cannot be respected on the specified pins. Hierarchical pins are not supported.

To undo the settings made by the **set_clock_sense** command, use the **remove_clock_sense** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies positive unateness for a pin named XOR/Z with respect to the CLK1 clock:

```
prompt> set_clock_sense -positive -clocks [get_clocks CLK1] XOR/Z
```

The following example specifies a pulse type of **rise_triggered_high_pulse** for all clocks passing through a pin named MUX/Z:

```
prompt> set_clock_sense -pulse rise_triggered_high_pulse MUX/Z
```

SEE ALSO

[remove_clock_sense\(2\)](#)

set_clock_transition

Sets the transition time at the clock pins of all sequential devices clocked by the specified ideal clocks.

SYNTAX

```
status set_clock_transition
  transition
  [-rise | -fall]
  [-min]
  [-max]
  clock_list
```

Data Types

<i>transition</i>	float
<i>clock_list</i>	collection

ARGUMENTS

transition

Specifies the transition time at the clock pins of the sequential devices clocked by the specified ideal clocks, in time units of the technology library used during optimization.

-rise | -fall

Specifies whether the value applies to rising or falling transitions at the clock pins of the sequential devices. If neither is specified, both rising and falling clock transitions are set. If you specify only **-rise** or only **-fall** and do not specify a transition time for the other type of transition, the default value, 0.0, applies to the other type of transition.

-min

Specifies that the value applies to minimum delay analysis only. By default, the transition value applies to both minimum and maximum delay analysis.

-max

Specifies that the value applies to maximum delay analysis only. By default, the transition value applies to both minimum and maximum delay analysis.

clock_list

Specifies the ideal clocks to which the transition value applies. The specified transition time applies to all register clock pins in the transitive fanout of each specified clock.

DESCRIPTION

This command explicitly specifies the transition time of clock signals that reach the clock pins of sequential devices in the transitive fanout of one or more ideal clocks.

This command is especially useful before layout, when clock trees are incomplete and the clocks have ideal behavior. By default, ideal clocks have a transition time of zero. To get more accurate timing results, specify an estimated nonzero transition time.

If you specify the name of a propagated clock instead of an ideal clock, the transition time value is ignored; the calculated transition time is used instead. You should set clocks to be propagated clocks only after the final clock trees are constructed.

The command sets one or more of the **clock_transition_fall_max**, **clock_transition_fall_min**, **clock_transition_rise_max**, and **clock_transition_rise_min** attributes of the specified clock objects.

To undo the effects of the **set_clock_transition** command, use the **remove_clock_transition**, **remove_attribute**, or **reset_design** command.

To list all clock transition values that have been set, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command sets both the rise and fall transition times to 0.75 on the clock pins of all sequential elements clocked by the clock named CLK1:

```
prompt> set_clock_transition 0.75 CLK1
```

The following command sets the fall transition time to 0.64 for maximum-delay analysis on the clock pins of all sequential elements clocked by CLK1 and CLK2:

```
prompt> set_clock_transition 0.64 -fall -max {CLK1 CLK2}
```

The following command sets both the rise and fall transition times to 0.20 on the clock pins of all sequential elements clocked by ideal clocks:

```
prompt> set_clock_transition 0.20 [all_clocks]
```

[-hold]
uncertainty

Data Types

<i>object_list</i>	collection
<i>from_clock</i>	collection
<i>rise_from_clock</i>	collection
<i>fall_from_clock</i>	collection
<i>to_clock</i>	collection
<i>rise_to_clock</i>	collection
<i>fall_to_clock</i>	collection
<i>uncertainty</i>	float

ARGUMENTS

object_list

Specifies the clocks, ports, or pins for simple uncertainty. The uncertainty is applied either to the capturing latches clocked by one of the specified clocks or to the capturing latches whose clock pins are in the fanout of a specified port or pin.

You must specify either this argument or a clock pair with the **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options; you cannot specify both.

-from *from_clock*

Specifies the source clocks for interclock uncertainty.

You must specify either a clock pair with the **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options or the *object_list* argument; you cannot specify both.

-rise_from *rise_from_clock*

Specifies that the uncertainty applies only to the rising edge of the source clock.

You can use only one of the **-from**, **-rise_from**, and **-fall_from** options.

-fall_from fall_from_clock

Specifies that the uncertainty applies only to the falling edge of the source clock.

You can use only one of the **-from**, **-rise_from**, and **-fall_from** options.

-to to_clock

Specifies the destination clocks for interclock uncertainty.

You must specify either a clock pair with the **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options or the *object_list* argument; you cannot specify both.

-rise_to rise_to_clock

Specifies that the uncertainty applies only to the rising edge of the destination clock.

You can use only one of the **-to**, **-rise_to**, and **-fall_to** options.

-fall_to fall_to_clock

Specifies that the uncertainty applies only to the falling edge of the destination clock.

You can use only one of the **-to**, **-rise_to**, and **-fall_to** options.

-rise

Indicates that the uncertainty applies to only the rising edge of the destination clock.

By default, the uncertainty applies to both the rising and falling edges.

This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use the **-rise_to** option instead.

-fall

Indicates that the uncertainty applies to only the falling edge of the destination clock.

By default, the uncertainty applies to both rising and falling edges.

This option is valid only for interclock uncertainty, and is now obsolete. Unless you need this option for backward-compatibility, use the **-fall_to** option instead.

-setup

Indicates that the uncertainty applies only to setup checks.

By default, the uncertainty applies to both setup and hold checks.

-hold

Indicates that the uncertainty applies only to hold checks.

By default, the uncertainty applies to both setup and hold checks.

uncertainty

Specifies a floating-point number that indicates the uncertainty value. Typically, clock uncertainty should be positive. Negative uncertainty values are supported for constraining designs with complex clock relationships. Setting the uncertainty value to a negative number could lead to optimistic timing analysis and should be used with extreme care.

DESCRIPTION

This command specifies the clock uncertainty (skew characteristics) of the specified clock networks. This command can specify either interclock uncertainty or simple uncertainty. For interclock uncertainty, use the **-from/-rise_from/-fall_from** and **-to/-rise_to/-fall_to** options to specify the source clock and the destination clock; all paths between these clocks receive the uncertainty value. For simple uncertainty, use the *object_list* argument; the uncertainty value is either to the capturing latches clocked by one of the clocks in the *object_list* argument or to the capturing latches whose clock pins are in the fanout of a port or pin specified in the *object_list* argument.

Set the uncertainty to the worst skew expected to the endpoint or between the clock domains. You can increase the value to account for additional margin for setup and hold.

When you specify interclock uncertainty, ensure that you specify it for all possible interactions of the clock domains. For example, if you specify paths from CLKA to CLKB and CLKB to CLKA, you must specify the uncertainty for both even if the values are the same.

Interclock uncertainty is more specific than simple uncertainty. If a command that specifies interclock uncertainty conflicts with a command that specifies simple uncertainty, the command that specifies interclock uncertainty takes precedence.

If there is no applicable interclock uncertainty for a path, the value for simple uncertainty is used.

To remove the uncertainties set by the **set_clock_uncertainty** command, use the **remove_clock_uncertainty** command.

To view clock uncertainty information, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies that all paths leading to registers or ports clocked by CLK have setup uncertainty of 0.65 and hold uncertainty of 0.45:

```
prompt> set_clock_uncertainty -setup 0.65 [get_clocks CLK]
prompt> set_clock_uncertainty -hold 0.45 [get_clocks CLK]
```

The following example specifies interclock uncertainties between the PHI1 and PHI2 clock domains:

```
prompt> set_clock_uncertainty 0.4 -from PHI1 -to PHI1
prompt> set_clock_uncertainty 0.4 -from PHI2 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI1 -to PHI2
prompt> set_clock_uncertainty 1.1 -from PHI2 -to PHI1
```

The following example specifies interclock uncertainties between the PHI1 and PHI2 clock domains with specific edges:

```
prompt> set_clock_uncertainty 0.4 -rise_from PHI1 -to PHI2
prompt> set_clock_uncertainty 0.4 -fall_from PHI2 -rise_to PHI1
prompt> set_clock_uncertainty 1.1 -from PHI1 -fall_to PHI2
```

The following example shows conflicting **set_clock_uncertainty** commands, one for simple uncertainty and one for interclock uncertainty. The interclock uncertainty value of 2 takes precedence.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKB] -to [get_clocks CLKA]
```

The following example specifies the uncertainty from CLKA to CLKB and from CLKB to CLKA. Notice that both must be specified even though the value is the same.

```
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKA] -to [get_clocks CLKB]
prompt> set_clock_uncertainty 2 \
```

-from [get_clocks CLKB] -to [get_clocks CLKA]

The following example illustrates a situation in which simple uncertainty is used when there is no applicable interclock uncertainty for a path. The first command specifies a simple uncertainty of 5 for CLKA paths, and the second command specifies an interclock uncertainty of 2 for paths from CLKB to CLKA. If there are paths between CLKA and other clocks (for example, CLKC, CLKD, and so on) for which interclock uncertainty has not been specifically defined, the simple uncertainty (in this case, 5) is used.

```
prompt> set_clock_uncertainty 5 [get_clocks CLKA]
```

```
prompt> set_clock_uncertainty 2 \
    -from [get_clocks CLKB] -to [get_clocks CLKA]
```

SEE ALSO

report_clock(2)
set_clock_latency(2)
set_clock_transition(2)
```

set_combinational_type

Sets attributes on cell instances to specify which combinational cells from the target library are to be used by the **compile** command.

SYNTAX

```
status set_combinational_type
      -replacement_gate replacement_gate
      [cell_list]
```

Data Types

<i>replacement_gate</i>	string
<i>cell_list</i>	list

ARGUMENTS

-replacement_gate *replacement_gate*

Specifies a combinational gate from the target library to use by the **compile** command as the exact replacement gate for the cells in the cell list. This option sets the **combinational_type_exact** attribute to the *replacement_gate* on all cells in *cell_list*.

cell_list

Specifies a list of cells in which to use the replacement combinational gate.

DESCRIPTION

The **set_combinational_type** command specifies replacement combinational gate information for the **compile** command to use by setting attributes on the cell instances. Specifying **-replacement_gate** sets the **combinational_type_exact** attribute to *replacement_gate*, indicating to use this attribute as the replacement gate for those cells.

In the mapping process for combinational gates, **compile** attempts to convert combinational gates tagged by **set_combinational_type** to the specified replacement combinational gate. In the absence of attributes on a combinational cell instance to control the mapping, **compile** chooses the one best for timing, power, or area.

After mapping the cell instances to the replacement gate, **compile** sets the **dont_touch** attribute on these cell instances to disable further optimization on these cells.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example indicates that the replacement combinational gate for cell *U1* is cell *AN2P*. This sets the **combinational_type_exact** attribute to *AN2P* on the cell *U1*. The presence of this attribute indicates that cell *U1* attempts an exact mapping to gate *AN2P*.

```
prompt> set_combinational_type -replacement_gate AN2P U1
```

target_library(3)

set_compile_directives

Controls the application of high-level optimization operations on cells, hierarchical pins, references, designs, and library cells.

SYNTAX

```
status set_compile_directives
  object_list
  [-delete_unloaded_gate true | false]
  [-constant_propagation true | false]
  [-phase_inversion true | false]
  [-local_optimization true | false]
  [-critical_path_resynthesis true | false]
```

ARGUMENTS

object_list

Applies the **set_compile_directive** command on the list of objects (cells, hierarchical pins, references, designs, and library cells) you specify. This command is not applied on classes of cells that can only be internally generated (for example, generic logic, synthetic operators, and control logic to selector operators). If you include more than one object, the objects must be enclosed in quotation marks ("") or braces ({}). For more information about object names, see the **get_object_name** command man page.

-delete_unloaded_gate true | false

Allows you to delete unloaded gates from the cells specified in the *object_list* when set to **true** (the default). When set to **false**, cells referenced by *object_list* are not deleted, even if they do not drive any load.

-constant_propagation true | false

Allows constants to be propagated through the cells or hierarchical pins specified in *object_list* when set to **true** (the default). When set to **false**, constant propagation, within or across hierarchies, is disabled for the specified cells or hierarchical pins.

-phase_inversion true | false

Allows movement of inverters across hierarchical boundaries during boundary optimization on the cells or hierarchical pins specified in the *object_list* when set to **true** (the default). When set to **false**, prevents movement of inverters across hierarchies.

-local_optimization true | false

Allows you to perform operations on the cells specified in the *object_list* when set to **true** (the default). When set to **false**, operations that involve the immediate neighborhood of cells referenced by the object list are not performed. These operations include phase shift operations.

-critical_path_resynthesis true | false

Allows you to perform critical path resynthesis on cells specified in the *object_list* when set to **true** (the default). When set to **false**, critical path resynthesis is not performed on cells referenced by *object list*.

DESCRIPTION

You must have a DC Ultra license to use this command.

The **set_compile_directives** command controls switching on or off of certain high-level optimization steps on cells, hierarchical pins, references, designs, and library cells, where hierarchical pins are only accepted for the **-constant_propagation** option. The high-level optimization steps controlled by this command include deletion of unloaded gates, propagation of constants, local optimization (buffering, phase operations, and so on), and critical path resynthesis. Note that changing the default value of **true** of any of these command-line options also implies that the cells referenced by the object list are not structured.

An important application of this command is to direct synthesis to perform only sizing operations on a cell. You can achieve this by setting all command options to **false**. The **set_size_only** command achieves the same result. The **set_size_only** command does not require a DC Ultra license.

Setting **set_compile_directives** on a hierarchical cell implies **set_compile_directives** on all cells below it. Setting **set_compile_directives** on a library cell implies **set_compile_directives** on all instances of that cell. Setting **set_compile_directives** on a reference implies **set_compile_directives** on all cells of that reference during subsequent optimizations of the design.

Setting the compile directives on a design has an effect only when the design is instantiated within another design as a level of hierarchy. In this case, **set_compile_directives** on the design implies that all cells under that level of hierarchy acquire the same directives. Setting **set_compile_directives** on the top-level design has no effect because the top-level design is not instantiated within any other design.

Note that synthetic parts and generic cells ignore the **set_compile_directives** command; for example, many of the cells read in from an HDL description. Control logic feeding selector operator cells also ignore this command. Thus, the command is not applied on any class of cells that can only be internally generated.

When you specify an object name, **set_compile_directives** first looks within the current design for a hierarchical pin that matches that name. If it finds a match, the compile directives are assigned to that hierarchical pin. If no match is found, the command then looks for a cell that matches that name. If it finds a match, the compile directives are assigned to that cell. If no match is found, the command then looks for a reference, then a design in the system, and finally for a library cell in the system. This command assigns compile directives to the first object for which it finds a match.

The **report_cell** command prints all the compile directives set by the command in the attribute column.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies to size the *block1* and *analog1* cells during **compile** only:

```
prompt> set_compile_directives -del false -const false -local false \
           -crit false [get_cells {block1 analog1}]
```

SEE ALSO

`compile(2)`
`get_object_name(2)`
`report_cell(2)`
`set_size_only(2)`

set_compile_partitions

Specifies the compile partitions for the current design.

SYNTAX

```
status set_compile_partitions
  -level level
  | -designs design_list
  | -all
  | -auto
  [-force]
  [-no_reset]
```

Data Types

<i>level</i>	integer
<i>design_list</i>	list

ARGUMENTS

-level *level*

Creates partitions from all designs at the specified hierarchical level. Level one selects the subdesigns of the top-level design. The specified level must be greater than or equal to one. You must specify one, but not more than one, of the following options: **-level**, **-designs**, **-all**, or **-auto**.

-designs *design_list*

Creates partitions from the specified designs. You must specify one, but not more than one, of the following options: **-level**, **-designs**, **-all**, or **-auto**.

-all

Creates partitions from all subdesigns throughout the hierarchy of the current design. You must specify one, but not more than one, of the following options: **-level**, **-designs**, **-all**, or **-auto**.

-auto

Creates partitions from all designs automatically. You must provide the threshold for the partition size. See the *Automated Chip Synthesis User Guide* for threshold setting. You must specify one, but not more than one, of the following options: **-level**, **-designs**, **-all**, or **-auto**.

-force

Enables partitioning, even if the design contains multiple instances. If the specified design contains multiple instances, Automated Chip Synthesis selects as the master instance the instance with the hierarchical name that is first alphabetically. For more information about master instances, see the **MasterInstance** attribute man page.

By default, the **set_compile_partitions** command fails if the design contains multiple instances. You must either resolve these instances before running the command, or use the **-force** option.

-no_reset

Adds the specified partitions to the existing partition definitions.

By default, the **is_partition** attributes are removed from all subdesigns before creating the specified partitions.

DESCRIPTION

The **set_compile_partitions** command creates partitions from the specified designs by setting the **is_partition** attribute on the designs. When Automated Chip Synthesis (ACS) compiles a top-level design, it creates parallel compile jobs for each partition.

EXAMPLES

The following example assumes the design *RISC_CORE* is already in memory, and that the current design is *RISC_CORE*. It creates partitions from all designs automatically and uses **-force** to enable the partition since there are multiple instantiated designs.

```
prompt> set_compile_partitions -auto -force
```

In this example, the **report_partitions** command is used to see the results:

```
prompt> report_partitions
```

```
*****
Report : partitions
Design : RISC_CORE (unmapped)
Date   : Thu May 10 15:37:37 2001
*****
```

Partition attributes :

```
(*) - partition.
%  - the percentage w.r.t total design area.
d  - dont_touch.
m(n) - multiple instantiated design (number of instantiation).
```

Designs	Attributes
<hr/>	
RISC_CORE(*)	8.7%
STACK_TOP	3.9%
STACK_MEM(*)	7.6%, m(3), I_STACK_TOP/I1_STACK_MEM
STACK_FSM	3.2%
REG_FILE(*)	20.7%
DATA_PATH(*)	8.8%
PRGRM_CNT_TOP(*)	6.6%
PRGRM_CNT	2.2%
PRGRM_DECODE	2.2%
PRGRM_FSM	0.9%
CONTROL(*)	5.3%
INSTRN_LAT(*)	8.7%
ALU(*)	18.4%

The following example creates partitions on designs that are in hierarchical level one (subdesigns of the top-level design) and uses **-force** to enable the partition since there are multiple instantiated designs:

```
prompt> set_compile_partitions -level 1 -force
```

set_compile_power_high_effort

Enables high effort power options.

SYNTAX

```
set_compile_power_high_effort
  [-leakage true | false]
  [-total true | false]
```

ARGUMENTS

-leakage true | false

Controls whether high effort leakage power options are enabled in the flow.

The default is **false**.

If set to **true**, it runs high effort leakage options in incremental compile_ultra -spg and optimize_netlist -area for DCNXT.

-total true | false

Controls whether high effort Total power options are enabled in the flow.

The default is **false**.

If set to **true**, it runs high effort total power options in compile_ultra -spg, compile_ultra -spg -incr and optimize_netlist -area for DCNXT.

DESCRIPTION

This command is used to set high effort power options in DCNXT. This command takes arguments for two supported options: "-total" and "-leakage". Each of these two options can be set to either "true" or "false". When -total is set to true, the setting for -leakage option is ignored and the tool simply performs high effort total power optimization. By default, both "-total" and "-leakage" options are set to "false". Thus, the supported usage:

- a) **-total true** or **-total false**. and
- b) **-leakage true** or **-leakage false**.

High effort power optimization improves leakage and/or total power values while affecting other QoR metrics such as area and timing. High effort power optimization can increase compile and optimize_netlist -area runtimes.

EXAMPLES

The following example uses the **set_compile_power_high_effort** command to enable high effort leakage power optimization.

```
prompt> set_compile_power_high_effort -leakage TRUE  
1
```

The following example uses the **set_compile_power_high_effort** command to disable high effort leakage power optimization.

```
prompt> set_compile_power_high_effort -leakage FALSE  
1
```

The following example uses the **set_compile_power_high_effort** command to enable high effort total power optimization.

```
prompt> set_compile_power_high_effort -total TRUE  
1
```

The following example uses the **set_compile_power_high_effort** command to disable high effort total power optimization.

```
prompt> set_compile_power_high_effort -total FALSE  
1
```

SEE ALSO

[compile\(2\)](#)
[compile_enable_total_power_optimization\(3\)](#)

set_compile_spg_mode

Sets tool settings to improve timing correlation with either the IC Compiler II or IC Compiler tool. The **set_compile_spg_mode** command settings take effect when you use the **compile_ultra**, **compile_ultra -incremental**, or **optimize_netlist -area** command.

SYNTAX

```
status set_compile_spg_mode  
[-reset]
```

ARGUMENTS

-reset

Resets the updated settings to their default values, except user-set values.

DESCRIPTION

The **set_compile_spg_mode** command sets tool settings to improve timing correlation with the IC Compiler II or IC Compiler tool. Specify **icc2** mode to align the settings to the timer settings in the IC Compiler II tool. Specify **icc** mode to align the settings to the timer settings in the IC Compiler tool. For example, in **icc2** mode, the command enables enhanced timing modeling for RC estimation, removes long net pessimism, enables placement preclustering, and also enables recovery removal checks in the Design Compiler Graphical tool.

The **set_compile_spg_mode** command

- Prints a table of the updated tool settings
You can also get a report of the updated settings with the **report_compile_spg_mode** command.
- Does not override the tool settings that you have already set
- Does not align clock-gating check constraint
To have consistent clock-gating check settings between the Design Compiler and IC Compiler II tools, set the following command explicitly:

```
set_clock_gating_check -setup 0.0 -hold 0.0 [current_design]
```

The Design Compiler Graphical QoR with the **set_compile_spg_mode** command might look pessimistic and needs to be measured after using the **place_opt** command.

The command updates the settings before optimization starts during **compile_ultra**, **compile_ultra -incremental**, and **optimize_netlist**. The command is supported only in topographical mode.

For detailed information about the values that are changed when you use the **set_compile_spg_mode** command, see the "Improved Timing Correlation Between Design Compiler Graphical and IC Compiler II" topic in the *Design Compiler User Guide*.

EXAMPLES

The following examples show the usage of the command in different modes:

```
prompt> set_compile_spg_mode icc2
prompt> compile_ultra

prompt> set_compile_spg_mode icc
prompt> compile_ultra

prompt> set_compile_spg_mode -reset
prompt> compile_ultra
```

SEE ALSO

[compile_ultra\(2\)](#)
[optimize_netlist\(2\)](#)
[report_compile_spg_mode\(2\)](#)

set_congestion_optimization

Sets the **congestion_optimization** attribute on the specified hierarchical cells or designs, allowing congestion optimization to be performed on the objects. This command is supported only in topographical mode.

SYNTAX

```
status set_congestion_optimization  
    obj_list  
    [true | false]
```

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of hierarchical cell or design names for which to enable congestion optimization. Cell names in *obj_list* must be from the current design. If multiple objects are specified, they must be enclosed in quotation marks ("") or braces ({}).

true | false

Specifies the value for the **congestion_optimization** attribute. When the attribute is set to true (the default), congestion optimization is enabled on the specified objects (hierarchical cells or designs). Congestion optimization is performed on the specified objects only if you run the **compile_ultra** command with the -congestion option.

DESCRIPTION

The **set_congestion_optimization** command sets the **congestion_optimization** attribute on the specified *obj_list*. This attribute is used to specify the hierarchical cells or designs to be optimized for congestion.

Note that the optimizations for congestion are only performed by the **compile_ultra** command with the -congestion option.

If a cell with a specified name is found in the current design, the **congestion_optimization** attribute is set to the specified value in the cell. If no cell with a specified name is found, the tool searches for a design and the attribute is set for the design.

If a hierarchical cell is set with the **congestion_optimization** attribute and the cell contains other hierarchical cells, the attribute is propagated recursively on the cells unless they already have the attribute set on them.

EXAMPLES

The following example shows how to enable congestion optimization on hierarchical cells named c0 and c1/m2 and how to disable congestion optimization for the hierarchical cell named c0/m1:

```
prompt> set_congestion_optimization {c0 c1/m2} TRUE  
prompt> set_congestion_optimization c0/m1 FALSE
```

SEE ALSO

[compile\(2\)](#)
[set_attribute\(2\)](#)
[get_attribute\(2\)](#)
[remove_attribute\(2\)](#)

set_congestion_options

Sets options for congestion optimization.

SYNTAX

```
status set_congestion_options
  [-max_util value]
  [-layer name]
  [-availability value]
  [-coordinate {X1 Y1 X2 Y2}]
```

Data Types

<i>value</i>	float
<i>name</i>	string
<i>X1</i>	float
<i>Y1</i>	float
<i>X2</i>	float
<i>Y2</i>	float

ARGUMENTS

-max_util *value*

Specifies the maximum utilization factor.

-layer *name*

Specifies the layer name whose availability is reduced.

-availability *value*

Specifies the availability of the routing resource for the layer.

-coordinate {*X1 Y1 X2 Y2*}

Specifies the lower-left and upper-right coordinates for which the congestion options will apply. The numbers are in microns.

DESCRIPTION

Congestion optimization and reporting is available with Design Compiler Graphical. The **set_congestion_options** command sets congestion options for the current design. Congestion occurs because the number of wires going through a region exceeds the capacity of that region. If the ratio of usage-to-capacity is larger than 1, the region is congested.

The **-max_util** option specifies how densely the tool can pack cells in uncongested regions to remove congestion in congested regions. Set this variable based on how much placeable area is needed. The default maximum utilization is 0.95.

The **-layer** and **-availability** options specify how much of the routing resource for the given layer is available to be used. For example, in a design whose M5 and M6 will be 70% occupied by future P/G routing, you can set the availability of M5 and M6 to be 0.30. This means that even if currently there is no route in M5 and M6, they are considered to be 70% full. If you do not want to use M5 and M6 for signal routing at all, you can use **set_ignored_layer** to mark them as ignored. However, you should still specify the availability in this case, because the tool still needs to know the existence of these future nets to perform a good estimation on the coupling effects of them.

Congestion options can be design wide or regional. If the **-coordinate** option is not specified, the values are design wide. If the **-coordinate** option is specified, the values are only applied to the bounding box specified by the option. Regional congestion options are assigned an ID, which can be used to report or remove the regional options.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example runs the **set_congestion_options** command:

```
prompt> set_congestion_options -layer METAL5 -availability 0.5  
prompt> set_congestion_options -layer METAL5 -availability 0.7 \  
-coordinate {0 0 10 10}  
prompt> set_congestion_options -max_util 0.9
```

SEE ALSO

`current_design(2)`
`remove_congestion_options(2)`

`report_congestion_options(2)`
`set_ignored_layers(2)`

set_connection_class

Sets the connection class value on ports.

SYNTAX

```
status set_connection_class  
    connection_class_value  
    object_list
```

Data Types

<i>connection_class_value</i>	string
<i>object_list</i>	list

ARGUMENTS

connection_class_value

Specifies the desired connection class value of ports contained in *object_list*. The *connection_class_value* is a single string value. This string can contain any number of space-separated connection classes (see the example below).

object_list

Specifies ports whose connection classes are set.

DESCRIPTION

The **set_connection_class** command places the **connection_class** attribute on ports of designs being optimized (such as the current design). Connection classes are placed on ports of designs in a technology library by using Library Compiler. The **connection_class** attribute is used to indicate a connection class requirement for the network that is connected to the specified port.

The "connection class" label is an attribute that is used to describe connection requirements for a given technology. Only those loads and drivers with the same connection class label can be legally connected. The "universal" and "default" labels are reserved labels. The "universal" label indicates that a pin or port can legally connect with any other load or driver. The "default" label is used for those library pins that do not otherwise have a connection class assigned to them through any library attributes. For designs being optimized, the "universal" label is assigned to those ports that do not otherwise have an assigned connection class. To change the default connection class label for those ports, use the **default_port_connection_class** variable.

The connection requirements specified using connection classes are treated as Design Rule Constraints by the tool. Optimization attempts to build designs that meet connection class requirements even at the expense of other constraints on the design (such as area or power).

To view connection class values on ports, use the **report_port** or **get_attribute** command. To see the default connection class value for a library, use the **report_lib** command. To check your design for connection class violations, use the **check_design** command. To reset a connection class value, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a connection class "internal" to the port named *xyz* in the current design:

```
prompt> set_connection_class internal xyz
```

The following example sets the connection classes "internal" and "external" on the *out* port in the *test* design:

```
prompt> set_connection_class "internal external" test/out
```

In the following example, the connection class on a port is removed:

```
prompt> remove_attribute [get_ports xyz] connection_class
```

SEE ALSO

[target_library\(3\)](#)

set_constant_register_removal

Sets an attribute to constant register(s) to selectively preserve or optimize it.

SYNTAX

```
status set_constant_register_removal
  objects true / false
  object_list
```

ARGUMENTS

DESCRIPTION

The **set_constant_register_removal** command is applied on constant sequential cell(s) or hierarchical cell(s) to optimize or preserve it selectively. It sets an attribute **remove_constant_register** on specified register. The attribute can store true or false based upon your input. **set_constant_register_removal** when set to false on objects it sets the attribute **remove_constant_register** to value false and does not remove the constant register. When the command is set to true on objects it removes the constant register. You can use the attribute **remove_constant_register** to query the constant registers which are not removed after **compile_ultra**. This attribute can be used before **compile_ultra** to query registers which are to be removed. **set_constant_register_removal** honors **size_only** and issues warning if any register in this category is been set.

EXAMPLES

The following command optimizes register const_regA:

```
prompt> set_constant_register_removal const_regA true
```

The following command preserves register const_regB:

```
prompt> set_constant_register_removal const_regB false
```

The following command issues warning OPT-1221 as register const_sizeonly_regC is size_only:

```
prompt> set_constant_register_removal const_sizeonly_regC false
```

SEE ALSO

set_context_margin

Specifies the margin by which to tighten or relax constraints.

SYNTAX

```
string set_context_margin
      [-percent]
      [-relax]
      [-min]
      [-max]
      value
      [object_list]
```

Data Types

<i>value</i>	float
<i>object_list</i>	list

ARGUMENTS

-percent

Indicates that the specified value is a percentage of the delay.

-relax

Relaxes the constraint.

-min

Specifies the margin for minimum constraints.

-max

Specifies the margin for maximum constraints.

value

Determines the margin in absolute value or percentage value.

object_list

Specifies a list of cells or pins.

DESCRIPTION

The **set_context_margin** command specifies a margin to add to or to subtract from input and output delay values when the values are set_context_margin

generated by the **write_context** command. The margin can be specified as an absolute value or as a percentage of the constraint.

The constraints are created using the **characterize** or **dc_allocate_budgets** command, and then written out using the **write_context** command.

By default, the input and output delays are adjusted so that they are more constraining. This means that the specified margin is added to the maximum delay values and subtracted from the minimum delay values. If you specify the **-relax** option, the margin is subtracted from the maximum delay values and added to the minimum delay values.

The margin applies to the current design when no object list is specified. When determining the margin for a pin, the value set for the pin is used. If you do not specify a value for the pin, the value set for the parent cell is used. If neither value is set, the value set for the current design is used. If no margin is specified, the default value is 0.0

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command adds a margin of 0.5 to all maximum values of input and output delay constraints and subtracts the margin from all minimum values of input and output delay constraints. The margin applies to all objects in the current design.

```
prompt> set_context_margin 0.5
```

The following command relaxes (or reduces) the maximum value input delays on *I2/N* by 10 percent:

```
prompt> set_context_margin -relax -max -percent 10.0 I2/IN
```

SEE ALSO

[characterize\(2\)](#)
[dc_allocate_budgets\(2\)](#)
[write_script\(2\)](#)

set_cost_priority

Sets the **cost_priority** attribute to a specified value on the current design.

SYNTAX

```
status set_cost_priority
  [-default]
  [-delay]
  cost_list
  [-design_rules]
  [-min_delay]
```

Data Types

cost_list list

ARGUMENTS

-default

Removes the **cost_priority** attribute so that the **compile** command uses its default priority.

-delay

Specifies that **max_delay** has higher priority than the maximum design rules.

cost_list

Specifies a list of costs in decreasing order of priority, selected from the following: **max_delay**, **min_delay**, **max_transition**, **max_fanout**, **max_capacitance**, **cell_degradation**, and **max_design_rules**.

-design_rules

Specifies that **max_design_rules** cost has higher priority than the maximum delay cost.

-min_delay

Specifies that **min_delay** has higher priority than the **max_delay**, but lower priority than the maximum design rules.

DESCRIPTION

The **set_cost_priority** command sets the **cost_priority** attribute on the current design. This attribute changes the precedence that the **compile** command uses when different constraints conflict with each other. For example, by default the design rule **max_transition** has priority over **max_delay**, meaning that if both constraints cannot be met, **compile** fixes the transition violation at the expense of delay.

If a list of costs is given, any costs that are not in the list are assumed to follow afterwards in their default relative priority.

If **set_cost_priority** is specified more than once on a design, the most recent setting is used and the earlier values are removed.

To undo **set_cost_priority**, use the **-default** option, the **remove_attribute** command, or the **reset_design** command.

Use the **report_constraints** command to obtain a summary of the constraints of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the priority so that design rule violations are not fixed if they increase max delay cost:

```
prompt> set_cost_priority -delay
```

The following example sets the priority so that **max_fanout** and **max_capacitance** have higher priority than delay, but **max_transition** and **cell_degradation** have lower priority:

```
prompt> set_cost_priority {max_fanout max_capacitance max_delay}
```

set_critical_range

Sets the **critical_range** attribute to a specified value on a list of designs.

SYNTAX

```
status set_critical_range
      range_value
      designs
```

Data Types

```
range_value   float
designs       list
```

ARGUMENTS

range_value

Specifies the value to which the **critical_range** attribute is to be set.

designs

Indicates the list of designs to which the **critical_range** attribute applies.

DESCRIPTION

This command sets the **critical_range** attribute to the specified value on the specified designs.

The tool uses the **critical_range** attribute of the top-level design as the default critical range for path groups that do not have a critical range set. If you do not set the **critical_range** attribute, such path groups get a critical range of 0.0. You can assign critical range values to individual path groups with the **group_path -critical_range** command.

Critical range specifies a margin of delay for path groups in optimization. This must be a positive float number or 0.0. A critical range of 0.0 means that only the most critical paths (the ones with the worst violation) are optimized. If you specify a nonzero critical range, near-critical paths within that amount of the worst path will also be optimized, if possible.

To undo **set_critical_range**, use the **remove_attribute** or **reset_design** command.

To show the critical range values for each path group, use the **report_path_group** command. To show the critical range cost of the design, use the **report_constraint** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets the default critical range for the top design to 10.0:

```
prompt> set_critical_range 10.0 top
```

set_current_command_mode

SYNTAX

```
string set_current_command_mode
    -mode command_mode | -command command
```

Data Types

```
command_mode  string
command        string
```

ARGUMENTS

-mode *command_mode*

Specifies the name of the new command mode to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

-command *command*

Specifies the name of the command whose associated command mode is to be made current. **-mode** and **-command** are mutually exclusive; you must specify one, but not both.

DESCRIPTION

The **set_current_command_mode** sets the current command mode. If there is a current mode in effect, the current mode is first canceled, causing the associated clean up to be executed. The initialization for the new command mode is then executed as it is made current.

If the name of the given command mode is empty, the current command mode is cancelled and no new command mode is made current.

A current command mode stays in effect until it is displaced by a new command mode or until it is cleared by an empty command mode.

If the command completes successfully, the new current command mode name is returned. On failure, the command returns the previous command mode name which will remain current and prints an error message unless error messages are suppressed.

EXAMPLES

The following example sets the current command mode to a mode called "mode_1"

```
prompt> set_current_command_mode -mode mode_1
```

The following example clears the current command mode without setting a new mode.

```
prompt> set_current_command_mode -mode ""
```

The following example sets the current command mode to the mode associated with the command "modal_command"

```
prompt> set_current_command_mode -command modal_command
```

set_current_spfm

Set the current spfm value on the design.

SYNTAX

```
status set_current_spfm
      \fcurrent_spfm
```

DESCRIPTION

This command set the current spfm on the design. The value of the current spfm is between 0.0 to 100.0.

EXAMPLES

The following example set the current_spfm to be 1.2

```
prompt> set_current_spfm 1.2
```

SEE ALSO

[create_safety_register_rule\(2\)](#)

set_data_check

Sets data-to-data checks using the specified values of setup and hold time.

SYNTAX

```
status set_data_check
  -from from_object
  | -rise_from from_object
  | -fall_from from_object
  -to to_object
  | -rise_to to_object
  | -fall_to to_object
  [-setup | -hold]
  [-clock clock_object]
  [check_value]
```

Data Types

<i>from_object</i>	collection of 1 object
<i>to_object</i>	collection of 1 object
<i>clock_object</i>	collection of 1 object
<i>check_value</i>	float

ARGUMENTS

-from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. Both rising and falling delays are checked.

You must specify one of **-from**, **-rise_from**, or **-fall_from**.

-rise_from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. This option applies only to rising delays at the related pin.

-fall_from *from_object*

Specifies a pin or port in the current design as the related pin of the data-to-data check to be set. This option applies only to falling delays at the related pin.

-to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. Both rising and falling delays are constrained.

You must specify one of **-to**, **-rise_to**, or **-fall_to**.

-rise_to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. This option applies only to rising delays at the constrained pin.

-fall_to *to_object*

Specifies a pin or port in the current design as the constrained pin of the data-to-data check to be set. This option applies only to falling delays at the constrained pin.

-setup

Indicates that the data check value is for setup analysis only.

-hold

Indicates that the data check value is for hold analysis only.

If neither **-setup** nor **-hold** is specified, the value applies to both setup and hold.

-clock *clock_object*

Specifies a single clock that launches the signal for the related pin of the data check. The "from" object must be clocked by the specified clock.

check_value

Specifies the value of the setup or hold time for the check.

DESCRIPTION

The **set_data_check** command specifies a data-to-data check to be performed between the "from" (related) object and the "to" (constrained) object using the specified setup or hold value.

The pulse relation between clocks of the related pin and the constrained pin is considered to be zero cycles. The normal sequential check uses one cycle. Data checks on clock pins are not supported.

The data check is treated as nonsequential; that is, the path goes through the related and constrained pins and is not broken at these pins. To report the constraint related to the data check, use the **report_timing** command with the **-to** option to specify the data-check-constrained pin.

To remove information set by the **set_data_check** command, use the **remove_data_check** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example creates a data-to-data check from pin and1/B to pin and1/A with respect to the rising edge of the signal at and1/B, using a setup and hold time of 0.4.

```
prompt> set_data_check -rise_from and1/B -to and1/A 0.4
```

The following example creates a data-to-data check from pin and1/B to pin and1/A with respect to the rising edge of the signal at and1/B, coming from the clock domain of CK1, and constraining only the falling edge of the signal at and1/A, using a setup time of 0.5 and no hold check.

```
prompt> set_data_check -rise_from and1/B -fall_to and1/A \
-setup -clock [get_clock CK1] 0.5
```

SEE ALSO

`remove_data_check(2)`
`report_timing(2)`
`update_timing(2)`
`timing_enable_multiple_clocks_per_reg(3)`

set_datapath_gating_options

Specifies whether an instance should be included or excluded for datapath gating processing.

SYNTAX

```
status set_datapath_gating_options
  [-include instance_or_design]
  [-exclude instance_or_design]
  [-reset]
  [-dp]
  [-dw]
  [-noungroup]
  [-retime instance_or_design]
  [-retime_clk_period period_value]
```

Data Types

<i>instance_or_design</i>	list
<i>period_value</i>	float

ARGUMENTS

-include *instance_or_design*

Specifies a list of instances in the current design to be included for datapath gating. Datapath gating is performed only on the datapath elements in these instances.

-exclude *instance_or_design*

Specifies a list of instances in the current design to be excluded from datapath gating.

-reset

Specifies that the entire current design is to be considered for datapath gating and disregard all previous **-include** and **-exclude** option settings. The **-reset** option is mutually exclusive with the **-include** and **-exclude** options.

-dp

Specifies that only datapath blocks be considered for datapath gating. All the DesignWare singleton instances, even if they are specified in the **-include** list, are disregarded.

-dw

Specifies that only DesignWare singleton instances be considered for datapath gating. All the extracted datapath blocks, even if they are specified in the **-include** list, are disregarded.

-noungroup

Specifies that the gated instances are not ungrouped in the compile flow.

-retime *instance_or_design*

Specifies a list of instances or designs to be gated after retiming. Datapath gating is not performed on these objects before retiming is done.

-retime_clk_period *period_value*

Specifies the clock period used by retiming on the objects listed by **-retime**.

DESCRIPTION

The **set_datapath_gating_options** command sets an attribute on the list of specified instances or designs. The attribute controls whether or not an instance or a design is processed during the datapath gating optimization phase.

Datapath gating is enabled for the entire design by default when you set the **power_enable_datapath_gating** variable to **true**. However, if you explicitly include specific instances or designs for datapath gating using the **-include** option, only the specified instances or designs are considered for datapath gating. The current design and all instances under the current design are ignored.

If the **-dp** option is specified, only extracted datapath designs are considered for gating. All DesignWare singletons are ignored even if they are in the **-include** list. Datapath designs containing operators that appear in the **-exclude** list are ignored.

If the **-dw** option is specified, only DesignWare singleton instances are considered for gating. All extracted datapath cells are ignored. DesignWare singleton instances that appear in the **-exclude** list are ignored. Any DesignWare instance that has been included for gating is extracted to a datapath block.

If the **-retime** option is used, the instances or designs specified are not gated before retiming is done. They are gated after retiming.

If the **-retime_clk_period** option is specified, the clock period is used to guide datapath gating with retiming. This is recommended for a two-pass retiming flow and must be specified in the initial compile prior to retiming.

EXAMPLES

In the following example, datapath gating is performed on the datapath elements in the U4 and U5 instances:

```
prompt> set_datapath_gating_options -include [get_cells {U4 U5}]
```

The following example specifies that the U3/U5 instance should be excluded from the datapath gating processing:

```
prompt> set_datapath_gating_options -exclude [get_cells U3/U5]
```

The following example shows the cumulative behavior of the command:

```
prompt> set_datapath_gating_options -include {a b}
1
```

```
prompt> set_datapath_gating_options -include {c d}
1
```

```
prompt> set_datapath_gating_options -exclude {a}
1
```

```
prompt> set_datapath_gating_options
Included objects { b c d }
Excluded objects { a }
1
```

The following example lists all instances included and excluded for datapath gating:

```
prompt> set_datapath_gating_options
Included objects { U4 U5 }
```

```
Excluded objects { U3/U5 }
1
```

The following example removes all previous datapath gating settings:

```
prompt> set_datapath_gating_options -reset
1
```

```
prompt> set_datapath_gating_options
No objects included or excluded for gating.
1
```

The following examples show the behavior of the **-dw** and **-dp** options. U1 and U2 are not auto-ungrouped.

In the first example, only datapath blocks inside U2 are tried for gating because DesignWare cells are excluded.

In the second example, only datapath blocks inside U1 are tried for gating and DesignWare cells are excluded from gating.

```
prompt> set_datapath_gating_options -exclude U2 -dw
1
```

```
prompt> set_datapath_gating_options -include U1 -dw
1
```

The following example shows how to use the **-retime** option in the two-pass retiming flow. SUB_DESIGN will be retimed in the second pass. The DesignWare blocks in SUB_DESIGN will be gated after the retiming is done.

```
#Turn on datapath gating
set power_enable_datapath_gating true

#specify the sub-designs to be retimed and its retiming clock period
set_datapath_gating_options -retime SUB_DESIGN -retime_clk_period 0.5
compile_ultra

#perform retiming on "SUB_DESIGN"
current_design SUB_DESIGN
optimize_registers
```

The following example shows how to use the **-retime** option in the single-pass global retiming flow. SUB_DESIGN is specified by **set_optimize_registers**, so there is no need to use **-retime** to specify it for incremental datapath gating.

```
#Turn on datapath gating
set power_enable_datapath_gating true

#specify the sub-designs to be retimed
set_optimize_registers true SUB_DESIGN

#top-down compile with global retiming and incremental DG
compile_ultra
```

The following example shows how to use the **-retime** option in the single-pass adaptive retiming flow. The top design is to be retimed.

```
#Turn on datapath gating
set power_enable_datapath_gating true

#top-down compile with adaptive retiming and incr. DG
compile_ultra -retime
```

SEE ALSO

[report_datapath_gating\(2\)](#)

[set_datapath_gating_options](#)

2328

power_enable_datapath_gating(3)

set_datapath_optimization_effort

Sets the **datapath_optimization_effort** attribute on specified designs, cells, or references, indicating the level of datapath optimization during **compile_ultra** command activity.

SYNTAX

```
status set_datapath_optimization_effort  
    object_list  
    effort_level
```

Data Types

```
object_list    list  
effort_level   string
```

ARGUMENTS

object_list

Specifies a list of cells, references, or designs for the attribute to be set.

effort_level

Specifies the effort level with which to set the **datapath_optimization_effort** attribute. Valid values are **high**, **medium**, **low**. The default value is **high**.

DESCRIPTION

This command sets the **datapath_optimization_effort** attribute on the specified objects so that different levels of datapath optimization can be applied when running the **compile_ultra** command. The **compile** command does not ungroup cells or designs with the **datapath_optimization_effort** attribute.

This attribute is removed with the **remove_attribute** or **reset_design** command.

EXAMPLES

In the following example, the **datapath_optimization_effort** attribute is set to **medium** on the *U1* cell:

```
prompt> set_datapath_optimization_effort U1 medium
```

If the **datapath_optimization_effort** attribute is specified on a reference object, cells using that reference are not ungrouped during **compile**. In this example, all instances of *ADDER* in the current design are not ungrouped:

```
prompt> set_datapath_optimization_effort [get_references ADDER] medium
```

This example shows that a design *ND17* with the attribute set to **high** is ungrouped whenever **compile** encounters the design:

```
prompt> set_datapath_optimization_effort [get_designs ND17] high
```

set_default_drive

Sets the default driving strength for specified objects, to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_drive
  [-min]
  [-max]
  [-rise]
  [-fall]
  [-none]
  [resistance]
  [cell_or_pin_list]
```

Data Types

<i>resistance</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-min

Indicates that *resistance* is to apply only to minimum resistance.

-max

Indicates that *resistance* is to apply only to maximum resistance. This is the default if no **-min** or **-max** options is specified, and also if both options are given.

-rise

Indicates that *resistance* is to apply only to rise resistance.

-fall

Indicates that *resistance* is to apply only to fall resistance.

-none

Indicates that previous information set by **set_default_drive** is to be removed.

resistance

Specifies the resistance value. Allowed resistance values are any non-negative floating-point numbers.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default driving strength is to be set.

DESCRIPTION

This command specifies a default drive value, to be used later by Top-Down Environmental Propagation (TDEP).

Note that you can specify both maximum and minimum values by issuing two separate commands, one with the **-max** option and one with the **-min** option. However, if you specify both or none of these two options, only the maximum value is set and the minimum value is removed. To always remove both values use the **-none** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets default drives and then removes them by using the **-none** option:

```
prompt> set_default_drive -rise 5 U_L1
Performing set_default_drive on cell 'U_L1'.
1

prompt> set_default_drive -rise -min 7 U_L1
Performing set_default_drive on cell 'U_L1'.
1

prompt> set_default_drive -fall 6 U_L1
Performing set_default_drive on cell 'U_L1'.
1

prompt> set_default_drive -fall -min 8 U_L1
Performing set_default_drive on cell 'U_L1'.
1

prompt> set_default_drive -none
1
```

SEE ALSO

set_default_driving_cell

Sets the default driving cell for specified objects, to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_driving_cell
  [-lib_cell lib_cell_name]
  [-library lib]
  [-rise]
  [-fall]
  [-pin pin_name]
  [-from_pin from_pin_name]
  [-dont_scale]
  [-no_design_rule]
  [-multiply_by factor]
  [-none]
cell_or_pin_list
```

Data Types

<i>lib_cell_name</i>	string
<i>lib</i>	string
<i>pin_name</i>	string
<i>from_pin_name</i>	string
<i>factor</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of a library cell to be used to drive the ports. Both the **driving_cell_rise** and the **driving_cell_fall** string attributes are set to *lib_cell_name* on the ports. If the cell has more than one output pin, you must also use the **-pin** option. To specify different cells for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *lib_cell_name* for each.

-library *lib*

Specifies the library in which to find *library_cell_name*. This is either a library name or a collection. You must use this option with the **-lib_cell** option. By default, the libraries in **link_library** are searched for the cell. To specify different libraries for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *lib* for each.

-rise

Indicates that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the rising case. You can use this option with **-fall** to specify both the rising and the falling case.

-fall

Indicates that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the falling case. You can use this option with -

rise to specify both the rising and the falling case.

-pin *pin_name*

Specifies the output pin on the driving cell that is to drive the ports. This pin name is needed if the driving cell has more than one output pin, or if the **-from_pin** option is used. You must use this option with the **-lib_cell** option. The default is to use the first timing arc found on the library cell. To specify different pins for the rising and falling cases, execute the command twice, once with **-rise** and once with **-fall**, using the appropriate *pin_name* for each.

-from_pin *from_pin_name*

Specifies the name of the input pin on the driving cell that is to be used when finding a timing arc. This input pin is needed if the driving cell has more than one input pin and the arcs from those pins have different drive characteristics. You must use this option with both the **-pin** and the **-lib_cell** options. The default is to use the first timing arc found on the library cell.

-dont_scale

Indicates that the timing analyzer is not to scale the drive capability of the ports according to the current operating conditions. By default, the port drive capability is scaled for operating conditions exactly as the driving cell itself would have been scaled. You must use this option with the **-lib_cell** option.

-no_design_rule

Indicates that the design rules associated with the driving cell are not to be applied to the driven port. However, timing-related attributes are still applied. By default, design rule attributes (**max_fanout**, **max_capacitance**, **max_transition**, **min_fanout**, **min_capacitance**, **min_transition**) are derived from the driving cell and its library and applied to the port.

-multiply_by *factor*

Specifies a factor by which to multiply the delay characteristics of the ports. You must use this option with the **-lib_cell** option. The default value is 1.0. Both the load delay and the transition times of the port are affected.

-none

Deletes previous **set_default_driving_cell** information.

cell_or_pin_list

Specifies a list of names of cells or pins to which the information applies.

DESCRIPTION

This command sets a default driving cell for specified cells or pins. This driving cell will later be used by Top-Down Environmental Propagation (TDEP).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the default driving cell and then removes it using the **-none** option:

```
prompt> set_default_driving_cell -lib_cell ND2 -library Isi_10k \
    -pin Z -from_pin A -rise -dont_scale -mult 2.3;
1

prompt> set_default_driving_cell -lib_cell IVP -library Isi_10k \
```

```
-pin Y -from_pin B -fall;  
1  
  
prompt> set_default_driving_cell -none;  
1
```

[set_default_fanout_load\(2\)](#)
[set_default_load\(2\)](#)

set_default_fanout_load

Sets the default fanout load to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_fanout_load
  [-none]
  [fanout_load_value]
  [cell_or_pin_list]
```

Data Types

fanout_load_value float
cell_or_pin_list list

ARGUMENTS

-none

Indicates that previous information set by **set_default_fanout_load** is to be removed.

fanout_load_value

Specifies the fanout load value. Allowed values are any non-negative floating-point numbers.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default fanout load is to be set.

DESCRIPTION

This command specifies a default fanout load value, to be used later by Top-Down Environmental Propagation (TDEP).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a default load and then removes it by using the **-none** option:

```
prompt> set_default_fanout_load 2 U_L1/U10
Performing set_default_fanout_load on cell 'U_L1/U10'.
1

prompt> set_default_fanout_load -none
1
```

SEE ALSO

`set_default_load(2)`

set_default_input_delay

Sets the value of the input delay as a percentage of the clock period to be assigned during environment propagation.

SYNTAX

```
status set_default_input_delay
  [-none]
  percent_delay
  [cell_or_pin_list]
```

Data Types

<i>percent_delay</i>	float
<i>cell_or_pin_list</i>	collection

ARGUMENTS

-none

Resets any existing default delays.

percent_delay

Specifies the delay as a percentage of the clock period.

cell_or_pin_list

Specifies the list of cells or pins on which the input delay is to be set.

DESCRIPTION

This command sets the value of the input delay as a percentage of the clock period to be assigned during environment propagation. By default, a value of 30 is globally used. This value can be overridden on a global basis, on a cell-by-cell basis, or on a pin-by-pin basis. If no arguments are specified, it sets the global default to the new value. The environment propagation first looks for any values set on the pin. If no values exist, it looks at the cell of the pin, and if no values exist, the global default is used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resets existing default delays:

```
prompt> set_default_input_delay -none
```

SEE ALSO

[set_default_output_delay\(2\)](#)

set_default_load

Sets the default load to be used by Top-Down Environmental Propagation (TDEP).

SYNTAX

```
status set_default_load
  [-min]
  [-max]
  [-pin_load]
  [-wire_load]
  [-none]
  [value]
  [cell_or_pin_list]
```

Data Types

<i>value</i>	float
<i>cell_or_pin_list</i>	list

ARGUMENTS

-min

Indicates that *value* is to apply only to minimum capacitance.

-max

Indicates that *value* is to apply only to maximum capacitance. This is the default if no **-min** or **-max** option is specified, and also if both options are given.

-pin_load

Indicates that *value* is to apply only to pin capacitance.

-wire_load

Indicates that *value* is to apply only to wire capacitance.

-none

Indicates that previous information set by **set_default_load** is to be removed.

value

Specifies the capacitance value. Allowed values are any non-negative floating-point numbers.

cell_or_pin_list

Specifies a list of names of cells or pins for which the default load is to be set.

DESCRIPTION

This command specifies a default load value, to be used later by Top-Down Environmental Propagation (TDEP).

Note that you can specify both maximum and minimum values by issuing two separate commands, one with the **-max** and one with the **-min** option. However, if you specify both or none of these two options, only the maximum value is set and the minimum value is removed. To always remove both values, use the **-none** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a default load and then removes it by using the **-none** option:

```
prompt> set_default_load -wire -min 4  
1  
prompt> set_default_load -none  
1
```

SEE ALSO

derive_constraints(2)
set_default_drive(2)
set_default_driving_cell(2)
set_default_fanout_load(2)

set_default_output_delay

Sets the output delay as a percentage of the clock period to be assigned during environment propagation.

SYNTAX

```
status set_default_output_delay
  [-none]
  percent_delay
  [cell_or_pin_list]
```

Data Types

<i>percent_delay</i>	float
<i>cell_or_pin_list</i>	collection

ARGUMENTS

-none

Resets any existing default delays.

percent_delay

Specifies the delay as the percentage of the clock period.

cell_or_pin_list

Specifies the list of cells or pins on which the output delay is to be set.

DESCRIPTION

This command sets the value of the output delay as a percentage of the clock period to be used during environment propagation. By default, a value of 30 is used globally. This value can be overridden on a global basis, on a cell-by-cell basis, or on a pin-by-pin basis. If no arguments are specified, the command sets the global default to the new value. The environment propagation first looks for any values set on the pin. If no values exist, it looks at the cell of the pin, and if no values exist, the global default is used.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example resets any existing default delays:

```
prompt> set_default_output_delay -none
```

SEE ALSO

[set_default_input_delay\(2\)](#)

set_delay_estimation_options

Sets the parameters that influence preroute delay estimation. This command is supported only in topographical mode.

SYNTAX

```
status set_delay_estimation_options
[-min_unit_horizontal_capacitance unit_capacitance]
[-min_unit_vertical_capacitance unit_capacitance]
[-min_unit_horizontal_resistance unit_resistance]

[-default]
```

Data Types

<i>unit_capacitance</i>	float
<i>unit_resistance</i>	float
<i>scaling_factor</i>	float
<i>via_resistance</i>	float
<i>density</i>	float

ARGUMENTS

-min_unit_horizontal_capacitance *unit_capacitance*

Specifies the minimum horizontal capacitance per unit length for delay calculation.

-min_unit_vertical_capacitance *unit_capacitance*

Specifies the minimum vertical capacitance per unit length for delay calculation.

-min_unit_horizontal_resistance *unit_resistance*

Specifies the minimum horizontal resistance per unit length for delay calculation.

-min_unit_vertical_resistance *unit_resistance*

Specifies the minimum vertical resistance per unit length for delay calculation.

-max_unit_horizontal_capacitance *unit_capacitance*

Specifies the maximum horizontal capacitance per unit length for delay calculation.

-max_unit_vertical_capacitance *unit_capacitance*

Specifies the maximum vertical capacitance per unit length for delay calculation.

-max_unit_horizontal_resistance *unit_resistance*

Specifies the maximum horizontal resistance per unit length for delay calculation.

-max_unit_vertical_resistance *unit_resistance*

Specifies the maximum vertical resistance per unit length for delay calculation.

-min_unit_horizontal_capacitance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the minimum horizontal capacitance per unit length before use in delay calculation.

-min_unit_vertical_capacitance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the minimum vertical capacitance per unit length before use in delay calculation.

-min_unit_horizontal_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the minimum horizontal resistance per unit length before use in delay calculation.

-min_unit_vertical_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the minimum vertical resistance per unit length before use in delay calculation.

-max_unit_horizontal_capacitance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the maximum horizontal capacitance per unit length before use in delay calculation.

-max_unit_vertical_capacitance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the maximum vertical capacitance per unit length before use in delay calculation.

-max_unit_horizontal_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the maximum horizontal resistance per unit length before use in delay calculation.

-max_unit_vertical_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the maximum vertical resistance per unit length before use in delay calculation.

-min_via_resistance *via_resistance*

Specifies the minimum via resistance for delay calculation.

-max_via_resistance *via_resistance*

Specifies the maximum via resistance for delay calculation.

-min_via_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the minimum via resistance before use in delay calculation.

-max_via_resistance_scaling_factor *scaling_factor*

Specifies the factor that will be multiplied by the maximum via resistance before use in delay calculation.

-density_outside_block *density*

Specifies the density based thickness variations at the edge of a block. It defines the density outside a block. The density affects the silicon thickness value. This is called thickness variation (due to density). The thickness change is a function of density and variation tables (defined in TLUPlus). It applies to all layers on which IC Compiler performs density calculation. It applies to all scenarios in multicorner-multimode flow. IC Compiler issues an error if the value specified is less than 0.0 or greater than 1.0. When the value is specified as 0.0 or 1.0, the error is not issued. The default value is 0.0.

-default

Resets all per-unit resistance and capacitance scaling factors and all resistance and capacitance scaling factors to default values.

DESCRIPTION

The **set_delay_estimation_options** command specifies the parameters that influence preroute RC and delay estimation. Typical values for the scaling factors are between 0.5 and 5.0. The unit distance is 1 micron.

Specifying the **-default** option restores all per-unit resistances and capacitances to the library-derived values and all resistance and capacitance scaling factors to 1.0.

The design must be read before applying the delay estimation options using this command.

The scaling factors are scenario-aware. When you create a scenario or set a current scenario, you can use this command to create scaling factors for the current scenario.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example runs the **set_delay_estimation_options** command:

```
prompt> set_delay_estimation_options \
    -max_unit_vertical_resistance 0.00004 \
    -min_unit_horizontal_capacitance_scaling_factor 2.0 \
    -min_via_resistance 0.00001 \
    -min_via_resistance_scaling_factor 1.5 \
    -max_via_resistance 0.00002 \
    -max_via_resistance_scaling_factor 1.5
```

SEE ALSO

[report_delay_estimation_options\(2\)](#)

set_design_attributes

Sets the specified UPF attribute and value on the listed cells.

SYNTAX

```
string set_design_attributes
  [-elements list]
  [-models list]
  -attribute name_value_pair
```

Data Types

<i>list</i>	list
<i>name_value_pair</i>	string

ARGUMENTS

-elements *list*

Specifies the collection of cells on which the attribute is set. Wildcards are accepted in cell names. When the attribute is an user defined attribute, a collection of nets and/or supply nets can be specified too. If a logic net gets optimized away during implementation, it will be dropped from the list of the command in output UPF. As tool doesn't try to preserve these nets, attributes applied on them will be lost if they get optimized.

-models *list*

Specifies the collection of models on which the attribute is set. This option is only supported for certain attributes.

-attribute *name_value_pair*

Specifies the name and value of the attribute to be set. This option must be specified exactly one time per command. To specify multiple attributes on the same cell, multiple commands must be used.

This option can be specified multiple times.

DESCRIPTION

This command sets a UPF attribute and its value on a list of cells.

The supported attribute names and their associated values are as follows:

- **correlated_supply_group**

This attribute can be set at the top scope of the design or on any cell instance of the design. The value must be one or more groups of supply net names bracketed by curly braces {}. The value can also be the wildcard character (*) alone, which means all supply nets in the design.

This attribute specifies supply nets whose port state triplets and power state triplets should be considered correlated voltages. The tool considers only the minimum with minimum voltages, only nominal with nominal voltages, and only maximum with maximum voltages, without mixing between minimum, nominal, and maximum. This attribute accepts dot (.) or any cell instance as the value for the **-elements** option.

- **derived_external**

This attribute can be set on supply sets in the design. The value must be Boolean (true or false).

This attribute specifies the supply set to be used as a reference-only supply set. The supply set should not already be used for a power connection. This attribute is used with ports with the **iso_source** and **iso_sink** attributes.

- **reference_only**

This attribute can be set on supply sets or supply nets in the design. This attribute specifies the supply to be used as a reference_only supply. The supply should not already be used for power connection (e.g., as a domain primary, isolation supply, etc). This attribute is created by the tool during **characterize**.

- **derived_iso_strategy**

This attribute can be set on cell instances of the design. The value must be the name of an isolation strategy.

This attribute specifies the isolation strategy name to ensure a unique name for the derived strategies in the power domain. It is used in a hierarchical flow to support location fanout.

- **enable_state_propagation_in_add_power_state**

This attribute can be set at the top scope of the design and also on any hierarchical cell. The value must be **true** or **false**. The default value of this attribute is **false**.

When this attribute is set to **true**, the tool propagates the name of the supply set state (specified in the **add_power_state** command) to the functional net. After the state name is propagated to the functional net, you can use the net and the supply set state in the **create_pst** and **add_pst_state** commands. When the value is **true**, usage of the "&&" expression is not allowed in the **supply_expr** option of the **add_power_state** command.

When this attribute is set to **false**, the supply set state name is not propagated to the functional nets. The state name specified in the **add_power_state** command is a property of the supply set, so the name is not propagated to the functional nets. To create power state tables, you must create groups using the **create_power_state_group** command and refer to the supply set state names in the group. You can no longer refer to the state names in the **add_pst_state** command. When the value is **false**, usage of the "&&" expression is allowed in the **supply_expr** option of the **add_power_state** command.

- **external_supply_map**

This attribute can be set on cell instances of the design and the top design. The value must be the name of a supply set that is already created.

This attribute specifies the mapping between the reference-only supply set and the actual supply set. When this attribute is specified on the design, its value will be the reference-only supply set in the design. When this attribute is specified on the cell instance of the design, its value will be the actual supply set for which the reference-only supply set was created inside the design. This attribute is used with ports with the **iso_source** and **iso_sink** attributes.

- **lower_domain_boundary**

This attribute can be set at the top scope of the design and also on any hierarchical cell. The value must be **true** or **false**.

When this attribute is set to **true**, the tool considers the domain boundary between a domain and another domain that is contained in a lower-level block as the scope of the first (higher hierarchical level) domain.

- **macro_as_domain_boundary**

This attribute can be set at the top scope of the design, on any hierarchical cell, or on any macro library cell. It can only be used together with the **lower_domain_boundary** attribute. The value must be **true** or **false**.

When this attribute is set, hard macro instances which lie within the bounds of a power domain are considered to belong to a separate, anonymous power domain. The tool will treat the boundary of these macro instances as a lower domain boundary.

- **UPF_is_hard_macro**

This attribute can be set on library cells having the **is_macro_cell** Liberty attribute. The value must be **true** or **false**.

If a library cell has the **is_macro_cell** Liberty attribute, then it is considered as a hard macro. When this design attribute is set to **false** on such a library cell, the tool does not consider the library cell as a hard macro.

This attribute must be specified together with -models option.

- **merge_domain**

This attribute can be set on cell instances of the design. The value must be **true** or **false**.

If set to **true**, this attribute implies that the elements that belong to the same power domain can be merged. The cells specified in the **-elements** option should not be the root cell of a power domain.

- **SNPS_default_power_upf2sv_vct** and **SNPS_default_ground_upf2sv_vct**

These attributes specify the default for the UPF-to-SystemVerilog value conversion table. These attributes can be used with the **-models** option. The value must be set to one of the following: SV_TIED_HI, SV_TIED_LO, UPF_GNDZERO2SV_LOGIC, UPF2SV_LOGIC

- **SNPS_default_power_upf2vh_vct** and **SNPS_default_ground_upf2vh_vct**

These attributes specify the default for the UPF-to-VHDL value conversion table. These attributes can be used with the **-models** option. The value must be set to one of the following: VHDL_TIED_HI, VHDL_TIED_LO, UPF2VHDL_SL, UPF_GNDZERO2VHDL_SL

- **SNPS_default_power_sv2upf_vct** and **SNPS_default_ground_sv2upf_vct**

These attributes specify the default for the SystemVerilog-to-UPF value conversion table. These attributes can be used with the **-models** option. The value must be set to one of the following: SV_LOGIC2UPF, SV_LOGIC2UPF_GNDZERO

- **suppress_iss**

This attribute can be set at the top scope of the design. The value must be the name of one or more power domains. The value can also be the wildcard character (*) which means all power domains in the design. It specifies the domain names where supply set handles are not to be created. This attribute does not accept the **-elements** option.

- **terminal_boundary**

This attribute can be set at the top scope of the design and also on any cell in the list of **-elements** of the command **create_power_domain**. Typically, it is set on a block design, black box, or ETM cell. The value must be **true** or **false**.

When this attribute is set to **true**, the tool considers the boundary of the cell as a terminal and checks, in the **check_mv_design** command, that the driver/load pin's related supply is consistent with the driver/receiver supply defined on the boundary pin (either by **set_port_attributes -driver_supply -receiver_supply** or by **set_related_supply_net**).

- **upf_chip_design** (used on the top-level design)

This attribute can be set on the top-level design. The value must be **true** or **false**. It is used in the isolation strategy definition to support location fanout.

- **hetero_fanout_isolation**

The value must be **true** or **false**. When this attribute is **true**, the isolation strategy of location self or parent can insert the isolation cells at the sub-branches, when those branches have the proper sink supply as the isolation strategy specifies.

- **upf_reconcile_boundary**

The value of this attribute can be either **reconcile_voltages** or **skip**. This attribute is supported only for models and can be specified using option **-model**. This attribute is used while deriving the system power state table.

When this attribute is set to **reconcile_voltages** on a model, the instances of that model are enabled for voltage reconciliation.

For supplies defined in such instances, voltage equivalence checks are performed after range expanding their state voltages.

The range expansion limits are defined using **set_variation** command. In case, **set_variation** command is not specified, reconciliation does not happen and the attribute setting does not play any role in system PST derivation.

When this attribute is set to **skip** on a model, the power state tables defined at or below the instance of that model are skipped and are not included in the system PST.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **external_supply_map** attribute on the root cell of power domain PD2.

```
prompt> set_design_attributes \
```

```
-elements [get_cells -of_objects [get_power_domains PD2]] \
-attribute external_supply_map {SS2}
1
```

The following example sets the **derived_external** attribute on supply set SS1.

```
prompt> set_design_attributes \
-elements {SS1} \
-attribute derived_external true
1
```

The following example sets the **derived_iso_strategy** attribute on mid11 with power domain MID11.

```
prompt> set_design_attributes \
-elements {mid11} \
-attribute derived_iso_strategy iso1
1
prompt> set_isolation iso1 \
-domain MID11 -source sset1 \
-elements {mid11/*} \
-isolation_supply_set sset3
1
prompt> set_isolation_control iso1 \
-domain MID11 \
-isolation_signal in1 \
-location fanout
1
```

The following example sets the **merge_domain** attribute to **true** on cell mid1.

```
prompt> set_design_attributes \
-elements {mid1} \
-attribute merge_domain true
1
```

The following example sets the **suppress_iss** attribute to suppress implicit supply set for domain inner/PD_INNER specified for design 'top'.

```
prompt> set_design_attributes \
-attribute suppress_iss "inner/PD_INNER"
1
```

The following example sets the **upf_chip_design** attribute on a top-level design.

```
prompt> set_design_attributes -elements {} \
-attribute upf_chip_design true
1
```

The following example sets the **SNPS_default_power_sv2upf_vct** attribute SV_LOGIC2UPF on model bot and libcell GTECH_NOT.

```
prompt> set_design_attributes \
-models {bot GTECH_NOT} \
-attribute SNPS_default_power_sv2upf_vct SV_LOGIC2UPF
1
```

The following example sets the **correlated_supply_group** attribute to specify correlated voltage range comparison for port state triplets.

If a driver is powered by VDD1 and its load is powered by VDD2, a level shifter is not required because VDD1 and VDD2 are in the same correlated supply group and therefore treated as correlated voltage range during voltage comparison.

However, if the load is powered by VDD3, a level shifter is required because VDD1 and VDD3 are not in the same correlated supply group and therefore treated as independent voltage range during voltage comparison.

```
prompt> add_port_state VDD1 -state {HV 0.8 1.0 1.2}
1
```

```

prompt> add_port_state VDD2 -state {HV 0.8 1.0 1.2}
1
prompt> add_port_state VDD3 -state {HV 0.8 1.0 1.2}
1
prompt> add_port_state VDD4 -state {HV 0.8 1.0 1.2}
1
prompt> set_design_attributes \
    -elements {} \
    -attribute correlated_supply_group "{VDD1 VDD2} {VDD3 VDD4}"
1

```

The following example sets the **lower_domain_boundary** attribute to **true** on the top scope and cell mid1.

```

prompt> set_scope /
1
prompt> set_design_attributes -elements {} -attribute lower_domain_boundary true
Information: Resolving '!' to the current scope 'top'.
1
prompt> set_design_attributes -elements {mid1} -attribute lower_domain_boundary true
1

```

The following example sets the **enable_state_propagation_in_add_power_state** attribute to **false** on the top scope and to **true** on cell mid1.

```

prompt> set_scope
1
prompt> set_design_attributes \
    -elements {} \
    -attribute enable_state_propagation_in_add_power_state false
1
prompt> set_design_attributes \
    -elements {mid1} \
    -attribute enable_state_propagation_in_add_power_state true
1

```

The following example sets the **terminal_boundary** attribute to **true** on the top scope and cell mid1.

```

prompt> set_scope
1
prompt> set_design_attributes \
    -elements {} \
    -attribute terminal_boundary true
1
prompt> set_design_attributes \
    -elements {mid1} \
    -attribute terminal_boundary true
1

```

The following example sets the hard-macro attribute on model "model1" to **TRUE**.

```

prompt> set_design_attributes -models {model1} -is_hard_macro TRUE
1

```

The following example sets the upf_reconcile_boundary attribute

```

prompt> set_design_attributes -models {model1} -attribute \
    upf_reconcile_boundary skip
1
prompt> set_design_attributes -models {model2} -attribute \
    upf_reconcile_boundary reconcile_voltages
1

```

The following example sets the reference_only attribute on supply set "SS1".

```

prompt> set_design_attributes -elements {} -attribute reference_only {SS1}
1

```

The following example sets an user defined attribute attribute on a net and a supply net.

```
prompt> set_design_attributes -elements { net1 VDD1 } -attribute net_attribute my_value  
1
```

[set_variation\(2\)](#)

set_design_license

Adds license information to the current design and can be used to require a license before a design can be read in.

SYNTAX

```
status set_design_license
  [-dont_show references]
  [-quiet]
  [-limited limited_keys]
  regular_keys
```

Data Types

<i>references</i>	list
<i>limited_keys</i>	list
<i>regular_keys</i>	list

ARGUMENTS

-dont_show *references*

Specifies a list of references that will not be displayed.

-quiet

Specifies that no informational messages will be displayed.

-limited *limited_keys*

Specifies a list of licenses that provide limited access to the design.

regular_keys

Specifies a list of licenses that provide regular access to the design.

DESCRIPTION

This command adds license information to a design. For more information on licensing designs, see the section on licensing in the DesignWare manual.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In this example, the full license *ADDERS* and the limited license *EVAL* is added to the current design. In addition, **-dont_show** indicates that the design will not become visible until all existing references are changed.

```
prompt> set_design_license ADDERS \
           -limited EVAL -dont_show "*"
```

SEE ALSO

[list_licenses\(2\)](#)

set_design_top

Specifies the top-level design instance.

SYNTAX

```
status set_design_top
      instance_name
```

Data Types

instance_name string

ARGUMENTS

instance_name

Specifies the top-level instance in the design.

DESCRIPTION

The **set_design_top** command specifies the top-level design instance. This information is used only by simulation and verification tools.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLE

The following example shows how to use the **set_design_top** command:

```
prompt> set_design_top ALU07
```

set_device_constraint

For DCNXT, limits the usage of narrow and/or wide device library cells to a specified percentage of all cells.

SYNTAX

```
status set_device_constraint
  [-narrow_percentage percent_value]
  [-wide_percentage percent_value]
  [-cost cell_count]
  [-include_blackboxes]
  [-reset]
```

Data Types

percent_value float

ARGUMENTS

-narrow_percentage *percent_value*

Specifies the maximum allowable percentage of narrow device cells for the current design. The *percent_value* argument is a floating-point number between 0 and 100.

-wide_percentage *percent_value*

Specifies the maximum allowable percentage of wide device cells for the current design. The *percent_value* argument is a floating-point number between 0 and 100.

-cost cell_count

Only cell_count is supported.

-include_blackboxes

Includes black box cells in the percentage calculation. By default, black box cells are excluded from the calculation.

-reset

Removes the device group constraints from the current design.

DESCRIPTION

The **set_device_constraint** command identifies the narrow or wide device_group upper limit on the percentage of cells that are allowed to come from those groups. Limiting the usage of these cells should be done based on library vendor recommendations.

The **-narrow_percentage** or **-wide_percentage** option specifies the percentage usage constraint.

By default, black box cells are excluded from the percentage calculation. To include black box cells in the calculation, use the **-include_blackboxes** option.

The device group of a cell is defined by the **device_group** library cell attribute.

set_device_group_type should be used to assign device_group group labels to wide or narrow type.

To report the number and percentage of cells used in the design from each device group, use the **report_device_group** command.

When you use the **set_device_constraint** command without any options, it reports the device constraint(s) previously set on the design.

To remove the current device constraint(s) from the design, use the **-reset** option.

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a device constraint of a maximum of 20 percent narrow device group cells. The calculation is based on cell count and includes black box cells.

```
prompt> set_device_constraint -narrow_percentage 20 \
-include_blackboxes
```

The following example removes the device constraint(s) set on the current design.

```
prompt> set_device_constraint -reset
```

SEE ALSO

`compile_ultra(2)`
`set_device_group_type(2)`
`report_device_group(2)`

set_device_group_type

For DCNXT, assign device_group labels to narrow or wide device group type.

SYNTAX

```
status set_device_group_type
  [-type narrow | wide]
  [device_groups]
  [-reset]
```

Data Types

device_groups string list

ARGUMENTS

-type narrow | wide

Specifies the which device_group type the provided device_groups belong to.

-reset

Removes the device group type information from the current design.

DESCRIPTION

The **set_device_group_type** command identifies the narrow or wide library cell groups. Limiting the usage of these cells should be done based on library vendor recommendations.

The device group of a cell is defined by the **device_group** library cell attribute.

To report the number and percentage of cells used in the design from each device group, use the **report_device_group** command.

When you use the **set_device_group_type** command without any options, it reports the device group type(s) previously set on the design.

To remove the current device group type information from the design, use the **-reset** option.

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the slow device_group to the narrow device_group type.

```
prompt> set_device_group_type -type narrow {slow}
```

The following example removes the group type constraint(s) set on the current design.

```
prompt> set_device_group_type -reset
```

SEE ALSO

`compile_ultra(2)`
`set_device_constraint(2)`
`report_device_group(2)`

set_dft_clock_controller

Specifies the parameters for DFT-inserted clock controllers.

SYNTAX

```
status set_dft_clock_controller
  [-cell_name controller_cell_name]
  -design_name controller_design_name
  [-ateclocks port_list]
  [-pllclocks pin_list]
  [-1x_clocks pin_list]
  [-2x_clocks pin_list]
  [-4x_clocks pin_list]
  [-chain_count number_chains]
  [-cycles_per_clock number_cycles]
  [-test_mode_port port_name]
```

Data Types

<i>controller_cell_name</i>	string
<i>controller_design_name</i>	string
<i>port_list</i>	list
<i>pin_list</i>	list
<i>number_chains</i>	integer
<i>number_cycles</i>	integer
<i>port_name</i>	string

ARGUMENTS

-cell_name *controller_cell_name*

Specifies the instance name of the clock controller that will be inserted by the **insert_dft** command; for example, *pll_controller1*.

-design_name *controller_design_name*

Specifies the design name to insert a clock controller from the DFT library. The only allowed value is **smps_clk_mux**. Custom-designed clock controllers are not supported by this command. Note that the command is accepted without specifying **-design_name**, but it returns incorrect data to the DFT architect.

-ateclocks *port_list*

Specifies one slow clock used for scan shifting that you want to connect to the DFT clock controller. If the clock signal is a reference clock for the on-chip clock generator, the signal must be previously defined by using the **set_dft_signal** with the **-type Oscillator** option. Note that you can only specify one clock because custom-designed clock controllers are not supported by this command.

-pllclocks *pin_list*

For asynchronous OCC controllers, specifies the ordered list of PLL output clock pins to control. The pins must be previously defined as oscillator signals using the **set_dft_signal -type Oscillator** command.

This option is mutually exclusive with the **-1x_clocks**, **-2x_clocks**, and **-4x_clocks** options.

-1x_clocks pin_list

For synchronous OCC controllers, specifies the ordered list of PLL output clock pins to control that run at the slowest frequency. When inserting synchronous OCC controllers, this option is required; the first clock in the list is used as the master synchronization clock. The pins must be previously defined as oscillator signals using the **set_dft_signal -type Oscillator** command.

This option is mutually exclusive with the **-pllclocks** option.

-2x_clocks pin_list

For synchronous OCC controllers, specifies the ordered list of PLL output clock pins to control that run at two times the slowest frequency. The pins must be previously defined as oscillator signals using the **set_dft_signal -type Oscillator** command.

This option is mutually exclusive with the **-pllclocks** option.

-4x_clocks pin_list

For synchronous OCC controllers, specifies the ordered list of PLL output clock pins to control that run at the slowest frequency. The pins must be previously defined as oscillator signals using the **set_dft_signal -type Oscillator** command.

This option is mutually exclusive with the **-pllclocks** option.

-chain_count number_chains

Specifies the number of clock chains to insert per clock controller. The default is 1.

-cycles_per_clock number_cycles

Specifies the maximum number of capture cycles per clock. If not specified, the default is 1. Capture cycles are cycles where capture clocks are pulsed.

-test_mode_port port_name

Specifies the test mode port used to enable the clock controller. Use this option if you have multiple test mode ports and you want to use a specific port to enable the clock controller. The specified port must be defined as a TestMode signal using the **set_dft_signal** command.

DESCRIPTION

The **set_dft_clock_controller** command specifies the clock controller characteristics for the **insert_dft** command to insert and connect clock controllers and clock chains into the design.

A clock controller is a design that controls which clock signals will propagate into scan chains during scan shifting and capture. The clock controller selects between fast clocks coming from an on-chip clock generator (usually a phase-locked loop) and slow clocks coming from external ports.

A clock chain is a scan chain segment of one or more scannable control registers. This chain allows for a per-pattern clock selection mechanism by ATPG. Clock selection values are loaded into the clock chain as part of the regular scan load process.

The on-chip clock generator should already be connected, either directly or indirectly, to the intended sequential elements in the clock generator clock domain.

For asynchronous OCC controllers, specify the PLL clocks with the **-pllclocks** option. For synchronous OCC controllers, specify the clocks with the **-1x_clocks**, **-2x_clocks**, and **-4x_clocks** options. You cannot mix the asynchronous and synchronous options in the same **set_dft_clock_controller** command, but you can issue multiple **set_dft_clock_controller** commands for separate asynchronous and synchronous OCC controllers.

When clock controller insertion has been configured with the **set_dft_clock_controller** command, the **insert_dft** command performs the following steps:

1. Instantiates a clock controller design and clock chain design.

2. Inserts the clock controller in the clock path between the on-chip clock generator and the sequential cells that it drives.
3. Connects the clock chain to the clock controller.
4. Proceeds with the remainder of DFT insertion.

When a clock controller is inserted in the design, you are responsible for validating that this functionality works in the context of your design.

In high X-tolerance DFTMAX compression flows, the presence of clock chains affects the scan-in and scan-out pin requirements. For more information, see the TEST-1722 man page.

EXAMPLES

The following command set inserts a clock controller and clock chain into the design:

```
prompt> set_dft_configuration -clock_controller enable
prompt> set_dft_signal -view existing_dft -type ScanClock \
      -port slow_clock -timing {45 55}
prompt> set_dft_signal -view existing_dft -type Oscillator \
      -port slow_clock
prompt> set_dft_signal -view existing_dft -type Oscillator \
      -hookup_pin PLL/pll_fast_clock
prompt> set_dft_clock_controller -cell_name snps_pll_controller \
      -design_name snps_clk_mux -cycles_per_clock 2 -chain_count 1 \
      -pllclocks {PLL/pll_fast_clock} -ateclocks {slow_clock}
prompt> insert_dft
```

SEE ALSO

set_dft_clock_gating_configuration

Specifies the clock-gating configuration for a design.

SYNTAX

```
status set_dft_clock_gating_configuration
  [-exclude_elements object_list]
  [-dont_connect_cgss_of cell_list]
```

Data Types

object_list cells, lib_cells, or clocks
cell_list cells

ARGUMENTS

-exclude_elements *object_list*

Specifies a list of clock-gating cells, clock-gating observation cells, hierarchical cell instances containing these cells, lib_cells of these cells, or clocks of these cells that are to be excluded when the test control pins of clock-gating cells are connected during **insert_dft**. These excluded clock-gating cells are not checked for unconnected test pins during **dft_drc**, and therefore they do not cause TEST-130 violations. Downstream registers driven by these excluded clock-gating cells will have DRC violations if their clocks are uncontrollable.

If a hierarchical cell instance is specified, all clock-gating cells and clock-gating observation cells in that instance are included in the specification.

If a clock-gating library cell is specified, all instances of that cell are included in the specification.

If a clock is specified, clock-gating cells in the respective clock domain are included in the specification. The clock must be defined with the **create_clock** command.

Cells with CTL models or inside CTL models are ignored and excluded from the specification.

This option accepts wild cards and collection inputs. This option is cumulative across multiple commands.

-dont_connect_cgss_of *cell_list*

Specifies a list of registers or hierarchical cell instances containing registers, whose upstream clock-gating cells are to be excluded from test pin connections during **insert_dft**. An upstream clock-gating cell is only excluded from test pin connections if it does not drive any valid scan cells.

If a hierarchical cell instance name is specified, the specification applies to all registers in that instance.

Cells with CTL models or inside CTL models are ignored and excluded from the specification.

If an upstream clock-gating cell of a specified register also drives a CTL modeled cell then its test pin will be connected.

If DFT Compiler cannot find the upstream clock-gating cells for flip-flops during the preview_dft or insert_dft commands, it issues TEST-154 informational messages for those flip-flops.

This option also accepts wild cards and collection inputs. This option is cumulative across multiple commands.

DESCRIPTION

This command specifies the clock-gating configuration for DFT flows. It affects how clock-gating logic is handled by the **dft_drc** and **insert_dft** commands.

The **-exclude_elements** and **-dont_connect_cgsof** options both provide methods for excluding the test pins of clock-gating cells from being connected to global test signals during DFT insertion.

Exclusion works by leaving the default deasserted constant value connected to the test pins of excluded clock-gating cells. If an exclusion applies to a clock-gating cell with an existing test pin connection other than the default deasserted constant value, that existing test pin connection remains in place.

The precedence of clock-gating cell test pin connection control methods is as follows, in order of highest to lowest priority:

- **set_dft_connect** (highest priority)
- **set_dft_clock_gating_configuration -exclude_elements**
- **set_dft_clock_gating_configuration -dont_connect_cgsof** (lowest priority)

When the **-dont_connect_cgsof** option is used, upstream clock-gating cells of the specified registers are excluded from clock-gating cell test pin connection only if none of the downstream registers are valid scan cells. When the **-exclude_elements** option is used, the test pin connections of the specified clock-gating cells are suppressed even if there are downstream valid scan cells.

The **-exclude_elements** and **-dont_connect_cgsof** exclusion options will function with, but are not intended for, registers driven by user-defined clock-gating cells defined via **set_dft_clock_gating_pin** command. If you do not want to connect the test pins of these clock-gating cells, then they should not be defined. Registers driven by user-defined clock gating cells are traced through simple buffer and inverter logic only.

EXAMPLES

The following example excludes a particular clock-gating cell from having its test pin connected:

```
prompt> set_dft_clock_gating_configuration \
           -exclude_elements I_ADD/clk_gate_add_out_reg
```

The following example excludes clock-gating cells and clock-gating observation logic inside a hierarchical cell instance:

```
prompt> set_dft_clock_gating_configuration -exclude_elements U_block
```

The following example excludes all instances of a particular library cell of the 'slow' library:

```
prompt> set_dft_clock_gating_configuration \
           -exclude_elements [get_lib_cell slow/ABCD123XYZ]
```

The following example excludes a particular clock-gating observation leaf cell:

```
prompt> set_dft_clock_gating_configuration -exclude_elements Uclk_gate_obs
```

The following example excludes clock-gating cells in a particular clock domain:

```
prompt> create_clock -period 5 CLK
prompt> set_dft_clock_gating_configuration -exclude_elements CLK
```

The following example excludes any clock-gating cells driving register DATA_IN_reg if the upstream clock-gating cell does not drive

any other valid scan cells.

```
prompt> set_dft_clock_gating_configuration -dont_connect_cg_s_of DATA_IN_reg
```

SEE ALSO

[report_dft_clock_gating_configuration\(2\)](#)

set_dft_clock_gating_pin

Specifies the test pin of a clock-gating cell in a design. The main purpose of this command is to identify the unconnected test pins of the clock-gating cells that were not inserted by Power Compiler. These pins are connected to test ports when you run the **insert_dft** command.

SYNTAX

```
status set_dft_clock_gating_pin
  object_list
  -pin_name instance_pin_name
  [-control_signal ScanEnable | TestMode | scan_enable | test_mode]
  [-active_state 1 | 0]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies the clock-gating cell instances for which test pins are specified. This is a required argument.

Wildcards and collections are supported.

-pin_name *instance_pin_name*

Specifies the name of the test pin on the specified instances. This pin name is common to all specified instances. This is a required argument.

-control_signal ScanEnable | TestMode | scan_enable | test_mode

Specifies the type of control signal required by the test pin. The **insert_dft** command connects the pin to a test port of the specified type. This argument is optional. By default, the control signal type is ScanEnable.

-active_state 1 | 0

Specifies the active state of the test pin. This argument is optional. By default, the active state is high, that is, 1.

DESCRIPTION

Specifies the test pins of clock-gating cells not inserted by Power Compiler for DFT flows. The command affects how clock-gating logic is handled by the **dft_drc** and the **insert_dft** commands.

Identified cells can be connected to user-specified test ports by using the **set_dft_connect** command. However, they are not connected when clock-domain-based connection is done, by using the **set_dft_connect** command. For clock-domain-based

connection, only clock-gating cells recognized and inserted by Power Compiler are supported.

You must be careful when specifying the instance pin name because the test pin name is common to all specified instances.

There is no checking for the specified cells. It is your responsibility to make sure that the specified cell and pin are actually a clock-gating cell and test pin that was not identified by Power Compiler. Specifying a cell that is not a clock gating cell can cause undesired results when you run the **dft_drc** and **insert_dft** commands.

Existing connections are maintained. If the specified test pin is already connected to a test port or logic, the **insert_dft** command does not disconnect and reconnect the test pin. Also, the **dft_drc** command will not issue a TEST-130 message for the pin. Only test pins driven by a logic constant and not connected to a net or to a net without a driver are handled by the **dft_drc** command and subsequently connected by the **insert_dft** command.

The **-control_signal** option supports two different keyword conventions. The **ScanEnable** and **TestMode** values are consistent with the **set_dft_signal** command, while the **scan_enable** and **test_mode** values are consistent with the **set_clock_gating_style** command. Either convention can be used.

EXAMPLES

The following examples identify a particular clock-gating cell.

Identification using the default setting:

```
prompt> set_dft_clock_gating_pin {sub1/clk_gate_out1_reg} \
-pin_name TE
```

Identification using explicit specifications:

```
prompt> set_dft_clock_gating_pin {sub1/clk_gate_out1_reg} \
-pin_name TE -control_signal ScanEnable -active_state 1
```

```
prompt> set_dft_clock_gating_pin {sub2/clk_gate_out1_reg} \
-pin_name TE -control_signal ScanEnable -active_state 0
```

Identification using explicit specifications with the test pin controllable by a test mode:

```
prompt> set_dft_clock_gating_pin {sub3/clk_gate_out1_reg} \
-pin_name TE -control_signal TestMode
```

```
prompt> set_dft_clock_gating_pin {sub4/clk_gate_out1_reg} \
-pin_name TE -control_signal TestMode -active_state 0
```

Identify test pin SE on all instances of library cell MyCGCell with default settings

```
prompt> set_dft_clock_gating_pin [get_cells * -hier \
-filter "@ref_name == MyCGCell"] -pin_name SE
```

SEE ALSO

dft_drc(2)
insert_dft(2)
remove_dft_clock_gating_pin(2)
report_dft_clock_gating_pin(2)

set_dft_configuration

Sets the DFT configuration for the current design.

SYNTAX

```
status set_dft_configuration
[-scan enable | disable]
[-fix_clock enable | disable]
[-fix_set enable | disable]
[-fix_reset enable | disable]
[-fix_xpropagation enable | disable]
[-fix_bus enable | disable]
[-fix_bidirectional enable | disable]
[-testability enable | disable]
[-test_points enable | disable]
[-wrapper enable | disable]
[-boundary enable | disable]
[-bsd enable | disable]
[-clock_controller enable | disable]
[-mode_decoding_style binary | one_hot]
[-scan_compression enable | disable]
[-streaming_compression enable | disable]
[-pipeline_scan_data enable | disable]
[-connect_clock_gating enable | disable]
[-integration enable | disable]
[-power_control enable | disable]
[-ieee_1500 enable | disable]
[-control_points enable | disable]
[-observe_points enable | disable]
```

ARGUMENTS

-scan enable | disable

Enables or disables scan insertion.

The default is **enable**.

-fix_clock enable | disable

Enables or disables clock AutoFixing. By default, clocks are not AutoFixed.

-fix_set enable | disable

Enables or disables asynchronous set AutoFixing. By default, asynchronous set signals are not AutoFixed.

-fix_reset enable | disable

Enables or disables asynchronous reset AutoFixing. By default, asynchronous resets are not AutoFixed.

-fix_xpropagation enable | disable

Enables or disables X-propagation AutoFixing. By default, X-propagation is not AutoFixed.

-fix_bus enable | disable

Enables or disables three-state bus AutoFixing. By default, three-state buses are AutoFixed.

-fix_bidirectional enable | disable

Enables or disables bidirectional pad AutoFixing. By default, bidirectional pads are AutoFixed.

-testability enable | disable

Enables or disables the testability test-point client, which consists of:

- SpyGlass automatic test-point insertion
 - Configured with the **set_testability_configuration** command
 - Requires a SpyGlass license
- User-defined test-point insertion
 - Configured with the **set_test_point_element** command
 - Requires a DFTMAX license

This option, along with the **set_testability_configuration** command, replaces the deprecated **test_points** client. If the **-testability** option is enabled, those deprecated commands and options are ignored.

-test_points enable | disable

Enables or disables legacy automatic test point insertion. By default, it is disabled. When enabled, to automatically insert test points, you must also configure one or more test point targets with the **set_test_point_configuration** command.

This feature has been deprecated; use the **testability** test-point client instead.

A DFTMAX license is required to enable this feature.

-wrapper enable | disable

Enables or disables the Core wrapper and Shadow LogicDFT utilities. The specifications for the utilities are set with the **set_wrapper_configuration** command.

-boundary enable | disable

Enables or disables the integration of BIST or scan cores using ANSI/IEEE Std 1149.1-1 compliant boundary-scan circuitry. The newly-synthesized circuitry is unmapped, and must be mapped using the **compile** command.

-bsd enable | disable

Enables or disables the insertion of IEEE Std 1149.1/1149.6 compliant boundary-scan circuitry.

-clock_controller enable | disable

Enables or disables the clock controller for on chip clocking.

-mode_decoding_style binary | one_hot

Specifies the type of port decoding to be used for the test modes controller. Allowed values are **binary** and **one_hot**. Specify **binary** to decode ports for the test controller, or **one_hot** to not decode ports for the test controller. If n test modes are specified for the design, specifying **binary** allows mode architecting to use $\text{ceiling}(\log_2(n))$ ports for the test controller. The **one_hot** mode decoding style allows mode architecting to use $n-1$ ports for the test controller.

The default value is **binary**.

-scan_compression enable | disable

Enables or disables the insertion of combinational or serialized scan compression structures.

-streaming_compression enable | disable

Enables or disables the insertion of streaming scan compression structures.

-pipeline_scan_data enable | disable

Enables or disables the insertion of pipeline scan data registers to scan chains. By default, the pipeline scan data utility is disabled.

-connect_clock_gating enable | disable

Enables or disables checking for unconnected test pins of clock-gating cells during **dft_drc** and their connection in **insert_dft**. The default value is **enable**.

-integration enable | disable

Enables or disables the core integration functionality.

-power_control enable | disable

Enables or disables the power controller override functionality.

The power controller override functionality is disabled by default.

When enabled, the **insert_dft** command inserts a wrapper chain override logic along the control signal outputs of the specified power controller block, inside the level of hierarchy that contains the specified power controller block.

This logic is known as the power controller override logic. This logic allows critical power control signals, such as power switch control, isolation control and state retention control signals, to be controlled during test mode without the need for manually-created power controller initialization vectors. It also provides observability of the power controller outputs for improved test coverage.

-ieee_1500 enable | disable

Enables or disables the IEEE 1500 test-mode control functionality.

Use this option to enable both the DFT-inserted IEEE 1500 controller flow and the existing IEEE 1500 controller flow.

DESCRIPTION

The **set_dft_configuration** command specifies the DFT configuration for a design. The DFT configuration is specific to the current design. If you change the DFT configuration and then change the current design, your changes are no longer visible.

Use the **report_dft_configuration** command to display the current DFT configuration of the design.

Use the **reset_dft_configuration** command to reset the current DFT configuration on the design.

Setting the **set_dft_configuration** command with the **-scan disable -clock_gating enable** options and running the **insert_dft** command results in clock-gating cell routing only.

EXAMPLES

The following command enables the clock Autofix utility:

```
prompt> set_dft_configuration -fix_clock enable
```

The following command disables the check for unconnected test pins of clock-gating cells during **dft_drc** and their connection in **insert_dft**:

```
prompt> set_dft_configuration -connect_clock_gating disable
```

SEE ALSO

`set_ autofix_element(2)`
`set_dft_signal(2)`
`set_testability_configuration(2)`
`set_test_point_configuration(2)`

set_dft_connect

Specifies a list of DFT connectivity associations. The specified source is connected to objects specified in the target list.

SYNTAX

```
status set_dft_connect
  string_label
  -type clock_gating_control | scan_enable
  -source port_or_pin
  [-target object_list]
  [-rise_target rise_clock_list]
  [-fall_target fall_clock_list]
  [-exclude cell_list]
```

Data Types

<i>string_label</i>	string
<i>port_or_pin</i>	string
<i>object_list</i>	string
<i>rise_clock_list</i>	string
<i>fall_clock_list</i>	string
<i>cell_list</i>	string

ARGUMENTS

string_label

Specifies an identifier for the connectivity association. Each association must be unique. If the same label is specified with two connectivity associations, the earlier specification is overwritten.

-type **clock_gating_control** | **scan_enable**

Specifies the type of connectivity association described by the command.

If **-type** is specified as **scan_enable**, you must also use either the **-target**, **-rise_target**, or **-fall_target** option. If **-type** is specified as **clock_gating_control**, the **-target** option is not required.

-source **port_or_pin**

Specifies a DFT signal driver port or pin to be connected to the target cells.

For a DFT signal with a hookup pin, its port must be specified as driver. For an internal pin DFT signal, the driver must be the hookup pin.

For **-type clock_gating_control**, the driver must be defined as ScanEnable or TestMode with the **-usage clock_gating** option of the **set_dft_signal** command.

For **-type scan_enable**, the driver must be defined as ScanEnable with the **-usage scan** switch of the **set_dft_signal** command.

-target **object_list**

Specifies a list of objects to be connected to the specified DFT signal driver port or pin. Specified objects can be a list of cells, designs, clocks, or ScanEnable/TestMode pin/port on CTL modeled cells.

For **-type clock_gating_control**, the *cell_list* must be a list of either clock-gating cells, designs containing clock-gating cells, clock-gating observation cells, or a list of clocks *clock_list*.

For **-type scan_enable**, the *cell_list* must be a list of either valid scan cells or designs containing valid scan cells.

A specified pin/port can be only a clock or pin (ScanEnable/TestMode) on a CTL modeled cell.

When a clock or list of clocks *clock_list* is specified, the tool selects appropriate elements in the respective clock domain, based on the connectivity type. Specified clocks must be valid DFT clocks defined with the **set_dft_signal** command. In addition, for **-type clock_gating_control**, the clocks must be defined with the **create_clock** command.

When doing clock-domain-based scan enable connections, the CTL model of the modeled cell/design must contain the relation between a Scan enable and the clock domain. DFT Compiler puts this relation in the model when doing scan insertion at the block level. For hierarchical scan synthesis, this relation is utilized to perform clock-domain-based connections at the top level. If the relation does not exist in the block level CTL model, then you must specify appropriate pins on the block, leaving the CTL model to do the connections.

If the pins/ports on the CTL modeled cells are specified, then the physical connectivity inside the CTL modeled cell is not validated, and you must determine the valid polarity/active states of the pins/ports on the CTL model cells and specify connectivity appropriately.

If **-target** is not specified, then the tool selects appropriate design elements based on **-type** in the current design.

Pure combinational cells and CTL modeled cells are ignored and their specifications are discarded.

-rise_target rise_clock_list

Specifies a list of clocks. All scan cells triggered by the rising edge of the clock are connected to the specified DFT signal driver port or pin.

This option is valid only with **-type scan_enable**. Clocks specified in the *rise_clock_list* must be defined as a valid DFT signal clock with **set_dft_signal**.

-fall_target fall_clock_list

Specifies a list of clocks. All scan cells triggered by the falling edge of the clock are connected to the specified DFT signal driver port or pin.

This option is valid only with **-type scan_enable**. Clocks specified in the *fall_clock_list* must be defined as a valid DFT signal clock with **set_dft_signal**.

-exclude cell_list

Specifies a list of cells to be excluded from the list of cells that will be connected to the specified driver port or pin.

DESCRIPTION

The **set_dft_connect** command specifies a DFT connectivity association. It is used to connect a DFT signal driver port or pin to a list of specified target cells when the **insert_dft** command is run.

Note that this command has been deprecated; you should use the **set_dft_signal -connect_to** command instead.

Connections are done sequentially. First, connections are done for **-type clock_gating_control** and then for **-type scan_enable**. For each type, connections are again done sequentially, so that subsequent **set_dft_connect** commands take precedence over earlier commands. You must maintain order and precedence by specifying the **set_dft_connect** commands in the correct order.

Use the **report_dft_connect** command to display specified connectivity associations.

Use the **remove_dft_connect** command to remove specified connectivity associations.

EXAMPLES

The following example first sets the signals for ports *SE1* through *SE7*, and then connects the sources to the targets:

```
prompt> set_dft_signal -view spec -type ScanEnable -port SE1 \
           -usage clock_gating

prompt> set_dft_signal -view spec -type ScanEnable -port SE2 \
           -usage clock_gating

prompt> set_dft_signal -view spec -type ScanEnable -port SE3 \
           \fb-usage clock_gating

prompt> set_dft_signal -view spec -type ScanEnable -port SE4 -usage scan

prompt> set_dft_signal -view spec -type ScanEnable -port SE5 -usage scan

prompt> set_dft_signal -view spec -type ScanEnable -port SE6 -usage scan

prompt> set_dft_signal -view spec -type ScanEnable -port SE7 -usage scan

prompt> set_dft_connect label1 -source SE1 -type clock_gating_control \
           -target [list U1 U2]

prompt> set_dft_connect label2 -source SE2 -type clock_gating_control \
           -target [list U1/clk_gate*] -exclude U1/clk_gate_1

prompt> create_clock -p 5 clk1 -name CLK1

prompt> set_dft_signal -view exist -type ScanClock -port clk1 \
           -timing {45 55}

prompt> set_dft_connect label3 -source SE3 -type clock_gating_control \
           -target [list CLK1]

prompt> set_dft_connect label4 -source SE4 -type scan_enable \
           -target [list U1]

prompt> set_dft_connect label5 -source SE4 -type scan_enable \
           -target [list U2] -exclude U2/ff1

prompt> set_dft_signal -view exist -type ScanClock -port clk2 \
           -timing {45 55}

prompt> set_dft_signal -view exist -type ScanClock -port clk3 \
           -timing {45 55}

prompt> set_dft_signal -view exist -type ScanClock -port clk4 \
           -timing {45 55}

prompt> set_dft_connect label6 -source SE5 -type scan_enable \
           -target [list clk2]

prompt> set_dft_connect label7 -source SE6 -type scan_enable \
           -rise_target [list clk2]

prompt> set_dft_connect label8 -source SE7 -type scan_enable \
           -fall_target [list clk3 clk4]
```

The following example connects a dedicated ScanEnable/TestMode on a CTL modeled cell to *SE8*, *SE9*, and *TM* at the top level. The

core cell has CTL model with core/SE_scan and core/SE_cg as dedicated ScanEnable signals, and core/TM_cg as dedicated TestMode signal.

```
prompt> set_dft_signal -view spec -type ScanEnable -port SE8 \
           -usage clock_gating
prompt> set_dft_signal -view spec -type ScanEnable -port SE9 \
           -usage scan
prompt> set_dft_signal -view spec -type TestMode -port TM \
           -usage clock_gating
prompt> set_dft_connect label9 -source SE8 -type clock_gating_control \
           -target core/SE_cg
prompt> set_dft_connect label10 -source SE9 -type scan_enable \
           -target core/SE_scan
prompt> set_dft_connect label11 -source TM -type clock_gating_control \
           -target core/TM_cg
```

SEE ALSO

`remove_dft_connect(2)`
`report_dft_connect(2)`
`set_dft_signal(2)`

set_dft_drc_configuration

Sets the DFT DRC configuration for the current design.

SYNTAX

```
status set_dft_drc_configuration
  [-internal_pins enable | disable]
  [-pll_bypass enable | disable]
  [-assume_pi_scan enable | disable]
  [-assume_po_scan enable | disable]
  [-static_x_analysis enable | disable]
  [-use_test_model true | false]
  [-clock_gating_init_cycles integer]
  [-allow_se_set_reset_fix true | false]
  [-analyze_multi_clock_activation enable | disable]
```

ARGUMENTS

-internal_pins enable | disable

Enables the "internal pins" flow, in which internal pins can be specified as clock, reset, set, constant, scan-in, scan-out, scan-enable, and test_mode signals.

When **-internal_pins** is set to **enable**, you can specify internal pins to be as clock, reset, set, constant, scan-in, scan-out, scan-enable and test_mode signals. You can specify these internal pins using the **set_dft_signal** and **set_scan_path** commands. These signals are then used by the **dft_drc**, **preview_dft**, and **insert_dft** commands. However, the protocol generated at the end of post-DFT DRC is not complete and cannot be used by the user.

-pll_bypass enable | disable

Enables the PLL bypass mode during post-DFT DRC.

-assume_pi_scan enable | disable

Applies only when BIST is enabled. When this option is enabled (the default), Design Rule Checking does not check that all primary inputs are driven by scan elements, and just assumes that this is true. If you want Design Rule Checking to check that all primary inputs are driven by scan elements, set this option to **disable**. Design Rule Checking then reports L-24 violations on the primary inputs that are not driven by scan elements.

-assume_po_scan enable | disable

Applies only when BIST is enabled. When this option is enabled (the default), Design Rule Checking does not check that all primary outputs drive scan elements, and just assumes that this is true. If you want Design Rule Checking to check that all primary outputs drive scan elements, set this option to **disable**.

-static_x_analysis enable | disable

Enables pre-DFT DRC to report static-X scan cell violations. The default is **disable**.

-use_test_model true | false

Replaces DFT-inserted blocks with their test model representations during DFT DRC and scan architecting. The default is **true**.

When this option is set to **false**, **dft_drc** uses the gates instead of the test model attached to a block. Use this only for blocks containing scan chains and complex test control structures, where the test model does not accurately describe the test control logic.

-clock_gating_init_cycles integer

Adds the specified number of additional clock pulses to the test_setup section of the test protocol. This is useful for initialization of multiple cascaded sequential clock-gating cells. The default is zero.

-allow_se_set_reset_fix true | false

Controls whether pre-DFT and post-DFT DRC allow internally generated reset signals that are gated by the scan-enable signal. When set to the default of **false**, DFT DRC does not allow scan cells to be driven by any internally generated reset; they are marked as violations and excluded from scan chains. When set to **true**, DFT DRC allows scan cells whose internally generated reset signals are gated by the scan-enable signal during scan shift.

Note that scan-enable signals driving existing testability logic in your design must be defined with the **-view existing_dft** option of the **set_dft_signal** command for pre-DFT DRC to consider them, even if they are already also defined with the **-view spec** option.

This option is equivalent to the **set_drc -allow_unstable_set_reset** option in TetraMAX ATPG.

-analyze_multi_clock_activation enable | disable

Enables DFT DRC to analyze scan elements for multiple clock/reset/set active inputs. The D18 violation is reported on scan elements with such inputs. The default is **disable**.

DESCRIPTION

This command specifies the configuration for DFT DRC, which is performed explicitly by the **dft_drc** command and can be performed implicitly by the **preview_dft** and **insert_dft** commands if not previously run.

EXAMPLES

The following example enables the internal pins flow:

```
prompt> set_dft_drc_configuration -internal_pins enable
```

The following example applies additional initialization clock pulses:

```
prompt> set_dft_drc_configuration -clock_gating_init_cycles N \
;# where, N = number of clock pulses
```

`set_dft_configuration(2)`
`set_dft_signal(2)`
`set_scan_configuration(2)`
`set_scan_path(2)`
`write_test_protocol(2)`

set_dft_drc_rules

Alters how certain DRC rule violations affect DFT insertion for the specified cells.

SYNTAX

```
int set_dft_drc_rules
  [-allow drc_list]
  [-ignore drc_list]
  [-cell cell_list]
```

Data Types

drc_list string
cell_list string

ARGUMENTS

-allow *drc_list*

Specifies that for the specified DRC violations, DFT should allow violating cells to be included in scan chains. The violations are still reported.

-ignore *drc_list*

Specifies that for the specified DRC violations, DFT should completely ignore the violations. The violating cells are included in scan chains and the violations are not reported.

-cell *cell_list*

Limits the DFT DRC specification to certain cells. If no cells are specified, the specification applies globally to all cells.

DESCRIPTION

The **set_dft_drc_rules** command can be used to change how certain DRC rule violations affect DFT insertion. The list of DRC rule violation IDs supported by this command is:

- TEST-504 (warning) Cell %s has constant 0 value.
- TEST-505 (warning) Cell %s has constant 1 value.
- D17 (warning) D17 Clock input I of <type> S couldn't capture data.

By default, these DRC violations cause DFT to omit the violating cells from scan chains. You can use this command to include them in scan chains, with or without the violations being reported.

The **set_dft_drc_rules** command in DFT Compiler is similar to the **set_rules** command in TetraMAX in that both commands control

how the tool treats DRC rule violations. However, they are different in that the **set_dft_drc_rules** command controls how the DRC violations affect DFT insertion, while the **set_rules** command controls the severity of DRC violations for a static design.

Note that the following commands take precedence over a **set_dft_drc_rules** specification:

- If a flip-flop also has a **set_scan_element false** attribute applied, it takes precedence, and the **set_dft_drc_rules** specification has no effect.
- If a flip-flop holds a constant value due to the **set_test_assume** command, this assumed constant value takes precedence, and the **set_dft_drc_rules** specification has no effect.

Use the **report_dft_drc_rules** command to display the DFT DRC rule specifications that have been applied. Use the **reset_dft_drc_rules** command to reset all DFT DRC rule specifications.

EXAMPLES

The following example allows all cells that violate TEST-504 and TEST-505 to be included on scan chains, with the violations reported:

```
prompt> set_dft_drc_rules -allow {TEST-504 TEST-505}
```

The following example allows all cells that violate TEST-504 and TEST-505 to be included on scan chains in the hierarchical instance USPARE_GATES, with the violations not reported:

```
prompt> set_dft_drc_rules -ignore {TEST-504 TEST-505} -cell USPAREGATES
```

set_dft_equivalent_signals

Sets a given list of DFT signals as equivalents.

SYNTAX

```
integer set_dft_equivalent_signals  
      signal_list
```

Data Types

signal_list list

ARGUMENTS

signal_list

Lists the signals to check against the primary signal for equivalency requirements. The first signal in the list is the primary signal. The primary signal is used to check for valid equivalences with the remaining signals in the list for type and other (if any) equivalency requirements. All the signals must have the same signal type.

DESCRIPTION

This command sets a specified list of scan signals as equivalent for scan architect. This is supported only for clock signal types (ScanClock, MasterClock, and ScanMasterClock), as specified by the **set_dft_signal** command or inferred by the **create_test_protocol** command.

Use this command to specify a set of clocks as equivalent for scan architect. This enables the architect to consider all flops driven by these clocks as if driven by the same clock, and the architect will not add any synchronization elements when they are mixed in a scan chain.

EXAMPLES

The following example illustrates setting two clocks as equivalent to clock clk1:

```
prompt> set_dft_equivalent_signals [list clk1 clk2 clk3]
```

SEE ALSO

```
insert_dft(2)
preview_dft(2)
remove_dft_equivalent_signals(2)
report_dft_equivalent_signals(2)
set_dft_signal(2)
```

set_dft_insertion_configuration

Sets the DFT insertion configuration for the current design.

SYNTAX

```
int set_dft_insertion_configuration
    [-map_effort low | medium | high]
    [-synthesis_optimization none | all]
    [-route_scan_enable true | false]
    [-route_scan_clock true | false]
    [-route_scan_serial true | false]
    [-preserve_design_name true | false]
    [-unscan true | false]
```

ARGUMENTS

-map_effort low | medium | high

Specifies the optimization effort level during DFT insertion. Valid values are **low**, **medium**, and **high**.

The default is **medium**.

-synthesis_optimization none | all

Specifies whether to perform optimizations during DFT insertion.

In wireload mode, valid values are **all** to turn on all optimizations, and **none** to turn off all optimizations. The default is **all**.

In topographical mode, the only allowed value is **none**; it cannot be changed.

-route_scan_enable true | false

Specifies whether to route scan enables during DFT insertion. Valid values are **true** to perform scan enable routing, and **false** to turn off scan enable routing.

The default is **true**.

-route_scan_clock true | false

Specifies whether to route scan clocks during DFT insertion. Valid values are **true** to route the scan clocks, and **false** to turn off scan clock routing.

The default is **true**.

-route_scan_serial true | false

Specifies whether to route scan serial signals during DFT insertion. Valid values are **true** to route the scan serial signals, and **false** to turn off scan serial routing.

The default is **true**.

-preserve_design_name true | false

Specifies whether to preserve the design name when writing from the tool to the database during DFT insertion. Valid values are **true** to preserve the design name, and **false** to permit renaming the design.

The default is **false**.

-unscan true | false

Specifies whether to unscan invalid scan-replaced cells during DFT insertion.

A scan-replaced cell is invalid if it has a DRC violation or if it has the **scan_element** attribute set to **false**.

When set to **false** (the default), invalid scan-replaced cells remain scan-replaced despite not being included in scan chains. However, in wire load mode, if the **-synthesis_optimization** option of this command is set to its default of **all**, cells with the **scan_element** attribute set to **false** are still unscanned.

When set to **true**, invalid scan-replaced cells are unscanned. If an invalid scan-replaced cell has a **dont_touch** attribute, the **dont_touch** takes precedence and this option has no effect.

The **-unscan** option affects only the **insert_dft** command; it does not affect post-DFT optimization (implicit or explicit).

DESCRIPTION

The **set_dft_insertion_configuration** command specifies the configuration to use for the current design during the DFT insertion process. The settings apply only to the current design. If you change the DFT insertion configuration and then change the current design, your changes are no longer visible.

When **-synthesis_optimization none** is specified, the **insert_dft** command does not perform any timing or design rule optimization. In addition, scan cells with the **scan_element** attribute set to **false** are not unscanned.

When **-map_effort low** is specified, the **insert_dft** command resizes only the logic it added to the design.

When **-map_effort medium** is specified, **insert_dft** first resizes the logic it added. If constraints are still violated, it applies a set of heuristic optimizations to all critical points in the design. The heuristics include:

1. *Sizing*: Size one or more drivers or loads for appropriate drive strength.
2. *Phasing*: Replace the driver with one that has an opposing phase.
3. *Buffering*: Insert buffers or inverter pairs; transform inverter pairs to buffers, or transform buffers to inverter pairs or buffer inverters.
4. *Downsizing*: Downsize and swap out loads.
5. *Isolation*: Isolate noncritical loads using inverter pairs or buffers.
6. *Off-loading*: Offload noncritical loads to other driver outputs, use a driver output with a greater drive strength, use drivers with more outputs, or move loads to nets with earlier arrival times.
7. *Balancing*: Redistribute loads among drivers, balance buffers, or balance loads across driver outputs.
8. *Splitting*: Duplicate driver, distributing loads or dedicating one driver to the critical path.

When **-map_effort high** is specified, the **insert_dft** command first resizes the logic it added. If constraints are still violated, it performs critical-path optimization on the entire design. If constraints are still violated, it applies sequential mapping to sequential elements on critical paths. It then attempts to reduce design area by downsizing cells that are not on a critical path and eliminating extra inverters. It attempts to eliminate any remaining constraint violations by using normal critical-path optimization.

Use the **report_dft_insertion_configuration** command to display the current DFT insertion configuration of the design.

Use the **reset_dft_insertion_configuration** command to remove the current DFT insertion configuration from the design.

EXAMPLES

The following command sets the mapping effort level to **high**:

```
prompt> set_dft_insertion_configuration -map_effort high
```

The following command turns off all synthesis optimizations in Design Compiler wireload mode:

```
prompt> set_dft_insertion_configuration \  
-synthesis_optimization none
```

`report_dft_insertion_configuration(2)`
`reset_dft_insertion_configuration(2)`

set_dft_location

Specifies the DFT hierarchy location for DFT insertion.

SYNTAX

```
status set_dft_location
  dft_hier_name
  [-exclude CODEC | TCM | LOCKUP_LATCH | PIPELINE_SI_LOGIC | PIPELINE_SE_LOGIC | WRAPPER | BSR | TAP | REC_MUX |
   [-include CODEC | TCM | LOCKUP_LATCH | PIPELINE_SI_LOGIC | PIPELINE_SE_LOGIC | WRAPPER | BSR | TAP | REC_MUX |
```

Data Types

dft_hier_name string

ARGUMENTS

dft_hier_name

Specifies the hierarchical path name of an instance in the current design into which all DFT logic will be added during DFT insertion.

This argument is required.

```
-exclude CODEC | TCM | LOCKUP_LATCH | PIPELINE_SI_LOGIC | PIPELINE_SE_LOGIC | WRAPPER | BSR | TAP | REC_MUX |
PLL | SERIAL_CNTRL | SERIAL_REG | XOR_SELECT | RETIMING_FLOP | IEEE_1500
```

Specifies that all types of DFT logic except the specified types are to be included in the specified DFT location.

Note that this option overwrites any previous DFT location specifications for DFT logic types that are not specified. See the final -**exclude** example in the EXAMPLES section for more information.

More than one type of DFT logic can be excluded with this option.

There is no default for this option. When this option is not specified, the location specification applies as a default to all DFT logic types.

```
-include CODEC | TCM | LOCKUP_LATCH | PIPELINE_SI_LOGIC | PIPELINE_SE_LOGIC | WRAPPER | BSR | TAP | REC_MUX |
PLL | SERIAL_CNTRL | SERIAL_REG | XOR_SELECT | RETIMING_FLOP | IEEE_1500
```

Specifies the types of DFT logic to be included in the specified DFT location.

CODEC logic includes the compressor and decompressor (codec) logic inserted by the tool for compressed scan, serialized compressed scan, and streaming compressed scan modes.

PIPELINE_SI_LOGIC includes all head and tail pipelined scan data registers.

PIPELINE_SE_LOGIC includes all pipelined scan-enable logic.

PLL logic includes PLL controller and clock chain logic.

WRAPPER logic includes dedicated wrapper cells and wrapper mode logic.

BSR logic includes all BSR cells and instruction decode and mode logic.

TAP logic includes the TAP controller instance.

SERIAL_CNTRL logic includes the serializer clock controller used in serializer insertion flows.

SERIAL_REG logic includes the serializer and deserializer registers used in the serializer IP insertion flow. This type does not affect the normal serializer insertion flow.

XOR_SELECT includes the sharing compressor and block-select logic inserted at the compressor outputs in the shared codec I/O flow.

TCM logic includes the decoder and mode logic.

LOCKUP_LATCH logic includes all lock-up latches.

RETIMING_FLOP logic includes all retiming flip-flops.

REC_MUX logic includes scan-reconfiguration muxes, scan-out muxes, tri-state/bidir disable logic, and any other glue logic added during DFT insertion.

IEEE 15000 logic includes all DFT-inserted IEEE 1500 logic used for test-mode control. At the chip level, it also includes the server logic that interfaces to the IEEE Std 1149.1 TAP controller.

More than one type of DFT logic can be included with this option.

There is no default for this option. When this option is not specified, the location specification applies as a default to all DFT logic types.

DESCRIPTION

The **set_dft_location** command can be used to add all DFT logic into a user-specified hierarchy during DFT insertion.

If the **-include** and **-exclude** options are not specified, the location specification applies as a default to all DFT logic types. Any type-specific specifications take precedence over this default location specification. You can use the **report_dft_location** command to report the resulting location specification.

In the normal serializer insertion flow, the deserializer and serializer registers are always placed inside the decompressor and compressor, respectively, whose location is specified with the CODEC logic type. To place the deserializer and serializer registers in a different hierarchy location than the combinational codec logic, use the serializer IP insertion flow and specify the register location with the SERIAL_REG logic type.

EXAMPLES

The following example specifies a DFT hierarchy location for the design top. All types of DFT logic are included in the specified location.

```
prompt> set_dft_location core_inst/dft_inst
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for the design top. All wrapper and lock-up latch logic should not be inserted at this location.

```
prompt> set_dft_location core_inst/dft_inst \
    -exclude { WRAPPER LOCKUP_LATCH }
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for wrapper logic. The codec logic is inserted at another DFT location. Any other DFT logic should not be inserted in these locations.

```
prompt> set_dft_location core_inst/dft_inst1 -include { WRAPPER }
Accepted DFT location specification.
1
prompt> set_dft_location core_inst/dft_inst2 -include { CODEC }
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for BSD logic. Both BSR and TAP logic are added to this location.

```
prompt> set_dft_location core_inst/bsd_inst -include { BSR TAP }
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for BSR logic. The TAP logic is inserted at another DFT location.

```
prompt> set_dft_location core_inst/bsd_inst1 -include { BSR }
Accepted DFT location specification.
1
prompt> set_dft_location core_inst/bsd_inst2 -include { TAP }
Accepted DFT location specification.
1
```

The following example specifies a DFT hierarchy location for CODEC logic, then sets a DFT hierarchy location for everything except lock-up latches. Because the **-exclude** option includes all DFT logic types except the specified type(s), the CODEC specification is overwritten.

```
prompt> set_dft_location UCODEC -include { CODEC }
Accepted DFT location specification.
1
prompt> set_dft_location UDFT -exclude { LOCKUP_LATCH }
Accepted DFT location specification.
1
prompt> report_dft_location

set_dft_power_control

Specifies the power controller block instance for the current design.

SYNTAX

```
status set_dft_power_control
      power_controller_hierarchical_instance_name
```

ARGUMENTS

power_controller_hierarchical_instance_name

Specifies the power controller hierarchical instance name.

DESCRIPTION

This command allows you to identify the power controller block instance for the power control override insertion. DFT insertion then inserts a dedicated wrapper chain at the output pins to control power management structures such as power switches, isolation cells and retention registers during test. The power control signals at the block output pins are defined using commands that are part of the IEEE 1801 specification, also known as the Unified Power Format (UPF) specification.

You can only have one power controller block specified for the current design. Subsequent commands will override the previous specification.

Use the **report_dft_power_control** command to report the current power controller block specification. Use the **remove_dft_power_control** command to remove the current power controller block specification.

EXAMPLES

The following command specifies an instance of power controller instance.

```
prompt> set_dft_power_control U_PWC
```

SEE ALSO

remove_dft_power_control(2)
report_dft_power_control(2)

set_dft_configuration(2)

set_dft_signal

Specifies the DFT signal types for DRC and DFT insertion.

SYNTAX

```
status set_dft_signal
  [-view existing_dft | spec]
  [-test_mode mode_name_list]
  -type signal_type
  [-port port_list]
  [-active_state 0 | 1
    [-timing timing]

ARGUMENTS

-view existing_dft | spec

Indicates the view to which the specification applies. The following views are valid:

- **existing_dft** implies that the specification refers to the existing usage of a port. For example, when working with a design that is already DFT-inserted, the command to indicate that port SE is used as a scan-enable port is as follows:

```
set_dft_signal -view existing_dft -port SE -type ScanEnable
```

- **spec** (the default) implies that the specification refers to ports that the tool must use during DFT insertion. For example, when preparing a design for DFT insertion, the command to specify that port SE is used as a scan-enable port for DFT insertion is as follows:

```
set_dft_signal -view spec -port A -type ScanEnable
```

-test_mode mode_name_list

Specifies the test mode(s) to which the specification applies. Test modes are created with the **define_test_mode** command. A value of **all** or **all_dft** causes the specification to apply to all test modes.

If the **-test_mode** option is not specified, the command applies to the current test mode, which is determined by the last **define_test_mode** or **current_test_mode** command executed. If no test modes have been defined, the command applies to the default test mode.

-type signal_type

Specifies the signal type. The valid signal types are as follows:

- **Reset** is the asynchronous set or reset of the design.
- **Constant** is a continuously applied value to a port.
- **TestMode** is a continuously applied value to a test mode port that may have different values between test modes.
- **TestData** is the port used to apply scan data to a portion of the design that has had pre-DRC violations fixed by Autofix.
- **TestControl** is the port used to control the DFTMAX shift power groups feature.
- **ScanDataIn** is one of the scan inputs of the design.
- **ScanDataOut** is one of the scan outputs of the design.
- **ScanEnable** is the shift enable of a MUX-D scan design.
- **ScanClock** is a clock that performs both scan shift and capture in a MUX-D scan design. (This type is equivalent to defining the clock as both the MasterClock and ScanMasterClock types; there is no CTL signal type called ScanClock.)
- **ScanMasterClock** is the clock responsible for scan shift. In an LSSD scan style, the ScanMasterClock is the A clock, and in a clocked scan style it is the shift clock.
- **ScanSlaveClock** is the B clock in an LSSD scan style.
- **MasterClock** is the clock responsible for capture. In an LSSD scan style the MasterClock is the system clock, and in a clocked scan style it is the capture clock.

In general, the MasterClock is used for referring to the capture clock and ScanMasterClock for referring to the shift clock. In the LSSD scan style, the two shift clocks are specified as ScanMasterClock and ScanSlaveClock, and only the capture clock is specified as MasterClock.

In the MUX-D scan style, the same clock provides both shift and capture functionality. In this case, use the ScanClock signal type, which simultaneously specifies both MasterClock and ScanMasterClock types. To create a shift-only clock in the MUX-D scan style, use the ScanClock type, then apply the **add_pi_constraint** command in TetraMAX.

To specify the sense for an internal hookup-only pin (no port is associated with the hookup pin), use the **-active_state** option.

The following signal types are used in on-chip clocking (OCC) controller flows:

- **Oscillator** specifies the output pin of the on-chip clock generator or the output pins of the user-instantiated on-chip clock

controller. In both cases, the **-hookup_pin** option must be used. This is a constantly running clock signal that never turns off.

- **RefClock** is a constantly running external reference clock. The clock can have timing which differs from the test default period.
- **pll_reset** is the asynchronous signal resetting the OCC logic.
- **pll_bypass** is the signal making the OCC logic transparent when the active value is applied.

The following signal types can be used in core-wrapping flows:

- **wrp_shift** specifies the scan shift signal for wrapper cells.
- **wrp_clock** specifies the clock signal for dedicated wrapper cells.
- **input_wrp_shift** specifies the scan shift signal for input wrapper cells in the maximized reuse flow. It can be used only with the **-connect_to** option.
- **output_wrp_shift** specifies the scan shift signal for output wrapper cells in the maximized reuse flow. It can be used only with the **-connect_to** option.
- **wrp_ded_capture_in** specifies the input capture signal in the maximized reuse flow. It is used for input dedicated wrapper cells when creating a wrapped core for hierarchical wrapping flows. It is also used for input shared wrapper cells in custom core wrapping flows.
- **wrp_ded_capture_out** specifies the output capture signal in the maximized reuse flow. It is used for output dedicated wrapper cells when creating a wrapped core for hierarchical wrapping flows. It is also used for output shared wrapper cells in custom core wrapping flows.
- **wrp_ded_capture inout** specifies the input/output capture signal in the maximized reuse flow. It is used only for shared wrapper cells which are connected to both input and output ports in custom core wrapping flows.
- **wrp_safe_in** specifies the safe control signal for input wrapper cells in the maximized reuse flow. This signal is used when creating a wrapped core for hierarchical wrapping flows.
- **wrp_safe_out** specifies the safe control signal for output wrapper cells in the maximized reuse flow. This signal is used when creating a wrapped core for hierarchical wrapping flows.
- **wrp_td_test** specifies the signal used in core wrapping to aid transition delay testing. The signal controls the hold state of the wrapper cell in capture. The cell can either hold the state or toggle in capture based on this signal. This signal is used only in custom core wrapping flows.

The following signal types can be used to define IEEE 1500 controller signals in IEEE 1500 flows:

- **WSI** specifies the scan-in signal.
- **WRSTN** specifies the reset signal.
- **WRCK** specifies the clock signal.
- **CaptureWR** specifies the capture-enable signal.
- **ShiftWR** specifies the shift-enable signal.
- **UpdateWR** specifies the update-enable signal.
- **SelectWIR** specifies the shift-path selection signal, which selects between the instruction register and data registers.
- **WSO** specifies the scan-out signal.

The following signal types can be used to define LogicBIST signals in LogicBIST self-test flows:

- **IbistEnable** specifies the signal that enables self-test mode. This also enables any wrapper or test-point logic associated with the self-test mode.
- **IbistStart** specifies the signal that begins self-test operation.
- **IbistStatus_1** and **IbistStatus_0** specify: 00 when idle; 01 when running; 10 when test complete and passed; and 11 when

test complete and failed.

- **IbistSeedValue** specifies signals of a bus that provides the BIST seed value.
- **IbistSignatureValue** specifies signals of a bus that provides the BIST signature value.
- **IbistPatternCount** specifies signals of a bus that provides the pattern count used for BIST.
- **IbistShiftLength** specifies the signals of a bus that provide the number of shift cycles per pattern for each BIST pattern.
- **IbistBurnInEnable** specifies the signal that enables burn-in operation.
- **IbistBurnInStopOnFail** specifies whether burn-in operation should stop or continue if self-test fails.
- **IbistCaptureCycleEnable** specifies the signals of a bus that provide the number of capture cycles used for BIST.

The following signal type can be used in the shared codec I/O flow:

- **codec_enable** specifies a signal that enables a codec when the shared controls feature is used. It must be driven by a hookup pin; port-driven signals are not supported.

The following signal types can be used to define PCO wrapper chain signals in the power controller override (PCO) flow:

- **pco_shift_clk** specifies the shift clock signal.
- **pco_update_clk** specifies the update clock signal.
- **pco_override** specifies the override signal.

The following signal types can be used in BSD synthesis and integration:

- **tdi** specifies the TDI port or bsd reg tdi access pin.
- **tdo** specifies the TDO port or bsd reg tdo access pin.
- **tdo_en** specifies the TDO port enable pin.
- **tck** specifies the TCK port.
- **tms** specifies the TMS port.
- **trst** specifies the TRST port.
- **bsd_shift_en** specifies the register access pin to be hooked up to TAP shift_dr pin when the instruction that selects the register is active.
- **bsd_capture_en** specifies the register access pin to be hooked up to TAP sync_capture_en pin when the instruction that selects the register is active. This signal is also used in core integration.
- **bsd_capture_dr** specifies the register access pin to be hooked up to TAP Capture-DR state on the negative edge of TCK when the instruction that selects the register is active.
- **bsd_update_en** specifies the register access pin to be hooked up to TAP sync_update_dr pin when the instruction that selects the register is active. This signal is also used in core integration.
- **bsd_update_dr** specifies the register access pin to be hooked up to TAP Update-DR state on the negative edge of TCK when the instruction that selects the register is active.
- **capture_clk** specifies the register access pin to be hooked up to TCK/clock_dr pin when the instruction that selects the register is active.
- **update_clk** specifies the register access pin to be hooked up to TCK/update_dr pin when the instruction that selects the register is active.
- **inst_enable** specifies the register access pin to be held active when the instruction that selects the register is active.
- **bist_enable** specifies the register access pin to be held active when the instruction that selects the register is active and TAP is in Run-Test-Idle state.

- **bist_clk** specifies the register access pin to be hooked up to TCK when the instruction that selects the register is active and TAP is in Shift-DR state. This signal is also used in core integration.
- **bsd_reset** specifies the register access pin to be hooked up to the Test-Logic-Reset FSM state signal when the instruction that selects the register is active. When the bsd_reset signal is not part of any instruction's test data register definition, it is hooked up directly to the Test-Logic-Reset state signal.
- **bsd_test_logic_reset** specifies the Test-Logic-Reset TAP FSM state signal.
- **bsd_run_test_idle** specifies the Run-Test-Idle TAP FSM state signal.
- **bsd_select_dr_scan** specifies the Select-DR TAP FSM state signal.
- **bsd_capture_dr** specifies the Capture-DR TAP FSM state signal.
- **bsd_shift_dr** specifies the Shift-DR TAP FSM state signal.
- **bsd_exit1_dr** specifies the Exit1-DR TAP FSM state signal.
- **bsd_pause_dr** specifies the Pause-DR TAP FSM state signal.
- **bsd_exit2_dr** specifies the Exit2-DR TAP FSM state signal.
- **bsd_update_dr** specifies the Update-DR TAP FSM state signal.
- **bsd_select_ir_scan** specifies the Select-IR TAP FSM state signal.
- **bsd_capture_ir** specifies the Capture-IR TAP FSM state signal.
- **bsd_shift_ir** specifies the Shift-IR TAP FSM state signal.
- **bsd_exit1_ir** specifies the Exit1-IR TAP FSM state signal.
- **bsd_pause_ir** specifies the Pause-IR TAP FSM state signal.
- **bsd_exit2_ir** specifies the Exit2-IR TAP FSM state signal.
- **bsd_update_ir** specifies the Update-IR TAP FSM state signal.
- **bsd_mode_in** is the mode signal for input BSR cells.
- **bsd_mode_out** is the mode signal for output BSR cells.
- **bsd_mode1 inout** is the mode signal for mode1 of BC_7 BSR cells.
- **bsd_mode2 inout** is the mode signal for mode2 of BC_7 BSR cells.

-port *port_list*

Indicates the list of ports on which to apply the specifications.

-active_state 0 | 1

Specifies the active states for the following signal types:

ScanEnable
Reset
Constant
TestMode
pll_reset
pll_bypass

The active state can be 0 or 1 and it specifies the active sense of the port (high or low) or an internal hookup only pin (no port is associated with the hookup pin).

Wildcards and collections are supported.

-timing *timing*

Specifies the rise time and fall time for clocks. For example:

```
set_dft_signal -view existing_dft -type ScanClock \
    -port CLK -timing [list 45 55]
```

-period period

Specifies the period of the on-chip clocking (OCC) reference clock. The period value is a floating point number in nanoseconds. When **-period** is used, the values specified after **-timing** indicate the leading edge and the trailing edge of the reference clock. The **-period** option is valid only on signals of the RefClock type.

-hookup_pin hookup_pin

Specifies the pin to which signals are to be connected. By default, the **insert_dft** command connects wires to the core side of identified signal ports, jumping pads and buffers as needed. The **-hookup_pin** argument overrides this behavior and instructs **insert_dft** to connect wires to the specified pin. The pin can be either a leaf pin or hierarchical pin. Validation ensures that the pin direction (driver or load) is consistent with the signal type. Verify that a specific access pin is associated with only one design port.

If hookup pins are specified, only one port can be specified in the *port_list*.

However, if the internal pins flow is enabled (**set_dft_drc_configuration -internal_pins**), a hookup pin can be specified without specifying a port. The hookup pin specified should be either on a black box or should have a proper global driver. If a proper global driver is not found, **insert_dft** will not stitch to the specified hookup pin.

-hookup_sense hookup_sense

Specifies the hookup sense for the hookup pin. This option is valid only when a single hookup pin or a port is specified. The valid values are **inverted** and **non_inverted**. The default is **non_inverted**.

-internal_clocks none | single | multi

Specifies the setting for an internal clock. An internal clock is defined as an internal signal driven by a multiplexer (or multiple input gate) output pin. This option applies only to the multiplexed flip-flop scan style and it is ignored for other scan styles.

Note that the output of clock gating cells that are introduced by the Synopsys Power Compiler will not be treated as internal clocks, even if the **-internal_clocks** option is enabled.

The **-internal_clocks** option can be set to the following values:

- **single** specifies that **insert_dft** treats any internal clocks in the design as separate clocks for the purpose of scan chain architecting. The **single** value instructs the tool to stop at the first buffer or inverter driving the flip-flops clock.
- **none** (the default) specifies that **insert_dft** does not treat internal clocks as separate clocks.
- **multi** specifies that **insert_dft** treats any internal clocks in the design as separate clocks for the purpose of scan chain architecting. The **multi** value instructs the tool to jump over buffers and inverters, stopping at the first multi-input gate driving the flip-flops clock.

-ctrl_bits ctrl_bits_list

Lists triplets that specify the sequence of control bits needed to enable the propagation of the clock generator outputs. This option is used in the on-chip clocking (OCC) flow. The first element of each triplet is the cycle number (integer) indicating when the clock signal will be propagated. The second element is the pin name of the control bit (a valid design hierarchical pin name). The third element is the active value (0 or 1) of the control bit. For example:

```
set_dft_signal -type Oscillator -hookup_pin pll_controller/clk \
    -pll_clock pll_i/pll_clk -ate_clock ate_clk \
    -ctrl_bits [list \
        0 clk_chain_i/clk_ctrl_data[0] 1 \
        1 clk_chain_i/clk_ctrl_data[1] 1 \
        2 clk_chain_i/clk_ctrl_data[2] 1] \
    -view existing_dft
```

-pll_clock clock_name

Specifies the port name of the pll clock. This option is used in the on-chip clocking (OCC) flow.

-ate_clock *clock_name*

Specifies the port name of the ATE clock. This option is used in the on-chip clocking (OCC) flow.

-differential_clock *clock_port*

Specifies the pin name of a differential clock. For example, if clk_m is the minus side of clk_p:

```
set_dft_signal -view existing_dft -type ScanClock \
-port clk_m -differential {clk_p}
```

Note that the minus side will track all of the properties of the plus side with an inverted polarity. A complete example for clk_m and clk_p is as follows:

```
set_dft_signal -view existing_dft -type Oscillator \
-port clk_p
set_dft_signal -view existing_dft -type ScanClock \
-port clk_p -timing [list 45 55]
set_dft_signal -view existing_dft -type ScanClock \
-port clk_m -differential {clk_p}
```

-connect_to *object_list*

Specifies that the DFT signal should be connected from the port or hookup pin to only the specified design objects.

You can use the **-connect_to** option to define ScanEnable, TestMode, or wrp_shift signals that should only be connected to a specific set of design objects. These are known as object-specific signal definitions. Depending on the signal type, only certain design object types can be specified and certain signal usages are supported. For the different signal types and usages defined with the **-type** and **-usage** options, the allowed object types for the **-connect_to** option are:

- **-type ScanDataIn**
 - **pin** (ScanDataIn pins of CTL-modeled cores)
- **-type ScanDataOut**
 - **pin** (ScanDataOut pins of CTL-modeled cores)
- **-type ScanEnable -usage scan**
 - **cell** (leaf scan cells)
 - **cell** (hierarchical cell containing scan cells)
 - **design** (designs containing scan cells)
 - **clock** (scan cells clocked by specified clocks)
 - **pin** (ScanEnable pins of CTL-modeled cores)
- **-type ScanEnable | TestMode -usage clock_gating**
 - **cell** (clock-gating cells)
 - **cell** (hierarchical cell containing clock-gating cells)
 - **design** (designs containing clock-gating cells)
 - **clock** (test clocks gated by clock-gating cells)
 - **pin** (ScanEnable or TestMode pins of CTL-modeled cores)
- **-type wrp_shift | input_wrp_shift | output_wrp_shift**
 - **clock** (wrapper cells clocked by specified clocks)

For the **clock_gating** usage, you can specify ScanEnable or TestMode signal definitions, depending on the type of clock-gating control signal (scan-enable or test-mode) used by the specified objects.

Pins of CTL-modeled cores are not supported when performing simple HSS integration of standard scan cores.

When you specify a clock-domain-based signal specification by specifying clocks, they must be defined as valid test clocks with the **set_dft_signal** command. The propagation of the test clock determines the scope of the specification; the propagation of any underlying functional clocks at the clock source is not considered.

When using clock-domain-based signal specifications with CTL-modeled cores, the following requirements must be observed during core creation to ensure that the CTL models contain clock-domain information:

- Core-level ScanEnable signals must be defined using the **-usage** option of the **set_dft_signal** command. This ensures that the core's internal scan-enable signal is not used outside its intended usage.
- Core-level ScanEnable signals defined with a usage of **clock_gating** must also be defined as domain-specific signals using the **-connect_to clock_list** option of the **set_dft_signal** command. This ensures that clock-specific clock-gating annotations are included in the CTL model.

If the cores do not contain clock-domain information, you can directly specify the ScanEnable pins of the CTL-modeled core instead.

The following example defines two clock-domain-based ScanEnable signals:

```
set_dft_signal -view exist -type ScanClock -timing {45 55} \
  -port {CLK1 CLK2}

set_dft_signal -type ScanEnable -port SE1 -usage scan \
  -connect_to CLK1
set_dft_signal -type ScanEnable -port SE2 -usage scan \
  -connect_to CLK2
```

The following example defines a ScanEnable signal to be used only as the clock-gating control signal for a specific block:

```
set_dft_signal -type ScanEnable -port SE_CG_IP -usage clock_gating \
  -connect_to UIP_CORE
```

The **-connect_to** option is also used in the hierarchical on-chip clocking (OCC) flow to specify the correspondence between the top-level ATE clock port and the core-level ATE clock pins. For existing top-level connections, use the **-view existing** option. For connections to be made by DFT insertion, use the **-view spec** option. For example,

```
set_dft_signal -view spec -port TOP_CLK -type MasterClock \
  -connect_to {CORE1/ATECLK CORE2/ATECLK} -timing {45 55}
```

Clock-domain-based wrapper shift signals are supported only in the maximized reuse flow.

-connect_to_domain_rise clock_list

Specifies a clock-domain-based ScanEnable specification that applies only to rising-edge scan cells.

This option works the same as specifying a test clock with the **-connect_to** option, except that it applies only to scan cells clocked by the rising edge of the specified test clocks. It is valid only with **-type ScanEnable** and **-usage scan** options.

This option is not supported for wrapper shift signals.

-connect_to_domain_fall clock_list

Specifies a clock-domain-based ScanEnable specification that applies only to falling-edge scan cells.

This option works the same as specifying a test clock with the **-connect_to** option, except that it applies only to scan cells clocked by the falling edge of the specified test clocks. It is valid only with **-type ScanEnable** and **-usage scan** options.

This option is not supported for wrapper shift signals.

-usage use_type

Specifies the usage of the signal. You must also specify **-view spec** with this option. This option specifies that **insert_dft** is to use the specified signal for that purpose only.

The signal must be defined with suitable valid values when using it to connect design elements using the **set_dft_connect**

command. The valid values for *use_type* are as follows:

- **clock_gating** specifies that the signal is to be connected to the test pin of identified clock gating cells during **insert_dft**. This usage is valid only for **-type ScanEnable** and **-type TestMode**.

If clock-gating test pin connection is disabled by setting the **-connect_clock_gating** option of the **set_dft_configuration** command to **disable**, this signal is not used.

- **scan** specifies that the signal is to be connected to the enable of scan elements during **insert_dft**. This usage is valid only for **-type ScanEnable**.

Multiple usages can be specified for a signal by specifying them as a list. For example, a ScanEnable can be used to connect to test pins of clock gating cells as well as enabling scan elements.

For example,

```
set_dft_signal -view spec -port SE \
  -type ScanEnable -usage {scan clock_gating}
```

-associated_internal_clocks clock_pins_list

Specifies a list of internal pins associated to be associated with a clock source port.

The tool assumes that the port-driven clock signal is also driven at these internal pins, with the same timing waveform and polarity. The fanout from each internal clock pin is treated as a separate clock domain when architecting scan chains, and the pin names are shown as the clock names by the **preview_dft** and **insert_dft** commands.

Only leaf pins can be specified; hierarchical pins are not supported.

For example,

```
set_dft_signal -type ScanClock -port CLK \
  -associated_internal_clocks [list U1/int_clk U2/int_clk1 U1/int_clk2] \
  -view existing
```

During pre-DFT DRC, the tool does not check for logical connectivity between the port and internal clock pins. This provides a method to bypass black boxes or other logic with unknown functionality in the clock network.

The connectivity is checked in post-DFT DRC.

-associated_clock associated_clock

Specifies the pin or port name of a single clock that you want to associate with a specified scan-enable signal.

For example,

```
set_dft_signal -view spec -type ScanEnable \
  -port SE1 -associated_clock CLK1
```

This option is used only in a domain-based scan-enable flow, enabled by setting the **-domain_based_scan_enable** option of the **set_scan_configuration** command to **true**. If domain-based scan-enable signals are not enabled, this option is ignored.

When using this option, an **-associated_clock** specification must be issued for all scan clock domains that use scan-enable signals; otherwise, bad logic might result.

-exclude cell_list

Specifies a list of objects to be excluded from an object-specific DFT signal definition made with the **-connect_to**, **-connect_to_domain_rise**, or **-connect_to_domain_fall** option.

In some cases, an object-specific connection specification might require certain objects to be excluded, such as excluding specific leaf cells from a hierarchical block. In this case, you can specify the objects to exclude by using the **-exclude** option. The allowed object types for the **-exclude** option are:

- **-type ScanEnable -usage scan**
 - **cell** (leaf scan cells)

- **cell** (hierarchical cell containing scan cells)
- **design** (designs containing scan cells)
- **-type ScanEnable | TestMode -usage clock_gating**
 - **cell** (clock-gating cells)
 - **cell** (hierarchical cell containing clock-gating cells)
 - **design** (designs containing clock-gating cells)

This option excludes the specified objects from the current signal's specification, but it does not prevent those objects from being connected to other signals.

This option can only be used together with the **-connect_to**, **-connect_to_domain_rise**, or **-connect_to_domain_fall** option.

For example:

```
set_dft_signal -type ScanEnable -port SE1 -usage scan \
-connect_to {CLK1} -exclude UIP_BLOCK
```

-codec decompressor_name

Specifies the codec to be controlled by a signal defined with the **-type codec_enable** option. Reference the codec's decompressor using the *cell_name:decompressor_name* syntax.

By default, the tool chooses a codec for the signal to control.

DESCRIPTION

The **set_dft_signal** command can be used to specify one or more primary input or output ports as DFT signals. It can be used either to describe the existing usage or to prescribe the usage during implementation.

A DFT signal has a port and a signal type. You can specify multiple DFT signals, but you can specify only one signal type. Port directions must be consistent with the signal type.

You can use the **set_dft_signal** command to declare different DFT signals for different test modes. For example, each test mode can have different scan-in and scan-out ports, or different constant, set, or reset signals. However, all test modes share the same scan-enable signals. You cannot specify different scan-enable signals for different test modes.

The **set_dft_signal** commands are not incremental. A **set_dft_signal** command that identifies a port overwrites any previous **set_dft_signal** command that identifies the same port.

To review your DFT signal specifications, use the **report_dft_signal** command. To remove a specification, use the **remove_dft_signal** command. To implement the DFT signal, use the **insert_dft** command.

Descriptive specification (using **-view existing_dft**) will invalidate test protocol and details about DFT structures.

```
set_dft_drc_configuration(2)
write(2)
```

set_direct_power_rail_tie

Sets the **direct_power_rail_tie** attribute on library pins.

SYNTAX

```
int set_direct_power_rail_tie  
    lib_pin_list [true | false]
```

ARGUMENTS

lib_pin_list

A list of library pins on which the **direct_power_rail_tie** attribute is to be set. If more than one library pin name is specified, they must be enclosed either in quotes or in braces ({}). For more information about object names, refer to the **find** command manual page.

true | false

Specifies the value with which to set the **direct_power_rail_tie** attribute. The default is *true*.

DESCRIPTION

Sets the **direct_power_rail_tie** attribute on library pins. If a match is found, a **direct_power_rail_tie** attribute is assigned to the library_pin(s).

If the value of **direct_power_rail_tie** attribute on a library pin is true, then all the pins in the design, for which this is the library pin, it won't connect it to a tieoff cell for connecting it to constant signal. Instead, it will keep them connecting to generic constant signals, so that during power routing these pins can be connected directly to power rails.

To remove **direct_power_rail_tie** attribute, use **remove_attribute**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the all the **GND** pins of cells with the library cells **leaf_cell** won't be connected to tieoff cells to connect it to a constant signal.

```
prompt> set_direct_power_rail_tie target_lib/leaf_cell/GND
```

SEE ALSO

set_disable_clock_gating_check

Disables the clock-gating check for the specified objects in the current design.

SYNTAX

```
status set_disable_clock_gating_check  
    object_list
```

Data Types

object_list collection

ARGUMENTS

object_list

Specifies the cells and pins for which the clock-gating check is to be disabled.

DESCRIPTION

This command disables the clock-gating check for the specified cells and pins in the current design.

Any cell or pin in the current design or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*. Specify pins at lower levels in the design hierarchy as *instance1/instance2/cell_name/pin_name*.

For subdesigns in the hierarchy, specify instance names instead of design names.

When the clock-gating checking through a cell is disabled, all gating checks in the cell are disabled. When the checking through a pin is disabled, a gating check is disabled if it uses the disabled pin as a gating clock pin or a gating enable pin.

The **compile** command adjusts only the size of the cell by replacing it with other cells having the same logic function but with different drive capacity. No other logic transformations involving the clock-gating cell are permitted.

To restore the gating checks disabled by the **set_disable_clock_gating_check** command, use the **remove_disable_clock_gating_check** command.

Multicorner-Multimode Support

This command applies to all scenarios.

EXAMPLES

set_disable_clock_gating_check

2404

The following example disables clock-gating checks on the specified cell or pin:

```
prompt> set_disable_clock_gating_check an2/Z  
prompt> set_disable_clock_gating_check or1
```

SEE ALSO

[remove_disable_clock_gating_check\(2\)](#)

set_disable_timing

Disables timing arcs in the current design.

SYNTAX

```
status set_disable_timing  
    object_list  
    [-from from_pin_name -to to_pin_name]  
    [-restore]
```

Data Types

```
object_list    collection  
from_pin_name string  
to_pin_name   string
```

ARGUMENTS

object_list

Specifies the cells, pins, ports, library pins, or library cells through which timing is disabled. The specified cells or the cells of the specified pins are set to be size only to leave room to apply sizing on them.

-from *from_pin_name*

Specifies that only arcs from this pin on the specified cell are disabled.

This option must be used with the **-to** option.

If you use the **-from** and **-to** options, the *object_list* argument must contain only cells.

-to *to_pin_name*

Specifies that only arcs to this pin on the specified cell are disabled.

This option must be used with the **-from** option.

If you use the **-from** and **-to** options, the *object_list* argument must contain only cells.

-restore

Restores the specified arcs so that they are no longer disabled.

DESCRIPTION

The **set_disable_timing** command disables timing through the specified cells, pins, or ports in the current design.

Any cell, pin, or port in the current design or its subdesigns can be disabled. Cells at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name*. Pins at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/pin_name*. Ports at lower levels in the design hierarchy are specified as *instance1/instance2/cell_name/port_name*.

Library pins and library cells can also be disabled.

Note: For subdesigns in the hierarchy, you must specify instance names instead of design names.

When the timing through a cell is disabled, only those cell arcs that lead to the output pins of the cell are disabled. When the timing through a pin or port is disabled, only those cell arcs that lead to or from that pin or port are disabled.

When the **-from** and **-to** options are specified, all arcs between these pins on the cell are disabled.

Use the **report_lib -timing_arcs** command to list the timing arcs for a library cell, and the **report_design** command to list the disabled arcs in the current design.

To enable the disabled cells, pins, or ports, use the **set_disable_timing -restore** or **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

In the following example, all timing arcs are disabled that lead to output pins of cells U2 and U3 of the current design.

```
prompt> set_disable_timing {U2 U3}
```

In the following example, all timing arcs that lead to output pin Z of cell U5 in the current design are disabled.

```
prompt> set_disable_timing U5/Z
```

In the following example, all timing arcs between pins A and Z on cell U1/U1 in the current design are disabled.

```
prompt> set_disable_timing U1/U1 -from A -to Z
```

In the following example, all timing arcs between pins D and Q on cell FD1 in the library my_lib are disabled. This command disables arcs on a library cell; therefore, all instances of that library cell are affected in any design linked to the same library.

```
prompt> set_disable_timing my_lib/FD1 -from D -to Q
```

set_domain_supply_net

Sets the primary power net and primary ground net of an already existing power domain.

SYNTAX

```
status set_domain_supply_net
domain_name
-primary_power_net supply_net_name
-primary_ground_net supply_net_name
```

Data Types

<i>domain_name</i>	string
<i>supply_net_name</i>	string

ARGUMENTS

domain_name

Specify the name of the power domain.

If a power domain with the specified name does not exist, in the current scope, this command fails.

The *domain_name* option is a required option and must be specified.

-primary_power_net *supply_net_name*

Specify the power net of the power domain.

If a supply net with the specified name does not exist in the current scope, the command fails. If the supply net is not associated with specified power domain, the command fails.

This is a required option and must be specified.

-primary_ground_net *supply_net_name*

Specify the ground net of the power domain.

If a ground net with the specified name does not exist in the current scope, the command fails. If the ground net is not associated with specified power domain, the command fails.

This is a required option and must be specified.

DESCRIPTION

The *set_domain_supply_net* command enables you to set the primary power net and the primary ground net of a power domain. All extent of the power domain shares the same power/ground supply until explicitly excluded. Here "explicitly excluded" means it is

explicitly connected with another supply_net (non primary power/ground supply_net) by command `connect_supply_net`. This command errors out if power domain already has a primary power and ground net.

The supply_net must be created in the same power_domain at first before it could be set as the primary power or ground supply_net. Use command `create_supply_net` to create a supply_net at a specified power_domain.

This command cannot be used to specify the supply nets of a power domain which was created using the `-supply {primary ..}` argument.

Command returns 1 on success, returns 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates two supply nets on power_domain PD1, and then sets them as a primary power or ground net.

```
prompt> create_power_domain PD1 -elements INST_1  
PD1  
prompt> create_supply_net A_VDD -domain PD1  
A_VDD

set_dont_retime

Sets the **dont_retime** attribute on cells and designs in the current design to prevent sequential cells from being moved by retiming optimizations.

SYNTAX

```
int set_dont_retime  
    object_list  
    [true | false]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies list of objects (cells or designs) on which the **dont_retime** attribute is to be set, so that the cells themselves (if they are sequential cells) or the sequential child cells of designs or hierarchical cells will not be moved by retiming optimizations, if the effective attribute value is true.

true | false

Specifies the value with which to set the **dont_retime** attribute. The default is **true**.

DESCRIPTION

This command sets the **dont_retime** attribute on cells, and designs in \ the current design to prevent moving of sequential cells during retiming optimizations. Setting the **dont_retime** attribute on a hierarchical cell implies "dont_retime" on all sequential cells below it that do not have **dont_retime** set to a **false** value. Setting the **dont_retime** attribute on a leaf level cell implies "dont_retime" on the cell, if it is a sequential cell. Setting the **dont_retime** attribute on a design implies "dont_retime" on all sequential cells inside that do not have **dont_retime** set to a **false** value. **dont_retime** attributes set on child cells or designs have preference over **dont_retime** attributes set on any ancestor cell or design. **dont_retime** attributes set on hierarchical cells that are instances of a design have preference over **dont_retime** attributes set on the design itself.

You can see the **dont_retime** value explicitly on cells or designs by using the **report_cell**, **report_design** or **report_attribute** command.

To remove the **dont_retime** attribute, use **remove_attribute**.

EXAMPLES

The following example specifies that the cells named *z1_reg* and *z2_reg* are not to be modified during compile.

```
prompt> set_dont_retime [get_cells {z1_reg z2_reg}] true
```

The following example specifies that the cell named *H1/z_reg* can be moved during retiming, but any other sequential cell inside cell *H1* cannot be moved.

```
prompt> set_dont_retime [get_cells "H1"] true
prompt> set_dont_retime [get_cells "H1/z_reg"] false
```

The following example specifies that no sequential cells inside any instance of design *Controller* may be moved by retiming optimizations.

```
prompt> set_dont_retime find [get_designs "Controller"] true
```

`balance_registers(2)`

set_dont_touch

Sets the **dont_touch** attribute on cells, nets, references, and designs in the current design, and on library cells, to prevent modification or replacement of these objects during optimization.

SYNTAX

```
status set_dont_touch
  object_list
  [true | false]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies list of objects (cells, nets, references, designs, and library cells) on which the **dont_touch** attribute is to be set, so that the objects will not be modified or replaced. If more than one object name is specified, each name must be enclosed in quotation marks (" ") or braces ({}).

true | false

Specifies the value with which to set the **dont_touch** attribute. The default is **true**.

DESCRIPTION

This command sets the **dont_touch** attribute on cells, nets, references, designs in the current design, and on library cells, to prevent modification or replacement of these objects during optimization.

Setting the **dont_touch** attribute on a hierarchical cell implies "dont_touch" on all cells below it that do not have **dont_touch** set to **false**.

Setting the **dont_touch** attribute on a library cell implies "dont_touch" on all instances of that cell. Setting the **dont_touch** attribute on a net implies "dont_touch" only on mapped combinational cells connected to that net. All mapped combinational cells connected to the net must be at the same level of hierarchy.

Note that if the **enable_keep_signal_dt_net** variable is set to **true**, a different mechanism is used to preserve a dont_touch net. See the **enable_keep_signal_dt_net** man page for more information.

Setting the **dont_touch** attribute on a reference implies "dont_touch" on all cells of that reference during subsequent optimizations of the design.

Setting the **dont_touch** attribute on a design has an effect only when the design is instantiated within another design as a level of hierarchy. In this case, "dont_touch" on the design implies that all cells under that level of hierarchy are "dont_touch." Setting

dont_touch on the top-level design has no effect because it is not instantiated within any other design.

Note the following information:

- The **dont_touch** attribute is ignored on nets that have unmapped cells on them.
- The **dont_touch** attribute applied by the tool on the cells and nets in the transitive fanout of **dont_touch_network** objects overrides the **false dont_touch** attribute value that is set by the **set_dont_touch** command. You can see the **dont_touch** value on cells or nets by using the **report_cell** or **report_net** command.
- Setting the **dont_touch** attribute on unmapped cells in Design Compiler topographical mode causes the **compile_ultra** command to fail during execution.
- Setting the **dont_touch** attribute on selectops and their control logic is not supported if this logic resides at the top level of the design.
- A **dont_touch** attribute on a clock gating cell or its parent hierarchical cell will prevent clock gating optimizations from removing or modifying it.
- The **dont_touch** attribute should be removed by **remove_attribute** command. It is not equivalent to **set_dont_touch** to false which will have its meaning depending on the context. E.g. its parent has **set_dont_touch** is true. In the DC Explorer flow, **set_dont_touch** to false on a cell will be ignored if none of the cell's parent has **dont_touch** set to true. In this case, the cell may be optimized away during compile. If the cell does not get optimized away during compile, the **dont_touch** false attribute may still be lost after compile.

The **dont_touch** attribute affects DFT insertion as follows:

- The **dont_touch** attribute indirectly affects DFT insertion by preventing the cell type from being changed. It is ignored for scan stitching, test signal routing, logic insertion. It is also ignored when an identified shift register is split by the scan architect; the head scan flip-flops of any new shift register segments are scan-replaced even if they have the **dont_touchfP attribute applied**.
- A **dont_touch** attribute applied to a nonscan sequential cell keeps the cell as a nonscan cell. It will not be scan-replaced or stitched into scan chains. However, nonscan cells identified as shift register elements can be stitched into scan chains.
- A **dont_touch** attribute applied to a test-ready (scan-replaced) sequential cell keeps the cell as a scan-replaced cell. If the cell is a valid scan cell, it will be stitched into scan chains. If not (due to DRC violations or other directives such as **set_scan_element false**), it will remain as an unstitched test-ready cell.

When an object name is specified, the **set_dont_touch** command first looks within the current design for a cell that matches that name. If it finds a match, a **dont_touch** attribute is assigned to that cell. If no match is found, the command next looks within the current design for a net that matches the specified name. If a match is found, a **dont_touch** attribute is assigned to that net. If no match is found, the command next looks for a reference, then a design in the system, and finally for a library cell in the system. The tool assigns a **dont_touch** attribute to the first object for which it finds a match.

To remove the **dont_touch** attribute, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that the cells named *block1* and *analog1* are not to be modified during optimization:

```
prompt> set_dont_touch [get_cells {block1 analog1}]
```

The following example specifies the removal of the **dont_touch** attribute from the cell named *block1*:

```
prompt> remove_attribute [get_cells block1] dont_touch
```

The following example specifies that the net named *N1* is not to be modified during optimization:

```
prompt> set_dont_touch [get_nets N1] true
```

```

set_dont_touch_network

Sets the **dont_touch_network** attribute on clocks, pins, or ports in the current design to prevent cells and nets in the transitive fanout of the **set_dont_touch_network** objects from being modified or replaced during optimization.

SYNTAX

```
status set_dont_touch_network  
    objects  
    [-no_propagate]
```

Data Types

objects collection

ARGUMENTS

objects

Specifies the clocks, pins, or ports in the current design on which to set the **dont_touch_network** attribute. If you include more than one object, they must be enclosed in either quotation marks or braces ({}).

-no_propagate

Indicates that the dont_touch network is not propagated through logic gates.

DESCRIPTION

This command sets the **dont_touch_network** attribute on clocks, pins, or ports in the current design. When a design is optimized, the tool assigns **dont_touch** attributes to all cells and nets in the transitive fanout of the **dont_touch_network** objects so that they are not modified or replaced during optimization. A **dont_touch** attribute assigned by the tool using the **set_dont_touch_network** command overrides the **false dont_touch** attribute value from the **set_dont_touch** command.

If you specify a pin or a port, all nets and cells in its transitive fanout are recursively marked **dont_touch**. This recursion propagates through combinational cells but stops at registers (without marking the registers as **dont_touch**). An element is recognized as a register only if it has setup or hold constraints. If you specify an input pin, its own cell is marked **dont_touch** but its connected net is not marked **dont_touch**. If you specify an output pin, its own cell is not marked **dont_touch** but its connected net is marked **dont_touch**.

If you specify a clock, the transitive fanout of all the clock's sources is affected. The **set_dont_touch_network** command is intended primarily for clock circuitry. Placing a **dont_touch_network** on a clock object prevents the tool from modifying the clock buffer network during optimization.

The **set_dont_touch_network** command does not prevent clock gating optimizations from modifying or removing clock gating cells. To prevent this, use the **set_dont_touch** command instead.

If you specify the **-no_propagate** option, the dont_touch network is not propagated through logic gates. These logic gates are marked

as size_only.

To see the **dont_touch** value on the cells or nets, use the **report_cell** or **report_net** command. The **report_net** command displays the nets that are implicitly **dont_touch** as a result of using the **set_dont_touch_network** command. You can also use the **report_dont_touch** command to report the cells and nets with implicit **dont_touch** attributes.

Note that the **dont_touch_network** attribute does not prevent compile from mapping unmapped logic (for example, cells read in from an HDL description).

To remove the **dont_touch_network** attribute, use the **remove_attribute** command on the specific object on which the **dont_touch_network** attribute has been set.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command adds the **dont_touch_network** attribute to a port named `clock_in`:

```
prompt> set_dont_touch_network clock_in
```

The following command removes the **dont_touch_network** attribute from the port named `clock_in`:

```
prompt> remove_attribute [get_port clock_in] dont_touch_network
```

The following command adds the **dont_touch_network** attribute to a net named `net1` and a cell named `cell2` but not to the cell named `cell1`:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y cell2/A}
prompt> set_dont_touch_network [get_pins cell1/Y]
1
```

The following command adds the **dont_touch_network** attribute to a net named `net1` and cells named `cell1` and `cell2` but not on the net named `net0`:

```
prompt> get_pins -of_objects [get_nets net1]
{cell1/Y cell2/A}
prompt> get_pins -of_objects [get_cells cell1]
{cell1/A cell1/Y}
prompt> get_nets -of_objects [get_pins cell1/A]
{net0}
prompt> set_dont_touch_network [get_pins cell1/A]
1
```

set_dont_use

Sets the **dont_use** attribute on library cells, modules, and implementations. Library objects with the **dont_use** attribute are excluded from the target library during optimization.

In addition, if you optimize a design that contains cell instances that are mapped to standard cells in the target library that have the **dont_use** attribute, those cell instances are remapped to equivalent standard cells from the target library that do not have the **dont_use** attribute.

SYNTAX

```
status set_dont_use
  [-power]
  object_list
```

Data Types

object_list list

ARGUMENTS

-power

Specifies that the specified objects should not be considered for clock-gate mapping in addition to excluding them from the target library.

By default, the objects are excluded from the target library, but are still available for clock-gate mapping.

object_list

Specifies the objects (library cells, modules, or implementations) on which to set the **dont_use** attribute.

The specified objects must be in one of the target libraries or in a library already loaded into the tool and the object names must include the library prefix. If you specify more than one object, they must be enclosed in quotes or braces ({}).

DESCRIPTION

Sets the **dont_use** attribute on the specified library objects, so that they are not used during optimization.

In addition, if you optimize a design that contains cell instances that are mapped to standard cells in the target library that have the **dont_use** attribute, those cell instances are remapped to equivalent standard cells from the target library that do not have the **dont_use** attribute.

If you use the **-power** option, the **pwr_cg_dont_use** attribute is also set on the specified objects. When this attribute is present on an object, it is not considered for clock-gate mapping.

NOTE:

This command affects only the copy of the library that is currently loaded into memory, and has no effect on the version that exists on disk. However, if the library is written out by using the **write_lib** command, any **dont_use** attributes are written out, which causes the library objects to be permanently disabled.

To remove **dont_use** attributes, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command disables the library cells named G1 and G2 in the tech_lib library:

```
prompt> set_dont_use {tech_lib/G1 tech_lib/G2}
```

The following command disables the implementations named imp1 and imp2 in the syn_lib/mod module:

```
prompt> set_dont_use {syn_lib/mod/imp1 syn_lib/mod/imp2}
```

The following command removes the library cells named icg_1 and icg_2 from the list of integrated clock gating cells available for clock-gate mapping.

```
prompt> set_dont_use -power {tech_lib/icg_1 tech_lib/icg_2}
```

[report_lib\(2\)](#)
[target_library\(3\)](#)

set_dp_int_round

Sets the rounding positions on the inferred multiplier and the multiplier-based instantiated DesignWare cells.

SYNTAX

```
status set_dp_int_round
  cell_list
  external_rounding_position
  [internal_rounding_position]
```

Data Types

<i>cell_list</i>	<i>object_list</i>
<i>external_rounding_position</i>	int
<i>internal_rounding_position</i>	int

ARGUMENTS

cell_list

Sets the rounding and internal rounding position on the specified cells.

external_rounding_position

Sets the bit position for external rounding.

internal_rounding_position

Sets the bit position for internal rounding.

DESCRIPTION

This command specifies the external and internal rounding positions (IR) on the inferred multiplier and the multiplier-based instantiated DesignWare cells.

The supported cells are: MULT_UNS_OP and MULT_TC_OP operators and the following DesignWare components: DW02_mult, DW_mult_uns, DW_mult_tc, DW_square, DW02_prod_sum, DW02_prod_sum1, DW_prod_sum_uns, DW_prod_sum_tc, DW02_mac, DW_mac_tc, DW_mac_uns, DW02_multp, DW_squarep, and DW02_tree.

Internal rounding allows a tradeoff between precision and area in arithmetic circuits. All bits lower than the internal rounding position are discarded from the internal addends. Area is saved because no logic is required to generate and add these bits. However, a rounding error is introduced, which degrades the precision of the result. An offset is automatically added to keep the error range as symmetric and the bias as small as possible.

The result of a datapath with internal rounding is usually truncated somewhere above the internal rounding position. This truncation can also be rounded by setting the external rounding position to this bit position. Rounding is achieved by adding a constant 1 at the

next lower bit position.

Internal rounding changes the functionality of a datapath block or a multiplier-like DesignWare design. Use of this command results in a design that has functional differences from the original design. Comparison of the original design with the resulting netlist will show differences in formal equivalence checking tools.

A rounding error report is printed with the **report_resources** command.

To remove the rounding attribute, use the **remove_dp_int_round** command.

A few notes about using this command:

1. The tool only supports internal rounding on generated implementations. Therefore, if you use **set_implementation** on the non-generated implementation for a instantiated DesignWare cell, the internal rounding does not happen.
2. Multipliers with internal rounding will not be extracted, merged or shared.
3. All inferred multipliers driving a common output will use the same internal rounding information. If the internal rounding values are different among those multipliers, the minimum rounding positions will be used for each multiplier. If the shared multipliers include a multiplier with a set rounding position, and other multipliers with no internal rounding information, all multipliers will use the minimum of the set rounding positions.
4. An internal rounding setting of 0 for both the external and internal rounding position has meaning. It forces that operation to use exact precision; the output of the operation will not be rounded.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the external rounding position on cell mult_6 to 7 and the internal rounding position to 5:

```
prompt> set_dp_int_round mult_6 7 5
Setting rounding position 7, internal rounding position 5 on: mult_6
1
```

The **report_resources** command reports the rounding errors.

```
prompt> report_resources
...
DesignWare rounding error report in design mult_inst_DW_mult_uns_1(cell mult_6):
Rounding Error Report for product[15:0]
```

Rounding	to Bit	Relative Error			Absolute Error		
		Min	Max	Avg	Min	Max	Avg
Internal	5	-3.00	2.00	-0.50	-96	64	-16
External	7	-0.75	0.50	-0.12	-96	64	-16
Total	7	-0.50	0.49	-0.00	-64	63	-0.5
		-1.25	0.99	-0.13	-160	127	-16.5

The behavioral Verilog file has extension .bvr1 and is found in the dwsvf_* directory.

```
prompt> ls dwsvf_*
mult_inst_DW_mult_uns_1.round.bvr1
```

The following example sets the external rounding position on a multiplier mult_8. The **report_resources** command shows the original IR settings.

```
prompt> set_dp_int_round [find cell mult_8] 5
Setting rounding position 5, internal rounding position 5 on: mult_8
1
```

The **report_resources** command reports the rounding settings and errors.

```
prompt> report_resources
...
DW rounding error report in design test_DW_mult_uns_0(cell mult_x_8_1):
Rounding Error Report for product[11:0]

[-tp_opt_tree auto | true | false]
[-tp_oper_sel auto | true | false]
[-smart_compare auto | true | false]
[-optimize_for default | area | speed | area,speed]
[-power_effort off | auto | medium | high]
[-mult_arch auto | and | nand | and_radix4 | nand_radix4 | benc_radix4 | benc_radix8 | benc_radix4_mux | benc_radix8_mux]
[-hierarchy]
[design or cell list]
```

ARGUMENTS

-all_options auto | true | false | default

Specifies the default value for all smart generation options. Use this option with other options to provide a specific value to one option and default values to other options.

The **-all_options** argument also accepts the **default** value. This value sets all smart generation options to their defaults.

The **set_dp_smartgen_options** command always processes the value of the **-all_options** option before any other options.

-booth_encoding auto | true | false

Controls the usage of Booth-encoding architectures to implement multipliers.

When set to **auto**, the default, the tool uses the option only if there is a QoR benefit. When you set the **-booth_encoding** option to **true**, the tool always uses the option. When you set the **-booth_encoding** option to **false**, the tool never uses the option.

-booth_radix8 auto | true | false

Controls the usage of radix-8 Booth-encoding architectures to implement multipliers. This option is active only if the **-booth_encoding** option is set to **auto** or **true**.

When you set the **-booth_radix8** option to **auto**, the default, the tool uses the **-booth_radix8** option only if there is a QoR benefit. The tool always uses the **-booth_radix8** option when it is set to **true** and never uses the **-booth_radix8** option when it is set to **false**.

-booth_mux_based auto | true | false

Controls the usage of MUX-based Booth encoding. MUX-based encoding provides better QoR for technologies with fast multiplexer cells. Otherwise, the tool uses XOP-based Booth encoding.

When you set the **-booth_mux_based** option to **auto**, the default, the tool uses the option only used if it determines there is a QoR benefit. When you set the **-booth_mux_based** option to **true**, the tool always uses the option. When you set the **-booth_mux_based** option to **false**, the tool never uses the option.

-booth_cell auto | true | false

Controls the usage of special Booth multiplier cells in the target library for compilation.

When you set the **-booth_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-booth_cell** option to **true**, the tool always uses the option. When you set the **-booth_cell** option to **false**, the tool never uses the option.

-mult_radix4 auto | true | false

Controls the use of radix-4 non-Booth architectures to implement multipliers. This option cannot be used if the **-booth_encoding** option is set to **true**. The **-booth_encoding** option must be inactive (set to **auto** or **false**).

When you set the **-mult_radix4** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-mult_radix4** option to **true**, the tool always uses the option. When you set the **-mult_radix4** option to **false**, the tool never uses the option. This option is only available in the DesignWare minPower flow.

-mult_nand_based auto | true | false

Controls the usage of NAND-based multiplier structures. Non-Booth multipliers use AND gates or anINVERT-NOR structure to generate the partial-product bits. This option allows you to use the NAND gates to produce inverted bits that you can add directly. This can result in lower dynamic power and lesser glitches.

When you set the **-mult_nand_based** option to **auto**, the default, the tool uses the option only when the minPower flow is enabled and if it determines there is a QoR benefit. When you set the **-mult_nand_based** option to **true**, the tool always uses the option. When you set the **-mult_nand_based** option to **false**, the tool never uses the option. The option has no effect when you use Booth encoding in multipliers.

-inv_out_adder_cell auto | true | false

Controls the usage of full-adder cells with inverted sum-and-carry outputs in the target library for compilation.

When you set the **-inv_out_adder_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-inv_out_adder_cell** option to **true**, the tool always uses the option. When you set the **-inv_out_adder_cell** option to **false**, the tool never uses the option.

-4to2_compressor_cell auto | true | false

Controls the usage of 4-2 compressor cells in the target library for compilation.

When you set the **-4to2_compressor_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-4to2_compressor_cell** option to **true**, the tool always uses the option. When you set the **-4to2_compressor_cell** option to **false**, the tool never uses the option.

-adder_radix auto | 2 | 3 | 4

Controls the radix of the prefix structure in adders. Most adder architectures use a parallel-prefix structure to propagate carries. The default prefix structure has radix 2 (combines 2 bits per prefix node). Radix 3 and 4 (combine 3 or 4 bits per prefix node) result in fewer, but more complex prefix nodes. They can deliver better QoR if special cells are available in the technology to implement them.

When you set the **-adder_radix** option to **auto**, the tool automatically selects the optimal radix for best QoR. When you set the **-adder_radix** option to **2**, **3**, or **4**, the tool sets the radix accordingly. The default is **2**.

-ling_adder auto | true | false

Controls the usage of Ling adder architectures.

When you set the **-ling_adder** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-ling_adder** option to **true**, the tool always uses the option. When you set the **-ling_adder** option to **false**, the tool never uses the option.

-hybrid_adder auto | true | false

Controls the usage of hybrid parallel-prefix or carry-select adder architectures (spanning-tree adders).

When you set the **-hybrid_adder** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-hybrid_adder** option to **true**, the tool always uses the option. When you set the **-hybrid_adder** option to **false**, the tool never uses the option.

-carry_select_adder_cell auto | true | false

Controls the usage of carry-select adder cells in the target library for compilation.

When you set the **-carry_select_adder_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-carry_select_adder_cell** option to **true**, the tool always uses the option. When you set the **-carry_select_adder_cell** option to **false**, the tool never uses the option.

-cond_sum_adder auto | true | false

Controls the usage of conditional-sum adder architectures.

When you set the **-cond_sum_adder** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-cond_sum_adder** option to **true**, the tool always uses the option. When you set the **-cond_sum_adder** option to **false**, the tool never uses the option.

-sklansky_adder auto | true | false

Controls the usage of Sklansky parallel-prefix adder architectures. This is a static architecture that is not optimized for context. It usually results in QoR degradation, but it can be more predictable.

When you set the **-sklansky_adder** option to **auto**, the tool uses the option only if it determines there is a QoR benefit. When you set the **-sklansky_adder** option to **true**, the tool always uses the option. When you set the **-sklansky_adder** option to **false**, the default, the tool never uses the option.

-brent_kung_adder auto | true | false

Controls the usage of Brent-Kung parallel-prefix adder architectures. This is a static architecture that is not optimized for context. It usually degrades QoR, though it is more predictable.

When you set the **-brent_kung_adder** option to **auto**, the tool uses the option only if it determines there is a QoR benefit. When you set the **-brent_kung_adder** option to **true**, the tool always uses the option. When you set the **-brent_kung_adder** option to **false**, the default, the tool never uses the option.

-bounded_fanout_adder auto | true | false

Controls the usage of bounded fanout adder architectures (Kogge-Stone parallel-prefix architectures).

When you set the **-bounded_fanout_adder** option to **auto**, the tool uses the option only if it determines there is a QoR benefit. When you set the **-bounded_fanout_adder** option to **true**, the tool always uses the option. When you set the **-bounded_fanout_adder** option to **false**, the default, the tool never uses the option.

-mux_based auto | true | false

Controls the usage of MUX-based architectures by datapath generators.

When you set the **-mux_based** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-mux_based** option to **true**, the tool always uses the option. When you set the **-mux_based** option to **false**, the tool never uses the option.

-inv_adder_cell auto | true | false

Controls the usage of full adder cells with inverted carry-in or carry-out in the target library for compilation.

When you set the **-inv_adder_cell** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-inv_adder_cell** option to **true**, the tool always uses the option. When you set the **-inv_adder_cell** option to **false**, the tool never uses the option.

-sop2pos_transformation auto | true | false

Controls the usage of "sop to pos" optimization strategies in datapath blocks. An example of a "sop 2 pos" transformation is as follows:

$$a*b + a*c \rightarrow (b + c) * a$$

This optimization can improve design area, at the cost of delay.

When you set the **-sop2pos_transformation** option to **auto**, the default, the tool uses the option only if it determines there is a QoR benefit. When you set the **-sop2pos_transformation** option to **true**, the tool always uses the option. When you set the **-sop2pos_transformation** option to **false**, the tool never uses the option.

-tp_opt_tree auto | true | false

Controls the usage of carry-save adder tree for low power optimization based on transition probabilities (TP). This optimization reduces internal switching activity and therefore the dynamic power in SOPs when the inputs have a non-uniform transition probability distribution.

When you set the **-tp_opt_tree** option to **auto**, the default, the tool uses the option only if it determines a QoR benefit and optimized dynamic power. When you set the **-tp_opt_tree** option to **true**, the tool always uses the option if dynamic power is optimized. When you set the **-tp_opt_tree** option to **false**, the tool never uses the option.

-tp_oper_sel auto | true | false

Controls the selection or ordering of multiplier input operands for low power based on transition probability (TP). This optimization can reduce internal switching activity and therefore dynamic power in booth multipliers when the inputs have significantly different transition probabilities.

When you set the **-tp_oper_sel** option to **auto**, the default, the tool uses the option only if it determines a QoR benefit and optimized dynamic power. When you set the **-tp_oper_sel** option to **true**, the tool always uses the option if dynamic power is optimized. When you set the **-tp_oper_sel** option to **false**, the tool never uses the option. The option only affects multipliers with booth encoding.

-smart_compare auto | true | false

Controls the ordering of comparator inputs for better timing. Depending on the logic depth of the comparator logic, an inverter is required at the output. Flipping the inputs eliminates the need for the inverter and shortens the critical path.

When you set the **-smart_compare** option to **auto**, the default, or **true**, the tool uses the option only if it determines a QoR benefit. When you set the **-smart_compare** option to **false**, the tool never uses the option.

-optimize_for default | area | speed | area,speed

Supplies a specific optimization goal for the specified cells. This option overrides the default optimization goals for the specified cell or cells.

-power_effort off | auto | medium | high

Supplies a specific power optimization goal for the specified cells. This option takes effect in the DesignWare minPower flow. It guides the generator on power optimization. When the effort is **off**, the generator does not optimize the netlist for power. When the effort is **medium**, the generator sacrifices delay for power optimization. When the effort is **high**, the generator sacrifices more delay for power.

When you set the power effort to **medium** or **high**, the tool calculates the delay or power tradeoff on the generated netlist. After the generated design is ungrouped, Design Compiler might recover the timing and give back the power gain. Therefore, the power savings from **medium** and **high** effort is not guaranteed. The delay or power tradeoff feature is most useful for designs that can meet the timing constraint. Note: DC Explorer does not support this option.

-mult_arch auto | and | nand | and_radix4 | nand_radix4 | benc_radix4 | benc_radix8 | benc_radix4_mux | benc_radix8_mux

Specifies the multiplier architecture to be implemented. This option is a concise representation for a subset of six smart generation options.

The different **-mult_arch** options translates to the following combinations of smart generation settings: **and**: AND-based non-booth architecture -booth_encoding false -mult_radix4 false -mult_nand_based false **nand**: NAND-based non-booth architecture -booth_encoding false -mult_radix4 false -mult_nand_based true **and_radix4**: AND-based radix-4 non-booth architecture -booth_encoding false -mult_radix4 true -mult_nand_based false **nand_radix4**: NAND-based radix-4 non-booth architecture -booth_encoding false -mult_radix4 true -mult_nand_based true **benc_radix4**: radix-4 booth architecture -booth_encoding true -booth_radix8 false -booth_mux_based false **benc_radix8**: radix-8 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based false **benc_radix4_mux**: MUX-based radix-4 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based true **benc_radix8_mux**: MUX-based radix-8 booth architecture -booth_encoding true -booth_radix8 true -booth_mux_based true

When combined with other smart generation options related to multiplier architecture, the **-mult_arch** option takes precedence. For example, the following command sets the **-booth_encoding** option to **true**: prompt> **set_dp_smartgen_options -mult_arch benc_radix8 -booth_encoding false**

Note: The **-mult_radix4** option, when used either individually or with the **-mult_arch** option, is available only when you enable the minPower flow. If the minPower flow is not enabled, the tool drops the **-mult_radix4** option when you run the **compile_ultra** command.

-hierarchy

By default, when the smart generation options are specified on a design or a hierarchical cell, the specified options are only applied to the current level of hierarchy of the specified objects. When this option is specified, the command automatically applies the smart generation options on all the child instances of the specified objects.

design or cell list

An optional list of cells and designs. When present, the switch settings in this command affect only the specified objects.

If you set conflict smart generation options on a design and an instance that instantiates this design, you get a warning message. The setting on the instance is used by the generator.

DESCRIPTION

The **set_dp_smartgen_options** command controls smart generation strategies used in datapath synthesis.

The default value for all smart generation strategies is **auto**. By default, the best strategies are automatically chosen based on the given design constraints.

When the smart generation options are specified without an object list, the specified options are automatically applied to the entire design through all level of hierarchy regardless of the use of **-hierarchy** option. When the smart generation options are specified with an object list, the specified options are applied only on the specified objects. The object can be a design, a hierarchical cell, or a synthetic operator. The options do not take effect when they are applied on the generic GTECH cell or the cell that is already mapped to the technology library.

When the options are applied on a synthetic operator, most options take effect only when the operator is not extracted into a DP_OP cell. When the operator is extracted into DP_OP cell, only the **-optimize_for** option and the options that control multiplier architecture (**-mult_arch**, **-booth_encoding**, **-booth_radix8**, **-booth_mux_based**, **-booth_cell**, **-mult_radix4**, and **-mult_nand_based**) will be inherited to the DP_OP cell. When the options are copied to the DP_OP cell, the options are applied on all operators within the same DP_OP cell.

When synthetic operators with different option values are extracted into a DP_OP cell, the DP_OP cell takes the option value based on the following priority: For the **-optimize_for** option, the option value **speed** has the highest priority, **area,speed** is the next, and **area** has the lowest priority. For the options that control multiplier architectures, the option value **true** has the highest priority. **false** is the

next, and **auto** has the lowest priority.

The synthetic operators could go through multiple complex transformations during compile_ultra. For example, two operators may be shared at the beginning and unshared later depending on the design constraints. When the synthetic operator with the smart generation options go through such transformations, it is possible that the initial option setting is not preserved. Pay attention to the SYNOPT messages in the log file. The message is generated when the smart generation options on the synthetic operators are changed during compile_ultra.

When you specify the multiple smart generation options on the same object, all options must be set by a single command, except the **-optimize_for** and **-power_effort** options. Only the **-optimize_for** and **-power_effort** options can be set using a separate **set_dp_smartgen_options** command.

When the smart generation options are specified on the object that already has other smart generation options, the options set by the previous command are removed, and only the options set by the new command are applied. The following example removes the **-mult_arch** option from the U1 cell and apply only the **-4to2_compressor** option: prompt> **set_dp_smartgen_options -mult_arch benc_radix4 [get_cells U1]** prompt> **set_dp_smartgen_options -4to2_compressor_cell true [get_cells U1]** Warning: Overriding the settings from the previous **set_dp_smartgen_options** command on U1. (UISN-84)

All options are applied on the U1 cell in the following example: prompt> **set_dp_smartgen_options -mult_arch benc_radix4 -4to2_compressor_cell true [get_cells U1]** prompt> **set_dp_smartgen_options -optimize_for speed [get_cells U1]** prompt> **set_dp_smartgen_options -power_effort high [get_cells U1]**

The option values set by **set_dp_smartgen_options** command are listed in the datapath optimization report by **report_resources** command.

EXAMPLES

The following example uses **set_dp_smartgen_options** to control the usage of booth encoded architectures when generating multipliers.

```
prompt> set_dp_smartgen_options -booth_encoding true
```

The following example sets all the options to **auto**, except for **-booth_encoding**, which is set to **true** and overrides the value of **-all_options**:

```
set_dp_smartgen_options -all_options auto -booth_encoding true
```

SEE ALSO

[report_dp_smartgen_options\(2\)](#)

set_drive

Sets the **rise_drive** or **fall_drive** attributes to the specified resistance values on the specified input and inout ports.

SYNTAX

```
status set_drive
  resistance
  [-rise] [-fall] [-min] [-max]
  port_list
```

Data Types

```
resistance float
port_list list
```

ARGUMENTS

resistance

Specifies a nonnegative resistance value to which the **rise_drive** or **fall_drive** attributes are to be set on the ports in *port_list*. The *resistance* is the output resistance of the cell that drives the port, such that a higher drive strength (resistance) means less drive capability and longer delays. Thus, a *resistance* of 0 is infinite drive, or no delay between the ports and all that is connected to them. The *resistance* must be in unit consistent with the technology library used during optimization.

-rise -fall

Indicates that the **rise_drive** or **fall_drive** attributes of *port_list* are to be set to *resistance*. If you don't specify either, both are set to *resistance*.

-min -max

Indicates that the drive strength is to be applied for minimum or maximum delay analysis. If no value is specified for minimum analysis, the maximum value is used.

port_list

Specifies a list of input or inout port names of the current design on which the drive attributes are to be set. If you specify more than one port, you must enclose the ports in either quotes or braces ({}).

DESCRIPTION

Sets the **rise_drive** or **fall_drive** attributes to *resistance* on specified input and inout ports in the current design.

Note: The **set_driving_cell** command is more convenient and accurate than **set_drive** for describing the drive capability of a port. The **set_drive** command removes any corresponding rise or fall driving cell attributes on the specified ports. Use **set_driving_cell** instead of **set_drive**, if possible.

During optimization, the drive of an input port is used to calculate the timing delay to gates driven by that port. The delay to these gates is computed as follows for the generic CMOS delay model: Time = arrival_time + [drive * load(net)] + connect_delay (*if any*)

To view drive information on ports, use **report_port -drive**. To remove drive attributes from ports, use **remove_attribute**. The **reset_design** command removes all attributes from a design, including the drive attributes.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets the rise and fall drives of ports A, B, and C to 2.0.

```
prompt> set_drive 2.0 {A B C}
```

The following example sets the rise and fall drives of all input ports to 2 and sets the rise drive on port B to 1.

```
prompt> set_drive 2 [all_inputs]
prompt> set_drive -rise 1 [get_ports B]
```

The following example sets both the rise and fall drives of port C to the corresponding drives of pin OUT of the INVERTER cell from the TECH_LIBRARY technology library using the **drive_of** command.

```
prompt> set_drive -rise drive_of(-rise TECH_LIBRARY/INVERTER/OUT) \
           [get_ports C]
prompt> set_drive -fall drive_of(-fall TECH_LIBRARY/INVERTER/OUT) \
           [get_ports C]
```

set_driving_cell(2)
set_load(2)

set_driving_cell

Sets attributes on input or inout ports of the current design that specify that a library cell or output pin of a library cell drives the specified ports.

SYNTAX

```
status set_driving_cell
[-lib_cell lib_cell_name]
[-library lib]
[-rise]
[-fall]
[-min]
[-max]
[-pin pin_name]
[-from_pin from_pin_name]
[-dont_scale]
[-no_design_rule]
[-none]
[-input_transition_rise rtran]
[-input_transition_fall ftran]
[-multiply_by factor]
port_list
[-cell obsolete_-_please_use_-lib_cell_instead]
```

Data Types

<i>lib_cell_name</i>	string
<i>lib</i>	string
<i>pin_name</i>	string
<i>from_pin_name</i>	string
<i>rtran</i>	float
<i>ftran</i>	float
<i>factor</i>	float
<i>port_list</i>	list

ARGUMENTS

-lib_cell *lib_cell_name*

Specifies the name of the library cell to use to drive ports. You can use this option with the **-pin** option when the cell has more than one output pin to set the **driving_cell_rise** and the **driving_cell_fall** string attributes to *lib_cell_name* on the ports. To specify different cells for the rising and falling cases, execute the command twice, once using the **-rise** option and once using the **-fall** option, specifying the appropriate *lib_cell_name* for each. When you use this option, you must also use the **-dont_scale** and **-multiply_by** options. By default, the command searches the libraries in **link_library** for the cell.

-library *lib*

Specifies the library name or a collection of libraries in which to find the name of the library cell to use to drive ports (*lib_cell_name*). If the lib cell can be found in multiple libraries, the library with matching operating condition on the port will be used. When no library is specified, all the libraries will be searched for the lib cell with matching operating condition. If a library cell with a matching

operating condition cannot be found, the first one found with a matching lib cell name will be used.

You can use this option only with the **-lib_cell** option. It sets the **driving_cell_library_rise** and the **driving_cell_library_fall** string attributes to the library name on the ports. To specify different libraries for the rising and falling cases, execute the command twice, using the **-rise** option once and the **-fall** option once, specifying the appropriate *lib* for each.

-rise

Specifies that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the rising case, and sets the **driving_cell_rise**, **driving_cell_library_rise**, **driving_cell_pin_rise**, and **driving_cell_from_pin_rise** attribute strings, respectively, on the objects. You can use this option with the **-fall** option to specify both the rising and falling cases.

-fall

Specifies that the *lib_cell_name*, *lib*, *pin_name*, and *from_pin_name* correspond to the falling case, and sets the **driving_cell_fall**, **driving_cell_library_fall**, **driving_cell_pin_fall**, and **driving_cell_from_pin_fall** attribute strings, respectively, on the objects. You can use this option with **-rise** to specify both the rising and falling cases.

-min

Sets driving cell information for analysis at the minimum operating condition only.

-max

Sets driving cell information for analysis at the maximum operating condition only.

-pin pin_name

Specifies the output pin on the driving cell that is to drive the ports. The **-pin** option is required when you use the **-lib_cell** option and the driving cell has more than one output pin or when using the **-from_pin** option. This option sets the **driving_cell_pin_rise** and the **driving_cell_pin_fall** string attributes to *pin_name* on the ports. To specify different pins for the rising and falling cases, execute the command twice, once using the **-rise** option and once using the **-fall** option, specifying the appropriate *pin_name* for each. The default is to use the first timing arc found on the library cell.

-from_pin from_pin_name

Specifies the input pin on the driving cell to use when finding a timing arc. This option is required when the driving cell has more than one input pin and the arcs from those pins have different drive characteristics, and when using the **-pin** and **-lib_cell** options. The **-from_pin** option sets the **driving_cell_from_pin_rise** and **driving_cell_from_pin_fall** string attributes to *from_pin_name* on the ports. The default is to use the first timing arc found on the library cell.

-dont_scale

Specifies that the timing analyzer is not to scale the drive capability of the ports according to the current operating conditions. You can use this option only with the **-lib_cell** option. The **-dont_scale** option sets the **driving_cell_dont_scale** Boolean attribute to **true** on the ports. By default, the port drive capability is scaled for operating conditions exactly as the driving cell would be scaled.

-no_design_rule

Indicates that the design rules associated with the driving cell are not to be applied to the driven port. This option sets the **driving_cell_no_drc** Boolean attribute to **true** on the ports. Timing-related attributes are still applied. The tool issues a warning if this option is not used. By default, design rule attributes (**max_fanout**, **max_capacitance**, **max_transition**, **min_fanout**, **min_capacitance**, **min_transition**) are derived from the driving cell and its library and applied to the port.

-none

Removes previous driving cell information.

-input_transition_rise rtran

Specifies the input rise transition time associated with the **-from_pin** option. Use the **-input_transition_rise** and **-input_transition_fall** options to obtain a more accurate transition time and delay time at the output pin by capturing the accurate transition time associated with the **-from_pin**. The default value is **0**.

-input_transition_fall ftran

Specifies the input fall transition time associated with the **-from_pin** option. The default value is **0**.

-multiply_by factor

Specifies a factor by which to multiply the delay characteristics of the ports. You can use this option only with the **-lib_cell** option. It affects both the load delay and the transition times of the port. It sets the **driving_cell_multiply_by** float attribute to the specified factor on the ports. The default is **1.0**.

port_list

Specifies a list of names of input or inout ports in the current design on which the driving cell attributes are to be placed. If more than one port is specified, they must be enclosed in either quotes or braces ({}).

DESCRIPTION

This command sets attributes on the specified input or inout ports in the current design to associate an external driving cell with the ports. The drive capability of the port is the same as if the specified driving cell were connected in the same context to allow accurate modeling of the port drive capability for nonlinear delay models. For the CMOS2 delay model, the edge rate of pins driven by the port is the same as if the driving cell were substituted for the port. Unless you specify the **-dont_scale** option, the drive capability of the port is scaled according to the current operating conditions.

To view drive information on ports, use the **report_port** command with the **-drive** option.

You can use the **characterize** command to automatically set driving cell attributes on subdesign ports based on their context in the entire design.

You can use the **remove_driving_cell** or **reset_design** command to remove driving cell attributes on ports. The **remove_driving_cell** command removes any corresponding rise or fall drive resistance attributes (from the **set_drive** command) on the specified ports. It is considered best practice to use the **set_driving_cell** command instead of **set_drive**, because **set_driving_cell** is more accurate.

In UPF mode, driving cell attribute is applied on the input ports only if the port's supply voltage (supply is specified using **set_related_supply_net** or **set_port_attributes -driver_supply** and the voltage is specified using **set_voltage** command) matches with the voltage of the driving cell. It will be an error if the voltages do not match and the command fails on ports not meeting this voltage compliance check.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example associates the drive capability of the AND2 library cell with the IN1 port.

```
prompt> set_driving_cell -lib_cell AND2 {IN1}
```

The following example associates the drive capability of the INV/Z library pin from the tech_lib library with all input and inout ports.

```
prompt> set_driving_cell -lib_cell INV -pin Z \
           -library tech_lib [all_inputs]
```

The following example associates the drive capability of the INV library cell with the IN1 port and specifies that the delay values should not be scaled by operating condition factors.

```
prompt> set_driving_cell -lib_cell INV -dont_scale {IN1}
```

The following example associates the Z pin of the BUF1_TS library cell with the IN1 port for rising delays and the Q pin of the DFF_TS library cell for falling delays.

```
prompt> set_driving_cell -rise -lib_cell BUF1_TS -pin Z  
prompt> set_driving_cell -fall -lib_cell DFF_TS -pin Q {IN1}
```

The following example associates the AN2 driving cell with the top1 input port with an input rise transition time of 2.3 on pin A.

```
prompt> set_driving_cell -lib_cell AN2 \  
-input_transition_rise 2.3 -from_pin A top1
```

set_dynamic_optimization

Enables or disables dynamic-power optimization on the current design.

SYNTAX

```
status set_dynamic_optimization
      true | false
```

ARGUMENTS

true | false

Controls whether dynamic-power optimization is enabled.

When the setting is **true**, enables dynamic-power optimization. When the setting is **false**, disables dynamic-power optimization.

DESCRIPTION

This command enables or disables dynamic-power optimization on the current design. This command does not support scenario-specific settings in a multicorner-multimode design. To perform scenario-dependent dynamic-power optimization, use the **set_scenario_option -dynamic_power true** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example enables dynamic-power optimization in a non-multicorner-multimode design.

```
prompt> set_dynamic_optimization true
1
```

The following example disables dynamic-power optimization in a non-multicorner-multimode design.

```
prompt> set_dynamic_optimization false
1
```

SEE ALSO

[set_leakage_optimization\(2\)](#)
[set_scenario_options\(2\)](#)

set_equal

Defines two input ports as logically equivalent.

SYNTAX

```
int set_equal  
    port1  
    port2
```

Data Types

```
port1  string  
port2  string
```

ARGUMENTS

port1 *port1*

Two logically-equivalent input port in the current design.

DESCRIPTION

Defines two input ports in the current design as logically equivalent. This information is used to eliminate redundant ports, improving optimization quality.

Logical inconsistencies are checked for in relationships between ports. Specifying an inconsistent logical relationship between ports is not allowed.

Use the **reset_design** command to remove this property from a port.

EXAMPLES

The following example sets two input ports "A" and "B" logically equal:

```
prompt> set_equal A B
```

The following example sets up a contradictory relationship between two ports and creates an error:

```
prompt> set_equal A B  
prompt> set_opposite A B  
Warning: Can't set equal ports opposite in design 'example.ddc': 'A' 'B'
```

SEE ALSO

`reset_design(2)`
`set_opposite(2)`

set_equivalent

Declares that supply nets or supply sets are electrically or functionally equivalent.

SYNTAX

```
string set_equivalent
  [-nets supply_net_name_list]
  [-sets supply_set_name_list]
  [-function_only]
```

Data Types

<i>supply_net_name_list</i>	collection
<i>supply_set_name_list</i>	collection

ARGUMENTS

-nets *supply_net_name_list*

Specifies a list of supply ports, supply nets, supply set functions, and macro PG pin names that are equivalent.

-sets *supply_set_name_list*

Specifies a list of supply set names that are equivalent.

-function_only

Specifies that the supply set is only functionally equivalent.

DESCRIPTION

The **set_equivalent** command declares that two or more supplies are equivalent. This means that they always have the same state at any given time.

If the **-nets** is specified, the command defines equivalence for a list of supply ports and supply nets. If the **-sets** is specified, the command defines equivalence for a list of supply sets and supply set handles. One or the other of these options, but not both, can be specified.

If the **-function_only** option is specified, the supplies are only declared to be functionally equivalent; otherwise, the supplies are declared to be electrically equivalent, which implies that they are also functionally equivalent.

It is an error to declare that supplies are equivalent if other constraints contradict this equivalence.

EXAMPLES

```
prompt> set_equivalent -nets {VDD1 VDD2}  
prompt>  
prompt> set_equivalent -sets {sstop ssext} -function_only  
prompt>
```

SEE ALSO

`create_supply_net(2)`
`create_supply_set(2)`
`set_isolation(2)`

set_extraction_options

Sets the parameters that influence parasitic data extraction.

SYNTAX

```
status set_extraction_options
[-max_process_scale max_process_scaling]
[-min_process_scale min_process_scaling]
[-reference_direction vertical | horizontal | use_from_tluplus]
[-default]
```

Data Types

max_process_scaling float
min_process_scaling float

ARGUMENTS

-max_process_scale *max_process_scaling*

Specifies the maximum process scaling factor. The default is 1.0.

-min_process_scale *min_process_scaling*

Specifies the minimum process scaling factor. The default is 1.0.

-reference_direction vertical | horizontal | use_from_tluplus

Specifies the reference direction. Based on this information, the tool applies orientation-based etch tables. The reference direction applies to all scenarios in the multicorner-multimode flow. The default is **use_from_tluplus**.

vertical - Specifies that the reference direction is vertical when applying the orientation-based etch tables, regardless of the **REFERENCE_DIRECTION** setting in the TLUPPlus files.

horizontal - Specifies that the reference direction is horizontal when applying the orientation-based etch tables, regardless of the **REFERENCE_DIRECTION** setting in the TLUPPlus files.

use_from_tluplus - Specifies that the reference direction is defined by the **REFERENCE_DIRECTION** setting in the TLUPPlus files. The TLUPPlus files are specified by the **set_tlu_plus_files** command.

-default

Resets all options to their defaults.

DESCRIPTION

The **set_extraction_options** command specifies parameters that influence parasitic capacitance and resistance extraction in the Design Compiler topographical tool.

You can specify process scaling factors with the **-max_process_scale** and **-min_process_scale** options. The lengths and widths of the interconnect wires are scaled by the specified factors, without affecting interconnect wire depths or metal geometries inside standard cells and macros. You can use process scaling factors to adjust RC estimation for a process shrink, such as shrinking from 90 nm to 65 nm.

Use this command with the **set_tlu_plus_files** command.

You can report the settings made with the **set_extraction_options** command by using the **report_extraction_options** command.

Limitations

The command is available only in DC-Topographical mode.

Multicorner-Multimode Support

This command applies to both active and inactive scenarios.

EXAMPLES

The following example runs the **set_extraction_options** command with a **-max_process_scale** factor of 0.8 and a **-min_process_scale** factor of 0.7:

```
prompt> set_extraction_options -max_process_scale 0.8 -min_process_scale 0.7
```

`read_parasitics(2)`
`report_extraction_options(2)`
`set_delay_estimation_options(2)`
`set_tlu_plus_files(2)`

set_failsafe_fsm_rule

Associates the registers with the rule.

SYNTAX

```
status set_failsafe_fsm_rule
  -rule failsafe_fsm_rule_name
  -registers registers
  -error_signal error_signal_pin
```

Data Types

<i>failsafe_fsm_rule_name</i>	string
<i>registers</i>	collection

ARGUMENTS

-rule *failsafe_fsm_rule_name*

Specifies the name of failsafe_fsm_rule to apply to the registers. This must be an existing and valid rule rule name.

-registers *registers*

Explicitly specifies the register(s) on which the constraint should be applied.

-error_signal *error_signal_pin*

This option can be an input pin of an error handler logic inside the design or input port of an error handler hierarchy inside the design.

DESCRIPTION

Sets the failsafe_fsm_rule on all the specified registers. If a specified register already has another rule associated with it, that register will be skipped and the original rule will remain applied to it.

EXAMPLES

The following example creates an association of a rule with registers.

```
prompt> set_failsafe_fsm_rule -rule rule1 \
  -registers {flop1 flop2 flop3 flop4}
```

SEE ALSO

`create_failsafe_fsm_rule(2)`
`report_failsafe_fsm_rules(2)`

set_false_path

Removes timing constraints from particular paths.

SYNTAX

```
status set_false_path
  [-rise | -fall] [-setup | -hold]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list
   | -through through_list
   | -rise_through rise_through_list
   | -fall_through fall_through_list
   | -to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list
   | -reset_path]
  [-comment comment_string]
```

Data Types

<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list
<i>comment_string</i>	string

ARGUMENTS

-rise

Marks rising delays false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, both rise and fall timing are marked false.

-fall

Marks falling delays false, as measured on the path endpoint. If you do not specify either **-rise** or **-fall**, both rise and fall timing are marked false.

-setup

Marks setup (maximum) paths false. **-setup** disables setup checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-hold

Marks hold (minimum) paths false. **-hold** disables hold checking for specified paths. If you do not specify either **-setup** or **-hold**, both setup and hold timing are marked false.

-from from_list

Specifies start points (clocks, ports, pins, or cells) of disabled paths. If you do not specify a *from_list*, all paths to end points in *to_list* are disabled. *from_list* can include clocks, pins, or ports. If you specify a clock, all path startpoints related to the specified clock are affected. If you specify an internal pin, the pin must be a path startpoint (the clock pin of a flip-flop, for example). If a cell is specified, one path startpoint on that cell is affected.

-rise_from rise_from_list

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from fall_from_list

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through through_list

A list of path throughpoints (port, pin, or leaf cell names) of the current design. The false path applies only to paths that pass through one of the points in the *through_list*. If more than one object is included, you must enclose the objects in quotes or in '{}' braces. If you specify the **-through** option multiple times, the false path setting applies to paths that pass through a member of each *through_list* in the order the lists were given. That is, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the false path applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through rise_through_list

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through fall_through_list

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to to_list

Specifies end points (clocks, ports, pins, or cells) of paths disabled. If you do not specify *to_list*, all paths from start points in *from_list* are disabled. The *to_list* can include clocks, pins, or ports. If you specify a clock, all path endpoints related to the specified clock are considered. If you specify an internal pin, the pin must be a path endpoint (for example, the data pin of a flip-flop). If you specify a cell, one path endpoint on that cell is affected.

-rise_to rise_to_list

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to fall_to_list

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Removes existing point-to-point exception information on the specified paths. Only information of the same rise/fall or setup/hold type is reset. This is equivalent to using the **reset_path** command with similar arguments before the **set_false_path** is issued.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

DESCRIPTION

Removes timing constraints from specified paths that you know do not affect circuit operation. **set_false_path** can disable both maximum delay (setup) checking and minimum delay (hold) checking.

The **set_false_path** command disables timing from path startpoints through path throughpoints to path endpoints. Path startpoints are input ports or register clock pins. Path throughpoints can be cells, pins, or ports. Path endpoints are register data pins or output ports.

To disable the timing at a particular cell in the design, use **set_disable_timing**. This removes certain timing arcs on a cell from the timing graph, so that paths along those arcs are not traced. The **set_false_path** command still allows tracing of the paths, but removes any timing constraints on them.

set_false_path is a point-to-point timing exception command. This means it assists in overriding the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_max_delay**, **set_min_delay**, and **set_multicycle_path**.

If a path satisfies multiple timing exceptions, the following rules assist in determining which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands might conflict with each other. But a **group_path** exception by itself does not conflict with another type of exception. So the remaining rules apply for two **group_path** exceptions, or two non-**group_path** exceptions.
2. If both exceptions are **set_false_paths**, there is no conflict.
3. If one exception is a **set_max_delay** and the other is **set_min_delay**, there is no conflict.
4. If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, there is no conflict.
5. If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
8. If one exception has a **-from pin** or **-from cell** and the other does not, the former takes precedence.
9. If one exception has a **-to pin** or **-to cell** and the other does not, the former takes precedence.
10. If one exception has any **-through** points and the other does not, the former takes precedence.
11. If one exception has a **-from clock** and the other does not, the former takes precedence.
12. If one exception has a **-to clock** and the other does not, the former takes precedence.
13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To undo the effect of **set_false_path**, use **reset_path** or **reset_design**.

Use **report_timing_requirements** to list the point-to-point exceptions on a design.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example removes timing constraints on paths from cell ff12 to cell ff34.

```
prompt> set_false_path -from {ff12} -to {ff34}
```

The following example removes timing constraints on paths through pin u14/Z to pin ff29/Reset that are rising at the endpoint.

```
prompt> set_false_path -rise -through {u14/Z} -to {ff29/Reset}
```

The following example disables hold checking (minimum delay timing) for endpoints clocked by PHI1. The flip-flops and latches clocked by PHI1 are checked for setup violations, but not for hold violations.

```
prompt> set_false_path -hold -to [get_clocks PHI1]
```

The following example removes timing constraints for all paths that first pass through either pin u1/Z or u2/Z and then pass through pin u5/Z or u6/Z.

```
prompt> set_false_path -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

The following example disables rising timing paths through pin U14/Z to pin ff29/Reset.

```
prompt> set_false_path -rise_through {U14/Z} -to {ff29/Reset}
```

set_fanout_load

Sets the **fanout_load** attribute on the specified output ports of the current design.

SYNTAX

```
status set_fanout_load
      value
      ports
```

Data Types

<i>value</i>	float
<i>ports</i>	collection

ARGUMENTS

value

Specifies the value for the **fanout_load** attribute. The *value* argument must be expressed in units consistent with the **max_fanout** and **fanout_load** values in the technology library used during optimization.

ports

Specifies the ports in the current design on which to set the **fanout_load** attribute.

DESCRIPTION

Sets the **fanout_load** attribute to the specified value on the specified output ports in the current design. The optimization process tries to ensure that the sum of this value together with all **fanout_load** attributes for pins connected to the driver that drives this port does not exceed the driving pin's **max_fanout** capability. The default **fanout_load** value for a port is 0.0.

NOTE: Bidirectional ports are not included in maximum fanout calculations, so using the **set_fanout_load** command with a bidirectional port has no effect on optimization.

Use the **remove_attribute** or **reset_design** command to remove **fanout_load** values from ports. Use the **report_port** command to list fanout load values on ports.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command sets a fanout load of 2 units on all output ports:

```
prompt> set_fanout_load 2 [all_outputs]
```

SEE ALSO

[all_outputs\(2\)](#)
[compile\(2\)](#)

[report_port\(2\)](#)
[reset_design\(2\)](#)
[set_max_fanout\(2\)](#)
[port_attributes\(3\)](#)

set_fix_hold

Sets the **fix_hold** attribute on clocks in the current design.

SYNTAX

```
status set_fix_hold  
       clocks
```

ARGUMENTS

clocks

Specifies the clocks on which to set the **fix_hold** attribute.

DESCRIPTION

This command sets the **fix_hold** attribute on the specified clock objects in the current design. The **fix_hold** attribute informs optimization that hold time violations of the specified clocks should be fixed.

Fixing a hold violation requires slowing down data signals. Optimization fixes hold violations while fixing the design rules, but only if the maximum delay cost is not increased or if the **set_cost_priority** command is used to prioritize hold violations ahead of maximum delay cost. Optimization can violate setup and fix hold as long as the worst negative slack (WNS) is not made worse. Optimization might fix hold and violate setup on noncritical paths.

The **report_clock_attributes** command identifies the clocks that have the **fix_hold** attribute.

Use the **remove_attribute** command to remove the **fix_hold** attribute.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command sets the **fix_hold** attribute on clock clk1.

```
prompt> set_fix_hold clk1
```

The following command removes the **fix_hold** attribute from clock clk1.

```
prompt> remove_attribute [get_clocks clk1] fix_hold
```

SEE ALSO

`compile(2)`
`create_clock(2)`
`remove_attribute(2)`
`report_clock(2)`
`reset_design(2)`
`set_prefer(2)`

set_fix_multiple_port_nets

Sets the **fix_multiple_port_nets** attribute to a specified value on the current design or a list of designs.

SYNTAX

```
int set_fix_multiple_port_nets
  [-default | -all]
  [-feedthroughs]
  [-outputs]
  [-constants]
  [-buffer_constants]
  [-no_rewire]
  [-exclude_clock_network]
  [design_list]
```

ARGUMENTS

-default

Removes the **fix_multiple_port_nets** attribute so that **compile** will use its default priority, that is no multiple port nets fixing.

-all

Inserts the same as **-feedthroughs -outputs -constants**. Note that logic constants are duplicated, not buffered. To fix constant port nets by buffering them, use the **-buffer_constants** option.

-feedthroughs

Inserts buffers to isolate input ports from output ports at all levels of the hierarchy.

-outputs

Inserts buffers so that no cell driver pin drives more than one output port at any level of the hierarchy.

-constants

Duplicates logic constants so that no constant drives more than one output port at any level of the hierarchy.

-buffer_constants

Buffers logic constants instead of duplicating them.

-no_rewire

Disables a rewiring attempt before buffering multiple port nets and constant port nets.

-exclude_clock_network

Excludes nets belonging to the clock network from multiple port net fixing.

design_list

Specifies a list of designs. The default is the current design.

DESCRIPTION

Sets the **fix_multiple_port_nets** attribute on the current design, unless a list of designs is specified.

When the command is used with a list of designs, the constraints of each design will be available when that design is made current by using the **current_design** command before running **compile**. The same way, **report_constraints** will only show the constraints of the current design.

This attribute controls whether **compile** inserts extra logic into the design to ensure that there are no feedthroughs, or that there are no two output ports connected to the same net at any level of hierarchy.

The default is not to add any extra logic into the design to fix such cases.

Certain three-state nets cannot be buffered, because this changes the logic functionality of the design.

If **set_fix_multiple_port_nets** is specified more than once on a design, the most recent setting is used and the earlier values are removed. To undo **set_fix_multiple_port_nets**, use the **-default** option, the **remove_attribute** command, or the **reset_design** command.

To view the current setting of the **fix_multiple_port_nets** attribute, use **report_compile_options**.

For some backward compatibility, if **compile** is run on a design with no **fix_multiple_port_nets** attribute and the obsolete variable **compile_fix_multiple_port_nets** is set to true, the attribute is set on the design to correspond with **set_fix_multiple_port_nets -all**. The attribute always has precedence over the variable setting. If **compile** is run when the attribute exists and has a different value than the variable, a warning is printed that the variable is being ignored. Consequently, if the choice of multiple port net fixing has to be changed between two **compile** commands on the same design, the **set_fix_multiple_port_nets** command must be used since changes to the **compile_fix_multiple_port_nets** variable after the first compile will be ignored.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **fix_multiple_port_nets** attribute so that feedthroughs are buffered and constants are duplicated.

```
prompt> set_fix_multiple_port_nets -feedthroughs -constants
```

The following example sets the **fix_multiple_port_nets** attribute so that multiple outputs and constants are buffered.

```
prompt> set_fix_multiple_port_nets -outputs -buffer_constants
```

SEE ALSO

compile(2)
current_design(2)
remove_attribute(2)
reset_design(2)

set_flatten

Sets or removes the **flatten** attribute on specified designs or on the current design, to enable or disable the flattening optimization step during **compile**.

SYNTAX

```
int set_flatten
  [true | false]
  [-effort low | medium | high]
  [-minimize single_output | multiple_output | none]
  [-phase true | false] [-design design_list] [-quiet]
```

Data Types

design_list list

ARGUMENTS

true | false

When *true*, sets the **flatten** attribute on the designs in *design_list* and enables flattening for those designs. When *false* (the default value), the **flatten** attribute is removed and flattening is turned off for those designs.

-effort low | medium | high

Indicates the level of CPU effort that **compile** uses to flatten a design. The default is *low*.

-minimize single_output | multiple_output | none

Indicates the minimization strategy to be used after a design is flattened. If *single_output* (the default value), Design Compiler independently minimizes the equations for each output in a design. If *multiple_output*, Design Compiler minimizes all logic for a design. If *none*, Design Compiler does not perform minimization.

-phase true | false

When *true*, allows logic flattening to invert the phase of outputs during **compile**. When *false* (the default value), logic flattening does not invert the phase of outputs. This option is used only if the **flatten** attribute is set.

-design *design_list*

Specifies a list of designs to be flattened. The default is the current design.

-quiet

Indicates that warning messages are not to be displayed.

DESCRIPTION

Sets or removes the **flatten** attribute on specified designs or on the current design, enabling or disabling the flattening optimization step during **compile**. If no options are specified, the **flatten** attribute is set on the current design.

To enable flattening during optimization across the entire design hierarchy, issue the **set_flatten** command on the top design and each subdesign. To display the values of all **flatten** attributes, use **report_compile_options**.

This optimization step reduces a logic network to a two-level sum-of-products (AND/OR) representation by removing all intermediate variables. Full flattening eliminates all existing logic structure. By removing sub-optimal intermediate variables, **compile** is able to use other intermediate variables that otherwise might not have been found.

If phase assignment has been enabled by invoking the **set_flatten** command with **-phase true**, then the flattening optimization step in **compile** will compare the implementation of each logic equation in both its original and complemented form and choose the form with the smallest estimated area.

When the minimization strategy is set to *single_output*, Design Compiler minimizes the equations for each output individually. This results in the smallest implementation for each output, but the design as a whole might not be the most efficient because product (AND terms) are not well shared between outputs. When the strategy is *multiple_output*, Design Compiler minimizes all the logic for a design, and shares as many product terms between outputs as possible.

NOTE: Setting the **flatten** attribute can potentially cause **compile** to have long run times or to run out of memory, because logic flattening and equation minimization is a potentially exponential process. If you encounter an "out of memory" error or excessive run time, you can modify the options one at a time and re-run after each modification. Here is the recommended order for modifying the options:

1. Use *single_output* instead of *multiple_output* minimization strategy.
2. Use the **-phase false** option instead of the default **-phase true** option.
3. Use a lower effort setting.

To remove the **flatten** attribute, use **remove_attribute** or execute **set_flatten false**. **reset_design** removes **all** attributes, including **flatten**.

For more details on flattening during optimization, refer to the *Design Compiler Reference Manual: Optimization and Timing Analysis*

EXAMPLES

In this example, **flatten** is enabled on the design "TEST".

```
prompt> set_flatten -design TEST
```

In this example, **flatten** is enabled on the current design with the **effort** and **minimize** options specified, and **flatten** is disabled on the design "OLD."

```
prompt> read TEST
prompt> set_flatten -effort high -minimize multiple_output
prompt> set_flatten -design OLD false
```

set_fp_base_gate

Sets either a library leaf cell area or a user-specified cell area as the base unit area to use for gate equivalence calculations related to estimating the size of black boxes.

SYNTAX

```
status set_fp_base_gate  
 {-cell master_name | -area cell_area}
```

ARGUMENTS

-cell *master_name*

Specifies the master name of the library leaf cell to use as the base unit area for gate equivalence calculations.

-area *cell_area*

Specifies the cell area in square microns to use as the base unit area for gate equivalence calculations.

DESCRIPTION

Sets either a library leaf cell area or a user designated cell area as the base unit area to use for gate equivalence calculations related to estimating the size of black boxes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

Set base gate area to cell master UNIT

```
prompt> set_fp_base_gate -cell UNIT
```

Set base gate area to 10 square microns

```
prompt> set_fp_base_gate -area 10
```

SEE ALSO

`estimate_fp_black_boxes(2)`

set_fsm_encoding

Specifies the bit encodings for states in the current design.

SYNTAX

```
int set_fsm_encoding  
    encoding_list
```

Data Types

encoding_list list

ARGUMENTS

encoding_list

Specifies a list of all the states in the current design with the assigned bit encodings. Each state name and encoding must be enclosed in double quotation marks. (" ").

Encodings are specified using one of two formats. The first format consists of a base specifier followed by the pound (#) character, followed by a string of digits in the given base numbering system. The string of digits can be separated by an optional underscore character to make the encodings easier to read. If the base specifier and pound (#) character are omitted, the string of digits are interpreted as a decimal (base 10) value. For example, 15 can be entered in this format as:

```
2#1111  
8#17  
10#15  
15  
16#
```

The second format consists of the caret (^) character, followed by a character base specification, followed by a string of digits in the given base. For example, 15 can be entered in this format as:

```
^B1111 (Binary)  
^O17 (Octal)  
^D15 (Decimal)  
^Hf (Hexadecimal)
```

If the list contains more than one state, the list of states must be enclosed in braces ({}).

DESCRIPTION

The **set_fsm_encoding** command specifies the set of all legal states and state encodings in the current design.

Only one *encoding_list* can be active at a time on the current design.

EXAMPLE

The following example assigns codes to two states in the machine. The encodings are removed for states not in the list.

```
prompt> set_fsm_encoding { "IDLE=2#000" "FIVE=2#001" }
```

SEE ALSO

`compile(2)`
`set_fsm_encoding_style(2)`

set_fsm_encoding_style

Defines the encoding style for assigning unencoded states.

SYNTAX

```
int set_fsm_encoding_style  
{one_hot | zero_one_hot | binary | gray | auto | neutral}
```

ARGUMENTS

{one_hot | zero_one_hot | binary | gray | auto | neutral}

Specifies the encoding style that is to be used during state assignment. The encoding styles are described in the DESCRIPTION section. The default is **auto**.

DESCRIPTION

Defines the encoding style to be used for determining unencoded states during the generation of a state machine design. (The process of determining encodings for states is referred to as state assignment.) If you have manually specified encodings for any of the states in the design, state assignment does not reassign any of these encodings. The code length is based on 1) the length of any manually-assigned encodings, or 2) the number of instance names specified in the **set_fsm_state_vector** command. If the code length cannot be determined by any of these criteria, it is determined by the encoding style selected. one_hot encoding style can be re-implemented as zero_one_hot because of register constant removal or register merging.

The encoding styles are described below.

The **one_hot** encoding style generates codes with a bit length equal to the number of states in the state machine, each state being represented by one bit position. The code is a string of zeros, interrupted by a one in the state's particular bit position. A warning is generated if the number of elements in the state vector is not equal to the number of states, in which case the length of the code is reset to the number of states in the machine. If the **one_hot** encoding style is specified, all manually-assigned codes must also be **one_hot** codes.

The **binary** and **gray** encoding styles sequentially assign codes to unassigned states using a binary numbering or gray numbering sequence, respectively. The binary numbering sequence consists of using binary values to encode the sequence of counting integers. For example, four states encoded using two bits would be numbered 0, 1, 2, and 3, represented by the binary encodings of 00, 01, 10, and 11. The **gray** numbering sequence assigns codes to states such that successive codes never differ by more than one bit. In this case, the same four states encoded using the gray encoding style would be numbered 0, 1, 3, and 2, represented by the encodings of 00, 01, 11, and 10. Note that in this encoding sequence only one bit position changes value in going from one to the next (for example, 01 to 11.) The sequence in which the codes are assigned to the states is based on the ordering of the states. States are ordered via their entry in the state table, or may be manually assigned using the **set_fsm_order** command. If any states have manually assigned encodings, then these states and their respective codes are omitted from the ordering of binary or gray codes. Additionally, if any state is unordered, an arbitrary ordering is used that does not affect any existing order. The default code length is base log2 of the number of states in the machine.

The **auto** encoding style generates codes chosen in a manner to best minimize the logic of the state machine. If the length of the bit encodings cannot be determined using the criteria specified below, the Design Compiler's **auto** encoding style selects the code length

that best minimizes the state machine.

The **neutral** encoding style will keep state assign as user defined in the HDL code, i.e., keep the encoding style unchanged.

EXAMPLES

The following example shows four states, "IDLE", "FIVE", "TEN", and "OWE_DIME", with a **one_hot** encoding style:

```
prompt> set_fsm_encoding_style one_hot
```

During **compile**, the state assignment encodes the states as 1000, 0100, 0010, and 0001, respectively.

The following example shows the same machine with the states ordered as "IDLE", "FIVE", "TEN", and "OWE_DIME", with a **binary** encoding style:

```
prompt> set_fsm_encoding_style binary
```

During **compile**, the state assignment encodes the states as 00, 01, 10, and 11, respectively.

SEE ALSO

```
compile(2)  
current_design(2)  
set_fsm_order(2)  
set_fsm_state_vector(2)
```

set_fsm_minimize

Determines whether or not state minimization is to be performed on the state machine design during **compile**.

SYNTAX

```
int set_fsm_minimize  
    true | false
```

ARGUMENTS

true | false

Indicates whether or not state minimization is to be performed. The default is *false*.

DESCRIPTION

Determines whether or not state minimization is to be performed on the state machine design during **compile**. State minimization is not performed again on a design that has already had state minimization performed (for example, with the **fsm_minimize** command). You can additionally specify states that are to be preserved by using the **set_fsm_preserve_state** command.

EXAMPLES

The following examples show a state table design being read in, set up for state minimization, and **compiled**.

```
prompt> read -f st example.st  
prompt> set_fsm_minimize true  
prompt> compile
```

SEE ALSO

compile(2)
set_fsm_preserve_state(2)

set_fsm_order

Sets the ordering of states in a state machine design.

SYNTAX

```
int set_fsm_order  
    state_list
```

Data Types

state_list list

ARGUMENTS

state_list

List of states in the state machine to which an order is assigned. All states in the *state_list* must be states in the state machine. If more than one state is specified, they must be enclosed in braces ({}).

DESCRIPTION

Defines an ascending ordering of states in the current design. Any previously-assigned order is removed and replaced by the new order specified in *state_list*. Any states that are not included in *state_list* are given an arbitrary order that does not violate the specified ordering.

compile uses state ordering when determining encodings for unencoded states using the **binary** or **gray** encoding style. (See **set_fsm_encoding_style** for a description of those encoding styles.) The first state is assigned the lowest unused state code, and each successive state is assigned the next unused code in the **binary** or **gray** numbering sequence.

An empty *state_list* removes the ordering of all states.

EXAMPLES

The following example defines the ordering of states such that "IDLE" is the first state, "FIVE" is the second state, and so on:

```
prompt> set_fsm_order { IDLE FIVE TEN OWE_DIME }
```

To remove the ordering from all states, enter an empty *state_list*:

```
prompt> set_fsm_order { }
```

SEE ALSO

`compile(2)`
`set_fsm_encoding_style(2)`

set_fsm_preserve_state

Specifies states to be preserved during state minimization.

SYNTAX

```
int set_fsm_preserve_state  
    state_list
```

Data Types

state_list list

ARGUMENTS

state_list

List of state names to be preserved. If more than one state is specified, they must be enclosed in braces ({}).

DESCRIPTION

Specifies those states which are to be preserved during state minimization.

This command overrides any previously specified state preservation. To undo this command, enter **set_fsm_preserve_state** with an empty *state_list*.

EXAMPLES

The following command specifies that state "IDLE" is to be preserved during state minimization:

```
prompt> set_fsm_preserve_state { IDLE }
```

SEE ALSO

set_fsm_state_vector

Specifies the instance names for flip-flops used to implement the state vector.

SYNTAX

```
int set_fsm_state_vector  
vector_list
```

Data Types

vector_list list

ARGUMENTS

vector_list

Specifies a list of instance names for the state vector in the state machine. If more than one name is specified, they must be enclosed in braces ({}). The first instance name in the list is considered to be the most significant bit of the vector, while the last instance name is considered the least significant bit of the vector.

DESCRIPTION

Explicitly names the instances of the flip-flops used to store the current state of the state machine. Additionally, the specification of a state vector defines the length of the codes used for the encoded states in the machine.

EXAMPLES

The following example specifies the state vector's instance names:

```
prompt> set_fsm_state_vector { ff0 ff1 ff2 ff3 }
```

SEE ALSO

`compile(2)`
`set_fsm_encoding(2)`

set_gui_stroke_binding

Set the command binding for a stroke.

SYNTAX

```
set_gui_stroke_binding
  dictionary_name
  stroke_sequence
  [-builtin builtin_cmd_name]
  [-clear]
  [-tcl_cmd tcl_command]
  [-label tcl_command_label]
```

ARGUMENTS

dictionary_name

Specify the dictionary to set the binding into. Windows that support stroke commands have one or more dictionaries to use when evaluating stroke commands.

stroke_sequence

Specifies the sequence of grids that defines the path of the stroke. See the *Stroke Sequences* section, below, for more information.

-builtin builtin_cmd_name

Specifies the name of a built-in command option to be executed.

-clear

Clears the existing command for the specified stroke sequence.

-tcl_cmd tcl_command

Specifies the Tcl command to be executed when the stroke is entered.

-label tcl_command_label

Specifies the menu label for the tcl command. This menu is displayed for line and snap_line strokes after a delay to provide information on the current bindings.

DESCRIPTION

Select a stroke by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

You can use the **report_gui_stroke_builtins** command to determine the available built-in (non-Tcl) commands. You can use the **report_gui_stroke_bindings** command to determine the existing bindings.

Stroke Types

The stroke command facility supports the following modes for entering strokes: line-based, rectangle-based, and path-based. All stroke entry types generate stroke bindings that are the same.

If you are an occasional user, the line-based and rectangle-based entry modes are easier to specify, but they limit the number of strokes that can be generated. If you are an advanced user, the path-based entry mode, which is more difficult to specify, allows many more strokes to be generated.

See the man page for the **set_gui_stroke_preferences** command for complete information on stroke entry types,

Stroke Sequences

The path of a stroke is mapped onto a 3x3 grid. The size of the grid squares are determined to ensure that the stroke covers the width or height of the grid. The stroke is centered in the grid of horizontal or vertical strokes.

The grid is numbered as shown below:

```
1 2 3  
4 5 6  
7 8 9
```

The stroke is mapped onto the grid and converted to a sequence of these grid numbers, which is called a *stroke sequence*. For example, a diagonal stroke from the top-left corner of the grid to the bottom-right corner has a stroke sequence of **159**; a left-to-right horizontal stroke has a stroke sequence of **456**.

Since the strokes are path-based, a single grid might occur more than once in a sequence. For example, a stroke that moves horizontally left-to-right and right-to-left has a stroke sequence of **12321**.

Strokes also support the Shift, Control, and Alt modifier keys. If one or more of these modifiers are depressed when the stroke is started, they are applied to the stroke. The modifiers are prepended to the stroke sequence, with **s** delimiting Shift, **c** delimiting control, and **a** specifying Alt. The modifiers are separated from the sequence by using a colon (:). For example, a left-to-right horizontal stroke sequence is **123**, if unmodified; **s:123** with Shift; **c:123** with Control; and **sc:123** with Shift-Control modifiers.

A click is supported as a special (degenerate) case of a stroke. If the mouse down-click and mouse up-click event happen close enough together (in both time and location), the stroke is recognized as a click and a stroke sequence of **5** is generated.

The stroke facility also supports the definition of a default command binding that is to be used for any bindings not explicitly set. This default binding is specified by using a simple stroke sequence of **0**. If no binding is registered for a given set of modifiers and sequence, the tool searches for a stroke binding with the same modifiers and a sequence of **0** and uses that if it is found.

Built-In Commands

The application supporting stroke commands might support operations that are not available from the Tcl command language to be invoked via the stroke command. These commands are given a name, and you can use the **-builtin** option to specify a stroke binding to invoke these commands

The stroke facility always supports the built-in commands for zooming and panning listed below.

Zoom_In

Zoom in by a fixed percentage.

Zoom_Out

Zoom out by a fixed percentage

Zoom_In_Rect

Zoom in to fix the rectangle specified by the bounding box for the stroke.

Zoom_Out_Rect

Zoom out centering on the rectangle specified by the bounding box for the stroke.

Zoom_Full

Zoom and pan to fit the entire drawing centered in the window.

Pan_Center_Rect

Pan to center the rectangle specified by the bounding box for the stroke.

Tcl Command Bindings

The bindings support invoking Tcl-based commands to allow the functionality of the mechanism to be expanded. Tcl-based commands are allowed to contain key values that are substituted with data from the command before they are executed by the interpreter, thus allowing these commands to have access to the context information for the stroke. A leading percent (%) character specifies a key value..

The keys listed below are supported by tcl commands.

%rect

Substitutes the coordinates for the bounding box of the stroke. The value is a list of points {{x1 y1} {x1 y2}}, where you substitute bounding box coordinates for x1, y1,x1, and y2.

%startPoint

Specifies the starting point of the stroke. The value is in the form {x y}, where you substitute starting point coordinates for x and y.

%endPoint

Specifies the ending point of the stroke. The value is in the form {x y}, where you substitute starting point coordinates for x and y.

%sequence

Specifies the stroke sequence that invoked this command.

%modifiers

Specifies the modifiers of the stroke sequence that invoked this command.

EXAMPLES

The following example defines a left-to-right horizontal binding to execute the built-in operation that centers the location of the stroke in the viewport.

```
psyn_gui-t> set_gui_stroke_binding Graphics 123 \
    -builtin Pan_Center_Rect
```

The following example calls a tcl command for the Shift-modified, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics \
    -tcl s:753 my_tcl_command
```

The following example calls a tcl command taking a rectangle as an argument for the Shift-control, lower-left to upper-right stroke sequence.

```
psyn_gui-t> set_gui_stroke_binding Graphics \
    ss:753 -tcl {my_tcl_command %rect}
```

SEE ALSO

[report_gui_stroke_bindings\(2\)](#)
[report_gui_stroke_builtin\(2\)](#)
[set_gui_stroke_preferences\(2\)](#)

set_gui_stroke_preferences

Set preferences controlling stroke command entry.

SYNTAX

set_gui_stroke_preferences

```
[-type stroke_entry_type]  
[-shift]  
[-ctrl]  
[-alt]  
[-extended_help_delay ms_delay]
```

ARGUMENTS

-type *stroke_entry_type*

Specifies the type are **snap_line**, **line**, **rect**, **snap_path**, and **path**.

-shift

Sets the type for the shift modifier. This option is valid only when using the **-type** option.

-alt

Sets the type for the alt modifier. This option is valid only when using the **-type** option.

-ctrl

Sets the type for the ctrl modifier. This option is valid only when using the **-type** option.

-extended_help_delay *ms_delay*

Specifies the number of milliseconds to wait before showing the extended help (menu) for a stroke. A value of less than 500 makes the extended feedback immediate. Extremely large values suppress the extended feedback almost completely.

DESCRIPTION

Select a stroke command by specifying a symbol with the mouse. The location of the down-click starts the stroke, and the path that the mouse follows while the mouse button is pressed determines the stroke that is entered. This stroke is mapped onto a numbered 3x3 grid and is transformed into a series of these grid numbers. A stroke dictionary is used to map this sequence of numbers to the command to be executed. When you release the mouse button, this command is executed.

Use this command to control the user interface behavior when you are specifying a stroke. The preferences allow the strokes to be used by both application experts and occasional users of the application.

The two primary types of stroke entry mechanisms are the line-based type and the stroke type. The primary preference supported is the stroke type. A line-based type determines the stroke based on the values of the stroke's start and end points. The path between

the points is ignored. A line-based stroke turns the stroke facility into a form of "pie-menu" that supports nine different menu items. A path-based type determines the stroke based on the path between the stroke's start and end points. This allows an extremely large number of unique strokes to be defined, and it also requires a significantly-higher amount of precision when specifying the stroke than when using the line-based type.

The snap_line, line, and rect stroke types are all line-based strokes: the snap_path and path are path-based strokes.

Stroke Types

snap_line

The line between the start and end points is snapped onto the nearest 45 degree angle. It allows the generation of eight different stroke sequences and the click stroke sequence.

line

The line between the start and end points specifies the stroke. It allows the generation of eight different stroke sequences and the click stroke sequence.

rect

The rectangle between the start and end points specifies the stroke. It allows the generation of four different stroke sequences and the click stroke sequence.

snap_path

This path-based stroke snaps the segments of the path onto the nearest 45 degree angle to make it easier to generate stroke sequences with diagonals and straight lines. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

path

This path-based stroke is a free-formed path from the start point to the end point. Since it is a path-based stroke, the number of unique sequences supported for this entry type is extremely large.

The unmodified stroke type is the default type for all modifiers when a type has not been specified for the modifier. Different stroke types can be used for each combination of modifiers by setting the stroke type for the modifier with this command.

EXAMPLES

The following example sets the stroke type to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -type \
snap_line
```

The following example sets the stroke type for Shift-Control modified strokes to snap_line.

```
psyn_gui-t> set_gui_stroke_preferences -shift \
-ctrl -type snap_line
```

SEE ALSO

[report_gui_stroke_builtins\(2\)](#)
[set_gui_stroke_binding\(2\)](#)

set_host_options

Controls the maximum number of CPU cores that can be used for parallel execution.

SYNTAX

status **set_host_options**
 -max_cores *number_of_cores*

Data Types

number_of_cores integer

ARGUMENTS

-max_cores *number_of_cores*

Specifies the maximum number of CPU cores that are allowed for parallel execution.

The **-max_cores** option checks the number of CPU cores available on the execution host. If you specify a higher number of CPU cores than are available, the tool limits the maximum CPU cores to the number of available cores and issues a UIO-230 warning message.

The **-max_cores** option also checks the load on the execution host. If the host is heavily loaded, the tool uses fewer cores than requested to avoid an overall system slow down. In this event, the tool issues a UIO-231 warning message.

To disable these checks and use the number of CPU cores you requested, set the **disable_multicore_resource_checks** variable to **true**. However, this setting can slow down the tool if the host does not have the necessary cores or is heavily loaded.

DESCRIPTION

The **set_host_options** command is used to specify the maximum number of CPU cores that the tool can use during parallel execution. The default is 1, which indicates that parallel execution is not enabled. The maximum number of cores that can be specified is 16.

To disable parallel execution, set the **-max_cores** option to 1 or run the **remove_host_options** command.

EXAMPLES

The following example tells the tool that it can use up to four cores for parallel execution:

```
prompt> set_host_options -max_cores 4
```

SEE ALSO

[UIO-230\(n\)](#)
[UIO-231\(n\)](#)

set_hpc_options

Applies high performance core settings to the current design

SYNTAX

```
status set_hpc_options
      [-list]
      [-core core_name]
      [-stage stage_name]
      [-report_only]
```

ARGUMENTS

-list

Lists the supported core names and stage names

-core *core_name*

Specifies the high performance core. Use the **-list** option to view the supported core names

-stage *stage_name*

Specifies the stage name. Use the **-list** option to view the supported stage names

-report_only

Reports only the core and technology-node settings and does not apply any design constraints

DESCRIPTION

This command applies high performance core settings to the current design. It sets the parameters and application options for synthesis, placement, and route engines for better performance and power. When you use the **set_hpc_options** command, all the controls are applied to the design and the "hpc_core" attribute is also set on the design.

You must use the **set_technology** command before using the **set_hpc_options** command.

You can use this feature in Design Compiler NXT topographical mode.

EXAMPLES

In following example, the **set_hpc_options** command lists the cores and stages that are supported in the tool:

```
prompt> set_hpc_options -list
cores: A55 A76
stages: compile compile_inc
```

SEE ALSO

[set_technology\(2\)](#)

set_icc2_options

Specifies the options used to launch the IC Compiler II tool from within Design Compiler Graphical or DC Explorer physical mode.

SYNTAX

```
int set_icc2_options
    -icc2_executable      executable
    -ref_libs             library
    [-check]
    [-work_dir            directory]
    [-golden_upf          upf_file]
    [-technology          technology_file
     | -use_technology_lib tech_lib_name]
    [-keep_files]
    [-reset]
    [-convert_sites       convert_sites]
    [-scale_factor         scale_factor]
    [-congestion_use_global_route {true | false}]
    [-silent]
```

Data Types

<i>executable</i>	string
<i>library</i>	string
<i>directory</i>	string
<i>upf_file</i>	string
<i>technology_file</i>	string
<i>scale_factor</i>	int

ARGUMENTS

-icc2_executable *executable*

Specifies the path to the IC Compiler II executable that is used to invoke the IC Compiler II tool from within Design Compiler Graphical or DC Explorer physical mode. By default, the Design Compiler tool uses the `icc2_shell` executable specified by the `$PATH` variable.

-ref_libs *library*

Specifies the IC Compiler II reference libraries that are used when invoking the IC Compiler II tool. This is a required option.

-check

Performs the startup checks and reports any errors that would prevent the `start_icc2` or `start_icc2_dp` command from successfully launching the IC Compiler II tool.

-work_dir *directory*

Specifies the directory where the temporary files are stored when the IC Compiler II tool is launched. Enter the name of your working directory with the relative path from the current directory.

If you do not provide the path to a specific directory, the files are stored in the directory created at the \$TMPDIR/dcg_unique_string location if you specified a location with the **TMPDIR** UNIX environment variable. If you did not specify a location with the **TMPDIR** variable, the files are stored in the /tmp directory location.

-golden_upf upf_file

Specifies the golden UPF file that is used in the IC Compiler II tool. This is a required option in the golden UPF flow.

-technology technology_file

Specifies the technology file used by the **create_lib** command in the IC Compiler II tool. This option is required with the exception of the **start_icc2** or **start_icc2_dp** command in Milkyway mode.

If you do not provide the technology file, the **start_icc2** or **start_icc2_dp** command writes out the technology file that is used by the IC Compiler II tool. In NDM mode, this option is not required and ignored.

-use_technology_lib tech_lib_name

Specifies the reference library to use as a dedicated technology library. The library must contain a technology section and must be one of the libraries specified with the **-ref_libs** option. If the library does not contain a technology section, the **set_icc2_options** command does not fail, but the **create_lib** command in the IC Compiler II tool fails.

This option is mutually exclusive with the **-technology** option, and it must be used with the **-ref_libs** option.

-keep_files

Prevents deletion of the temporary files that are created during and after the launch of the IC Compiler II session.

-reset

Resets the options specified to invoke IC Compiler II.

-convert_sites convert_sites

Specifies the mapping of DEF site names using the following syntax: { **from_site to_site** } ...}.

This option converts all DEF rows of site from_site to rows of site to_site in the IC Compiler II tool.

-scale_factor scale_factor

You can use this option only in Milkyway mode to create IC Compiler II design library using IC Compiler II Link. It specifies the length precision for this library. The length precision for the library and all its reference libraries must be identical. The value is specified in terms of units per micron. By default, a length precision of 10000 is used, which implies one internal unit is equal to one Angstrom or 0.1 nm.

Make sure to set a scale factor value that results in a whole number of database units (dbu) per minimum grid spacing. For example, if your minimum grid spacing is 1 nm, you can use the default scale factor value of 10000 dbu per micron.

In NDM mode, the tool handles the settings of the **create_lib -scale_factor** command in IC Compiler II Link internally. You do not have to use the **-scale_factor** option with the **set_icc2_options** command.

-congestion_use_global_route {true | false}

If this option is set to **true**, the **report_congestion** command computes and displays congestion statistics for the current design using the IC Compiler II tool.

If you also set the **placer_enable_enhanced_router** variable to **true** along with this option, the tool enables Zroute-based congestion-driven placement using IC Compiler II. This option is available only in the Design Compiler NXT tool.

To improve congestion correlation with the IC Compiler II tool with 7 nm and lower-process nodes, you should use the **set_icc2_options -congestion_use_global_route true** command for congestion estimation during placement, as well as for **report_congestion**.

-silent

If this option is specified, the **suppress_icc2_message** command takes effect and suppresses specified messages into IC Compiler II tool.

DESCRIPTION

The **set_icc2_options** command specifies the options used to launch the IC Compiler II tool from within Design Compiler Graphical or DC Explorer physical mode. After specifying the **set_icc2_options** command settings, use the **start_icc2** or **start_icc2_dp** command to begin floorplanning with the IC Compiler II tool.

You can also use the **report_icc2_options** command to report the **set_icc2_options** settings.

EXAMPLES

The following example sets the IC Compiler II libraries and executable to invoke the IC Compiler II tool from within Design Compiler Graphical:

```
prompt> set_icc2_options -ref_libs "lib1.ndm lib2.ndm" \
    -icc2_executable /my_executable_location/icc2_shell
1
```

The following example sets the technology library

```
prompt> set_icc2_options -use_technology_lib technology_lib.nlib
Error: Cannot specify option '-use_technology_lib' of command 'set_icc2_options' without '-ref_libs'. (DCT-310)
0

prompt> set_icc2_options -use_technology_lib technology_lib.nlib \
    -ref_libs { lib1.nlib }
Error: Technology library '%s' does not match any library on the reference library list. (DCT-311)
0

prompt> set_icc2_options -use_technology_lib technology_lib.nlib \
    -ref_libs { technology_lib.nlib }
1

prompt> set_icc2_options -use_technology_lib ..\nlibs/technology_lib.nlib \
    -ref_libs { ..\nlibs/technology_lib.nlib }
1

prompt> set_icc2_options -use_technology_lib technology_lib.nlib \
    -ref_libs { ..\nlibs/technology_lib.nlib }
1
```

The following example performs startup checks and issues an error due to the nonexistent IC Compiler II executable:

```
prompt> set_icc2_options -ref_libs "lib1.ndm" \
    -icc2_executable my_path/icc2_shell -check
Error: Could not find the IC Compiler II executable my_path/icc2_shell. (DCT-224)
0
```

The following example stores the temporary files generated during the launch of the IC Compiler II session in the `my_work_dir` location and does not delete them once you exit the IC Compiler II session:

```
prompt> set_icc2_options -ref_libs "lib1.ndm" \
    -work_dir my_work_dir -keep_files
1
```

SEE ALSO

[start_icc2_dp\(2\)](#)
[report_icc2_options\(2\)](#)

set_icc_dp_options

Specifies the options used to invoke floorplan exploration from Design Compiler Graphical.

SYNTAX

```
int set_icc_dp_options
    -work_dir directory
    -icc_executable executable
    -check flag
    -file_name_prefix prefix
    -keep_files flag
```

Data Types

<i>directory</i>	string
<i>executable</i>	string
<i>flag</i>	flag
<i>prefix</i>	string

ARGUMENTS

-work_dir *directory*

Specifies the directory where the temporary files are stored during floorplan exploration. Enter the name of your working directory with the relative path from the current directory. If you do not specify the **-work_dir** option, the tool stores the temporary files in the directory created at the \$TMPDIR/dcg_*unique_string* location if you specified a location by using the **TMPDIR** UNIX environment variable. If you did not specify a location with the **TMPDIR** variable, the tool stores the files in the /tmp directory.

-icc_executable *executable*

Specifies the path to the IC Compiler executable that is used for floorplan exploration. By default, Design Compiler uses the *icc_shell* executable specified by the **\$PATH** variable.

-check *flag*

Performs the startup checks and issues errors, if any.

-file_name_prefix *prefix*

Specifies the prefix name for any generated files, such as the floorplanning scripts and floorplan files. The default file prefix naming style is %s_%d where %s is the design name and %d is the process ID. You can provide any format using these two directives. See the Examples section.

-keep_files *flag*

Specifies not to delete the temporary files that are created during and after the launch of the floorplan exploration session.

DESCRIPTION

This command specifies the options used to launch Design Compiler Graphical floorplan exploration. After setting **set_icc_dp_options**, use the **start_icc_dp** command to begin floorplanning. You can also use the **report_icc_dp_options** command to report the **set_icc_dp_options** settings.

EXAMPLES

```
prompt> set_icc_dp_options \
    -work_dir /tmp/work_dir \
    -icc_executable /your/location/icc_shell

prompt> set_icc_dp_options \
    -check

prompt> set_icc_dp_options \
    -file_name_prefix "temp_cel"

prompt> set_icc_dp_options \
    -file_name_prefix "Tryrun1"

prompt> set_icc_dp_options \
    -file_name_prefix "Tryrun%$s"
```

SEE ALSO

[compile_ultra\(2\)](#)
[report_icc_dp_options\(2\)](#)
[start_icc_dp\(2\)](#)

set_ideal_latency

Specifies ideal network latency.

SYNTAX

```
status set_ideal_latency
      [-rise | -fall]
      [-min | -max]
      delay
      object_list
```

Data Types

```
delay      float
object_list list
```

ARGUMENTS

-rise | -fall

Specifies whether the latency is for data rise or data fall transition. If you do not specify **-rise** or **-fall**, both values are set. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies whether the latency is to be used for minimum delay analysis or maximum delay analysis. By default, the delay is used for both maximum and minimum delay analysis. The **-min** and **-max** options are mutually exclusive.

delay

Specifies the ideal latency value on pins in the ideal network. The delay must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies delay values in nanoseconds, *delay* must be expressed in nanoseconds.

object_list

Specifies a list of leaf cell pins or top-level ports that are the startpoints of the timing arcs for which ideal latency is to be set.

DESCRIPTION

Sets the ideal latency on top-level ports and leaf cell pins of the ideal network.

Design Compiler assumes ideal timing for ideal networks and ideal nets, which means pins have a specified ideal latency (from the **set_ideal_latency** command) or zero ideal latency by default. The ideal network is normally used for pre-layout to reduce runtime by avoiding unnecessary DRC optimization and retiming. Ideal latency provides an estimate of the ideal network or ideal nets for pre-layout.

The specified latency value overrides the internally-estimated cell delay value and net delay value. If the specified pins do not belong to the ideal network, ideal nets, or auto disable drc nets, the **report_ideal_network** command generates an error message and the *delay* value is not used for those pins.

The **set_ideal_latency** command affects all pins in the transitive fanout of the pins or ports. The total ideal latency at an ideal boundary pin is the sum of latency on the ideal network source and all ideal latencies on the path.

You can use **set_ideal_latency** for pins at lower levels of the design hierarchy. Pins are specified in the form of "INSTANCE1/INSTANCE2/PIN_NAME."

To list ideal latency values, use the **report_ideal_network** command.

To remove ideal latency values from a design, use the **remove_ideal_latency** or **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies a rise latency of 1.2 and a fall latency of 0.9 for the ports named A, B, and C.

```
prompt> set_ideal_latency 1.2 -rise {A B C}  
prompt> set_ideal_latency 0.9 -fall {A B C}
```

SEE ALSO

`report_ideal_network(2)`
`report_timing(2)`
`set_ideal_net(2)`
`set_ideal_network(2)`
`set_ideal_transition(2)`

set_ideal_net

Sets the specified nets as ideal. Note that this command has been deprecated; you should use the **set_ideal_network -no_propagate** command instead.

SYNTAX

```
status set_ideal_net  
      nets
```

Data Types

nets collection

ARGUMENTS

nets

Specifies the nets on which to set the **ideal_net** attribute. These nets must be visible from the current design.

DESCRIPTION

This command sets the specified nets as ideal nets. Note that this command has been deprecated; you should use the **set_ideal_network -no_propagate** command instead.

The global driver pins of the specified nets are marked as sources of an ideal network. These nets must be visible in the current design. The tool treats a net as an ideal net if all global driver pins of the net are ideal. By default, the tool treats all clock nets as ideal nets. However, this does not include the logic gates in the networks, and the nets driven by those logic gates. The ideal properties of the net's global driver pins do not propagate through logic gates. However, they propagate through hierarchies. Setting the global driver pins as ideal enables the ideal properties on all nets that are electrically connected to those pins.

To prevent clock nets from being treated as ideal nets, use the **set_auto_disable_drc_nets -clock false** or **set_propagated_clock [all_clocks]** command. After you run the **set_propagated_clock [all_clocks]** command, the **ideal_net** attribute is not reported by the **report_net** command.

Ideal nets are networks of nets that are free from maximum capacitance, maximum fanout, and maximum transition design rule constraints. Ideal nets are useful for reducing DRC violations caused by clock trees, because these networks usually have large maximum capacitance and maximum fanout violations. Ideal nets use the ideal latency specified by the **set_ideal_latency** command and ideal timing specified by the **set_ideal_transition** command for timing calculation. By default, zero ideal latency and zero transition are used. To automatically spread ideal attributes through a network, use the **set_ideal_network** command without the **-no_propagate** option.

The tool automatically sets the **size_only** attribute on the cells of the ideal network sources. In addition, an ideal net implies that this net is **dont_touch**. Note that the tool might optimize away combinational cells in the fanout of the ideal net. However, it guarantees that the ideal network sources are never lost. To automatically set clock, constant, or scan nets in the design as ideal, use the **set_auto_disable_drc_nets** command.

Use the **remove_ideal_net** command to remove the attributes set by the **set_ideal_net** command in the current design. Use the **set_auto_disable_drc_nets -none** command to remove the **auto_disable_drc_net** attribute. The **reset_design** command removes all attributes from the design, including both the ideal attributes and the **auto_disable_drc_net** attributes; however, by default, the tool still treats clock networks as ideal nets.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **ideal_net** attribute on all nets in the current design:

```
prompt> set_ideal_net [get_nets]
```

SEE ALSO

`remove_ideal_net(2)`
`reset_design(2)`
`set_auto_disable_drc_nets(2)`

`set_ideal_network(2)`
`set_ideal_transition(2)`
`set_dont_touch(2)`
`set_dont_touch_network(2)`

set_ideal_network

Marks a set of ports or pins in the current design as sources of an ideal network. No delay computation is performed. However, the arrival time and required information is propagated in the transitive fanout of the ideal source.

SYNTAX

```
integer set_ideal_network
    object_list
    [-dont_care_placement]
    [-no_propagate]
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of objects (ports, pins, or nets) to mark as the sources of an ideal network. If more than one object name is specified, each must be enclosed in quotation marks or braces {}. The source objects are input ports on the design or any internal pin, except for pins at hierarchical boundaries. If nets are provided, all of the nets' global driver pins are marked as ideal network sources, and the corresponding ideal network attributes are actually set on all of the global driver pins of the specified nets. These objects must be visible from the current design.

The **set_ideal_network** command accepts nets only when you specify the **-no_propagate** option.

-dont_care_placement

Indicates that the ideal network is not considered in placement. The nets in the ideal network are treated as disconnected. Random locations are assigned to ideal network cells. By default, the ideal network is placed at the lowest priority.

-no_propagate

Indicates that the ideal network is not propagated through logic gates, but it still propagates through hierarchies. Ideal properties are enabled on all nets that are electrically connected to ideal network sources. By default, this option is off.

DESCRIPTION

This command marks a set of ports or pins in the current design as sources of an ideal network. Ideal networks are an extension of ideal nets that incorporate automatic propagation of the **ideal** attribute. You specify only the source of the network; the **compile** command treats all nets, cells, and pins on the transitive fanout of these objects as ideal. The ideal property is automatically spread by the tool and respread as necessary during **compile** optimizations. The criteria for propagating the ideal property, starting at the source pins and ports, are as follows:

- A pin is marked as ideal if you specify it by using the **set_ideal_network** command if it is either a driver pin and its cell is ideal or

it is a load pin attached to a net that is ideal.

- A net is marked as ideal if all of its driving pins are ideal.
- A combinational cell is marked as ideal if all of its input pins are either ideal or attached to a constant net (and other input pins are ideal). Objects with the **case analysis** attribute set are not treated as constant.

Propagation traverses through combinational cells but stops at sequential cells. If an ideal network overlaps a clock network, the clock timing overrides the ideal timing for the clock part of the network.

In addition to disabling timing updates and timing optimizations, all cells and nets in the ideal network have the **dont_touch** attribute set.

The **size_only** attribute is set on all cells of ideal network sources. If nets are specified, **size_only** is set on all cells that are cells of the specified nets' global driver pins. This guarantees that ideal network sources are not optimized away by compile.

NOTE: The implied **size_only** attribute set by this command overrides the four **FALSE** attribute values set by the **set_size_only** command. Use the **report_cell** command to determine if a cell is **size_only** or not.

DRC checking is turned off so the nets in an ideal network are free of **max_capacitance**, **max_fanout**, and **max_transition** design rule constraints. Disabling all of these features improves runtime and timing optimization; for example, by not resetting and scanning networks that you might want synthesized separately when using the **compile** command.

The latency and transition times of an ideal network are 0 by default, but you can override them by using the **set_ideal_latency** and **set_ideal_transition** commands.

If the **ideal_network** attribute is set on floating objects in a design, these objects are still optimized away during compile.

The **set_ideal_network** command will not prevent clock gating optimizations from modifying or removing clock gating cells. To prevent this use **set_dont_touch** command instead.

To reverse the effect of the **set_ideal_network** command, use the **remove_ideal_network** command and specify the source pins or ports for the network. Timing, source pins, and boundary pins of an ideal network are displayed by using the **report_ideal_network** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an ideal network on objects in a design named *CLOCK_GEN*.

```
prompt> current_design CLOCK_GEN
prompt> set_ideal_network {port1 port2}
```

SEE ALSO

set_dont_touch_network(2)

```
set_ideal_latency(2)
set_ideal_net(2)
set_ideal_transition(2)
set_size_only(2)
```

set_ideal_transition

Specifies ideal transition for the ideal network and ideal nets.

SYNTAX

```
status set_ideal_transition
      [-rise | -fall]
      [-min | -max]
      transition_time
      object_list
```

Data Types

<i>transition_time</i>	float
<i>object_list</i>	list

ARGUMENTS

-rise | -fall

Indicates whether the specified transition time is applicable for rising or falling transition. If you do not specify **-rise** or **-fall**, both values are set. The **-rise** and **-fall** options are mutually exclusive.

-min | -max

Specifies whether the transition is to be used for minimum delay analysis or maximum delay analysis. By default, the delay is used for minimum and maximum delay analysis. The **-min** and **-max** options are mutually exclusive.

transition_time

Specifies the ideal transition value on the pins in an ideal network. The transition time must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies transition values in nanoseconds, *transition_time* must be expressed in nanoseconds.

object_list

Specifies a list of leaf cell pins or top-level ports that are the startpoints of the timing arcs for which ideal transition is set.

DESCRIPTION

Sets the ideal transition on top-level ports and leaf cell pins of an ideal network.

Design Compiler assumes ideal timing for the ideal network, which means pins have a specified ideal transition (from the **set_ideal_transition** command) or zero ideal transition by default. The ideal network is normally used for pre-layout to reduce runtime by avoiding unnecessary DRC optimization and retiming. Ideal transition provides an estimate of the ideal network for pre-layout.

The specified transition value overrides the internally-estimated cell and net transition value. If the specified pins do not belong to the ideal network, an error message is generated by the **report_ideal_network** command and *transition_time* is not used for those pins.

The ideal transition at an ideal boundary pin is the ideal transition of the closest pin with specified ideal transition.

You can use **set_ideal_transition** for pins at lower levels of the design hierarchy. Pins are specified in the form of "INSTANCE1/INSTANCE2/PIN_NAME."

To list ideal transition values, use the **report_ideal_network** command.

To remove the ideal transition values from a design, use the **remove_ideal_transition** or **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies a rise transition of 1.2 and a fall transition of 0.9 for the ports named A, B, and C.

```
prompt> set_ideal_transition 1.2 -rise {A B C}
prompt> set_ideal_transition 0.9 -fall {A B C}
```

set_ieee_1500_configuration

Sets the IEEE 1500 insertion configuration for the current design.

SYNTAX

```
integer set_ieee_1500_configuration
      [-wir_width integer]
```

ARGUMENTS

-wir_width *integer*

Specifies the width of the IEEE 1500 wrapper instruction register (WIR) to be implemented by IEEE 1500 test-mode control insertion.

By default, the WIR width is automatically determined by the tool based on the number of test-mode encodings needed and the type of encoding specified by the **-mode_decoding_style** option of the **set_dft_configuration** command.

DESCRIPTION

This command specifies the configuration of the IEEE 1500 test-mode control logic to be inserted in the current design. Note that IEEE 1500 logic is implemented only when IEEE 1500 test-mode control is enabled by the **set_dft_configuration -ieee_1500 enable** command.

Use the **report_ieee_1500_configuration** command to display the current IEEE 1500 configuration of the design.

Use the **reset_ieee_1500_configuration** command to reset the current IEEE 1500 configuration of the design.

To configure IEEE 1500 control data registers, use the **set_scan_path** command.

EXAMPLES

The following command changes the WIR width to 4:

```
prompt> set_ieee_1500_configuration -wir_width 4
```

SEE ALSO

```
report_ieee_1500_configuration(2)
reset_ieee_1500_configuration(2)
set_scan_path(2)
```

set_ignored_layers

Specifies the routing layers that are ignored for RC estimation and congestion analysis. This command is supported only in topographical mode.

SYNTAX

```
status set_ignored_layers
  [-rc_congestion_ignored_layers layer_names]
  [-min_routing_layer min_name]
  [-max_routing_layer max_name]
```

Data Types

<i>layer_names</i>	list
<i>min_name</i>	string
<i>max_name</i>	string

ARGUMENTS

-rc_congestion_ignored_layers *layer_names*

Specifies the routing layers to be ignored during congestion analysis and RC estimation.

-min_routing_layer *min_name*

Specifies the minimum (lowest) layer that can be used for routing. The tool marks all routing layers below the specified layer as ignored layers for RC and congestion estimation.

-max_routing_layer *max_name*

Specifies the maximum (highest) layer that can be used for routing. The tool marks all routing layers above the specified layer as ignored layers for RC and congestion estimation.

DESCRIPTION

In Design Compiler topographical mode, this command sets the routing layers that are ignored during congestion analysis and RC estimation. You can use either the **-rc_congestion_ignored_layers** option to explicitly exclude specific layers from consideration, or the **-min_routing_layer** and **-max_routing_layer** options to specify the range of layers considered (causing all other layers to be ignored).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the m5 and m6 layers to be ignored during congestion analysis and RC estimation:

```
prompt> set_ignored_layers -rc_congestion_ignored_layers {m5 m6}
```

The following example sets m2 as the minimum routing layer and m5 as the maximum routing layer. All layers below m2 and above m5 are set as ignored layers for congestion analysis and RC estimation.

```
prompt> set_ignored_layers -min_routing_layer m2 -max_routing_layer m5
```

SEE ALSO

```
remove_ignored_layers(2)  
report_ignored_layers(2)  
report_lib(2)
```

set_impl_priority

Sets the formula attribute of the priority parameter and/or the set_id attribute for implementations in synthetic libraries.

SYNTAX

```
status set_impl_priority
  [-priority formula]
  [-set_id id]
  implementation_list
```

Data Types

<i>formula</i>	string
<i>id</i>	int
<i>implementation_list</i>	list

ARGUMENTS

-priority *formula*

Specifies the string to which the **formula** attribute of the **priority** parameter should be set. An empty string causes the **priority** parameter to be removed from the specified implementations. The formula should evaluate to an integer between 0 and 10.

-set_id *id*

Specifies the value to which the **set_id** attribute should be set.

implementation_list

Specifies a list of implementations for which the **priority** parameter and/or the **set_id** attribute are to be set. Implementation names must contain a library prefix. For more information, refer to the EXAMPLES section of this man page. If more than one object is included, they must be enclosed in quotes or braces ({}).

DESCRIPTION

The **set_impl_priority** command sets the **formula** attribute of the **priority** parameter and/or the **set_id** attribute on the specified implementations. Either **-priority** or **-set_id** must be specified. The synthetic libraries containing the implementations must be loaded into **dc_shell**.

NOTE: This command cannot be used in **dc_shell** scripts embedded in HDL descriptions. In addition, the command affects only the copy of the library that is currently loaded into memory, and has no effect on the version that exists on disk. However, if the library is written out using **write_lib**, all **priority** parameters or **set_id** attributes will be written out, causing library objects to be permanently changed.

EXAMPLES

The following command sets the formula attribute in the **priority** parameter to "n < 4 ? 6 : 2" and the **set_id** attribute to 4 for 'my_lib.sldb/m1/rpl':

```
prompt> set_impl_priority -priority "n < 4 ? 6 : 2" -set_id 4 my_lib.sldb/m1/rpl
```

The following command sets the **set_id** attribute to 3 for all the implementations of module 'm2' in the synthetic library 'my_lib.sldb':

```
prompt> set_impl_priority -set_id 3 my_lib.sldb/m2/*
```

The following command removes the **priority** parameter for implementations 'imp1' and 'imp2' of the module 'syn_lib.sldb/mod':

```
prompt> set_impl_priority -priority "" { syn_lib.sldb/mod/imp1, syn_lib/mod/imp2 }
```

SEE ALSO

compile(2)
report_synlib(2)

set_implementation

Specifies the implementation to use for synthetic library cell instances in a design.

SYNTAX

```
status set_implementation
  implementation_name
  cell_list
  [-check_impl]
```

Data Types

<i>implementation_name</i>	string
<i>cell_list</i>	list

ARGUMENTS

implementation_name

Specifies the name of the implementation used to implement the function of the *cell_list* synthetic library cell instances. A single period (.) in the implementation name locks in the current implementation of the instance. The implementation name must also contain the module name, such as *DW01_add/cla*, when setting implementation on synthetic operators.

cell_list

Specifies the synthetic library cell instances to be implemented by *implementation_name*. If more than one instance name is specified, enclose the names in quotes ("") or in braces ({}). Specify either instantiated cell instances or inferred cell instances, but not both, in *cell_list*.

-check_impl

Checks for the existence of the specified implementation before setting implementation on the cell instances.

DESCRIPTION

The **set_implementation** command tags specified synthetic library cell instances with the name of an implementation to use to implement them. When the **compile** command is run, the tool chooses the user-specified implementation to implement a cell instance. Otherwise, **compile** chooses the implementation it considers most appropriate for a cell instance. For a design that has already been compiled, **set_implementation** with a period (.) locks in the current implementation. Subsequent compiles do not change the implementation.

The **set_implementation** command does not function on cell instances that are not defined in a synthetic library.

The **report_resources** command lists the current implementation of all synthetic library instances, and indicates whether the implementation has been locked by **set_implementation**.

Use the **report_synthlib** command for the possible implementations of a synthetic library cell.

EXAMPLES

If *A1* is an instance of the *DW01_ADD* cell in the current design, a *cla* carry-lookahead implementation can be specified to implement *A1*. The following example assumes that *DW01_ADD* is a module defined in a synthetic library listed in **synthetic_library**, and that *DW01_ADD* has a *cla* carry-lookahead implementation associated with it:

```
prompt> set_implementation cla A1
```

The following example directs **compile** to use *rpl* for both *Adder1* in the design *FIFO1* and *Adder2* in the design *FIFO2*:

```
prompt> set_implementation rpl { FIFO1/Adder1 FIFO2/Adder2 }
```

The following example removes any effects of **set_implementation** from all synthetic cells of the current design:

```
prompt> remove_attribute [get_cells *] implementation
```

The following example locks the implementation of all synthetic cells in the current design. On subsequent compiles, the implementation does not change.

```
prompt> set_implementation . "*"**
```

The following example sets a *cla* implementation on an ADD operator cell named *A1*:

```
prompt> set_implementation DW01_add/cla A1
```

SEE ALSO

```
compile(2)
remove_attribute(2)
report_resources(2)
report_synthlib(2)
synthetic_library(3)
```

set_input_delay

Sets input delay on pins or input ports relative to a clock signal.

SYNTAX

```
status set_input_delay
  delay_value
  [-reference_pin pin_port_name]
  [-clock clock_name]
  [-clock_fall]
  [-level_sensitive]
  [-network_latency_included]
  [-source_latency_included]
  [-rise]
  [-fall]
  [-max]
  [-min]
  [-add_delay]
  port_pin_list
```

Data Types

<i>delay_value</i>	float
<i>clock_name</i>	collection of 1 object
<i>port_pin_list</i>	collection

ARGUMENTS

delay_value

Specifies the path delay. The *delay_value* must be in units consistent with the technology library used during optimization. The *delay_value* represents the amount of time the signal is available after a clock edge. This represents a combinational path delay from the clock pin of a register.

-reference_pin *pin_port_name*

Specifies the clock pin or port to which the specified delay is related. If you use this option, and if propagated clocking is being used, the delay value is related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The options *-network_latency_included* and *-source_latency_included* cannot be used at the same time as the *-reference_pin* option. For ideal clock network, only source latency is applied.

The pin specified with the *-reference_pin* option should be a leaf pin or port in a clock network, in the direct or transitive fanout of a clock source specified with the *-clock* option. If multiple clocks reach the port or pin where you are setting the input delay, and if the *-clock* option is not used, the command considers all of the clocks.

-clock *clock_name*

Specifies the clock to which the specified delay is related. If *-clock_fall* is used, **-clock *clock_name*** must be specified. If **-clock** is not specified, the delay is relative to time zero for combinational designs. For sequential designs, the delay is considered relative to a new clock with the period determined by considering the sequential cells in the transitive fanout of each port.

The *clock_name* can be either a string or collection of one object.

-clock_fall

Specifies that the delay is relative to the falling edge of the clock. The default is the rising edge.

-level_sensitive

Specifies that the source of the delay is a level-sensitive latch. This allows the tool to derive the setup and hold relationship for paths from this port as if the port is a level-sensitive latch. If **-level_sensitive** is not used, the input delay is treated as if it is a path from a flip-flop.

-network_latency_included

Specifies that the clock network latency is not added to the input delay value. If this option is not specified, the clock network latency of the related clock is added to the input delay value. It has no effect if the clock is propagated or the input delay is not specified with respect to any clock.

-source_latency_included

Specifies that the clock source latency is not added to the input delay value. If this option is not specified, the clock source latency of the related clock will be added to the input delay value. It has no effect if the input delay is not specified with respect to any clock.

-rise

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, rising and falling delays are assumed to be equal.

-fall

Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, rising and falling delays are assumed equal.

-max

Specifies that *delay_value* refers to the longest path. If neither **-max** nor **-min** is specified, maximum and minimum input delays are assumed equal.

-min

Specifies that *delay_value* refers to the shortest path. If neither **-max** nor **-min** is specified, maximum and minimum input delays are assumed equal.

-add_delay

Specifies whether to add delay information to the existing input delay or to overwrite. The **-add_delay** option enables you to capture information about multiple paths leading to an input port that are relative to different clocks or clock edges.

For example, the following command removes all other maximum rise input delay from A, since **-add_delay** is not specified. Other input delay with a different clock or with **-clock_fall** is removed.

```
set_input_delay 5.0 -max -rise -clock phi1 {A}
```

In the following example, **-add_delay** is specified. If there is an input maximum rise delay for A relative to clock *phi1* rising edge, the larger value is used. The smaller value will not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise input delay relative to a different clock or different edge of the same clock, it remains with the new delay.

```
prompt> set_input_delay 5.0 -max -rise -clock phi1 -add_delay {A}
```

port_pin_list

Specifies a list of input port or internal pin names in the current design to which *delay_value* is assigned. If more than one object is specified, the objects are enclosed in quotes ("") or in braces ({}). If input delay is specified on a pin, the cell of the pin is set to size only to leave room for compile applying sizing on it.

DESCRIPTION

The **set_input_delay** command sets input path delay values for the current design. Used with **set_load** and **set_driving_cell**, the input and output delays characterize the operating environment of the current design.

A path starts from a primary input or clock of sequential element and ends at a sequential element or primary output. The **delay_value** to be specified is the delay between the startpoint and the object on which the **set_input_delay** is being set, relative to the clock edge.

The **set_input_delay** command sets input path delays on input ports relative to a clock edge. Input ports are assumed to have zero input delay, unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay from a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the input delay relative to the rising clock edge; if it is negative-enabled, set the input delay relative to the falling clock edge. If time is being borrowed at that latch, add that time borrowed to the path delay from the latch when determining input delay.

The **characterize** command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

The timer adds input delay to path delay for paths starting at primary inputs and output delay for paths ending at primary outputs.

Use the **report_port** command to list input delays associated with ports.

To list input delays of internal pins, use **report_design**.

Use **remove_input_delay** or **reset_design** to remove input delay values.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets an input delay of 2.3 for ports IN1 and IN2 on a combinational design. Because the design is combinational, no clock is needed.

```
prompt> set_input_delay 2.3 {IN1 IN2}
```

The following example uses a clock collection and sets an input delay of 1.2 relative to the rising edge of CLK1 for all input ports in the design:

```
prompt> set_input_delay 1.2 -clock [get_clocks CLK1] [all_inputs]
```

The following example sets the input and output delays for the bidirectional port INOUT1. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}
prompt> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

The following example has three paths to the IN1 input port. One of the paths is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The **-add_delay** option is used to indicate that new input delay information will not cause old information to be removed.

```
prompt> set_input_delay 2.2 -max -clock CLK1 -add_delay {IN1}
prompt> set_input_delay 1.7 -max -clock CLK1 -clock_fall \
    -add_delay {IN1}
prompt> set_input_delay 4.3 -max -clock CLK2 -clock_fall \
    -add_delay {IN1}
```

In this example, two different maximum delays and two minimum delays for port A are specified using the **-add_delay** option. Because

the information is relative to the same clock and clock edge, only the largest of the maximum values and the smallest of the minimum values are maintained, in this 5.0 and 1.1. If the **-add_delay** option is not used, the new information overwrites the old information.

```
prompt> set_input_delay 3.4 -max -clock CLK1 -add_delay {A}
prompt> set_input_delay 5.0 -max -clock CLK1 -add_delay {A}
prompt> set_input_delay 1.1 -min -clock CLK1 -add_delay {A}
prompt> set_input_delay 1.3 -min -clock CLK1 -add_delay {A}
```

set_input_transition

Sets the **max_transition_rise**, **max_transition_fall**, **min_transition_rise**, or **min_transition_fall** attributes to the specified transition values on the specified input and inout ports.

SYNTAX

```
status set_input_transition  
      transition  
      [-rise] [-fall] [-min] [-max]  
      port_list
```

Data Types

<i>transition</i>	float
<i>port_list</i>	collection

ARGUMENTS

transition

Specifies a nonnegative transition value to which the **max_transition_rise**, **max_transition_fall**, **min_transition_rise** or **min_transition_fall** attributes are to be set on the ports in *port_list*. The *transition* is the transition time of a slope that drives the port, such that a higher transition value means longer delays. Thus, a *transition* of 0 is infinite transition, or no delay between the ports and all that is connected to them. *transition* must be in units consistent with the technology library used during optimization.

-rise -fall

Indicates that the **rise** or **fall** attributes of *port_list* are to be set to *transition*. If neither is specified, both are set to *transition*.

-min -max

Indicates that the transition value is to be applied for minimum or maximum delay analysis. If no value is specified for minimum analysis, the maximum value is used.

port_list

Specifies a list of names of input or inout ports in the current design, on which the transition value is to be set. If you specify more than one port, you must enclose the ports in either quotes or braces ({}).

DESCRIPTION

Sets the **max_transition_rise**, **max_transition_fall**, **min_transition_rise** or **min_transition_fall** attributes to *transition* on specified input and inout ports in the current design.

Note: The **set_input_transition** command removes any corresponding rise or fall driving cell attributes and rise or fall drive attributes on the specified ports. If you want a fixed transition value, use **set_input_transition**, otherwise, use **set_driving_cell** instead of

set_drive, if possible.

To view transition information on ports, use **report_port -verbose**. To remove transition attributes from ports, use **remove_attribute**. The **reset_design** command removes all attributes from a design, including the transition attributes.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets the maximum rise and fall transition values of ports A, B, and C to 7.0.

```
prompt> set_input_transition 7.0 {A B C}
```

The following example sets the maximum rise and fall transition values of all input ports to 7 and sets the maximum rise transition value on port B to 11.

```
prompt> set_input_transition 7 [all_inputs]
prompt> set_input_transition -rise 11 B
```

The following example sets the minimum fall transition value on port C to 13.

```
prompt> set_input_transition -fall -min 13.0 {C}
```

[set_drive\(2\)](#)
[set_driving_cell\(2\)](#)
[set_load\(2\)](#)

set_isolate_ports

Specifies the ports to be isolated from the internal fanouts of the driver nets.

SYNTAX

```
int set_isolate_ports
  [-type inverter | buffer]
  [-driver cell_name]
  [-force]
  port_list
```

Data Types

cell_name string
port_list list

ARGUMENTS

-type inverter | buffer

Specifies whether inverter pairs or buffers are used to isolate the ports. Note that Design Compiler might perform sizing optimization on the inserted cell, which can cause the actual isolation cell type to be different from the specified cell type. If this behavior is not desired, use the **-force** option with the **-type** option, to ensure that the specified type of isolation cell is inserted.

-driver *cell_name*

Indicates that the specified target library cell should be used to isolate the ports. The library cell can be either a buffer or an inverter. Note that Design Compiler might perform sizing optimization on the inserted cell, which can cause the actual driver cell to be different from the specified cell type. If this behavior is not desired, use the **-force** option with the **-driver** option, to ensure that the specified driver cell is used.

-force

Specifies that isolation must be performed on the ports, even if an isolation is not required because of the absence of internal loads on the nets driving the ports. Note: Isolation might not be performed if a buffer, inverter pair, or cell corresponding to the specified isolation logic, is already present.

port_list

Specifies the ports in the current design that are to be isolated.

DESCRIPTION

The **set_isolate_ports** command specifies the input or output ports in the current design that are to be isolated. For an output port, the **compile** command attempts to ensure that the net driving the port does not have any other internal fanout by inserting an isolation cell. For an input port, an isolation cell is inserted if the port drives multiple cells or if the port drives a pin of a cell that contains more

than one input pin.

By default, no action is taken if output ports are already isolated from internal fanouts of their driver nets and input ports are already isolated from driving multiple cells. If the **-force** option is specified, isolation is performed on the ports even if the ports do not need isolation with above two conditions.

Note that bidirectional ports cannot be isolated using this command. In addition, no isolation is performed on a port by **compile** if the net connected to the port has a **dont_touch** attribute or if the port has been defined as a clock source.

Use the **remove_isolate_ports** or the **reset_design** command to remove a port from the list of ports to be isolated. Use the **report_isolate_ports** command to list the isolation status of these ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that isolation is required on the output port qout with a buffer.

```
prompt> set_isolate_ports -type buffer qout
```

The following command specifies isolation using a particular cell from the target library on an output port.

```
prompt> set_isolate_ports -driver IVDAP qout
```

SEE ALSO

[report_isolate_ports\(2\)](#)
[reset_design\(2\)](#)

set_isolation

Sets the UPF strategy for inserting isolation cells between a specified power domain and other power domains.

SYNTAX

```
status set_isolation
  isolation_strategy_name
  -domain power_domain
  [-isolation_power_net isolation_power_net]
  [-isolation_ground_net isolation_ground_net]
  [-isolation_supply isolation_supply_set]
  [-clamp_value 0 | 1 | latch]
  [-applies_to inputs | outputs | both]
  [-applies_to_boundary upper | lower | both]
  [-source source_supply_set_name]
  [-sink sink_supply_set_name]
  [-diff_supply_only true | false]
  [-elements objects]
  [-exclude_elements objects]
  [-no_isolation]
  [-force_isolation]
  [-name_prefix prefix_string]
  [-name_suffix suffix_string]
  [-isolation_signal isolation_signal]
  [-isolation_sense low | high]
  [-location self | parent | fanout]
    [-async_set_reset async_set_reset_signal high | low]
    [-update]
  [-async_clamp_value boolean]
```

Data Types

<i>isolation_strategy_name</i>	string
<i>power_domain</i>	string
<i>isolation_power_net</i>	string
<i>isolation_ground_net</i>	string
<i>source_supply_set_name</i>	string
<i>sink_supply_set_name</i>	string
<i>objects</i>	list
<i>prefix_string</i>	string
<i>suffix_string</i>	string
<i>isolation_signal</i>	string

ARGUMENTS

isolation_strategy_name

Specifies the new UPF isolation strategy name for the power domain.

-domain *power_domain*

Specifies the power domain name to which this UPF isolation strategy applies.

-isolation_power_net *isolation_power_net*

Specifies the power net used to power isolation cells inserted by the isolation strategy.

-isolation_ground_net *isolation_ground_net*

Specifies the ground net for isolation cells inserted by the isolation strategy.

-isolation_supply *isolation_supply_set*

Specifies the supply set whose power and ground functions supply power to isolation cells inserted by the isolation strategy. It is mutually exclusive with the **-isolation_power_net** and **-isolation_ground_net** options. This option is supported with UPF 3.0 standard.

-clamp_value 0 | 1 | latch

Specifies the constant value of the isolation cell output when the isolation function is enabled: **0**, **1**, or **latch**. The default is **0**. A clamp value of **latch** is implemented by an isolation cell that latches the current data and holds that value constant during isolation.

-applies_to inputs | outputs | both

Specifies explicitly whether to apply the strategy to inputs only, to outputs only, or to both inputs and outputs of the power domain. The default is **outputs** unless the **-source** or **-sink** option is used, or the **-diff_supply_only** option is set to **true** and the supplies are defined by supply sets, in which case the default is **both**.

-applies_to_boundary upper | lower | both

Specifies explicitly whether to apply the strategy to upper boundaries(lowConns) only, to lower boundaries(highConns) only, or to both upper and lower boundaries of the power domain.

The default is

upper

- if the power domain does not have lower_domain_boundary attribute OR
- if the power domain lower_domain_boundary attribute set to FALSE

both

- if the power domain lower_domain_boundary attribute set to TRUE

-source *source_supply_set_name*

Restricts the strategy to only domain-crossing nets that are driven by a cell powered by the specified supply set.

-sink *sink_supply_set_name*

Restricts the strategy to only domain-crossing nets that fan out to one or more cells powered by the specified supply set.

-diff_supply_only true | false

When set to **true**, applies the strategy only to domain-crossing nets in which the driver and receivers are powered by different supply sets or supply nets. The default is **false**, meaning no isolation restriction based on matching driver and receiver supplies. The **-source**, **-sink**, and **-diff_supply_only** options cannot be used at the same time.

-elements *objects*

Restricts the strategy to only the listed objects in this power domain. The objects can be design elements such as cells, pins, and ports. Cells should be in the **-elements** of the **create_power_domain** command. Pins and ports should be the interface of a power domain.

-exclude_elements *objects*

Excludes the listed objects from the strategy in this power domain. The objects can be design elements such as cells, pins, and ports.

-no_isolation

Prevents any isolation of elements specified by this strategy.

-force_isolation

Forces isolation of the elements specified for this strategy, irrespective of priority rules for conflicting strategies. Isolation cells inserted with this option cannot be optimized away by implementation tools.

-name_prefix *prefix_string*

Specifies the string to add to the beginning of names of isolation cells inserted by the strategy, overriding the **name_format** command. An empty string is allowed as a setting.

-name_suffix *suffix_string*

Specifies the string to add to the end of names of isolation cells inserted by the strategy, overriding the **name_format** command. An empty string is allowed as a setting.

-isolation_signal *isolation_signal*

Specifies the enable isolation signal for cells created by the isolation strategy. The *isolation_signal* can be a port, pin, or net.

-isolation_sense low | high

Specifies the sense of the enable isolation signal, either **low** or **high**. The default is **high**.

-location self | parent | fanout

Specifies the hierarchical location for inserting isolation cells created by the strategy: **self** (the default) to place isolation cells inside the design being isolated, **parent** to place isolation cells in the parent level of the design being isolated, or **fanout** to place the isolation cells at all fanout locations (sinks) of the port being isolated.

-async_set_reset async_set_reset_signal high | low

Specifies the asynchronous set/reset signal for cells created by the isolation strategy. Also specifies the sense of the signal. Both must be specified at the same time. Can only be used if **-clamp_value** is latch. The *async_set_reset_signal* can be a port, pin or net.

-update

Indicates that this command provides additional information for a previous command with the same *strategy_name* and *domain_name* and executed in the same scope. The additional information includes elements specified with the **-elements**, **-exclude_elements** or **-location** options.

-async_clamp_value boolean

Specifies the constant value of the output of the isolation cells created by the isolation strategy when the *async_set_reset_signal* is sensed. If the value is 0 the set/reset pin behaves as an asynchronous reset for the output, if it's 1, it behaves as a set. Can only be used if **-clamp_value** is latch.

DESCRIPTION

The **set_isolation** command specifies an isolation strategy for a power domain. The strategy specifies the elements of the domain to which the strategy applies, the supply set or supply nets to be used for the isolation cells, and any insertion constraints based on the supply sets of the driver and receiver of the net being isolated. To complete the isolation strategy, you also need to use the **set_isolation_control** command to specify the isolation control signal, and optionally, the hierarchical location for inserting the cells on the domain boundary.

Synthesis and implementation tools insert isolation cells strictly according the isolation strategies specified by the **set_isolation** and **set_isolation_control** commands, without considering other information such as the power state table. If the isolation strategies are not consistent with the allowed states defined in the power state table, you can find and report these inconsistencies by using the **check_mv_design** command after the isolation cells are inserted.

Where the Strategy Applies

By default, the strategy of a **set_isolation** command applies to all outputs that cross the boundary of the specified power domain.

To restrict the strategy to specific elements of the power domain, use the **-elements** option. The specified elements can be ports of the power domain or the pins of root cells on the boundary of the power domain. You can use the **set_isolation** command multiple times to create different isolation strategies for different elements in the power domain.

The ports of a power domain are the logical ports of the root cells of the power domain, or in the case of a power domain containing the top-level design, the logical ports of the design. Input ports of a power domain are the ports defined as inputs in the corresponding HDL module. Similarly, output ports of a power domain are the ports defined as outputs in the corresponding HDL module.

The **-exclude_elements** list explicitly identifies a set of ports to which this strategy does not apply. The *exclude_list* might contain instances or ports in the specified domain. If an instance name is specified in the *exclude_list*, it is equivalent to specifying all the ports of the instance in the *exclude_list*.

The **-update** option adds information to the base command executed in the same scope. When specified with the **-update** option, the **-elements** and **-exclude_elements** are additive. The **-update** option must be specified with the isolation name, the power domain name, and either the **-elements**, **-exclude_elements** or **-location**. All other options are not allowed with the **-update** option.

The **-applies_to** option lets you specify explicitly whether to apply the strategy to **inputs** only, to **outputs** only, or to **both** inputs and outputs of the power domain:

- Applying the strategy to the outputs of a shutdown domain ensures that during shutdown, the outputs continue to drive the inputs of other domains with a known value (optionally specified by the **-clamp_value** option).
- Applying the strategy to the inputs of a power domain might be necessary if another domain drives the inputs, the other domain can be shut down, and the outputs of the other domain are not already isolated according to that domain's isolation strategy.

Without the **-applies_to** option, the strategy applies to both inputs and outputs of the domain if you use one or both of the **-source** and **-sink** options, or if you set the **-diff_supply_only** option to **true** and the supplies are defined by supply sets (rather than supply nets). Otherwise, the strategy applies to outputs only.

The tool, by strictly following the isolation strategies, might insert more isolation cells than necessary, for example, at both the output of the driver domain and the input of the receiver domain. You can find such occurrences with the **check_mv_design** command. The tool merges redundant cells during optimization.

Isolation Constraints Based on Source and Sink Supply Sets

The **-source**, **-sink**, and **-diff_supply_only** options restrict the insertion of isolation cells to only the domain-crossing nets whose driver and receiver cells meet specified supply set conditions. These options act as "filters" to reduce the number of ports on the domain boundary considered for isolation.

- The **-source** option specifies a supply set name. The isolation strategy applies only to the domain-crossing nets that are driven by a cell powered by the specified supply set.
- The **-sink** option specifies a supply set name. The isolation strategy applies only to the domain-crossing nets that fan out to cells powered by the specified supply set.

You can use both the **-source** and **-sink** options to restrict the insertion of isolation cells to only the domain-crossing nets that are driven by a cell powered by a specified supply set and that fan out to cells powered by a different specified supply set.

- The **-diff_supply_only** option, when set to **true**, applies the strategy only to the domain-crossing nets in which the driver and receivers are powered by different supply sets or supply nets. This setting prevents isolation when the driver and receiver cells use matching supplies. The default is **false**, meaning no restriction on isolation based on matching driver and receiver supplies.

Setting the **-diff_supply_only** option to **true** restricts the isolation strategy to all combinations of differing source and sink supply sets, whereas setting the **-source** and **-sink** options restrict the strategy to specifically named combinations of supply sets. Note that you cannot use the **-diff_supply_only**, **-source**, and **-sink** options all together in the same strategy.

Isolation Cell Supply Set or Supply Nets

The power and ground supplies for the inserted isolation cells must be active while the driver domain is shut down and the receiver domain is active. For each isolation strategy, the power supplies for the isolation cells must be specified by one of the following options:

- The **-isolation_supply** option of the **set_isolation** command
- The **-isolation_power_net** and **-isolation_ground_net** options of the **set_isolation** command
- The **-supply {default_isolation supply_set_name}** option of the **create_power_domain** command

Using the **-isolation_supply** option of the **set_isolation** command completely specifies the supplies for the isolation cells.

Alternatively, you can specify the power and ground supply nets explicitly using one or both of the **-isolation_power_net** and **-isolation_ground_net** options. If you specify only the power net or only the ground net, the primary supply of the power domain is used for the unspecified supply net.

If you use none of these options in the **set_isolation** command, the **default_isolation** supply set specified by the **-supply** option of the **create_power_domain** command applies.

Clamp Value

The **-clamp_value** option specifies the constant value of the isolation cell output when the isolation function is enabled. It can be set to **0**, **1**, or **latch**. A clamp value of **0** (the default) can be implemented with an AND gate. A clamp value of **1** can be implemented with an OR gate. A clamp value of **latch** is implemented with an isolation cell that latches the current data, either 0 or 1, when the isolation function is enabled, and holds that value constant during isolation.

Additionally the clamp value that should be used when implementing an isolation strategy on a given port or pin can be set using the **-clamp_value** option of the **set_port_attributes** command. A **set_port_attribute -clamp_value** setting has precedence over the clamp value of the isolation strategy being implemented.

Forcing or Preventing Isolation

In case of conflicting isolation strategies, the tool follows certain precedence rules to determine which strategy to use. For details, see the *Power Compiler User Guide*.

Using the **-force_isolation** option of the **set_isolation** command ensures that an isolation strategy is applied to the specified elements, irrespective of the default priority order. The isolation cells inserted with this option cannot be optimized away by implementation tools.

To prevent the insertion of isolation cells for the specified elements of the power domain, use the **-no_isolation** option. In that case, there is no need to specify the isolation power supplies for the strategy, and there is no need for the **set_isolation_control** command for the strategy.

Isolation control signal, sense and location

The **-isolation_signal** argument specifies the enable isolation signal name. You can specify the enable signal as a port, pin, or net. A port or pin has priority over an identically named net.

The **-isolation_sense** option specifies the sense of the enable isolation signal, either **high** or **low**. The default is **high**.

The isolation signal need not exist in the logical hierarchy where the isolation cells are to be inserted; the synthesis or implementation tool can perform port-punching to make the connection. Port-punching means automatically creating a port to make a connection from one hierarchical level to the next.

Punched ports are not considered for isolation or level shifting. Existing ports, even if they reside on an always-on path, are isolated and level-shifted according to the applicable isolation and level shifter strategy.

The **-location** option defines where the isolation cells are placed in the logic hierarchy:

- The **self** setting (the default) places isolation cells just inside the power domain boundary.
- The **parent** setting places isolation cells in the parent level of the design being isolated, just outside the power domain boundary.
- The **fanout** setting places isolation cells at all fanout locations (sinks) of the port being isolated. This option is valid only for an isolation strategy defined by the **set_isolation** command using the **-source** and **-sink** options or the **-diff_supply_only true** setting.

Using the **fanout** setting might be necessary when an output port fans out to multiple power domains, each requiring a different type of isolation.

Async options

The **-async_set_reset** and **-async_clamp_value** options are used to specify the behavior of the asynchronous set/reset pin of certain latch isolation cells. They can only be used if **-clamp_value** argument is latch and otherwise return an error message.

Additionally, the async clamp value to be used when implementing the strategy on a given port or pin of the set can also be specified using **-attribute UPF_async_clamp_value** option of the **set_port_attributes** command, in case the value is specified in both commands, **set_port_attributes** takes precedence.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates an isolation strategy called ISO1, which applies all output ports of power domain PD1. The strategy specifies the power and ground nets used for the isolation cells inserted by the strategy.

```
prompt> set_isolation ISO1 -domain PD1 \
    -isolation_power_net PN1 -isolation_ground_net GN1
```

The following example creates an isolation strategy called ISO2, which applies only to port OUT2 of block instance U3 in power domain PD1. The power domain PD1 was defined on the block U3, a block that can be shut down.

```
prompt> set_isolation ISO2 -domain PD1 \
    -isolation_power_net PN2 -isolation_ground_net GN2 \
    -elements U3/OUT2
```

The following example creates an isolation strategy called ISO3, which applies only to port OUT3 of block instance U3 in power domain PD1. The strategy specifies the supply set used for isolation cells inserted by the strategy.

```
prompt> set_isolation ISO3 -domain PD1 \
    -isolation_supply MY_SS1 \
    -elements U3/OUT3
```

The following example creates an isolation strategy called ISO4, which applies only to port OUT4 of block instance U3 in power domain PD1. No supply set or supply net is specified in the command, so the tool uses the **default_isolation** supply set previously defined in the **-supply** option of the **create_power_domain** command (which created power domain PD1).

```
prompt> set_isolation ISO4 -domain PD1 \
    -elements U3/OUT4
```

The following example creates an isolation strategy using the **-source** and **-sink** options. The strategy applies only to domain-crossing nets that are driven by a cell powered by the PD_primary_set supply set and are received by one or more cells powered by the SSET supply set.

```
prompt> set_isolation ISO5 -domain PD1 \
    -isolation_supply MY_SS1 \
    -source PD_primary_set -sink SSET
```

The following example creates an isolation strategy using the **-source** and **-diff_supply_only** options. The strategy applies only to domain-crossing nets that are driven by a cell powered by the PD_primary_set supply set and are received by cells powered by a different supply set.

```
prompt> set_isolation ISO6 -domain PD1 \
    -isolation_supply my_iso_supply_set \
    -source PD_primary_set \
    -diff_supply_only true
```

The following example specifies the active low, isolation enable signal, ENISO. The strategy name is ISO1 in power domain PD1. Isolation cells are inserted at the parent level, just outside the power domain boundary.

```
prompt> set_isolation ISO1 -domain PD1 \
    -isolation_supply my_iso_supply_set \
    -isolation_signal ENISO -isolation_sense low \
    -location parent
```

The following example creates an isolation strategy using the **-name_prefix** and **-name_suffix** options. The name of the new isolation cell created for the domain boundary pin "m1/b1/OUT4" is "PD1_snps_PD1_ISO7_snps_OUT4_iso_1".

```
prompt> set_isolation ISO7 -domain PD1 \
    -isolation_supply my_iso_supply_set \
    -elements {m1/b1/OUT4} \
    -name_prefix PD1 -name_suffix iso_1
```

If you do not use the **-name_prefix** and **-name_suffix** options, the **name_format** command determines the prefix and suffix. If you do not use the **name_format** command either, the default suffix is "_UPF_ISO" and there is no prefix.

The following example specifies an isolation strategy that applies to lower domain boundary (highConn). In this example ISO1 applies to output pins which are highConns of power domain PD_TOP. Isolation cells will be inserted in power domain PD_TOP driving inputs of mid.

```
prompt> create_power_domain PD_TOP
prompt> create_power_domain PD_MID -elements {mid}
prompt> set_isolation ISO1 -domain PD_TOP \
    -applies_to_boundary lower
```

The following example specifies the active low, isolation enable signal, ENISO. The strategy name is ISO1 in power domain PD1. Isolation cells are inserted at the parent level, just outside the power domain boundary. The isolation cells inserted will be of the latch type with an asynchronous reset pin that is active low, controlled by signal SRISO.

```
prompt> set_isolation ISO1 -domain PD1 \
    -isolation_supply my_iso_supply_set \
    -isolation_signal ENISO -isolation_sense low \
    -location parent -clamp_value latch \
    -async_clamp_value 0 -async_set_reset {SRISO low}
```

set_isolation_cell

Sets the specified library cells as isolation cells.

SYNTAX

```
status set_isolation_cell
  cell_name
  [-data_pin data_pin_name]
  [-enable_pin enable_pin_name]
```

Data Types

```
cell_name      string
data_pin_name  string
enable_pin_name string
```

ARGUMENTS

cell_name

Specifies the name of the library cell to be defined as an isolation cell.

-data_pin *data_pin_name*

Specifies the name of the data pin of the isolation cell.

-enable_pin *enable_pin_name*

Specifies the name of the enable pin of the isolation cell.

DESCRIPTION

The **set_isolation_cell** command sets the specified library cells as isolation cells. You can also specify the data and enable pin details for the isolation cell.

EXAMPLES

In the following example, all cells in the library whose name starts with ISO are set as isolation cells. The EN pin of those library cells is considered the enable pin of the isolation cell.

```
prompt> set_isolation_cell ISO* -enable_pin EN
```

SEE ALSO

`report_lib(2)`
`check_library(2)`

set_isolation_control

Specifies the isolation control signal and the side of the domain boundary on which to insert isolation cells.

SYNTAX

```
status set_isolation_control
  isolation_strategy
  -domain power_domain
  -isolation_signal isolation_signal
  [-isolation_sense low | high]
  [-location self | parent | fanout]
```

Data Types

<i>isolation_strategy</i>	string
<i>power_domain</i>	string
<i>isolation_signal</i>	string

ARGUMENTS

isolation_strategy

Specifies the name of a UPF isolation strategy previously created by the **set_isolation** command. The option settings apply to this strategy.

-domain *power_domain*

Specifies the name of the power domain previously created by the **create_power_domain** command to which the strategy options apply.

-isolation_signal *isolation_signal*

Specifies the name of the signal that enables and disables the isolation function of cells created by the isolation strategy. The *isolation_signal* can be a port, pin, or net.

-isolation_sense low | high

Specifies the sense of the isolation signal, either **low** or **high**, that enables the isolation function of cells created by the strategy. The default is **high**.

-location self | parent | fanout

Specifies the hierarchical location for inserting isolation cells created by the strategy: **self** (the default) to place isolation cells inside the design being isolated, **parent** to place isolation cells in the parent of the design being isolated, or **fanout** to place the isolation cells at all fanout locations (sinks) of the port being isolated.

DESCRIPTION

This command specifies the isolation control signal for a specified isolation strategy, and optionally, the hierarchical location for inserting isolation cells on the domain boundary.

The **-isolation_signal** argument specifies the name of the control signal that enables and disables the isolation function of cells created by the isolation strategy. You can specify control signal as a port, pin, or net. A port or pin has priority over an identically named net.

The **-isolation_sense** option specifies the logic state of the isolation control signal, either **high** or **low**, that enables the isolation function of the isolation cells. The default is **high**.

The isolation signal need not exist in the logical hierarchy where the isolation cells are to be inserted; the synthesis or implementation tool can perform port-punching as needed to make the connection. Port-punching means automatically creating a port to make a connection from one hierarchical level to the next.

Punched ports are not considered for isolation or level shifting, even though these ports might reside within the coverage of an isolation or level shifter strategy. Existing ports, even if they reside on an always-on path, are isolated and level-shifted according to the applicable isolation and level shifter strategy.

The **-location** option defines where the isolation cells are placed in the logic hierarchy:

- The **self** setting (the default) places isolation cells just inside the power domain boundary.
- The **parent** setting places isolation cells in the parent of the design being isolated, just outside the power domain boundary.
- The **fanout** setting places isolation cells at all fanout locations (sinks) of the port being isolated. This option is valid only for an isolation strategy defined by the **set_isolation** command using the **-source** and **-sink** options or the **-diff_supply_only true** setting.

Using the **fanout** setting might be necessary when an output port fans out to multiple power domains, each requiring a different type of isolation.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies the control signal, ENISO, that enables the isolation function for isolation cells inserted by the strategy named ISO1 in power domain PD1. A logic low on the signal enables the isolation function. The command also specifies that isolation cells are to be inserted in at the parent level, just outside the power domain boundary.

```
prompt> set_isolation_control ISO1 -domain PD1 \
    -isolation_signal ENISO -isolation_sense low \
    -location parent
```

SEE ALSO

`create_power_domain(2)`
`set_isolation(2)`

set_keepout_margin

Creates a keepout margin of the specified type for the specified cell or library cell.

SYNTAX

```
status set_keepout_margin
[-type hard | soft]
[-outer {lx by rx ty}]
[-tracks_per_macro_pin value]
[-min_padding_per_macro value]
[-max_padding_per_macro value]
[-all_macros]
[-macro_masters]
[-macro_instances]
[-north]
[object_list]
```

Data Types

<i>lx</i>	float
<i>by</i>	float
<i>rx</i>	float
<i>ty</i>	float
<i>value</i>	float
<i>object_list</i>	float

ARGUMENTS

-type hard | soft

Specifies the type of the keepout margin to be created. The value can be either **soft** or **hard**. By default, the type is **hard**.

-outer {lx by rx ty}

Specifies the margin parameters for a keepout. The values **lx**, **by**, **rx** and **ty** represent the left, bottom, right, and top margins respectively. The margin parameters must be positive and all four parameters are required. The units are microns. If the margins are set on a standard cell instance or a standard cell master, and the standard cell instance is fixed, then all four margins are honored. However, if the standard cell instance is movable, only **lx** and **rx** are honored for horizontal designs and only **by** and **ty** are honored for vertical designs.

Setting a top or bottom keepout margin on movable standard cells is not recommended. If a standard cell has a top or bottom keepout margin, the top or bottom keepout margin is usually ignored. If the movable standard cell becomes a fixed cell, then cell overlaps might be reported when you run the **check_legality** command. For example, clock tree synthesis commands, such as **compile_clock_tree** and **optimize_clock_tree**, might change movable standard cells to fixed standard cells. As a result, cell overlaps might be reported by the **check_legality** command. To avoid this problem, do not set a top or bottom keepout margin on movable standard cells. Use the top or bottom keepout margin only on fixed standard cells.

-tracks_per_macro_pin value

Specifies the number of tracks per macro pin. This value is used to calculate the keepout margin around macro cells based on pin

count. A pin count-based keepout margin type is always **hard**, the **-type** option is ignored when you specify the **-tracks_per_macro_pin** option. The **-all_macros**, **-macro_masters**, and **-macro_instances** options are not allowed together with the **-tracks_per_macro_pin** option. By default, the value is 0.5 tracks per pin.

-min_padding_per_macro value

Specifies the minimum padding per macro size. This value is used to calculate the keepout margin based on pin count. The **-type** option is ignored. The **-all_macros**, **-macro_masters** and **-macro_instances** options are not allowed when you specify the **-min_padding_per_macro** option. Note: the margin calculation for the left and right macro sides considers the *height* of the cell, the top and bottom sides consider the *width* of the cell. By default, the value is 0, which is the minimum grid size.

-max_padding_per_macro value

Specifies the maximum padding per macro. This value is used to calculate the keepout margin based on pin count. The **-type** option is ignored. The **-all_macros**, **-macro_masters** and **-macro_instances** options are not allowed when you specify the **-max_padding_per_macro** option. Note: the margin calculation for the left and right macro sides considers the *height* of the cell, the top and bottom sides consider the *width* of the cell. By default, the value is -1.

-all_macros

Specifies that the keepout margin of the specified type is created on all macro cells in the design.

-macro_masters

Creates keepout margins of the specified type on all macro masters or the macro masters of the macro instances specified in the *object_list*. Note: If you specify this option, the keepout margin is created on only macro masters, the tool ignores all standard cells and standard library cells specified in the *object_list*.

-macro_instances

Creates keepout margins of the specified type on all macro instances or all the macro instances of the macro masters specified in the *object_list*. If you specify macro master instances in the object list, the tool creates the keepout margin on macro instances of the macro master. Note: If you specify this option, the keepout margin is created on only the macro instances, the tool ignores all standard cells and standard library cells specified in the *object_list*.

-north

Specifies that the specified keepout values are with respect to the north orientation of the cell.

object_list

Specifies the list of cells or library cells for which to create keepout margins.

DESCRIPTION

The **set_keepout_margin** command creates keepout margins for the specified cells and library cells. The tool derives the keepout margins for the cells in the following order.

1. Keepout margin specified on the cell itself
2. Keepout margin specified on the library cells of the cell
3. Pin count-based derived keepout margin values for macro cells

Note that the tool derives pin count-based keepout margin values only for the macro cells. If the tool does not find the keepout margin on the cell, it looks for the keepout margin specified on the library cells. For macro cells, if there is no user-specified keepout margin on cells and lib cells, the tool looks for the pin count-based derived keepout margin values. A keepout is created for a cell or library cells whether or not the cell has a `fixed_placement` attribute. Keepout margins can be set on ILM or block abstraction cells and references also.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets a keepout margin on MY_CELL and MY_LIB_CELL.

```
prompt> set_keepout_margin -type hard \
    -outer {10 10 10 10} MY_CELL
prompt> set_keepout_margin -type hard \
    -outer {10 10 10 10} MY_LIB_CELL
```

The following command sets a keepout margin on the ILM reference blk.

```
prompt> set_keepout_margin -type hard \
    -outer {10 10 10 10} [get_ilms -reference blk]
```

The following command sets a keepout margin on all the macro cells in the design.

```
prompt> set_keepout_margin -type hard -all_macros \
    -outer { 10 10 10 10}
```

This sets a keepout margin on the basis of pin count of the macro.

```
prompt> set_keepout_margin -tracks_per_macro_pin .6 \
    -min_padding_per_macro .1 -max_padding_per_macro 0.2
```

The following command sets a keepout margin on all the ILM instances in the design.

```
prompt> set_keepout_margin -type hard \
    -outer {10 10 10 10} [get_ilms]
```

The following command sets a keepout margin on all the block abstraction instances in the design.

```
prompt> set_keepout_margin -type hard \
    -outer {10 10 10 10} [get_cells -hierarchical -filter "@is_block_abstraction==true"]
```

[report_keepout_margin\(2\)](#)

set_latch_loop_breakers

Specifies transparent latch data pins to be used as loop-breaker latch data pins when the variable **timing_enable_through_paths** is set to true.

SYNTAX

```
string set_latch_loop_breakers
    -pin pin_list
    [-remove]
    [-avoid]
```

Data Types

pin_list list

ARGUMENTS

-pin *pin_list*

Specifies data pins of transparent latches that are to be made loop-breakers (when no other command options are used).

-remove

Removes previously specified settings on the listed pins.

-avoid

Requests that the tool to avoid choosing the listed pins when it selects loop-breaker pins. These requests cannot always be honored, especially if there is a loop from the pin through combinational logic to itself.

DESCRIPTION

When sequential loops of transparent latches exist in a design, the tool selects certain latch data pins for special analysis as loop-breaker data pins. Reporting paths through these latch data pins is not allowed except by using the **-trace_latch_borrow** feature of the **report_timing** command.

The **set_latch_loop_breakers** command allows you to guide the tool in selecting the pins to be used as loop-breaker data pins. By guiding the tool to select some latch data pins and not others, you are more likely to be able to report the paths of interest.

This command has no effect if the variable **timing_enable_through_paths** is not enabled.

EXAMPLES

The following example specifies that the pin L1/D should be selected as a loop-breaker pin.

```
prompt> set_latch_loop_breakers -pin [get_pin L1/D]
```

SEE ALSO

`report_latch_loop_groups(2)`
`get_latch_loop_groups(2)`
`timing_enable_through_paths(3)`

set_leakage_optimization

Enables or disables leakage-power optimization on the current design. **Note:** This command is no longer needed for the **compile_ultra** command because leakage-power optimization is enabled by default and cannot be disabled within the **compile_ultra** command. This man page describes the previous usage for this command.

SYNTAX

```
status set_leakage_optimization  
true | false
```

ARGUMENTS

true | false

Controls whether leakage-power optimization is enabled.

When the setting is **true**, enables leakage-power optimization. When the setting is **false**, disables leakage-power optimization.

DESCRIPTION

This command enables or disables leakage-power optimization on the current design. This command does not support scenario-specific settings in a multicorner-multimode design. To perform scenario-dependent leakage-power optimization, use the **set_scenario_option -leakage_power true** command.

Multicorner-Multimode Support

This command is not supported in a multi-scenario design flow.

EXAMPLES

The following example enables leakage-power optimization in a non-multicorner-multimode design.

```
prompt> set_leakage_optimization true  
1
```

The following example disables leakage-power optimization in a non-multicorner-multimode design.

```
prompt> set_leakage_optimization false  
1
```

SEE ALSO

`set_dynamic_optimization(2)`
`set_scenario_options(2)`

set_leakage_power_model

Specifies the model that will be optimized by leakage optimizations.

SYNTAX

```
status set_leakage_power_model
  [-type model_name]
  [-mvth_weights weights]
  [-reset]
```

Data Types

<i>model_name</i>	string
<i>weights</i>	string

ARGUMENTS

-type *model_name*

Specifies the name of the leakage power model. Valid model names are **leakage** and **channel_width**. The default model is **leakage**.

-mvth_weights *weights*

Specifies the design-level weights for the voltage groups. The library level values specified in the technology library are ignored and the values specified with the **-mvth_weights** option are used to calculate the weighted sum of channel widths.

-reset

Resets the model to **leakage** and clears the weights that were previously set.

DESCRIPTION

Specifies the model that will be optimized by leakage. The leakage optimizations during compile optimize a model. One of the following models may be chosen as the leakage power model:

leakage
channel_width

When the model is **leakage**, the leakage power is computed and optimized. When the model is **channel_width**, a weighted sum of channel width is computed and optimized.

The default model is **leakage**.

For this command to work, the library must contain:

- threshold-voltage groups
- the channel width for cells

Furthermore, if the `threshold_voltage_channel_width_factor` is not present in the library, you must assign `-mvth_weights` at the design level.

EXAMPLES

In this example, the weights specified at the library level are used to calculate the weighted sum:

```
prompt> set_max_leakage_power 0
prompt> set_leakage_power_model -type channel_width
prompt> compile_ultra
```

The weights specified in the library are used to calculate the weighted sum. The following example illustrates the specification of design-level weights. This specification overrides the library-level weights specified in the technology library.

```
prompt> set_max_leakage_power
prompt> set_leakage_power_model -type channel_width \
    -mvth_weights "lvt = 1000 nvt = 300 hvt = 1"
prompt> compile_ultra
```

SEE ALSO

`report_power(2)`
`set_max_leakage_power(2)`

set_level_shifter

Sets a strategy for level shifting during implementation.

SYNTAX

```
status set_level_shifter
  level_shifter_name
  -domain domain_name
  [-elements list]
  [-exclude_elements list]
  [-applies_to inputs | outputs | both]
  [-applies_to_boundary upper | lower | both]
  [-threshold value]
  [-rule low_to_high | high_to_low | both]
  [-location self | parent | other | automatic]
  [-no_shift]
  [-force_shift]
  [-source source_supply_set_name]
  [-sink sink_supply_set_name]
  [-input_supply input_supply_set_name]
  [-output_supply output_supply_set_name]
  [-name_prefix prefix]
  [-name_suffix suffix]
  [-update]
```

Data Types

<i>level_shifter_name</i>	string
<i>domain_name</i>	string
<i>list</i>	list
<i>value</i>	float
<i>source_supply_set_name</i>	string
<i>sink_supply_set_name</i>	string
<i>input_supply_set_name</i>	string
<i>output_supply_set_name</i>	string
<i>prefix</i>	string
<i>suffix</i>	string

ARGUMENTS

level_shifter_name

Specifies the level-shifter strategy name, which is used only for reporting. This is a required argument.

-domain *domain_name*

Specifies the domain for which the strategy is applied. This is a required argument.

-elements *list*

Specifies a list of design elements, pins, or ports to which this strategy is applied.

-exclude_elements *list*

Specifies a list of design elements, pins, or ports to which this strategy is not applied.

-applies_to inputs | outputs | both

Specifies whether the domain's input ports, output ports, or both are level shifted. The default is **both**.

-applies_to_boundary upper | lower | both

Specifies explicitly whether to apply the strategy to upper boundaries(*lowConns*) only, to lower boundaries(*highConns*) only, or to both upper and lower boundaries of the power domain.

The default is

upper

- if the power domain does not have *lower_domain_boundary* attribute OR
- if the power domain *lower_domain_boundary* attribute set to FALSE

both

- if the power domain *lower_domain_boundary* attribute set to TRUE

-threshold *value*

Specifies the voltage threshold (in volts) for determining when level-shifter cells are required. The default is **0**.

-rule low_to_high | high_to_low | both

Specifies the type of level-shifter cells that are required. The default is **both**.

-location self | parent | other | automatic

Specifies where the level-shifter cell is placed in the logic hierarchy. The default is **automatic**.

-no_shift

Prevents the insertion of level-shifter cells on the specified ports, pins, and nets when used with the **-elements** option.

-force_shift

Allows specific and unconditional level-shifter insertion if possible.

-source *source_supply_set_name*

Causes level shifter insertion to occur only on ports where the source matches the provided supply set.

-sink *sink_supply_set_name*

Causes level shifter insertion to occur only on ports where the sink matches the provided supply set.

-input_supply *input_supply_set_name*

Specifies the supply set used to power the input portion of the level-shifter.

-output_supply *output_supply_set_name*

Specifies the supply set used to power the output portion of the level-shifter.

-name_prefix *prefix*

Specifies the prefix string for the names of newly inserted level-shifter cells. Prefix can also be an empty string. This option overrides the settings specified by the **name_format** command.

-name_suffix *suffix*

Specifies the suffix string for the names of newly inserted level-shifter cells. Suffix can also be an empty string. This option overrides the settings specified by the **name_format** command.

-update

Specifies extra elements to be added to the **-elements** and **-exclude_elements** lists of a level shifter strategy, which must exist previously.

DESCRIPTION

The **set_level_shifter** command is used to set a strategy for level shifting during implementation. Level-shifter cells are placed on the signals that have sources and sinks operating at different voltages, as their associated design elements are connected to different supply nets.

If a level-shifter strategy is not specified on a power domain, the default level-shifter strategy consists of all elements in the power domain, and uses the default strategy settings. Power state tables and operating conditions are considered to determine if level-shifter cells are needed for design elements on the boundaries of power domains.

If **-elements** *list* is specified, the elements must be in the domain specified by **-domain** *domain_name*.

If **-exclude_elements** *list* is specified, the strategy doesn't apply to the elements on the list, whether they belong to the boundary of specified domain or are explicitly included using the **-elements** option. If an excluded element didn't previously apply to the strategy, then its presence on the list is ignored.

The **-threshold** option defines how large the voltage difference between the driver and the sink needs to be before level-shifter cells are inserted. Normally, this threshold value is determined from the cell libraries. Use the **-threshold** option to override the library values.

The **-rule** value can be **low_to_high**, **high_to_low**, or **both**.

- If **low_to_high** is specified, signals going from a lower voltage to a higher voltage get a level-shifter cell when the voltage difference exceeds that specified by **-threshold**.
- If **high_to_low** is specified, signals going from a higher voltage to a lower voltage get a level-shifter cell when the voltage difference exceeds that specified by **-threshold**.
- If **both** is specified, it is equivalent to having specified both rules in the strategy.

The **-location** option defines where the level-shifter cells are placed in the logic hierarchy. All necessary supplies need to be available in the specified location. The option values are as follows:

- **self** specifies that the level-shifter cell is placed inside the model or cell being shifted.
- **parent** specifies that the level-shifter cell is placed in the parent of the cell or model being shifted.
- **other** specifies that the level-shifter cell is placed in the parent domain for an upper boundary port, and in the child domain for a lower boundary port.
- **automatic** specifies that the implementation tool chooses the appropriate locations.

The **-no_shift** option cannot be specified with the **-rule**, **-location** or **-threshold** options. In this case, only the **-no_shift** option is used.

The **-force_shift** option cannot be specified with the **-no_shift** option. If **-force_shift** option is used with a **-threshold** option, the threshold is ignored as if it is not specified. If the **-force_shift** option is used along with a **-rule** option, the rule determines the type of **-force_shift** level shifter inserted. The **-location** option might be used along with the **-force_shift** option to specify the location where the level shifter is required.

The **-update** option adds design elements to the **-elements** and **-exclude_elements** of an existing level shifter strategy, as if they had been specified with the original command. Adding design elements to the **-elements** list is allowed only if the first **set_level_shifter** command which defined the strategy also included the **-elements** option. In other words, a domain-based strategy cannot be changed to an elements-based strategy. The *level_shifter_name*, *strategy_name*, and the *domain_name*, and at least one of the **-elements** or **-exclude_elements**, are required options when specifying the **-update** option. No other option is allowed.

Note that this command does not apply to inout ports. Also, it is an error if the specified location is not within the logic design starting at

the design root.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the level-shifter strategy on PowerDomainZ:

```
prompt> set_level_shifter shift_up -domain PowerDomainZ -applies_to_outputs \
           -threshold 0.02 -rule both
```

The following example shows how **-name_prefix** and **-name_suffix** are used and how they are specified for a UPF level-shifter strategy.

The name of the new level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "PD1_x_ls_1" in this example.

```
prompt> set_level_shifter ls_1 -domain PD1 \
           -elements {m1/b1/x} \
           -location self \
           -name_prefix PD1_ \
           -name_suffix _ls_1
```

If you have not specified the **-name_prefix** and **-name_suffix** options, the **-level_shift_prefix** and **-level_shift_suffix** options specified by the **name_format** command are used as the prefix and suffix substrings for the level-shifter cell.

In the following example, the name of the new level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "top_x_ls".

```
prompt> set_level_shifter ls_1 -domain PD1 \
           -elements {m1/b1/x} \
           -location self
prompt> name_format -level_shift_prefix "top_" \
           -level_shift_suffix "_ls"
```

If you have not specified the **-level_shift_prefix** and **-level_shift_suffix** options specified by the **name_format** command either, the level-shifter cell name is suffixed with the "**_UPF_LS**" substring. By default, the level-shifter cell name is not prefixed with any substring.

In the following example, the name of the new level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "x_UPF_LS".

```
prompt> set_level_shifter ls_1 -domain PD1 \
           -elements {m1/b1/x} \
           -location self
```

The following example shows how the UPF level-shifter strategy and isolation strategy options **-name_prefix** and **-name_suffix** are used to name the inferred enable level-shifter cell.

In the following example, the name of the new enable level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "PD1_x_iso_1_ls_1".

```
prompt> set_isolation iso_1 -domain PD1 \
           -isolation_supply_set iso_supply_set \
           -elements {m1/b1/x} \
           -name_prefix PD1_ \
           -name_suffix _iso_1
prompt> set_level_shifter ls_1 -domain PD1 \
           -elements {m1/b1/x} \
           -location self \
           -name_prefix PD1_ \
           -name_suffix _ls_1
```

In this example, the **-name_prefix** that is specified with the **set_isolation** and **set_level_shifter** commands is the same, so the prefix substring is used only when naming the inferred enable level-shifter cell.

If you have not specified the **-name_prefix** and **-name_suffix** options for the **set_isolation** or **set_level_shifter** commands, the **-isolation_prefix**, **-isolation_suffix**, **-level_shift_prefix**, and **-level_shift_suffix** options specified by the **name_format** command are used to decide the prefix and suffix substrings for the enable level-shifter cell.

In the following example, the name of the new enable level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "top_ls_top_iso_x_iso_ls_1".

```
prompt> set_isolation iso_1 -domain PD1 \
    -isolation_supply_set iso_supply_set \
    -elements {m1/b1/x}
prompt> set_level_shifter ls_1 -domain PD1 \
    -elements {m1/b1/x} \
    -location self \
    -name_suffix _ls_1
prompt> name_format -level_shift_prefix "top_ls_" \
    -level_shift_suffix "_ls" \
    -isolation_prefix "top_iso_" \
    -isolation_suffix "_iso"
```

If you have not specified the **-level_shift_prefix**, **-level_shift_suffix**, **-isolation_prefix**, or **-isolation_suffix** options specified by the **name_format** command either, the enable level-shifter cell name is suffixed with the **_UPF_ISO** substring. By default, the enable level-shifter cell name is not prefixed with any substring.

In the following example, the name of new enable level-shifter cell that is created for the domain boundary pin "m1/b1/x" is "x_UPF_ISO".

```
prompt> set_isolation iso_1 -domain PD1 \
    -isolation_supply_set iso_supply_set \
    -elements {m1/b1/x}
prompt> set_level_shifter ls_1 -domain PD1 \
    -elements {m1/b1/x} \
    -location self
```

In the following example applies level-shifter strategy ls_1 on all output pins of block m1, except its m1/in1 pin. Strategy is not applied to any pin of block m2.

```
prompt> set_level_shifter ls_1 -domain PD1 \
    -location self \
    -elements {m1 m2/in1 m2/in2}
prompt> set_level_shifter ls_1 -domain PD1 \
    -exclude_elements {m1/in1 m2} \
    -update
```

The following example specifies a level-shifter strategy that applies to lower domain boundary (highConn). In this example LS1 applies to output pins which are highConns of power domain PD_TOP. Level-shifter cells will be inserted in power domain PD_TOP driving inputs of mid.

```
prompt> create_power_domain PD_TOP
prompt> create_power_domain PD_MID -elements {mid}
prompt> set_level_shifter LS1 -domain PD_TOP \
    -applies_to_boundary lower -applies_to_outputs
```

name_format(2)

set_level_shifter_cell

Sets on-the-fly specification of a library level-shifter cell.

SYNTAX

```
status set_level_shifter_cell
  cell_name
  [-cell_type cell_type]
  [-cell_input_voltage_range {lower_range upper_range}]
  [-cell_output_voltage_range {lower_range upper_range}]
  [-std_cell_main_rail_pg_pin pg_pin_name]
  [-data_pin data_pin_name]
  [-input_voltage_range {lower_range upper_range}]
  [-output_voltage_range {lower_range upper_range}]
  [-input_signal_level signal_level]
  [-enable_pin enable_pin_name]
  [-enable_signal_level signal_level]
  [-output_signal_level signal_level]
```

Data Types

<i>cell_name</i>	string
<i>lower_range</i>	float
<i>upper_range</i>	float
<i>pg_pin_name</i>	string
<i>data_pin_name</i>	string
<i>signal_level</i>	string
<i>enable_pin_name</i>	string

ARGUMENTS

cell_name

Specify the name of the level-shifter library cell.

-cell_type *cell_type*

Specifies the cell type of the level-shifter cell.

-cell_input_voltage_range {*lower_range* *upper_range*}

Specifies the cell input voltage range of the level-shifter cell.

-cell_output_voltage_range {*lower_range* *upper_range*}

Specifies the cell output voltage range of the level-shifter cell.

-std_cell_main_rail_pg_pin *pg_pin_name*

Specifies the standard cell P/G pin of the level-shifter cell.

-data_pin *data_pin_name*

Specifies the data pin of the level-shifter cell.

-input_voltage_range {*lower_range upper_range*}

Specifies the input voltage range of the level-shifter cell.

-output_voltage_range {*lower_range upper_range*}

Specifies the output voltage range of the level-shifter cell.

-input_signal_level *signal_level*

Specifies the input signal level of the level-shifter cell.

-enable_pin *enable_pin_name*

Specifies the enable pin of the level-shifter cell.

-enable_signal_level *signal_level*

Specifies the enable signal level of the level-shifter cell.

-output_signal_level *signal_level*

Specifies the output signal level of the level-shifter cell.

DESCRIPTION

The **set_level_shifter_cell** command specifies the properties of the level-shifter cells.

EXAMPLES

In the following example, library cells whose names start with LVLLH are set as level-shifter cells of type low to high.

```
prompt> set_level_shifter_cell LVLLH* -cell_type LH -std_cell_main_rail_pg_pin VDD \
           -enable_pin EN -input_signal_level VDDL -enable_signal_level VDDH \
           -output_signal_level VDDH -cell_input_voltage_range {0.7 1.4} \
           -cell_output_voltage_range {0.7 1.4}
```

SEE ALSO

`report_lib(2)`
`check_library(2)`

set_lib_attribute

Sets the value of an attribute on a library object.

SYNTAX

```
list set_lib_attribute
  object_list
  attribute_name
  attribute_value
```

Data Types

<i>object_list</i>	list
<i>attribute_name</i>	string
<i>attribute_value</i>	datatype of attribute_name

ARGUMENTS

object_list

A list of the library objects on which the attribute is to be set.

attribute_name

The name of the attribute to set.

attribute_value

The value of the attribute. The datatype must be the same as that of the attribute.

DESCRIPTION

Sets the value of an attribute on a library object. Only the attribute values of a small set of library objects can be set using this command. For the complete list of such library objects and their related "updatable" attributes, please refer to the user manual.

This command returns the list of objects that have the specified attribute value set. A returned empty list means that the command was not successful.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

This command is used to find the cell "INV" and set its area value to 1.0:

```
prompt> set_lib_attribute sample/INV area 1.0
Performing set_lib_attribute on library object 'sample/INV'.
{sample/INV}
```

In this example, an error is issued because the cell "INV1" is not found:

```
prompt> set_attribute sample/INV1 area 1.0
Error: The 'INV1' object does not exist in the 'sample' technology library. (UIL-54)
{}
```

In the following command, the "lib_udg_attr" value for the user-defined group "lib_udg1" in the library "sample" is set to "test":

```
prompt> set_lib_attribute sample/lib_udg1 lib_udg_attr test
Performing set_lib_attribute on library object 'sample/lib_udg1'.
{sample/lib_udg1}
```

In the following command, the area values for gates "G1" and "G2" in the library "tech_lib" are both set to 2.0:

```
prompt> get_lib_attribute {sample/G1, sample/G2} area
Performing set_lib_attribute on library object 'sample/G1'.
Performing set_lib_attribute on library object 'sample/G2'.
{sample/G1 sample/G2}
```

SEE ALSO

[get_attribute\(2\)](#)

set_libcell_dimensions

Sets the width and height of a library cell.

SYNTAX

```
int set_libcell_dimensions  
  -cell cell_name  
  -width width  
  -height height
```

Data Types

<i>cell_name</i>	string
<i>width</i>	float
<i>height</i>	float

ARGUMENTS

-cell *cell_name*

Specifies the name of the cell in the target library.

-width *width*

Specifies the width (dimension in x direction) of the library cell.

-height *height*

Specifies the height (dimension in y direction) of the library cell.

DESCRIPTION

The **set_libcell_dimensions** command sets the width and height of the specified library cell. All the arguments to this command are required. The units of width and height are in microns.

During **reoptimize_design**, LBO will use the pin location in conjunction with the cell location, dimension, and orientation to determine the absolute location of the pin. This will improve the accuracy of delay prediction during LBO, especially when large cells such as RAMs and large macros are used.

EXAMPLES

In the following example, the width of library cell INVERT_2 is set to 10 microns and the height is set to 15 microns.

```
prompt> set_libcell_dimensions -cell INVERT_2 -width 10 -height 15
```

SEE ALSO

`set_libpin_location(2)`

set_libcell_subset

Restricts the optimization of sequential cells and instantiated combinational cells to a family of target libraries.

SYNTAX

```
status set_libcell_subset
    -object_list cells
    -family_name name
```

Data Types

<i>cells</i>	list
<i>name</i>	string

ARGUMENTS

-object_list *cells*

Specifies a list of sequential cells or instantiated combinational cells for which the target library family is used during optimization. The cells must be either unmapped or instantiated to one of the library cells in the target library family.

-family_name *name*

Specifies the target library family to be used for optimization of these cells. A family is a subset of target library cells and is defined by the **define_libcell_subset** command.

DESCRIPTION

The **set_libcell_subset** command specifies a family of target libraries that are available for use during the optimization of the specified instances. A family is defined by the **define_libcell_subset** command.

The target library family restriction applies only to the new cells that are created or mapped during optimization. This restriction does not affect the cells that are already mapped. Therefore, the unoptimized portions of the design are not affected. Use the **report_libcell_subset** command to see the cells that are already mapped to the library cells outside their subset.

This command is supported only in topographical mode.

To remove the target library family from an instance, use the **remove_libcell_subset** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the target library family for the u1 and u2 instances to special_flops, which consists of the library cells, SDFLOP1 and SDFLOP2.

```
prompt> define_libcell_subset -libcell_list "SDFLOP1 SDFLOP2" -family_name special_flops  
prompt> set_libcell_subset -object_list [get_cells u1 u2] -family_name special_flops
```

SEE ALSO

```
remove_libcell_subset(2)  
report_libcell_subset(2)  
set_libcell_subset(2)  
define_libcell_subset(2)
```

set_libpin_location

Sets the location of a pin of a library cell relative to the origin of the library cell.

SYNTAX

```
int set_libpin_location
    -cell library_cell_name
    -pin pin_name_of_the_library_cell
    -coordinate {x_coordinate y_coordinate}
```

Data Types

<i>library_cell_name</i>	string
<i>pin_name_of_the_library_cell</i>	string

ARGUMENTS

-cell *library_cell_name*

Specifies the name of the library cell.

-pin *pin_name_of_the_library_cell*

Specifies the name of the pin of the library cell.

-coordinate {*x_coordinate y_coordinate*}

Specifies the x and y coordinates of the pin. These coordinates are relative to the origin of the cell specified. The units of the coordinates are in microns.

DESCRIPTION

The **set_libpin_location** command sets the location of the specified pin of the specified library cell. All the arguments to this command are required.

This command should be issued before **reoptimize_design**. During **reoptimize_design**, LBO will use the pin location in conjunction with the cell location and orientation to determine the absolute location of the pin. This will improve the accuracy of delay prediction during LBO, especially when large cells such as RAMs and large macros are used.

Specify **set_libpin_location** only once for all the pins on the library cell, irrespective of the number of times the cell is instantiated or where it will be instantiated.

EXAMPLES

In the following example, location of the pin Z of library cell INVERT_2 is set to {10.1 5.2}.

```
prompt> read_clusters design.pdef prompt> set_libpin_location -cell INVERT_2 -pin A -coordinate {10.1 5.2}
```

SEE ALSO

[set_port_location\(2\)](#)

set_link_library_subset

Restricts the selection of library cells so they are chosen from a subset of the libraries specified by the **link_library** variable. This command can resolve ambiguity among libraries with the same voltage, temperature, and process.

SYNTAX

```
status set_link_library_subset
  [-object_list cells]
  [-top]
  [library_list]
```

Data Types

<i>cells</i>	list
<i>library_list</i>	list

ARGUMENTS

-object_list *cells*

Specifies a list of cells for which the link library subset is used. The cells must be instances of hierarchical designs, macros, or pads. The subset restriction applies to these and their child instances. You must specify either the **-top** option or the **-object_list** option. Otherwise, the link library subset is not applied.

-top

Sets the link library subset on the current design. You must specify either the **-top** option or the **-object_list** option. Otherwise, the link library subset is not applied.

library_list

Specifies a subset of libraries belonging to the **link_library** variable. For any reference name that appears in a library of the subset, only library cells within the subset are used. For reference names that do not appear in the subset, library cells are selected from any library in the **link_library** variable, as usual. If *library_list* is not specified, the subset is empty at the specified hierarchy, and therefore all characterizations are selected from the full **link_library**.

DESCRIPTION

The **set_link_library_subset** command restricts the set of libraries from which library cells will be selected. You can use the command to resolve ambiguity among libraries that are characterized for the same voltage, temperature, and process, but that are characterized differently for other known arbitrary parameters.

In a multivoltage or multicorner design, the tool would normally determine a cell's timing and power from a library in the **link_library** whose voltage, temperature, and process match the cell. If more than one library satisfied these conditions, an "Ambiguous Libraries" warning (MV-086) would be reported. By using the **set_link_library_subset** command, you can identify which library is appropriate for a particular block and/or scenario.

The command does not override existing library selection rules; it augments them. The tool still matches voltage, temperature, and process within the libraries listed in the subset. The link library subset provides an additional filter on the libraries to be considered.

Reference names that are not included in the subset libraries are not affected by the subset. Their characterizations are selected from all the libraries in the link library, as usual. You could, for example, use the command to make macro libraries unambiguous by specifying just the relevant macro library, without the need to list all the other libraries in the link library. See the Examples section.

Macros created by the PrimeTime **extract_model** command, for different modes, might still need to be merged with the PrimeTime **merge_models** command. A LIBSETUP-030 error message is issued if a macro's related library cells have different timing arcs. For example, the same cell across multiple libraries must have the same characteristics, such as **when** conditions and number of pins. Only the timing and power numbers can vary. If these conditions are not met, the tool issues an error.

To remove a link library subset from the design or a design instance, use the **remove_link_library_subset** or **reset_design** command.

As with most design constraints, the subset specifications are tied to the current design. If you change the current design to another level, and want the subset to affect optimization at that level, you need to reapply the **set_link_library_subset** command, or use the **characterize** or **propagate_constraints** command.

Multicorner-Multimode Support

This command affects the current scenario only. The same block can have different link library subsets in different scenarios. Because the command is scenario-specific, it must be specified in each scenario where it should take effect.

EXAMPLES

The following example has two libraries, lib1.db and lib2.db, with the same voltage, temperature, and process. Ordinarily this would result in an "Ambiguous Libraries" warning, but it does not because the ambiguity is resolved. Library values are taken from lib1.db everywhere in the design, except for the hierarchy under cell u1, which uses values from lib2.db.

```
prompt> set link_library "* lib1.db lib2.db"
prompt> set_link_library_subset "lib1.db" -top
prompt> set_link_library_subset "lib2.db" -object_list [get_cells u1]
```

The following example uses two macro libraries, extracted as models by PrimeTime with different parasitics in effect.

```
prompt> set link_library "* stdlib.db macro_corner1.db macro_corner2.db"
prompt> create_scenario A
prompt> set_link_library_subset "macro_corner1.db" -object_list [get_cells u1/my_macro]
prompt> create_scenario B
prompt> set_link_library_subset "macro_corner2.db" -object_list [get_cells u1/my_macro]
```

This example has the same effect as the previous example. The libraries in the subsets only contain the macro part name, so only this name is affected by the subsets. Any instance of this macro name will use the subset, but all other cells, such as standard cells, will be taken from the full link library, as usual.

```
prompt> set link_library "* stdlib.db macro_corner1.db macro_corner2.db"
prompt> create_scenario A
prompt> set_link_library_subset "macro_corner1.db" -top
prompt> create_scenario B
prompt> set_link_library_subset "macro_corner2.db" -top
```

SEE ALSO

[remove_link_library_subset\(2\)](#)
[report_link_library_subset\(2\)](#)
[link_library\(3\)](#)

set_load

Sets the **load** attribute on the specified ports and nets.

SYNTAX

```
status set_load
      value
      objects
      [-subtract_pin_load]
      [-min]
      [-max]
      [[-pin_load] [-wire_load]]
```

Data Types

<i>value</i>	float
<i>objects</i>	list

ARGUMENTS

value

Specifies the value to which to set the **load** attribute on the ports and nets specified in the *objects* argument. The *value* argument must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies load values in picofarads, the *value* argument must also be expressed in picofarads.

objects

Specifies a list of ports and nets in the current design whose loads are to be set.

-subtract_pin_load

Indicates that the current pin capacitances of the net are to be subtracted from the specified value before the net load value is set. If the resulting net load value is negative, it is set to 0.

This option sets the **subtract_pin_load** attribute on the specified nets. When this attribute is set, the total load computed on these nets during the **update_timing** command does not include pin loads. Note that the **subtract_pin_load** attribute is not placed on ports.

Use this option if the *value* argument includes pin and port capacitances.

-min

Indicates that the load value is to be used for minimum delay analysis.

If no minimum load value is specified, the maximum value is used.

-max

Indicates that the load value is to be used for maximum delay analysis.

If no value is specified for maximum analysis on a net, and a value has been specified for minimum analysis, the minimum value is ignored. (You cannot annotate only a minimum value on a net.)

-pin_load -wire_load

Indicates whether the specified load value on the port is to be treated as a pin load, a wire load, or both.

These options can be used only with ports; an error message is displayed if the *objects* argument contains any nets. If you do not specify either **-pin_load** or **-wire_load**, **-pin_load** is used as the default. You can use both arguments together, in which case the load value is set as both a pin load and as a wire load on the specified ports.

DESCRIPTION

This command sets the **load** attribute on the specified ports and nets in the current design.

If the current design is hierarchical, it must have been linked with the **link** command.

The total load on a net is the sum of all of pin loads, port loads, and wire loads associated with that net. The specified load value overrides the internally-estimated net load value.

You also can use the **set_load** command for nets at lower levels of the design hierarchy. These nets are specified as BLOCK1/BLOCK2/NET_NAME.

If you use the **-wire_load** option, the load value is set as a wire load on the specified port. However, the value is actually counted as part of the total wire load and not as part of the pin or port load.

To view load values on ports, use the **report_port** command. To view load values on nets, use the **report_net** or **report_internal_loads** command.

To reset a load value, use the **remove_attribute** command. To reset all annotated load values in a design, use the **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a load of 2 units on the port named in1:

```
prompt> set_load 2 in1
```

The following example sets a load of 2.5 units (the estimated wire load) plus the load of 3 inverter input pins from the tech_lib library on all output ports. The user-defined **port_load** variable is used to store this load value.

```
prompt> link -all
prompt> set port_load [expr 2.5 + 3 * [load_of tech_lib/IV/A]]
prompt> set_load $port_load [all_outputs]
```

The following example sets a load of pin Z of IV from the tech_lib library to the input_1 and input_2 ports using the **load_of** command:

```
prompt> set_load [load_of tech_lib/IV/Z] {input_1 input_2}
```

In the following example, a load of 3 is set on the U1/U2/NET3 net. The wire capacitance is set to 3. (Total net capacitance is 3 plus the sum of the pin and port capacitances.)

```
prompt> set_load 3 U1/U2/NET3
```

In the following example, a total net capacitance (wire capacitance plus pin capacitances) of 3 is set on the U1/U2/NET3 net. If the pin and port capacitances equal 2, the wire capacitance is annotated with 1. If the pin and port capacitances are 3 or more, the wire capacitance is annotated with 0.

```
prompt> set_load -subtract_pin_load 3 U1/U2/NET3
```

The following example sets a wire load of 5 units on the port named in1:

```
prompt> set_load -wire_load 5 in1
```

The following commands remove the back-annotated load on a port and on a net:

```
prompt> remove_attribute [get_ports in1] load  
prompt> remove_attribute [get_nets U1/U2/NET3] load
```

set_local_link_library

Sets the **local_link_library** attribute to specified files and libraries on the current design.

SYNTAX

```
int set_local_link_library  
    local_link_library
```

Data Types

local_link_library string

ARGUMENTS

local_link_library

Specifies a list of files with which the **local_link_library** attribute is to be set on the current design. The **local_link_library** files are not loaded or checked until the **link_library** is used.

DESCRIPTION

Sets the **local_link_library** attribute to *local_link_library* on the current design. The *local_link_library* is a list of design files and libraries that is added to the beginning of the **link_library** whenever a link operation is performed. Files in the *local_link_library* are searched first.

The **compile**, **insert_dft**, and **translate** commands set this attribute to the same value as the **target_library** variable.

Use **report_design** or **get_attribute** to identify the **local_link_library** for a design.

To remove this attribute, use the **remove_attribute** or **reset_design** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command sets the **local_link_library** "tech_lib.db" on the current design "my_design":

```
prompt> set_local_link_library tech_lib.db
```

Setting local link library 'tech_lib.db' on design 'my_design'

remove_attribute(2)
reset_design(2)
translate(2)
design_attributes(3)
link_library(3)
target_library(3)

set_logic_dc

Specifies one or more input ports in the current design that are to be driven by don't care. The **set_logic_one** and **set_logic_zero** commands are used the same way as this command.

SYNTAX

```
int set_logic_dc  
    port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by don't care. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_dont-care** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note:

This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

When a **set_logic_dc** command is used on an input port, **compile** is given the freedom to assign any signal to that input (including, but not limited to, zero and one). The meaning of this command is that the outputs of the design are significant only when the non-don't care inputs completely determine all outputs, independent of the don't care inputs. This information is used to optimize the design.

For example, suppose the design is a 2:1 multiplexer with inputs S, A, B, and output Z. The function computed is as follows:

$$Z = S^*A + S^{**}B$$

If you issue the following command,

```
prompt> set_logic_dc B
```

the implication is that the value of Z is significant only when S=1, and is a don't care when S=0. The resulting simplification done by **compile** represents the reduced logic as a wire, and the function is as follows:

Z = A

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

```
prompt> set_logic_zero {A B}  
prompt> set_logic_one C  
prompt> set_logic_dc D
```

set_logic_lock_configuration

Sets the default logic lock configuration for the current design.

SYNTAX

```
status set_logic_lock_configuration
  [-parameters parameter_list]
  [-exec_name executable_name]
  [-location instance_path_name]
  [-exclude_cells cell_list]
  [-key_signals ordered_list_of_dft_signals_of_type_SecurityKey]
```

Data Types

<i>parameter_list</i>	list
<i>executable_name</i>	string
<i>cell_list</i>	list

ARGUMENTS

-parameters *parameter_list*

Specifies list of parameters to logic lock insertion.

Here is syntax of parameter.

<parameter_name>:<parameter_value>

These parameters are applied to logic lock insertion in **insert_security command**.

-exec_name *executable_name*

Specifies leaf level executable name of performer tool that inserts logic lock gates into the design.

Complete path name of the executable is inferred from path environment in **insert_security command**.

-location *instance_path_name*

Specifies instance name into which logic lock gates are inserted in **insert_security command**.

Specified instance name should be a hierarchical instance name.

-exclude_cells *cell_list*

Specifies list of cells of current design which are excluded from logic locking in **insert_security command**.

These cells can be leaf level cells or hierarchical cells.

Complete path name of cells should be specified.

Simple regular expressions that contain * are also accepted.

DESCRIPTION

This command specifies the default logic lock configuration to be used for logic lock insertion by the **insert_securitycommand**.

Use the **reset_logic_lock_configuration** command to reset the current logic lock configuration of the design.

EXAMPLES

The following example specifies TRLL as executable name for gate level logic lock insertion and associated parameters.

```
prompt> set_logic_lock_configuration -exec_name TRLL \
-parameters { P:logic_locking_v3/bin/ m:des_unit t:des_unit \
F:Outputs R:rst_st C:clk_st f:1 d:1 p:10 s:0 k:32 S:123 } \
-level gate
Accepted logic lock configuration for design '...'.
1
```

SEE ALSO

insert_security(2)
reset_logic_lock_configuration(2)
report_logic_lock_configuration(2)

set_logic_one

Specifies one or more input ports in the current design that are to be driven by logic one. The **set_logic_zero** and **set_logic_dc** commands are used the same way as this command.

SYNTAX

```
int set_logic_one  
    port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by logic one. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_logic_one** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note:

This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

```
prompt> set_logic_zero {A B}  
prompt> set_logic_one C  
prompt> set_logic_dc D
```

[set_logic_zero\(2\)](#)
[set_unconnected\(2\)](#)
[simplify_constants\(2\)](#)

set_logic_zero

Specifies one or more input ports in the current design that are to be driven by logic zero. The **set_logic_one** and **set_logic_dc** commands are used the same way as this command.

SYNTAX

```
int set_logic_zero  
    port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of input port names in the current design that are to be driven by logic zero. You can use only one of **set_logic_one**, **set_logic_zero**, or **set_logic_dc** on any given port. If you specify more than one port, you must include them in braces ({}).

DESCRIPTION

Assigns a **driven_by_logic_zero** attribute to the ports in *port_list*; a given port can have only one of the **driven_by_logic_one**, **driven_by_logic_zero**, and **driven_by_dont-care** attributes. This information is used by **compile** to create smaller designs by eliminating logic that is tied to a specific value and therefore might not need to be maintained during optimization. After optimization, a port connected to logic one, logic zero, or don't care usually does not drive anything inside the optimized design.

Note:

This command cannot be used on output ports. To specify output ports as unconnected, use the **set_unconnected** command.

Use the **remove_attribute** command to remove these attributes.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands are issued to drive input ports "A" and "B" by logic 0, input port "C" by logic 1, and input port "D" by don't care:

set_logicbist_configuration

Specifies the LogicBIST compression configuration for the design.

SYNTAX

```
status set_logicbist_configuration
  [-chain_count chain_count
   | -max_length max_chain_length]
  [-clock clock_name]
  [-pattern_counter_width register_width]
  [-shift_counter_width register_width]
  [-prpg_width register_width]
  [-misr_width register_width]
  [-burn_in disable | enable]
  [-occ_clock_weights weight_list]
  [-reset_weights weight_list]
  [-power_ramp_up disable | enable]
  [-power_ramp_down disable | enable]
  [-base_mode base_mode_name]
  [-test_mode logicbist_mode_name]
  [-self_test_mode autonomous_mode_name]
```

Data Types

<i>chain_count</i>	integer
<i>max_chain_length</i>	integer
<i>clock_name</i>	string
<i>register_width</i>	integer
<i>weight_list</i>	list
<i>base_mode_name</i>	string
<i>logicbist_mode_name</i>	string
<i>autonomous_mode_name</i>	string

ARGUMENTS

-chain_count *chain_count*

Specifies the number of scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-max_length *max_chain_length*

Specifies the maximum allowed length of the compressed scan chains. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-clock *clock_name*

Specifies the scan clock to be used for the LogicBIST codec (compressor and decompressor) to be inserted. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. By default, the tool selects the first-defined scan clock.

-pattern_counter_width register_width

Specifies the width of the pattern counter register. The maximum number of patterns is determined by the width of this register as follows:

```
max_patterns == (2 ^ pattern_counter_register_width) - 2
```

The default is 8, which allows a maximum of 254 patterns.

-shift_counter_width register_width

Specifies the width of the shift counter register, which counts down the shift cycles for each pattern.

By default, the tool sizes this register according to the longest shift chain in the design. You normally do not need to specify this value.

-prpg_width register_width

Specifies the width of the pseudo-random pattern generator (PRPG) register. This register generates pattern data that feeds the compressed scan chains through an XOR phase shifter. The PRPG seed value is also this width.

By default, the tool sizes this register using a heuristic based on the number of compressed scan chains.

-misr_width register_width

Specifies the width of the multiple-input signature register (MISR). This register captures data from the compressed scan chains through an XOR compactor. The final MISR signature value is also this width.

If this register width is set to the same value as the number of compressed scan chains, the tool does not implement an XOR compactor.

By default, the tool sizes register this using a heuristic based on the number of compressed scan chains.

-burn_in disable | enable

Specifies whether to enable burn-in capability.

By default, self-test always stops with a pass/fail status after running self-test once. When burn-in capability is implemented, self-test can be configured to repeat continuously.

The burn-in behavior is configured by two signals, **IbistBurnInEnable** and **IbistBurnInStopOnFail**. See their descriptions in the **set_dft_signal** man page.

-occ_clock_weights weight_list

Specifies a list of clock signal groups and their weights.

By default, all OCC clocks capture in each pattern. If asynchronous cross-clock paths exist, you can use this option to group clocks into capturing groups. Each capture group has a weight value that specifies its probability of capture relative to the other groups.

Each group is itself a list containing an integer weight value followed by one or more clock signals:

```
-occ_clock_weights {{75 SYSCLK} {25 CLK33 CLK66}}
```

-reset_weights weight_list

Specifies a list of reset signal groups and their weights.

This option is similar to the **-occ_clock_weights** option, except that it is used for asynchronous reset signals.

-power_ramp_up disable | enable

Specifies whether to run power ramp-up patterns prior to self-test.

By default, when self-test starts, it immediately begins operating at the provided clock frequencies. If the design was previously in an idle/reset state, this could cause a transient drop in the power rail voltage.

When this option is set to **enable**, the self-test logic is augmented to shift through two "ramp-up" dummy patterns - one at 1/4

frequency, then one at 1/2 frequency - before beginning full-frequency self-test. The ramp-up patterns perform no testing and are not included in the pattern count; the seed value is loaded in the PRPG after ramp-up completes.

-power_ramp_down disable | enable

Specifies whether to run power ramp-down patterns after self-test completes.

This is similar to the **-power_ramp_up** option, except that the logic performs two "ramp-down" dummy patterns - one at 1/2 frequency, then one at 1/4 frequency - after self-test completes. The status signals are not asserted until the ramp-down patterns complete.

The ramp-down feature requires that the ramp-up feature also be enabled.

-base_mode base_mode_name

Specifies the standard scan base mode that is to be associated with the LogicBIST mode indicated by the **-test_mode** option. The default is **Internal_scan**.

-test_mode logicbist_mode_name

Specifies the LogicBIST test mode to which the specification applies. The default is **all_dft**, except when **define_test_mode** is used. In this case, the default is the value of the last **test_mode** defined.

Note that this is the test mode used by TetraMAX for seed/signature computation; it is not the test mode used for autonomous self-test operation.

-self_test_mode autonomous_mode_name

Specifies the test mode that must be in place during autonomous self-test operation. The LBIST_EN signal enables autonomous self-test only when this test mode's encoding is asserted on the test-mode signals. This mode cannot be a scan compression mode of any type (LogicBIST, DFTMAX, DFTMAX Ultra, etc.). The default is the mission-mode test mode.

Note that this is the test mode used for autonomous self-test operation; it is not the test mode used by TetraMAX for seed/signature computation.

DESCRIPTION

The **set_logicbist_configuration** command allows you to specify certain LogicBIST insertion parameters prior to using the **insert_dft** command. The parameters include specifications such as compressed scan chain count, pattern count register width, and MISR and PRPG register widths.

There are two related options to control the number of compressed scan chains for LogicBIST insertion, **-chain_count** and **-max_length**. You must specify one of these options to configure LogicBIST compression. If both are specified, the **-max_length** option takes precedence over the **-chain_count** option.

reset_logicbist_configuration(2)
```

set_map_only

Sets the **map_only** attribute on specified objects so that they can be excluded from logic-level optimization during **compile**.

SYNTAX

```
status set_map_only
  object_list
  [flag]
```

Data Types

<i>object_list</i>	list
<i>flag</i>	string

ARGUMENTS

object_list

Specifies a list of cells, references, or designs on which to set the **map_only** attribute.

flag

Determines the value to which the **map_only** attribute is to be set. Valid values are true (the default) or false.

DESCRIPTION

The **set_map_only** command places the **map_only** attribute on the specified objects, and sets the attribute value to either true or false. The default value of the **map_only** attribute is false. Setting the value to true excludes specified objects from logic-level optimization (flattening and structuring) during **compile**. Setting the **map_only** attribute to false resets the attribute to its default value, allowing the objects to be included in logic-level optimization.

To remove the **map_only** attribute, use the **remove_attribute** command. Alternatively, you can set **map_only** to false, which has the same effect as removing it. The **reset_design** command removes all attributes from a design, including **map_only**.

When the **map_only** attribute is set to true on a cell, reference, or design, the optimization of that part is treated specially. In general, **compile** attempts to map the cell exactly in the target library. For example, if you flag a GTECH_ADD_ABC cell as **map_only**, **compile** will try to find a full adder in your target library to use in the implementation. This allows you to suggest to **compile** (in a technology-independent manner) to use a gate that it otherwise might not have used.

While **map_only** suggests a gate for **compile** to use, it does not guarantee the gate's use. If **compile** cannot find a gate in your target library that has the correct function, **map_only** will be ignored. If the **map_only** gate is fed by a constant, **compile** will ignore the **map_only** attribute in order to simplify the gate.

The **map_only** attribute may be overridden in order to meet timing constraints. When **compile -map_effort** is set to high, an extra synthesis is done on the design. This synthesis selectively replaces **map_only** gates in order to meet design constraints. Gates that are **map_only** are kept if they are not on the critical path or have proved to be the best (fastest) choice for optimization. The

map_only gates are remapped only if they are preventing constraints from being met.

EXAMPLES

In the following example, the **map_only** attribute is set to true on the U1 cell:

```
prompt> set_map_only U1
```

If the **map_only** attribute is set on a reference object, cells using that reference have the **map_only** attribute set during **compile**. In the following example, the **map_only** attribute is set to false on the U1 cell:

```
prompt> set_map_only U1 false
```

In the following example, all instances of MUX21 in the current design are considered **map_only**:

```
prompt> set_map_only [get_references MUX21]
```

If the **map_only** attribute is set on a library design object, cell instances of that design have the **map_only** attribute during **compile**. In this example, all the instances of AND2 from **my_library** are considered **map_only**:

```
prompt> set_map_only my_library/AND2
```

[reset_design\(2\)](#)

set_max_area

Sets the **max_area** attribute to a specified value on the current design.

This command is only supported in DC Expert with the **compile** command. If you specify a **max_area** value and run the **compile_ultra** command, the **max_area** value is ignored and the default (zero) is used.

SYNTAX

```
int set_max_area
  [-ignore_tns]
  area_value
```

Data Types

area_value float

ARGUMENTS

-ignore_tns

Specifies that the area is prioritized above total negative slack (TNS).

area_value

Specifies the value to which the **max_area** attribute is to be set. The units of *area* must be consistent with the units in the technology library used during optimization.

DESCRIPTION

This command sets the **max_area** attribute to *area* on the current design. The **max_area** attribute represents the target area of the design and is used by the **compile** command to calculate area cost of the design.

This command is only supported in DC Expert with the **compile** command.

By default, **compile** prioritizes total negative slack (TNS) above area. This means that **compile** does not create new delay violations or worsen existing delay violations on a path that has negative delay slack in order to improve area.

When the **-ignore_tns** option is used, the **ignore_tns** attribute is set on the design. When this attribute is set, **compile** prioritizes area above TNS. This means that **compile** may increase delay violations at an endpoint in order to improve area, as long as the new delay violation is smaller than the delay violation on the endpoint of the most critical path in the same path group.

If you specify **max_area** more than once on a design, the most recent *area* is used and the earlier values are removed.

If the **set_max_area** command is used without the **-ignore_tns** option, then the **ignore_tns** attribute (if any) on the design is deleted.

To undo **set_max_area**, use the **remove_attribute** or **reset_design** command.

Use the **report_area** command to get a detailed summary of area of the design. Use the **report_constraint** command to show area cost of the design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the target area for the current design to 0.0 (zero). This causes **compile** to create a design that has been optimized for the smallest possible size.

```
prompt> set_max_area 0.0
```

SEE ALSO

`compile(2)`

`remove_attribute(2)`
`report_area(2)`
`report_constraint(2)`
`reset_design(2)`

set_max_capacitance

Sets the **max_capacitance** attribute to a specified value on the specified clocks, ports and designs.

SYNTAX

```
int set_max_capacitance  
    capacitance_value  
    [-data_path]  
    [-clock_path]  
    object_list
```

ARGUMENTS

capacitance_value

Specifies a value to which the **max_capacitance** attribute is to be set. *capacitance_value* must be expressed in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then *capacitance_value* must also be expressed in picofarads.

-data_path

Restricts the scope of the command to only the pins that are in datapaths launched by the clocks specified in the *object_list*. This option is valid only when the specified object is a clock.

-clock_path

Restricts the scope of the command to only the pins that are in clock paths of the clocks specified in the *object_list*. This option is valid only when the specified object is a clock.

object_list

Specifies a list of names of specified clocks, ports, or designs on which the **max_capacitance** attribute is to be set.

DESCRIPTION

The command sets the **max_capacitance** attribute to a specified value on the specified clocks, ports or designs. Tool attempts to ensure that the capacitance value for a net is less than the specified value. The maximum capacitance value for a net is defined as the least of the maximum capacitance values of the cell pins and design ports on that net.

In cases where both a global maximum capacitance value is set on a design and a local value is set on a port, tool attempts to meet the smaller (more restrictive) value.

If **max_capacitance** attributes are already specified in a technology library (implicit constraints), tool automatically tries to meet them.

By default, a clock, port or design has no **max_capacitance** constraint. You can't set a **max_capacitance** attribute on an output or bidirectional port.

The maximum capacitance constraint is a design rule constraint, which has higher priority over optimization constraints. Thus, the tool gives priority to maximum capacitance constraint, even if it adversely affects optimization constraints on a design. The **max_delay** and **max_area** are optimization constraints, whereas **max_capacitance**, **max_fanout** and **max_transition** are design rule constraints. Design rule constraints reflect those technology-specific restrictions that must be met for a design to function correctly. Optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. The tool attempts to meet all constraints placed on a design, but gives priority to design rule constraints during optimization.

When you specify a clock object with the **set_max_capacitance** command, by default, the constraint applies to all pins in the datapaths launched by the clock and to all pins in the clock network. To restrict the scope of the command to either datapaths or clock paths, use the **-data_path** or **-clock_path** option.

To get information about optimization and design rule constraints, use **report_constraint**; to get information on the current port settings, use **report_port**. To remove the **max_capacitance** attribute from a port or a design, use **remove_attribute**.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a maximum capacitance value of 2.0 units on the port named late_riser:

```
prompt> set_max_capacitance 2.0 [get_ports late_riser]
```

The following example specifies a maximum capacitance value of 2.0 units for the TEST design:

```
prompt> set_max_capacitance 2.0 [current_design]
```

The following example specifies a maximum capacitance value of 2.0 for the clock paths of clk1 and the datapaths launched by clk1:

```
prompt> set_max_capacitance 2.0 [get_clocks clk1]
```

The following example specifies a maximum capacitance value of 2.0 for the datapaths launched by clk1:

```
prompt> set_max_capacitance 2.0 -data_path [get_clocks clk1]
```

The following example shows the **-data_path** and **-clock_path** options are invalid when the object is not a clock:

```
prompt> set_max_capacitance 2.0 -data_path [get_port port1]
Error: Cannot specify -data_path/-clock_path without clock object. (CMD-003)
prompt> set_max_capacitance 2.0 -clock_path [current_design]
Error: Cannot specify -data_path/-clock_path without clock object. (CMD-003)
```

through_list	list
rise_through_list	list
fall_through_list	list
to_list	list
rise_to_list	list
fall_to_list	list
group_name	string
comment_string	string

ARGUMENTS

delay_value

Specifies the value of the desired maximum delay for paths between start and end points. You must express *delay_value* in the same units as the technology library used during optimization. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output delay specified, that delay is added into the path delay.

-rise | -fall

Specifies whether endpoint rising or falling delays are constrained. If you don't specify either, both rising and falling delays are

constrained.

-from *from_list*

Specifies a list of path startpoints (port, pin, clock, or cell names) of the current design. If you specify a clock, all path startpoints related to that clock are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the *to_list* are constrained to *delay_value*. If you don't specify *to_list*, all paths from *from_list* are affected. This list cannot include output ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}).

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Determines a list of path throughpoints (port, pin, or leaf cell names) of the current design. The max delay value applies only to paths that pass through one of the points in the *through_list*. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify the **-through** option multiple times, the max delay values apply to paths that pass through a member of each *through_list* in the order in which the lists were given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on, for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** option, max delay applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies a list of path endpoints (port, clock, cell, or pin names) of the current design. All paths to the endpoints in the *to_list* are constrained to *delay_value*. If you don't specify a *from_list*, all paths to *to_list* are affected. This list cannot include input ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify a cell, one path endpoint on that cell is affected. If you specify a clock, all path endpoints related to that clock are affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-group_path *group_name*

Specifies the name of the group to which the paths are to be added. If the group does not already exist, it is created. This is equivalent to separately specifying the **group_path** command with the **-name *group_name* -from *from_list* -to *to_list*** options in addition to specifying the **set_max_delay** command. If you do not specify this option, the existing path grouping is not changed.

-reset_path

Removes existing point-to-point exception information on the specified paths. Only information of the same rise/fall setup/hold type is reset. This is equivalent to using the **reset_path** command with similar options before executing the **set_max_delay** command.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

-ignore_clock_latency

Indicates that the launch and capture clock latencies are to be ignored when computing slack on the specified paths. Note that these paths will be considered as clock-less, and therefore, reporting these paths by their respective ignored clocks will result in unconstrained paths. To report these paths with ignore_clock_latency, the user may specify the launched and/or captured devices as options in the report_timing command.

DESCRIPTION

Specifies the desired maximum delay for paths in the current design. This command specifies that the maximum path length for any startpoint in *from_list* to any endpoint in *to_list* must be less than *delay_value*.

Individual maximum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, see the **create_clock**, **set_input_delay**, and **set_output_delay** man pages.

The optimization cost of the design depends on how path groups have been specified. For more information, see the **group_path** man page.

The **set_max_delay** command is a point-to-point timing exception command; that is, it overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include the **set_multicycle_path**, **set_min_delay**, and **set_false_path** commands.

If a path satisfies multiple timing exceptions, the following rules are applied to determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands can conflict with each other. But a **group_path** exception by itself does not conflict with another type of exception. Thus, the remaining rules apply for two **group_path** exceptions or two non-**group_path** exceptions.
2. If both exceptions are **set_false_paths**, no conflict occurs.
3. If one exception is a **set_max_delay** and the other is a **set_min_delay**, no conflict occurs.
4. If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, no conflict occurs.
5. If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
8. If one exception has a -from pin or -from cell and the other does not, the former takes precedence.
9. If one exception has a -to pin or -to cell and the other does not, the former takes precedence.
10. If one exception has any -through points and the other does not, the former takes precedence.
11. If one exception has a -from clock and the other does not, the former takes precedence.
12. If one exception has a -to clock and the other does not, the former takes precedence.
13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher

value.

The value of a **max_rise_delay** attribute cannot be less than that of a **min_rise_delay** attribute on the same path (and similarly for fall attributes). If this occurs, the old attribute is removed.

Note: Specifying a **min_delay** or **max_delay** to a pin that is not a path endpoint places an implicit **dont_touch** attribute on that cell.

The **-group_path** option modifies the path grouping. Path grouping affects the maximum delay cost function. The worst violator within each group adds to the cost. For optimization, grouping some paths separately can improve their delay cost, but it might also increase design area, and compile time.

Use the **report_timing_requirements** command to list the **max_delay**, **min_delay**, **multicycle_path**, and **false_path** information for the design. Use **report_path_group** to list the path groups which are defined.

To undo **set_max_delay**, use **reset_path**.

To modify paths grouped with the **-group_path** option, use the **group_path** command to place the paths in another group or the default group.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example shows how to optimize the design so that any delay path to a port named Y is less than 10 units.

```
prompt> set_max_delay 10.0 -to {Y}
```

This example shows how to specify that all paths from cell ff1a or ff1b that pass through cell u1 and end at cell ff2e must be less than 15.0 units.

```
prompt> set_max_delay 15.0 -from {ff1a ff1b} -through {u1} -to {ff2e}
```

This example shows how to specify that all paths to endpoints clocked by PHI2 must be less than 8.5 units.

```
prompt> set_max_delay 8.5 -to [get_clocks PHI2]
```

This example shows how to set a requirement that all paths leading to ports named busA[*] have a delay of less than 5.0 and are included in the path group named busA.

```
prompt> set_max_delay 5.0 -to "busA[*]" -group_path "busA"
```

This example shows how to set a maximum delay requirement of 3.0 for all paths that first pass through either pin u1/Z or u2/Z then pass through pin u5/Z or u6/Z.

```
prompt> set_max_delay 3.0 -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

This example specifies that all timing paths from pin ff1/CP to pin ff2/D that rise through at least one of pins U1/Z and U2/Z and fall through at least one of pins U3/Z and U4/C must have delays less than 8.0 units.

```
prompt> set_max_delay 8.0 -from {ff1/CP} -to {ff2/D} \
    -rise_through {U1/Z U2/Z} -fall_through {U3/Z U4/C}
```

```

set_max_fanout

Sets the **max_fanout** attribute to a specified value on specified input ports and designs.

SYNTAX

```
status set_max_fanout
    fanout_value
    object_list
```

ARGUMENTS

fanout_value

Specifies the value to which the **max_fanout** attribute is to be set; that is, the maximum fanout value.

object_list

Specifies a list of input ports and/or designs on which the **max_fanout** attribute is to be set.

DESCRIPTION

Sets the **max_fanout** attribute on the specified input ports and/or designs. **compile** attempts to ensure that the sum of the **fanout_load** attributes for input pins on nets driven by the specified ports or all nets in the specified design is less than the given value. There is no maximum value placed by default, but if there is a **max_fanout** attribute already specified in a technology library (an implicit constraint), **compile** attempts to meet it.

In cases where both a global fanout limit is set on a design, and a local value is set on a port, **compile** attempts to meet the smaller (more restrictive) value.

In general, design rule constraints reflect technology-specific constraints that *must* be met for a design to function correctly. Optimization constraints are design goals and restrictions that are desirable but not crucial for the operation of a design. **compile** attempts to meet all constraints placed on a design, but it gives priority to design rule constraints in the optimization process.

The **max_fanout** attribute specifies Maximum Fanout, a *design rule constraint*. Thus, **compile** gives precedence to fixing a **max_fanout** violation, even if it adversely affects *optimization constraints* (for example, Maximum Delay and Maximum Area).

Use **report_constraint** to get information about optimization and design rule constraints.

To remove a maximum fanout from a port or design, use **remove_attribute**. **reset_design** removes all attributes, including **max_fanout**, from the current design.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a maximum fanout of 20.0 units on the port named going_places:

```
prompt> set_max_fanout 20.0 going_places
```

In the following example, the **max_fanout** attribute is set to 18.5 on the TEST design:

```
prompt> set_max_fanout 18.5 TEST
```

set_max_time_borrow

Sets the **max_time_borrow** attribute to a specified value on clocks, latch cells, data pins, or clock (enable) pins, to constrain the amount of time borrowing possible for level-sensitive latches.

SYNTAX

```
status set_max_time_borrow  
    delay_value  
    object_list
```

ARGUMENTS

delay_value

Specifies the value to which the **max_time_borrow** attribute is to be set; defines the desired limit of time borrowing on the latches specified in **object_list**. *delay_value* must be between zero and the default maximum derived from the waveform. By default, the maximum is derived from the ideal clock waveform driving each latch, and is equal to (closing_edge - open_edge). Library setup and data-to-Q propagation times are automatically taken into account. *delay_value* is assumed to be in the same units as those in the technology library used during optimization.

object_list

Specifies a list of objects in the current design for which time borrowing is to be limited to *delay_value*. The objects can be clocks, latch cells, data pins, or clock (enable) pins. If a cell is specified, all enable pins on that cell are affected. Note that if the **max_time_borrow** attribute is set on a cell and the cell is replaced during optimization, the attribute is moved from the cell to the enable pin.

DESCRIPTION

Sets the **max_time_borrow** attribute to **delay_value** to constrain the amount of time borrowing possible for level-sensitive latches. To meet delay targets, **set_max_time_borrow** prevents automatic use of all or part of the enabling clock pulse on a latch.

To get **max_time_borrow** attributes on the design, use **get_attribute**.

To undo **set_max_time_borrow**, use **remove_attribute**.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example restricts time borrowing on latches latch1a and latch2f to 4.0 units.

```
prompt> set_max_time_borrow 4.0 {latch1a latch2f}
```

The following example specifies that no time borrowing will take place on the latch latch1c.

```
prompt> set_max_time_borrow 0.0 {latch1c}
```

SEE ALSO

[remove_attribute\(2\)](#)

set_max_transition

Sets the maximum transition time for the specified clocks, ports, or designs.

SYNTAX

```
status set_max_transition
  transition_value
  [-data_path]
  [-clock_path]
  object_list
```

Data Types

<i>transition_value</i>	float
<i>object_list</i>	list or collection

ARGUMENTS

transition_value

Specifies the maximum transition time for the specified clocks, ports, or designs. It sets the **max_transition** attribute to the specified *transition_value* on the specified objects. The value must be expressed in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then *transition_value* must be expressed in nanoseconds.

-data_path

Restricts the scope of the command to only the pins that are in data paths launched by the clocks specified in the *object_list*.

-clock_path

Restricts the scope of the command to only the pins that are in clock paths of the clocks specified in the *object_list*.

object_list

Specifies the names of the clocks, ports, or designs affected by the command. The tool seeks to reduce transition times on the nets associated with these objects to no more than the time value specified by *transition_value*.

DESCRIPTION

This command sets the maximum transition time, a design rule constraint, on specified clocks, ports, or designs. The tool attempts to ensure that the transition time for a net is less than the specified value. The maximum transition time for a net is defined as the least of the maximum transition times of the cell pins and design ports on that net.

In cases where a global maximum transition time is set on a design and a local value is set on a port or clock group, the tool attempts to meet the more restrictive (smaller) value.

If the **max_transition** attributes are already specified in a technology library (implicit constraints), the tool attempts to meet them.

By default, no restriction is placed on the transition time for an input or output port, so the maximum transition time for the driven net is determined by the maximum transition time (if any) of the driven cell inputs or the driving cell output. Assigning a smaller maximum transition time to a port reduces the maximum transition time for the net; thus, the design constraints are more restrictive.

The maximum transition constraint is a design rule constraint, which has higher priority over optimization constraints. Thus, the tool gives priority to maximum transition constraint, even if it adversely affects optimization constraints on a design. Both **max_delay** and **max_area** are optimization constraints, whereas **max_fanout** and **max_transition** are design rule constraints. Design rule constraints reflect those technology-specific restrictions that must be met for a design to function correctly. Optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. The tool attempts to meet all constraints placed on a design, but gives priority to design rule constraints during optimization.

When you specify a clock object with the **set_max_transition** command, by default, the constraint applies to all pins in the data paths launched by the clock and to all pins in the clock network. To restrict the scope of the command to either data paths or clock paths, use the **-data_path** or **-clock_path** option.

Use the **report_constraint** command to get information about optimization and design rule constraints.

Use the **remove_attribute** command to remove a maximum transition time constraint from a port, design, or clock object. When you use the **remove_attribute** command to remove the maximum transition constraint from a clock object, the command removes the constraint from both the data paths and clock paths related to the specified clock.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a maximum transition time of 2.0 units on the port named late_riser:

```
prompt> set_max_transition 2.0 late_riser
```

The following example specifies a maximum transition time of 2.0 units for the design TEST:

```
prompt> set_max_transition 2.0 TEST
```

The following example specifies a maximum transition time of 2.0 units for the clock paths of clk1 and the data paths launched by clk1:

```
prompt> set_max_transition 2.0 [get_clocks clk1]
```

The following example specifies a maximum transition time of 2.0 units for the data paths launched by clk1:

```
prompt> set_max_transition 2.0 -data_path [get_clocks clk1]
```

SEE ALSO

set_message_info

Set some information about diagnostic messages.

SYNTAX

```
string set_message_info
    -id message_id [-limit max_limit | -stop_on
                    [-stop_off]]
```

Data Types

<i>message_id</i>	string
<i>max_limit</i>	integer

ARGUMENTS

-id *message_id*

Information is to be set for the given *message_id*. The message must exist. Although different constraints allow different message types, no constraint allows severe or fatal messages.

-limit *max_limit*

Set the maximum number of occurrences for *message_id*. This is an integer greater than or equal to zero. If you set it to zero, that means the number of occurrences of the message is unlimited. Messages which occur after a limit is reached are automatically suppressed.

-stop_on

Force Tcl error if message is emitted.

-stop_off

Turn off a previous -stop_on directive

DESCRIPTION

The **set_message_info** command sets constraints on diagnostic messages (typically error, warning, and informational messages).

Currently, you can set an upper limit for the number of occurrences of a message. You can set this to zero to indicate that there is no limit. You can retrieve the current limit for a message using the **get_message_info command**. **When the limit is exceeded, all future occurrences of the message are automatically suppressed. A count of total occurrences (including those suppressed) can be retrieved using get_message_info.**

EXAMPLES

The following example uses **set_message_info** to set a limit on the number of APP-027 messages to 100. When the 101st APP-027 message is about to be issued, you will be warned that the limit has been exceeded, and that all future occurrences will be suppressed.

```
prompt> set_message_info -id APP-027 -limit 100
prompt> do_command
Warning: can't find node U27.1 (APP-027)
Warning: can't find node U27.2 (APP-027)
Warning: can't find node U27.3 (APP-027)
...
Warning: can't find node U27.100 (APP-027)
Note - message 'APP-027' limit (100) exceeded. Remainder will be suppressed.
1
```

[get_message_ids\(2\)](#)
[print_message_info\(2\)](#)
[suppress_message\(2\)](#)

set_message_severity

Sets the severity level of violation messages for boundary-scan compliance checking.

SYNTAX

```
int set_message_severity  
  -names message_tags  
  severity
```

Data Types

message_tags list
severity string

ARGUMENTS

-names *message_tags*

Specifies the list of messages **message_tags** whose severity needs to be changed.

severity

Specifies the severity to use for the messages *message_tags*. Valid values are **error**, **warning**, and **ignore**.

DESCRIPTION

The **set_message_severity** command identifies the set of boundary-scan compliance violation messages whose severity needs to be changed. This can allow exceptions to the compliance checking performed by the **check_bsd** command. Both the **-names** and **severity** arguments are required.

The **set_message_severity** command can also be used to reset the severity of a message back to its original type.

EXAMPLES

The following example specifies the severity of the TEST-813 and TEST-893 messages to be warnings:

```
prompt> set_message_severity -names {TEST-813 TEST-893} warning
```

The following example resets the severity of the TEST-893 message to be an error:

```
prompt> set_message_severity -names {TEST-893} error
```

set_min_capacitance

Sets the **min_capacitance** attribute to a specified value on specified input ports in the current design.

SYNTAX

```
status set_min_capacitance
  capacitance_value
  object_list
```

Data Types

```
capacitance_value  float
object_list        list
```

ARGUMENTS

capacitance_value

Specifies a value to which the **min_capacitance** attribute is to be set. *capacitance_value* must be expressed in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then *capacitance_value* must also be expressed in picofarads.

object_list

Specifies a list of names of the input and/or bidirectional ports on which the **min_capacitance** attribute is to be set.

DESCRIPTION

Sets the **min_capacitance** attribute to *capacitance_value* on the specified input ports. **compile** attempts to ensure that the load driven by the input port is not reduced below *capacitance_value*. The minimum capacitance value for a net is defined as the greatest of the minimum capacitance values of the driving cell pins and ports on a net.

If **min_capacitance** attributes are already specified in a technology library (implicit constraints), **compile** automatically tries to meet them.

By default, a port has no **min_capacitance** constraint.

min_capacitance, along with **max_fanout** and **max_transition**, is a *design rule constraint*; **max_delay** and **max_area** are optimization constraints. Design rule constraints reflect those technology-specific restrictions that *must* be met for a design to function correctly, while optimization constraints reflect goals and restrictions that are desirable, but not crucial for the operation of a design. Design Compiler attempts to meet all constraints placed on a design, but gives priority to design rule constraints in the optimization process. Therefore, **compile** gives preference to **min_capacitance** and other design rule constraints, even if they adversely affect optimization constraints on a design.

To get information about optimization and design rule constraints, use **report_constraint**; to get information on the current port settings, use **report_port**. To remove the **min_capacitance** attribute from a port, use **remove_attribute**.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a minimum capacitance value of 12.0 units on the port named high_drive:

```
prompt> set_min_capacitance 12.0 high_drive
```

SEE ALSO

reset_design(2)
set_max_capacitance(2)

set_min_delay

Specifies a minimum delay target for paths in the current design.

SYNTAX

```
status set_min_delay
  delay_value
  [-rise | -fall]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
  [-reset_path]
  [-comment comment_string]
  [-ignore_clock_latency]
```

Data Types

<i>delay_value</i>	float
<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list
<i>comment_string</i>	string

ARGUMENTS

delay_value

Specifies the value of the desired minimum delay for paths between startpoints and endpoints. Express *delay_value* in the same units as the technology library used during optimization. If a path startpoint is on a sequential device, clock skew is included in the computed delay. If a path startpoint has an input external delay specified, that delay value is added to the path delay. If a path endpoint is on a sequential device, clock skew and library setup time are included in the computed delay. If the endpoint has an output external delay specified, that delay is added into the path delay.

-rise | -fall

Specifies whether endpoint rising or falling delays are constrained. If neither is specified, both rising and falling delays are constrained.

-from *from_list*

Lists the path startpoints (port, pin, clock, or cell names) of the current design. If a clock is specified, all path startpoints related to that clock are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the *to_list* are constrained to *delay_value*. If you do not specify *to_list*, all paths from *from_list* are affected. This list cannot include output ports. If more than one object is included, enclose the objects in double quotation marks ("") or in braces ({}).

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Lists the path throughpoints (port, pin, or leaf cell names) of the current design. The minimum delay value applies only to paths that pass through one of the points in the *through_list*. If you include more than one object, enclose the objects in double quotation marks ("") or in braces ({}). If you specify the **-through** option multiple times, the minimum delay values apply to paths that pass through a member of each *through_list* in the order the lists were given. The path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** options, the minimum delay applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Lists the path endpoints (port, clock, cell, or pin names) of the current design. All paths to the endpoints in the *to_list* are constrained to *delay_value*. If you do not specify *from_list*, all paths to *to_list* are affected. This list cannot include input ports. If more than one object is included, enclose the objects in either double quotation marks ("") or in braces ({}). If you specify a cell, one path endpoint on that cell is affected. If you specify a clock, all path endpoints related to that clock are affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to *fall_to_list*

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Removes existing point-to-point exception information on the specified paths. Only information of the same rise and fall setup or hold type is reset. This is equivalent to using the **reset_path** command with similar arguments before the **set_min_delay** command is issued.

-comment *comment_string*

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the

exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

-ignore_clock_latency

Indicates that the launch and capture clock latencies are to be ignored when computing slack on the specified paths.

DESCRIPTION

This command sets the minimum delay target for paths in the current design. Minimum delay is considered as an optimization constraint by the **compile** command. If a path violates the requirement given in a **set_min_delay** command, **compile** adds delay to fix the violation if maximum delay cost is not increased. You can prioritize minimum delay cost using the **set_cost_priority** command.

The value of a **min_rise_delay** attribute can never be greater than that of a **max_rise_delay** attribute for the same path (and similarly for fall attributes). If this occurs, the old attribute is removed.

Individual minimum delay targets are automatically derived from clock waveforms and port input or output delays. For more information, refer to the **create_clock**, **set_input_delay**, and **set_output_delay** command man pages.

The **set_min_delay** command is a point-to-point timing exception command. It overrides the default single-cycle timing relationship for one or more timing paths. Other point-to-point timing exception commands include **set_multicycle_path**, **set_max_delay**, and **set_false_path**.

If a path satisfies multiple timing exceptions, the following rules determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. Two **group_path** commands can conflict with each other, but a **group_path** exception alone does not conflict with another type of exception. Therefore, the remaining rules apply for two **group_path** exceptions, or two non **group_path** exceptions.
2. If both exceptions are **set_false_path**, there is no conflict.
3. If one exception is a **set_max_delay** and the other is a **set_min_delay**, there is no conflict.
4. If one exception is a **set_multicycle_path -hold** and the other is a **set_multicycle_path -setup**, there is no conflict.
5. If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
6. If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
7. If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
8. If one exception has a **-from pin** or **-from cell** and the other does not, the one with the **-from pin** takes precedence.
9. If one exception has a **-to pin** or **-to cell** and the other does not, the one with the **-to pin** takes precedence.
10. If one exception has any **-through** points and the other does not, the one with **-through** points takes precedence.
11. If one exception has a **-from clock** and the other does not, the one with the **from clock** takes precedence.
12. If one exception has a **-to clock** and the other does not, the one with the **-to clock** takes precedence.
13. The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To remove information set by **set_min_delay**, use the **reset_path** or **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

In the following example, the **set_min_delay** command requires that any delay path that passes through the UI cell and ends at the Y port is greater than 12.5 time units:

```
prompt> set_min_delay 12.5 -through U1 -to Y
```

The following example specifies that all paths from A1 and A2 to Z5 must be greater than 4.0 units:

```
prompt> set_min_delay 4.0 -from {A1 A2} -to Z5
```

The following example command sets a minimum delay requirement of 3.0 for all paths that first pass through either pin u1/Z or u2/Z and then pass through pin u5/Z or u6/Z:

```
prompt> set_min_delay 3.0 -through {u1/Z u2/Z} -through {u5/Z u6/Z}
```

The following example specifies that all timing paths from pin ff1/CP to pin ff2/D that rise through at least one of pins U1/Z and U2/Z and fall through at least one of pins U3/Z and U4/C must have delays greater than 3.0 units.

```
prompt> set_min_delay 3.0 -from ff1/CP -to ff2/D \
    -rise_through {U1/Z U2/Z} -fall_through {U3/Z U4/C}
```

set_min_library

Sets an alternate library to use for minimum delay analysis.

SYNTAX

```
int set_min_library  
    max_library  
    -min_version min_library | -none
```

Data Types

<i>max_library</i>	string
<i>min_library</i>	string

ARGUMENTS

max_library

Specifies the library file name to use as a link_library or target_library. This library is used for maximum delay analysis only. Do not include the path to the library file name.

-min_version *min_library*

Specifies the library file name that corresponds to the *max_library* and uses it for minimum delay analysis. The *min_library* should not be specified in the link_library or target_library. Do not include the path to the library file name.

-none

Unsets the setting of a minimum library.

DESCRIPTION

The **set_min_library** command creates a minimum/maximum relationship between two library files. The *max_library* is used for maximum delay analysis and the *min_library* is used for minimum delay analysis.

Whenever the tool computes a minimum delay value, it first consults the library cell from the max library. If a library cell exists with the same name, the same pins, and the same timing arcs in the min library, the timing information from the min library is used. If the tool cannot find a matching cell in the min library, the max library cell is used.

Do not include the path to the *max_library* nor *min_library* file name. Specify the path to those library files in \$search_path.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example is a typical usage of **set_min_library**:

```
prompt> set link_library "LIB_WC_COM.db"
prompt> set target_library $link_library
prompt> set_min_library LIB_WC_COM.db -min_version LIB_BC_COM.db
prompt> set_operating_conditions -max WC_COM -max_library LIB_WC_COM \
    -min BC_COM -min_library LIB_BC_COM
prompt> report_timing -delay max
prompt> report_timing -delay min
```

SEE ALSO

[link\(2\)](#)
[set_operating_conditions\(2\)](#)
[link_library\(3\)](#)
[target_library\(3\)](#)

set_min_pulse_width

Sets a minimum pulse width constraint for clocks or clock pins.

SYNTAX

```
status set_min_pulse_width
  [-low]
  [-high]
  value
  object_list
```

Data Types

<i>value</i>	float
<i>object_list</i>	list

ARGUMENTS

-low

Indicates that the minimum pulse width constraint specified by *value* applies only to low clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

-high

Indicates that the minimum pulse width constraint specified by *value* applies only to high clock signal levels. If you do not specify the *-low* or *-high* option, both low and high pulses of clock signals are constrained.

value

A positive floating-point value that specifies the minimum pulse width check to be applied to clock signals.

object_list

Specifies a list of clocks or clock pins in the current design to which the minimum pulse width check is applied. If you specify a clock, the constraint is applied to all clock pins connected to the clock.

DESCRIPTION

The **set_min_pulse_width** command specifies a minimum pulse width check to be applied to clock signals at clock pins of sequential devices. This value overrides the default values for clock tree minimum pulse width checks. Use this command for sequential clock pin pulse width checks to add a more restrictive value than the one specified in library. This setting is applied in all scenarios.

To generate a report of pulse width constraints, use **report_constraint** or **report_min_pulse_width**. To remove minimum pulse width constraints set by **set_min_pulse_width**, use the **remove_min_pulse_width** command.

EXAMPLES

The following example sets a minimum pulse width requirement of 2.0 for both low and high pulses of clock signals.

```
prompt> set_min_pulse_width 2.0 [get_clocks CK1]
```

The following example sets a minimum pulse width requirement of 2.5 for the low pulse of the clock signal on the clock pin reg1/CK.

```
prompt> set_min_pulse_width -low 2.5 reg1/CK
```

SEE ALSO

```
remove_min_pulse_width(2)  
report_constraint(2)  
report_min_pulse_width(2)
```

set_minimize_tree_delay

Sets the **minimize_tree_delay** attribute on a design or designs.

SYNTAX

```
integer set_minimize_tree_delay
  [true | false]
  [-design design_list]
  [design_list]
```

Data Types

design_list list

ARGUMENTS

true | false

Determines the value to which the **minimize_tree_delay** attribute is to be set. The default is **true**.

-design *design_list*

Specifies a list of designs on which to set the **minimize_tree_delay** attribute. The default is the current design.

DESCRIPTION

This command sets the **minimize_tree_delay** attribute on a design or designs, thus determining whether an arithmetic expression tree (for example, an adder chain) is to be restructured to minimize delay during **compile**. If **minimize_tree_delay** is not set, then the value of the **hlo_minimize_tree_delay** environment variable is used. The default value of this variable is **true**. Thus, by default, all expression trees are candidates for tree height minimization if timing constraints are specified. Setting the **minimize_tree_delay** attribute overrides the value of **hlo_minimize_tree_delay** for the design or designs on which the attribute is set.

The restructuring of arithmetic expression trees is based on the arrival times of inputs to the tree. In the case of equal arrival times, a balanced tree is constructed.

Note that even if **minimize_tree_delay** is set to **true**, tree height minimization is not performed if the design has no timing constraints, or if the **hlo_resource_allocation** variable is set to *area_only*, *area_no_tree_balancing*, or *none*.

For more details on tree height minimization, see the *VHDL Compiler Reference Manual* or the *HDL Compiler for Verilog Reference Manual*.

To remove the **minimize_tree_delay** attribute, use the **remove_attribute** command. The **reset_design** command removes all attributes from a design, including **minimize_tree_delay**.

EXAMPLES

In the following example, **minimize_tree_delay** is enabled on the design named TEST:

```
prompt> set_minimize_tree_delay -design TEST
```

In the following example, **minimize_tree_delay** is enabled on the current design and disabled on the design named OLD:

```
prompt> read TEST
```

```
prompt> set_minimize_tree_delay
```

```
prompt> set_minimize_tree_delay false -design OLD
```

set_mode

Selects the mode of a component.

SYNTAX

```
status set_mode  
  [mode_list]  
  [instance_list]
```

Data Types

<i>mode_list</i>	list
<i>instance_list</i>	list

ARGUMENTS

mode_list

Specifies the active modes for timing analysis. All other modes of the given mode group are implicitly inactive. The specified modes are active on the given instance list.

instance_list

Specifies the cells for which the specified modes are active.

DESCRIPTION

The **set_mode** command is used to select the active mode of a cell that has several functional modes. The other modes in the mode group that are not selected are disabled.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command selects the READ mode for the RAM instance Uram1.

```
prompt> set_mode READ Uram1
```

SEE ALSO

`report_mode(2)`
`reset_mode(2)`

set_model_drive

Sets the **model_drive** attribute to a specified value on specified input or inout ports to set their drive values during synthetic library modeling.

SYNTAX

```
int set_model_drive  
    drive_value  
    port_list
```

Data Types

```
drive_value   float  
port_list     list
```

ARGUMENTS

drive_value

Specifies the value to which the **model_drive** attribute is to be set, thus specifying the estimated drive value for the *port_list* in terms of standard drives of the current technology library. The value must be greater than or equal to zero.

port_list

Specifies a list of input or inout port names on which the **model_drive** attribute is to be set. If more than one port is specified, they must be enclosed in quotes ("") or in braces ({}).

DESCRIPTION

Sets the **model_drive** attribute to a specified value on specified input or inout ports when performing synthetic library modeling. Setting the attribute sets the estimated drive of ports in terms of standard drives of the current technology library. A standard drive is equal to the output drive of a typical gate in the current target library.

To view **model_drive** values on ports, use **report_port**.

To remove **model_drive** attributes from ports, use **remove_attribute**. **reset_design** removes all attributes, including **model_drive**.

CAVEATS

This command is valid only during synthetic library modeling, and has **no effect** when run directly from dc_shell. Therefore the command also has no effect when directly elaborating DesignWare parts that contain these directives in their embedded dc_shell scripts. To set the drive in dc_shell use the **set_drive** command.

EXAMPLES

The following example sets the **model_drive** attribute to 2.0 on ports "A", "B" and "C".

```
prompt> set_model_drive 2.0 {A B C}
```

SEE ALSO

[remove_attribute\(2\)](#)
[report_port\(2\)](#)
[reset_design\(2\)](#)
[set_drive\(2\)](#)
[set_model_load\(2\)](#)

set_model_load

Sets the **model_load** attribute to a specified value on specified ports to set their load values during synthetic library modeling.

SYNTAX

```
int set_model_load  
    load_value port_list
```

Data Types

```
load_value float  
port_list list
```

ARGUMENTS

load_value

Specifies the value to which the **model_load** attribute is to be set, thus specifying the estimated load value for the *port_list* in terms of standard loads of the current technology library. Must be greater than or equal to zero.

port_list

Specifies a list of output or inout port names on which the **model_load** attribute is to be set. If more than one port is specified, they must be enclosed in quotes ("") or in braces ({}).

DESCRIPTION

Sets the **model_load** attribute to a specified value on specified output or inout ports during synthetic library modeling. Setting the attribute sets the estimated load of ports in terms of standard loads of the current technology library. A standard load is equal to the input pin capacitance of a typical gate in the current target library. Load values are stored on ports as the **model_load** attribute.

To view **model_load** values on ports, use **report_port**.

To remove **model_load** attributes from ports, use **remove_attribute**. **reset_design** removes all attributes, including **model_load**.

CAVEATS

This command is valid only during synthetic library modeling, and has **no effect** when run directly from dc_shell. Therefore the command also has no effect when directly elaborating DesignWare parts that contain these directives in their embedded dc_shell scripts. To set the load in dc_shell use the **set_load** command.

EXAMPLES

The following example sets the **model_load** attribute to 2.0 on ports "A", "B" and "C".

```
prompt> set_model_load 2.0 {A, B, C}
```

SEE ALSO

```
find(2)
remove_attribute(2)
report_port(2)
reset_design(2)
set_load(2)
set_model_drive(2)
```

set_model_map_effort

Sets the **model_map_effort** attribute to a specified value on the current design, to specify the relative amount of CPU time to use during synthetic library modeling.

SYNTAX

```
int set_model_map_effort  
    low | medium | high
```

ARGUMENTS

low | medium | high

Specifies the value to which the **model_map_effort** attribute is to be set, which specifies the relative amount of CPU time spent during the mapping phase of modeling. Values of 1, 2, or 3 can also be used.

DESCRIPTION

Sets the **model_map_effort** attribute to a specified value on the current design during synthetic library modeling. A value of *low*, *medium*, or *high* indicates the relative amount of CPU time to be used during the mapping phase of modeling. This command would typically be used in an embedded dc_shell script in a synthetic library part. The value of **model_map_effort** attribute (*low*, *medium*, or *high*) indicates the relative amount of CPU time to be used during the mapping phase of modeling, and overrides the default value stored in the environment variable **synlib_model_map_effort**. If the **model_map_effort** attribute is not set, the value of **synlib_model_map_effort** is used.

CAVEATS

This command is valid only during synthetic library modeling, and has **no effect** when run directly from dc_shell. Therefore the command also has no effect when directly elaborating DesignWare parts that contain these directives in their embedded dc_shell scripts. To set the model_map_effort in dc_shell use the -map_effort option of the compile command.

SEE ALSO

compile(2)
set_model_load(2)
set_model_drive(2)

set_multi_vth_constraint

Limits the usage of low-threshold-voltage cells to a specified percentage of all cells.

SYNTAX

```
status set_multi_vth_constraint
  [-lvth_groups groups]
  [-lvth_percentage percent_value]
  [-cost cell_count | area]
  [-type hard | soft]
  [-include_blackboxes]
  [-reset]
```

Data Types

<i>groups</i>	string list
<i>percent_value</i>	float

ARGUMENTS

-lvth_groups *groups*

Specifies the threshold-voltage groups considered to be low-threshold-voltage groups. The *groups* argument is a list of threshold-voltage group identifiers, which are names defined by attributes in the Liberty (.lib) descriptions of the cells and cell libraries.

-lvth_percentage *percent_value*

Specifies the maximum allowable percentage of low-threshold-voltage cells for the current design. The *percent_value* argument is a floating-point number between 0 and 100.

-cost cell_count | area

This option is not supported in Design Compiler.

-type hard | soft

Specifies the constraint type, which can be either **hard** or **soft**. The default is **soft**; the tool meets this constraint only if it does not adversely affect the timing constraint.

When this option is set to **hard**, the tool monitors the percentage of low-threshold-voltage cells and reduces their usage to meet this constraint, even at the expense of timing.

-include_blackboxes

Includes black box cells in the percentage calculation. By default, black box cells are excluded from the calculation.

-reset

Removes the low-threshold-voltage percentage constraint from the current design.

DESCRIPTION

The **set_multi_vth_constraint** command identifies the low-threshold-voltage library cell groups and sets an upper limit on the percentage of cells that are allowed to come from these groups. Low-threshold-voltage cells are faster than regular cells but have more leakage and therefore increase power. Limiting the usage of these cells to a specified percentage helps to minimize power.

The **-lvth_groups** option identifies the low-threshold-voltage library groups and the **-lvth_percentage** option specifies the percentage usage constraint.

By default, black box cells are excluded from the percentage calculation. To include black box cells in the calculation, use the **-include_blackboxes** option.

By default, the constraint is a soft constraint, which is not enforced if it adversely affects timing. To make the constraint hard, use the **-type hard** option. In that case, the tool attempts to enforce the constraint, even if timing is adversely affected.

The threshold-voltage group of a cell is defined by the threshold-voltage group of its library cell reference, which is defined by the value of the **threshold_voltage_group** library cell attribute or the **default_threshold_voltage_group** library attribute in the Liberty (.lib) description of the cell or library.

For example, consider a design that contains cells that belong to the following threshold-voltage groups: lvt, xlvt, svt, and hvt. If lvt and xlvt are specified as the low-threshold-voltage groups, the percentage of the low-threshold-voltage cells in the design is:

$100 * (\text{lvt and xlvt cells used}) / (\text{total cells used})$

To report the number and percentage of cells used in the design from each threshold voltage group, use the **report_threshold_voltage_group** command.

When you use the **set_multi_vth_constraint** command without any options, it reports the multiple-threshold-voltage constraint previously set on the design.

To remove the current multiple-threshold-voltage constraint from the design, use the **-reset** option.

The **-type soft** option is supported only in topographical mode.

The **set_multi_vth_constraint** command is incompatible with the following commands:

```
set_max_leakage_power  
set_max_dynamic_power  
set_leakage_optimization  
set_dynamic_optimization
```

If any of these commands are used with the **set_multi_vth_constraint** command, they are ignored.

Multicorner-Multimode Support

At least one scenario must be a leakage scenario for the **set_multi_vth_constraint** command to work.

EXAMPLES

The following example sets a multiple-threshold-voltage soft constraint of a maximum of 20 percent low-threshold-voltage cells. The calculation is based on cell count and includes black box cells. Cells that belong to the xlvt and lvt threshold-voltage groups are considered low-threshold-voltage cells.

For example, if 10 percent of the cells belong to the xlvt group and 5 percent belong to the lvt group, this constraint is met. This is because only 15 percent of the cells belong to low-threshold-voltage groups. However, if 15 percent of the cells belong to the xlvt group and 10 percent belong to the lvt group, the constraint is not met because 25 percent of the cells in the design belong to low-threshold-voltage groups.

```
prompt> set_multi_vth_constraint -lvth_groups {xlvt lvt} \
```

-lvth_percentage 20.0 -include_blackboxes

The following example removes the multiple-threshold-voltage constraint set on the current design.

```
prompt> set_multi_vth_constraint -reset
```

SEE ALSO

`compile_ultra(2)`
`report_power(2)`
`report_threshold_voltage_group(2)`

set_multibit_options

Allows the user to customize and setup the multi-bit optimization flow.

SYNTAX

```
int set_multibit_options
  [-default]
  [-stage stage_name]
  [-mode multibit_mode]
  [-critical_range range]
  [-slack_threshold percentage]
  [-path_groups list_of_pathgroups]
  [-exclude_registers_with_timing_exceptions true]
  | [-exclude cells_to_exclude]
    [-name_prefix prefix_for_created_mb_cells]
    [-multibit_components_only]
  [-ignore_timing_exception list_of_timing_exceptions_to_not_exclude]
```

Data Types

<i>stage_name</i>	string
<i>multibit_mode</i>	string
<i>range</i>	string
<i>percentage</i>	string
<i>cells_to_exclude</i>	list of cells
<i>prefix_for_created_mb_cells</i>	string
<i>list_of_timing_exceptions_to_not_exclude</i>	list of strings

ARGUMENTS

-default

Sets the default multi-bit optimization flow setup. It can also be used as a way to reset the setup to default before adding new customization.

-stage *stage_name*

Sets the particular multi-bit optimization stage that will be subject of the specified settings during that call of the command. The possible values are: rtl, physical, debanking, banking_all and none. If not used, the command falls back to legacy compatibility and will forward the -critical_range and -path_groups options to the debanking stage, while any other options will go to the rtl stage.

-mode *multibit_mode*

Specifies the multi-bit optimization mode. The optimization mode has an effect on the target library cells selection, as well as the cost vector used for the evaluation of multi-bit transformations.

-critical_range *range*

Specifies the critical range to be used in order to determine which multibit registers need to be reworked for timing optimization during the *debanking* stage. It can also be used for as a way to exclude cells in the range from the specified optimization stage. The

range is expected to be a non-negative number representing a slack range with respect to the critical slack, or can be a percentage if the percentage sign is appended to the number, or it can be one of the special keywords default, none or full. When the word default is given, the tool will determine an appropriate critical range for each pathgroup based on the state of the timing constraints at the moment of the optimization. When the range is zero, only registers on the critical paths will be considered. When the range is the keyword none, it means no critical range for that context (either full design or specified path groups). When the keyword full is used, it means all negative slack cells will be in the range.

-slack_threshold *percentage*

An alias of the -critical_range option that only works with percentages. The same value can be given to critical_range and it will produce the same result.

-path_groups *list_of_pathgroups*

Restricts the given impact of the given -critical_range to the path groups specified in the list. This option must go together with the critical_range, otherwise it is meaningless.

-exclude_registers_with_timing_exceptions *true*

If true, indicates that registers with timing exceptions have to be excluded from multi-bit optimization.

-exclude *cells_to_exclude*

If the -exclude option is used, then the collection of cells given will be excluded from the multi-bit optimization of the specified -stage.

-name_prefix *prefix_for_created_mb_cells*

If the -name_prefix option is used, then the tool will include the given string as the local prefix of the name given to any multibit cell that it creates. The prefix will go after the hierarchical part of the name.

-multibit_components_only

If the -multibit_components_only option is given, then the tool will work only on cells that contained by a multibit component (as reported by the report_multibit command). A typical use will be for the physical banking stage, to restrict it to work only on bussed cells similar to rtl banking.

DESCRIPTION

The **multibit_mode** only affects the stages rtl and physical, and the value must be one of the following: **non_timing_driven**, **timing_driven**, **timing_only**, **timing_friendly** or **none**. The default **multibit_mode** is **non_timing_driven**.

In the **non_timing_driven** mode, the tool tries to use multibit registers whenever possible. It provides the best possible multibit register inference ratio.

In the **timing_driven** mode, multibit components are mapped to multibit registers only when it does not hurt timing or area QoR.

In the **timing_only** mode, multibit registers are used only when it does not hurt timing QoR even when it hurts area QoR.

In the **timing_friendly** mode, multibit registers are inferred as in the **non_timing_driven** mode, but the target library cell selection works as if the mode was **timing_only**, thus helping with timing QoR but not rejecting transformations that degrade the timing QoR cost.

If the mode specified is **none**, then no multibit optimizations will take place.

The **multibit_mode** value can be checked using the **report_compile_options** command.

The **-critical_range** and **-path_groups** options will trigger the **mbm_timing_opto** optimization step during incremental compile only when no -stage is given or -stage debanking is used. This optimization is only available in SPG mode, so specifying its controlling options in a non-SPG flow will have no impact on the final results. This optimization will attempt to unpack the multibit cells within the critical range of their path groups in order to help the critical bits meet their timing constraints. The non-critical bits will ideally be kept as multi-bit if their timing and packing constraints allow for that.

EXAMPLES

The following example sets the **multibit_mode** in backwards compatible way.

```
prompt> set_multibit_options -mode timing_only
```

The following example shows the attributes after the previous command:

```
prompt> report_compile_options
```

```
*****
Report : compile_options
Design : example
Version: J-2014.09-SP5-5
Date  : Tue Nov 3 22:40:04 2015
*****
```

Design	Compile Option	Value
example	flatten	false
	structure	true
	structure_boolean	false
	structure_timing	true
	isolate_port	disabled
	multibit_mode	timing_only

The following example sets the **multibit_mode** using -stage.

```
prompt> set_multibit_options -stage rtl -mode timing_only
```

This example sets the default values.

```
prompt> set_multibit_options -default
```

The following example shows the attributes after the previous command:

```
prompt> report_compile_options
```

```
*****
Report : compile_options
Design : example
Version: J-2014.09-SP5-5
Date  : Tue Nov 3 22:41:16 2015
*****
```

Design	Compile Option	Value
example	flatten	false
	structure	true
	structure_boolean	false
	structure_timing	true
	isolate_port	disabled
	multibit_mode	non_timing_driven

The following example shows the typical usage flow of the new mbm_timing_opto optimization:

```
prompt> set_multibit_options -critical_range default
1
prompt> compile_ultra -spg
prompt> insert_dft
prompt> compile_ultra -spg -incremental
```

The following example shows the typical usage flow of the mbm_timing_opto optimization using the -stage option:

```
prompt> set_multibit_options -stage debanking -critical_range default  
1  
prompt> compile_ultra -spg  
prompt> insert_dft  
prompt> compile_ultra -spg -incremental
```

The following example shows the usage of the timing exceptions exclude and ignore options. After executing the following commands, reg_b[0] and reg_b[1] will not get banked due to the false_path timing exception on them. But reg_a[0] and reg_a[1] will get banked since GROUP_PATH exception is ignored.

```
prompt> set_multibit_options -exclude_registers_with_timing_exceptions true -ignore_timing_exception GROUP_PATH  
prompt> group_path -name CLK -from "reg_a[0] reg_a[1]" -to "out1 out2"  
prompt> set_false_path -from "reg_b[0]/CK reg_b[1]/CK" -to "out3 out4"
```

set_multicycle_path

Modifies the single-cycle timing relationship of a constrained path.

SYNTAX

```
status set_multicycle_path
  path_multiplier
  [-rise | -fall]
  [-setup | -hold]
  [-start | -end]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
  [-reset_path]
  [-comment comment_string]
```

Data Types

<i>path_multiplier</i>	integer
<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list
<i>comment_string</i>	string

ARGUMENTS

path_multiplier

Specifies the number of cycles that the data path must have for setup or hold relative to the startpoint or endpoint clock before data is required at the endpoint. When used with **-setup**, this value is applied to setup path calculations. When used with **-hold**, this value is applied to hold path calculations. If neither **-hold** nor **-setup** are specified, *path_multiplier* is used for setup, and 0 is used for hold. Changing the multiplier for setup also affects the hold check.

-rise

Specifies that rising path delays are affected by *path_multiplier*. The default is that both rising and falling delays are affected. Rise refers to a rising value at the path endpoint.

-fall

Specifies that falling path delays are affected by *path_multiplier*. The default is that both rising and falling delays are affected. Fall refers to a falling value at the path endpoint.

-setup

Specifies that *path_multiplier* is used for setup calculations.

-hold

Specifies that *path_multiplier* is used for hold calculations.

-start | -end

Specifies whether the multicycle information is relative to the period of the start clock or the end clock. These options are only needed for multifrequency designs; otherwise start and end are equivalent. The start clock is the clock source related to the register or primary input at the path startpoint. The end clock is the clock source related to the register or primary output at the path endpoint. The default is to move the setup check relative to the end clock, and the hold check relative to the start clock. A setup multiplier of 2 with **-end** moves the relation forward one cycle of the end clock. A setup multiplier of 2 with **-start** moves the relation backward one cycle of the start clock. A hold multiplier of 1 with **-start** moves the relation forward one cycle of the start clock. A hold multiplier of 1 with **-end** moves the relation backward one cycle of the end clock.

-from *from_list*

Lists the names of clocks, ports, pins, or cells to use to find path startpoints. If a clock is specified, all registers and primary inputs related to that clock are used as path startpoints. If a cell is specified a cell, one path startpoint on that cell is affected.

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-from** option, except that the path must fall from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-through *through_list*

Lists the path throughpoints (port, pin, or leaf cell names) of the current design. The multicycle values apply only to paths that pass through one of the points in the *through_list*. If more than one object is included, the objects must be enclosed either in double quotation marks ("") or in braces ({}). If you specify the **-through** option multiple times, the multicycle values apply to paths that pass through a member of each *through_list* in the order the lists were given. The path must first pass through a member of the first *through_list*, then through a member of the second list, and so on for every through list specified. If the **-through** option is used in combination with the **-from** or **-to** options, the multicycle values apply only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Lists the names of clocks, ports, pins or cells to use to find path endpoints. If a clock is specified, all registers and primary outputs related to that clock are used as path endpoints. If a cell is specified, one path endpoint on that cell is affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-fall_to fall_to_list

Same as the **-to** option, but applies only to paths falling at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths launched by falling edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Removes existing point-to-point exception information on the specified paths. When used only with **-to**, all paths leading to the specified endpoints are reset. When used only with **-from**, all paths leading from the specified startpoints are reset. When used with **-from** and **-to**, only paths between those points are reset. Only information of the same rise/fall, setup/hold type is reset. This is equivalent to using the **reset_path** command with similar arguments before issuing **set_multicycle_path**.

-comment comment_string

Allows the command to accept a comment string. The tool honors the annotation and preserves it with the SDC object so that the exact string is written out when the constraint is written out when you use the **write_sdc** or **write_script** command. The comment remains intact through the synthesis, place-and-route, and timing-analysis flows.

DESCRIPTION

The **set_multicycle_path** command specifies that designated timing paths in the current design have nondefault setup or hold relations.

The synthesis timing engine applies certain rules to determine single-cycle timing relationships for paths between clocked elements. The rules are based on active edges. For flip-flops, a single active edge both launches and captures data. For latches, the open edge is used to launch data, and the close edge is used to latch data.

The setup check ensures that the correct data signal is available on destination registers in time to be properly latched.

The rule for setup is that for multifrequency designs, there can be multiple setup relations between two clocks. For every latch edge of the destination clock, find the nearest launch edge which precedes each capture edge. The smallest difference of (**setup_latch_edge** - **setup_launch_edge**) determines the maximum delay requirement for this path.

This is known as single-cycle setup. You can override this default relationship using **set_multicycle_path** or **set_max_delay**. You can apply these commands to clocks, pins, ports, or cells. For example, setting the setup path multiplier to 2 with the **set_multicycle_path** command delays the latch edge one clock pulse. Changing the setup multiplier also affects the default hold check.

The hold check verifies the following items:

- Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge.
- Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge.

The hold check is determined relative to each valid setup relationship, after applying multicycle path multipliers. The most restrictive (largest) difference of (**hold_latch_edge** - **hold_launch_edge**) is used as a minimum delay requirement for the path.

The hold relation is conservative. In some cases you might need to override the default hold relation. For multifrequency designs, it is more straightforward to use the **set_min_delay** command to override the default instead of using **set_multicycle_path -hold**.

Setting **path_multiplier** for setup moves the setup check in time by an integer number of active edges. For example, specifying **path_multiplier** of 2 for setup implies a 2 cycle data path.

Most often, the setup check is moved relative to the end clock. This move changes the data latch time at the path endpoint. In multifrequency designs, use the following command to move the data launch time backward:

set_multicycle_path -setup -start

To move the hold relation relative to the end clock use the command

set_multicycle_path -hold -end

If you do not specify **-setup** or **-hold**, the setup relation is set to *path_multiplier* and the hold relation is set to 0.

If you specify **-setup**, the setup multiplier is set to *path_multiplier*. The hold multiplier is unaffected.

If you specify **-hold**, the hold multiplier is set to *path_multiplier*. The setup multiplier is unaffected.

There are separate setup and hold multipliers for rise and fall. In most cases, these are set to the same value. You can use the **-rise** or **-fall** options to apply different values.

The **set_multicycle_path** command is a point-to-point timing exception command. If a path satisfies multiple timing exceptions, the following rules are used in order to determine which exceptions take effect. Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

- Two **group_path** commands can conflict with each other, but a **group_path** exception alone does not conflict with another type of exception. So the remaining rules apply for two **group_path** exceptions, or two non-**group_path** exceptions.
- If both exceptions are **set_false_paths**, there is no conflict.
- If one exception is a **set_max_delay** and the other is **set_min_delay**, there is no conflict.
- If one exception is a **set_multicycle_path -hold** and the other is **set_multicycle_path -setup**, there is no conflict.
- If one exception is a **set_false_path** and the other is not, the **set_false_path** takes precedence.
- If one exception is a **set_max_delay** and the other is not, the **set_max_delay** takes precedence.
- If one exception is a **set_min_delay** and the other is not, the **set_min_delay** takes precedence.
- If one exception has a **-from** pin or **-from** cell and the other does not, the former takes precedence.
- If one exception has a **-to** pin or **-to** cell and the other does not, the former takes precedence.
- If one exception has any **-through** points and the other does not, the former takes precedence.
- If one exception has a **-from** clock and the other does not, the former takes precedence.
- If one exception has a **-to** clock and the other does not, the former takes precedence.
- The exception with the more restrictive constraint then takes precedence. For **set_max_delay** and **set_multicycle_path -setup**, this is the constraint with the lower value. For **set_min_delay** and **set_multicycle_path -hold**, it is the constraint with the higher value.

To undo a **set_multicycle_path** command, use **reset_path** or **reset_design**.

Use **set_false_path** to disable setup or hold calculations for paths.

Use **report_timing_requirements** to list the point-to-point exceptions on a design.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets all paths between latch1b and latch2d to two-cycle paths for setup. Hold is measured at the previous edge of the clock at latch2d.

```
prompt> set_multicycle_path 2 -from {latch1b} -to {latch2d}
```

The following example moves the hold check to the preceding edge of the start clock:

```
prompt> set_multicycle_path -1 -from {latch1b} -to {latch2d}
```

The following example is a two-phase level-sensitive design, where the designer expects paths from phi1 to phi1 to be zero cycles:

```
prompt> set_multicycle_path 0 -from phi1 -to phi1
```

The following example uses the **-start** option to specify a three-cycle path relative to the clock at the path startpoint. Because clock sources are specified, the constraint affects all sequential elements clocked by that clock and ports with input or output delay relative to that clock.

```
prompt> set_multicycle_path 3 -start -from {clk50mhz} -to {clk10mhz}
```

The following example affects all paths that pass first through the U1 or U2 cell and later pass through the U3 cell. The path resulting in a rise transition at an endpoint is constrained to two cycles, but falling paths are constrained to one cycle.

```
prompt> set_multicycle_path 2 -rise -through {U1 U2} -through {U3}  
prompt> set_multicycle_path 1 -fall -through {U1 U2} -through {U3}
```

The following multifrequency example shows a path from a flip-flop, ff1, clocked by a 20-ns clock to a flip-flop, ff2, clocked by a 10-ns clock, with a multicycle path of two.

```
prompt> create_clock -period 20 -waveform {0 10} clk20  
prompt> create_clock -period 10 -waveform {0 5} clk10  
prompt> set_multicycle_path 2 -setup -from ff1/CP -to ff2/D
```

The single-cycle setup relationship is from the CLK1 edge at 0 ns to the CLK2 edge at 10 ns. With the multicycle path, the setup relationship is now 20 ns (from the CLK1 edge at 0ns to the CLK2 edge at 20ns). The hold relationships are determined according to that setup relationship.

- Data from the source clock edge that follows the setup launch edge must not be latched by the setup latch edge. This implies a hold relationship of 0 ns (from the CLK1 edge at 20 ns to the CLK2 edge at 20 ns).
- Data from the setup launch edge must not be latched by the destination clock edge that precedes the setup latch edge. This implies a hold relationship of 10 ns (from the CLK1 edge at 0 ns to the CLK2 edge at 10 ns).

The most restrictive (largest) hold relationship is used, so the minimum delay requirement for this path is 10 ns. This is a conservative check that might not apply to certain designs. Often you know that the destination register is disabled for the clock edge at 10 ns. You can modify this default hold relationship with the following command to get a 0-ns requirement:

```
prompt> set_min_delay 0 -from ff1/CP -to ff2/D
```

However, an easier approach is to use the following command:

```
prompt> set_multicycle_path 1 -hold -end -from ff1/CP -to ff2/D
```

`set_min_delay(2)`

set_mw_lib_reference

Sets the reference library for the Milkyway library.

SYNTAX

```
status_value set_mw_lib_reference
  [-mw_reference_library lib_list]
  [-reference_control_file file_name]
libName
```

Data Types

```
lib_list    string
file_name   string
libName    string
```

ARGUMENTS

-mw_reference_library *lib_list*

Specifies a list of libraries to be set as reference libraries for the Milkyway library.

This argument and **-reference_control_file** are mutually exclusive.

-reference_control_file *file_name*

Specifies a reference control file containing information to set the reference libraries for the Milkyway library.

This argument and **-mw_reference_library** are mutually exclusive.

libName

Specifies the Milkyway library to be worked on.

DESCRIPTION

Sets or changes the reference libraries for the Milkyway library. The Milkyway library being updated must be closed for the command to work correctly. The **-reference_control_file** and **-mw_reference_library** options are mutually exclusive, and at least one of the two must be specified.

A status indicating success or failure is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the reference libraries with a list:

```
prompt> set_mw_lib_reference -mw_reference_library {./lib/ref1 ./lib/ref2} design
```

SEE ALSO

`create_mw_lib(2)`
`set_mw_technology_file(2)`

set_mw_technology_file

Sets the technology file of the Milkyway library.

SYNTAX

```
status set_mw_technology_file
  [-technology tech_file]
  [-alf alf_file]
libName
```

Data Types

```
tech_file  string
alf_file   string
libName   string
```

ARGUMENTS

-technology *tech_file*

Specifies a new technology file to use with the Milkyway library. The command replaces the old technology information completely. Ensure that the new technology information is compatible, or else you must rebuild or re-create the Milkyway library accordingly.

-alf *alf_file*

Specifies a new alf file to use with the Milkyway library. This option is for purpose of importing signal EM data into the library. If there is existing signal EM information in the library, it is completely replaced by the data in the new alf file. Ensure that the new signal EM information is compatible with library technology. Signal EM data in the alf file is updated to the library immediately, but it does not have impact on the opened design.

libName

Specifies the Milkyway library to be updated. The value of *libName* must be a valid Milkyway library name.

DESCRIPTION

This command sets a technology file for a Milkyway library in Milkyway, plib, or alf format. The new information either replaces or is added to the existing library data, depending on the type of information added.

The command returns a status indicating success or failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the technology file of the library design to "new.tf":

```
prompt> set_mw_technology_file -technology new.tf design
1
```

`open_mw_lib(2)`
`rename_mw_lib(2)`
`set_mw_lib_reference(2)`
`write_mw_lib_files(2)`

set_net_routing_layer_constraints

Assigns routing layer constraints to the specified nets.

SYNTAX

```
status set_net_routing_layer_constraints
  list_of_nets
  -min_layer_name minimum_routing_layer_name
  -max_layer_name maximum_routing_layer_name
```

Data Types

<i>list_of_nets</i>	collection
<i>minimum_routing_layer_name</i>	string
<i>maximum_routing_layer_name</i>	string

ARGUMENTS

list_of_nets

Specifies the nets to which the routing layer constraints are applied. This is a required argument.

-min_layer_name *minimum_routing_layer_name*

Specifies the minimum routing layer. You can specify only a single layer name. This is a required option.

-max_layer_name *maximum_routing_layer_name*

Specifies the maximum routing layer. You can specify only a single layer name. This is a required option.

DESCRIPTION

This command assigns routing layer constraints to the specified nets.

The routing layer names you specify must exist in the physical library as well as in the design. In addition, the maximum routing layer must be higher than the minimum routing layer.

If a net already has routing layer constraints set, the tool issues a warning message and overrides the existing routing layer constraints.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns routing layer constraints to the net named netA.

```
prompt> set_net_routing_layer_constraints {netA}  
-min_layer_name metal1 -max_layer_name metal3
```

SEE ALSO

`report_net_routing_layer_constraints(2)`
`remove_net_routing_layer_constraints(2)`
`set_route_zrt_common_options(2)`

set_net_routing_rule

Assigns a nondefault or default routing rule to specific nets.

SYNTAX

```
status set_net_routing_rule
    -rule rule_name
    list_of_nets
    [-reroute normal | minorchange | freeze]
    [-timing_driven_spacing]
    [-top_layer_probe AnyPort | OutPort | AllPort]
    [-rule_is_user one-of-string]
```

Data Types

<i>rule_name</i>	string
<i>list_of_nets</i>	list

ARGUMENTS

-rule *rule_name*

Specifies the name of the routing rule to be assigned.

The *rule_name* argument can be either the name of an existing nondefault routing rule or the **default** keyword, which assigns the default routing rule to the specified nets.

list_of_nets

Specifies the nets to which to assign the routing rule.

-reroute normal | minorchange | freeze

Specifies the rerouting mode.

Valid values are

- **normal** (the default)
Performs a typical reroute on the net.
- **minorchange**
Reroutes only the minor changes to the nets.
- **freeze**
Does not perform any rerouting.

This option is not supported in Design Compiler topographical mode.

-timing_driven_spacing

Assigns timing-driven spacing constraints to the specified nets.

When crosstalk problems occur around the specified nets or the intralayer coupling capacitance of the nets is too high, the router spaces this net away from other nets and avoids placing long parallel wires next to this net.

The classic router honors this constraint during global routing and detail routing. Zroute honors this constraint only during global routing; during detail routing, this constraint is ignored.

This option is not supported in Design Compiler topographical mode.

-top_layer_probe AnyPort | OutPort | AllPort

Specifies how to route the nets close to ports at the top of the routing layers so that the top-layer segment of the net can be used for probing.

Valid values are

- **AnyPort** (the default)
Routes the net from either an input port or output port of the net at the top of the routing layers. The net needs to reach the top layer only once; the location does not matter. This is for signal probing only.
- **OutPort**
Routes only the net from an output port of the net at the top of the routing layers. The routing from the output pin has to reach the top layer prior to hitting the Steiner point or another pin. This is for post-mask surgery, which might want to disconnect the driving pin of the net.
- **AllPort**
Routes the net from the input and output ports of the net at the top of the routing layers. The routing from every pin has to reach the top layer prior to hitting the Steiner point or another pin. This is for post-mask surgery, which might want to disconnect any pin from the net.

For two-pin nets, all three options are essentially the same. You will only notice a difference for nets with three or more pins.

This option is for the classic router only.

This option is not supported in Design Compiler topographical mode.

DESCRIPTION

This command assigns a nondefault or default routing rule to specific nets. Nondefault rules are defined in the physical library or by using the **define_routing_rule** command and can have associated user-defined width and spacing rules and via types. These rules govern nondefault wiring such as the wide wires and vias that are typically used for clock signals and other sensitive signals.

Library-specific rules are defined in the physical library and stored in the .pdb file.

If nondefault routing rules are not defined in the physical library provided with the design database, you can define them in a separate .plib file that can be updated into the existing .pdb file by using the **update_lib** command. For more information about the **update_lib** command, see the man page.

You can define design-specific rules by using the **define_routing_rule** command and storing them in the design .db file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns a nondefault rule named WideMetal to a net named B_CLK.

```
prompt> set_net_routing_rule {B_CLK} -rule WideMetal
```

SEE ALSO

`update_lib(2)`
`define_routing_rule(2)`
`report_routing_rules(2)`

set_net_search_pattern_delay_estimation_options

Sets delay estimation options for a pattern.

SYNTAX

```
status set_net_search_pattern_delay_estimation_options
  -pattern id
  [-default]
  [-rule rule_name]
  [-min_layer_name layer_name]
  [-max_layer_name layer_name]
```

Data Types

```
id      integer
rule_name string
layer_name string
```

ARGUMENTS

-pattern *id*

This required option specifies the pattern ID that the delay estimation options will be applied to. The corresponding search pattern should already be defined.

-default

Resets all options to default, meaning that no rules or layer assignments will be applied to the nets that match the specified pattern ID. The **-default** option cannot be used with any other options.

-rule *rule_name*

Assigns a non-default routing rule to a specified net pattern ID. Once defined, the unit Rs and unit Cs of the matching nets will change accordingly.

This option is not supported in Design Compiler topographical mode.

-min_layer_name *layer_name*

Defines a minimum routing layer for nets that match the specified pattern ID. It must be used with the **-max_layer_name** option.

-max_layer_name *layer_name*

Defines a maximum routing layer for nets that match the specified pattern ID. It must be used with the **-min_layer_name** option.

DESCRIPTION

The **set_net_search_pattern_delay_estimation_options** command specifies layer assignments, which will ultimately alter the RC values of the matching nets. For example, if min and max routing layers of M9 and M10 are specified, virtual route-based optimizations will use the average R and C of layers M9 and M10 to compute RC delays for all matched nets.

In order for the layer constraints to be honored by the routers, net search patterns and corresponding delay estimation options must be applied before you run the **compile_ultra -spg -layer_optimization** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how **set_net_search_pattern_delay_estimation_options** can be used to assign a min routing layer of METAL7 and a max routing layer of METAL8 to all nets that match pattern ID 1.

```
prompt> set_net_search_pattern_delay_estimation_options -pattern 1 -min_layer_name METAL7 -max_layer_name METAL8
```

SEE ALSO

```
create_net_search_pattern(2)
report_net_search_pattern(2)
remove_net_search_pattern(2)
report_net_search_pattern_delay_estimation_options(2)
set_net_search_pattern_priority(2)
report_net_search_pattern_priority(2)
get_matching_nets_for_pattern(2)
```

set_net_search_pattern_priority

Sets the net search pattern matching priority.

SYNTAX

```
status set_net_search_pattern_priority  
      string | -default
```

ARGUMENTS

string

Provides a list of IDs of net patterns that have already been created.

-default

Resets the prioritization of net pattern matching. When you use the **-default** option, net pattern matching prioritization reverts to the original behavior, which is to use the order in which patterns were created. For example, if the **create_net_search_pattern** command was used only three times, the default matching priority will be "1 2 3".

DESCRIPTION

When multiple net patterns are defined, a net can match more than one search pattern. For example, if you create a search pattern for nets with a length less than 3 and another search pattern for nets with a length between 2 and 4, then a net with a length of 2.5 will match both search patterns.

During optimization, however, the first net pattern that was created takes precedence over the second net pattern. Therefore, in the previous example, the net with a length of 2.5 will belong to the first collection by default. If you want to change this behavior during optimization, you can specify **set_net_search_pattern_priority "2 1"**, and then the net with a length of 2.5 will belong to the second collection.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how the **set_net_search_pattern_priority** command can be used to change the priority of five existing patterns, which would by default have a match priority of "1 2 3 4 5".

```
prompt> set_net_search_pattern_priority "4 5 1 2 3"
```

set_obfuscation_configuration

Sets the default obfuscation configuration for the current design.

SYNTAX

```
status set_obfuscation_configuration
  [-parameters parameter_list]
  [-exec_name executable_name]
  [-location instance_path_name]
  [-exclude_cells cell_list]
```

Data Types

parameter_list	list
executable_name	string
cell_list	list

ARGUMENTS

-parameters *parameter_list*

Specifies list of parameters to obfuscation logic insertion.

Here is syntax of parameter.

<parameter_name>:<parameter_value>

These parameters are applied to obfuscation logic insertion in **insert_security command**.

-exec_name *executable_name*

Specifies leaf level executable name of performer tool that inserts obfuscation logic into the design.

Complete path name of the executable is inferred from path environment in **insert_security command**.

-location *instance_path_name*

Specifies instance name into which obfuscation logic is inserted in **insert_security command**.

Specified instance name should be a hierarchical instance name.

-exclude_cells *cell_list*

Specifies list of cells of current design which are excluded from obfuscation logic in **insert_security command**.

These cells can be leaf level cells or hierarchical cells.

Complete path name of cells should be specified.

Simple regular expressions that contain * are also accepted.

DESCRIPTION

This command specifies the default obfuscation configuration to be used for obfuscation logic insertion by the **insert_securitycommand**.

Use the **reset_obfuscation_configuration** command to reset the current obfuscation configuration of the design.

EXAMPLES

The following example specifies obfuscate as executable name for gate level obfuscation logic insertion and associated parameters.

```
prompt> set_obfuscation_configuration -exec_name obfuscate \
    -parameters { P:obfuscationing_v3/bin/ m:des_unit t:des_unit \
    F:Outputs R:rst_st C:clk_st f:1 d:1 p:10 s:0 k:32 S:123 } \
    -level gate
Accepted obfuscation configuration for design '...'.
1
```

SEE ALSO

insert_security(2)
reset_obfuscation_configuration(2)
report_obfuscation_configuration(2)

set_opcond_inference

Specifies the strategy for operating condition inference.

SYNTAX

```
status set_opcond_inference
  [-level level_value]
  [-match_process_temperature true | false]
  [-object_list cells]
  [-applies_to macro_cells pad_cells switch_cells]
```

Data Types

<i>level_value</i>	string
<i>cells</i>	collection

ARGUMENTS

-level *level_value*

Specifies the degree of freedom for the tool to infer the operating conditions. There are four possible levels of operating condition inference:

- **exact** The timing on the cells is critical and the tool is not allowed to infer operating conditions.
- **unique_resolved** In case of potential **LIBSETUP-001** errors, the tool infers an operating condition on the cells when the library contains only one cell that matches the reference name of the cell. If there are multiple library cells with the same reference name, the tool does not infer the operating condition on the cell.
- **closest_resolved** When the library contains multiple library cells that match the reference name, the tool attempts to select the cell whose operating condition is closest to the constrained operating condition. The tool requires exactly one library cell that is closest to the constrained operating condition than any other library cell. If there are multiple library cells that are equally close to the operating condition, the tool does not infer the operating condition.
- **closest_unresolved** When you use this option, the tool has maximum flexibility when inferring the operating conditions. The requirement to have a single library cell closer to the operating condition, than any other library cell is also waived.

When you do not use any of these options, the default is **closest_resolved**.

For more information about how the closest library cell relative to the operating condition is defined, see the user guide.

-match_process_temperature true | false

When this option is set to true, library cells whose process and temperature do not match the process and temperature in the specified operating condition, are ignored while inferring the operating condition. This option has no effect when the value of the **-level** option is **exact**. The default is **false**.

-object_list *cells*

Specifies the cells to which the operating condition inference strategy applies. The cells must be macro, pad, switch, or hierarchical cell.

When you do not specify the cells, the settings are applied to the top design. When hierarchical cells are specified, the strategy is applied to the instances and their child instances. When the **-applies_to** option is also specified, only child cells of the specified cell types are included.

-applies_to macro_cells pad_cells switch_cells

Specifies the cell types to which the strategy is applied. If this option is not specified, macro cells, pad cells and switch cell types are considered for the operating condition inference.

DESCRIPTION

If the specified operating condition does not match any available cell in the library and the timing on the cell is not critical, the tool can infer the operating condition on the macro, pad, and switch cells to avoid potential **LIBSETUP-001** errors.

The command specifies how the tool should infer operating conditions on macro, pad, and switch cells. At least one of **-level** or **-match_process_temperature** options must be specified. The command applies to the identified instances and their child instances. A strategy defined at a lower level that applies to the same cell type overrides the strategy specified at a higher level.

Multicorner-Multimode Support

This command applies to all scenarios.

EXAMPLES

The following example specifies that operating condition inference should not be performed on all macro cells under the hierarchical cell **subA**.

```
prompt> set_opcond_inference -level exact -object_list [get_cells {subA}] -applies_to macro_cells
```

`set_voltage(2)`
`report_lib(2)`

set_operating_conditions

Defines the operating conditions for the current design.

SYNTAX

```
status set_operating_conditions
[-analysis_type bc_wc | on_chip_variation]
[-min min_condition]
[-max max_condition]
[-min_library min_lib]
[-max_library max_lib]
[-min_phys min_proc]
[-max_phys max_proc]
[-library lib]
[-object_list objects]
[condition]
```

Data Types

<i>min_condition</i>	list
<i>max_condition</i>	list
<i>objects</i>	list
<i>condition</i>	list

ARGUMENTS

-analysis_type bc_wc | on_chip_variation

Specifies how to use the operating conditions. The **bc_wc** and **on_chip_variation** options are mutually exclusive; use only one per command.

Specifying either **bc_wc** or **on_chip_variation** switches the design to min_max mode. The **bc_wc** value specifies that the min and max operating conditions are two extreme operating conditions. In the **bc_wc** analysis, setup violations are checked only for the maximum operating condition, and the hold violations are checked only for the minimum operating condition.

The **on_chip_variation** value specifies that the minimum and maximum operating conditions represent, respectively, the lower and upper bounds of the maximum variation of operating conditions on the chip. All maximum path delays use the maximum operating condition, and all minimum path delays use the minimum operating condition.

-min *min_condition*

Specifies the operating condition to use for minimum delay analysis. If you do not specify an operating condition for minimum delay analysis, the tool uses the maximum operating condition. The **-min** option must be used with the **-max** option.

-max *max_condition*

Specifies the operating condition to use for maximum delay analysis.

-min_library *min_lib*

Specifies the library containing definitions of the operating conditions for minimum delay analysis. This is either a library name or a

collection. The tool selects the first library in the collection containing the definitions.

-max_library max_lib

Specifies the library containing definitions of the operating conditions for maximum delay analysis. This is either a library name or a collection. The tool selects the first library in the collection containing the definitions.

-min_phys min_proc

Specifies the name of the process resource to search for the resistance and capacitance values for minimum delay analysis. This option must be used in with the **-max_phys** option.

-max_phys max_proc

Specifies the name of the process resource to search for the resistance and capacitance values for maximum delay analysis. This argument must be used with the **-min_phys** option.

-library lib

Specifies the library containing definitions of the operating conditions for both maximum and minimum delay analysis. This is either a library name or a collection. The tool selects the first library in the collection containing the definitions.

-object_list objects

Specifies the cells or ports on which to set operating conditions. If you do not use this option, operating conditions are set on the design. This option accepts both leaf cells and hierarchical blocks. This option is only available for multivoltage features and requires the appropriate license.

condition

Specifies conditions that define environmental characteristics to use during maximum and minimum delay analysis.

DESCRIPTION

This command defines the operating conditions (or environmental characteristics) under which to time or optimize the current design. The operating conditions specified must be defined in *lib* or in one of the libraries in the **link_library**. A **local_link_library** set on the current design is added to the beginning of the **link_library**, before the **link_library** is searched. The order for a library search is as follows:

1. *lib*
2. **local_link_library**
3. **link_library**

If you do not specify any operating conditions for a design, the **compile** command searches in the first library of the link library for default operating conditions. If the library does not have default operating conditions, no operating conditions are used.

Operating conditions set by using the **-object_list** option override the operating conditions set on design or higher levels of hierarchy.

To see the operating conditions that are defined for the current design, and to see which libraries the current design is linked to, use the **report_design** command. To see the operating conditions defined in the specified library, use the **report_lib** command.

To remove operating conditions from the current design, use **set_operating_conditions** without specifying any operating conditions, or use the **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

You must use the **set_operating_conditions** command to define the operating conditions for each scenario.

EXAMPLES

The following example shows an operating condition definition, as it appears in the source text of a library:

```
operating_conditions("BCCOM") {  
    process : 0.6 ;  
    temperature : 20 ;  
    voltage : 5.25 ;  
    tree_type : "best_case_tree" ;  
}
```

The name of this set of operating conditions is *BCCOM*. The parameters are defined as follows:

process

A floating-point number that represents the characteristics of a semiconductor manufacturing process.

temperature

A floating-point number that represents the temperature of the defined environment.

voltage

A floating-point number that defines the upper boundary of the voltage range in which the defined environment operates. The lower boundary is always 0.0.

tree_type

The interconnect model for the environment. The **compile** command uses the interconnect model to select a formula for calculating interconnect delays. Three models are available:

- *best_case_tree*, which assumes the net delay to be 0
- *worst_case_tree*, which uses the lumped RC model
- *balanced_tree*, in which all loads share the wire resistance evenly.

When process factor, operating temperature, and operating voltage deviate from their nominal values, **compile** uses a linear model to compensate for the effect of deviations on such values as cell delays, input loads, and output drives. The nominal values used are defined in the same library that contains the definitions of the set of operating conditions.

The following example sets the operating conditions to *WCIND* if the link_library is *my_lib.db*, and the design does not have a local_link_library set. The library name for *my_lib.db* is *my_lib_core*.

```
prompt> set_operating_conditions WCIND
```

Using operating condition 'WCIND' found in library "my_lib_core".

In the following example, the BCIND values found in *other_lib.db* are used for minimum delay analysis, and WCIND values are used for maximum delay analysis. The library name for *other_lib.db* is *other_lib_core*.

```
prompt> set_operating_conditions -min BCIND -max WCIND \  
      -library other_lib_core
```

Using operating condition 'BCIND' found in library 'other_lib_core'.

Using operating condition 'WCIND' found in library 'other_lib_core'.

The following example shows how to remove operating conditions defined for the current design:

```
prompt> set_operating_conditions
```

set_opposite

Defines two input ports as logically opposite.

SYNTAX

```
int set_opposite  
    port1  
    port2
```

Data Types

```
port1  string  
port2  string
```

ARGUMENTS

port1 *port1*

Input port names in the current design that are logically opposite.

DESCRIPTION

Defines two input ports in the current design as logically opposite. Use the command to eliminate redundant inverters and improve the quality of optimization. Inconsistencies in logical relations among ports are detected. It is an error to specify such an inconsistency using **set_opposite**.

Use the **reset_design** command to remove this property from a port.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets two input ports named "A" and "B" to be logically opposite.

```
prompt> set_opposite A B
```

SEE ALSO

`reset_design(2)`
`set_equal(2)`

set_optimize_dft_options

Defines options for physical design-for-test (DFT) optimization.

SYNTAX

```
status set_optimize_dft_options
  [-repartitioning_method none | single_directional | multi_directional | adaptive]
  [-single_dir_option horizontal | vertical]
```

ARGUMENTS

-repartitioning_method none | single_directional | multi_directional | adaptive

Specifies the type of the scan chain repartition algorithm used in placement-aware scan optimization.

This command affects DFT optimization performed by the **compile_ultra -scan -incremental** command performed after DFT insertion.

If you specify **none**, DFT optimization does not do scan repartitioning.

If you specify **single_directional**, DFT optimization uses the traditional single-directional scan repartitioning algorithm. By default, the direction is **horizontal**. You can use the **-single_dir_option** option to specify the desired direction.

If you specify **multi_directional**, DFT optimization uses the multi-directional scan repartitioning algorithm. The multi-directional algorithm is designed to achieve better scan path total wire-length reduction efficiency, especially for designs with a large number of scan chains.

If you specify **adaptive**, DFT optimization chooses the scan repartitioning algorithm adaptively, according to the number of scan chains, for the best scan wire-length reduction efficiency. For designs with no more than 20 scan chains, the traditional single-directional scan repartitioning algorithm is used; otherwise, the multi-directional scan repartitioning algorithm is used. If the single-directional algorithm is chosen, the partition direction is determined by the setting of the **-single_dir_option** option.

The default of this option is **multi_directional**.

-single_dir_option horizontal | vertical

Specifies the desired direction for the single-directional scan repartitioning algorithm. The option takes effect only when the **-repartitioning_method** is set to **single_directional** or set to **adaptive** on a design with 20 or fewer scan chains.

The default of this option is **horizontal**.

DESCRIPTION

This command defines the options that are used for DFT optimization.

SEE ALSO

`compile_ultra(2)`
`remove_optimize_dft_options(2)`
`report_optimize_dft_options(2)`

set_optimize_registers

Sets the **optimize_registers** attribute on the specified designs or on the current design, so that **compile** automatically invokes the DC Ultra **optimize_registers** command to retime the design during optimization.

SYNTAX

```
status set_optimize_registers
  [true | false]
  [-designs design_list]
  [-minimum_period_only]
  [-sync_transform multiclass | decompose | dont_retime]
  [-async_transform multiclass | decompose | dont_retime]
  [-check_design [-verbose]]
  [-print_critical_loop]
  [-clock clock_name [-edge rise | fall]]
  [-latch]
  [-justification_effort low | medium | high]
  [-delay_threshold target_clock_period]
```

Data Types

<i>design_list</i>	list
<i>clock_name</i>	string

ARGUMENTS

true | false

Specifies the value with which to set the **optimize_registers** attribute. The default value is **true**.

-designs *design_list*

Specifies a list of designs to retime. The default is the current design.

-minimum_period_only

Indicates that only the minimum period step of the retiming algorithm (minimum clock period retiming) and not the minimum area (sequential cell count optimization) step is to be executed during compile. By default, both the minimum period and minimum area optimization steps are executed. This option is useful if you want a fast turnaround when trying to optimize the design's timing. The runtime is reduced, but your area results will not be optimal. After you are satisfied with the timing, you can attempt to reduce area by running the retiming command without this option.

-sync_transform multiclass | decompose | dont_retime

Specifies which transformation method is used for synchronous sequential cells in the design. An edge-triggered register is synchronous if none of its input pins change the outputs asynchronously. A level-sensitive latch is considered synchronous if none of its input pins can change the outputs during the clock phase where the latch is not transparent.

Selecting **multiclass** transformation specifies that the identifiable synchronous clear, set, and enable functionality is moved with the synchronous sequential cells if they are moved during retiming. Sequential cells are classified according to their set, clear, and

enable connections. The class of the sequential cells at the fanin or fanout of a combinational cell determines whether retiming across this cell can be performed.

Selecting the **decompose** transformation specifies that synchronous sequential cells in the design are transformed into an instance of a D-flip-flop or D-latch and additional combinational logic to create the necessary synchronous functionality. Only the D-flip-flop/D-latch instance can be moved during retiming.

Specifying **dont_retime** specifies that synchronous sequential cells will not be moved during retiming. Their mapping might still be changed to a different flip-flop from the technology library. The **dont_touch** attributes and retiming transformation attributes set on individual sequential cells override the value set in this option. To set retiming transform attributes, use the **set_transform_for_retimings** command. The default argument for this option is *multiclass*.

-async_transform multiclass | decompose | dont_retime

Specifies which transformation method is used for asynchronous sequential cells in the design. An edge-triggered register is asynchronous if at least one of its input pins changes the outputs asynchronously. A level-sensitive latch is asynchronous if at least one of its inputs can change the outputs during the clock phase where the latch is not transparent.

Selecting the **multiclass** transformation specifies that the identifiable asynchronous clear and set functionality, as well as any synchronous set, clear, and enable functionality, is moved with the asynchronous sequential cells, if they are moved during retiming. Sequential cells are classified according to their set, clear, and enable connections. The class of the sequential cells at the fanin or fanout of a combinational cell determines whether retiming can be performed across this cell.

Selecting the **decompose** transformation specifies that asynchronous sequential cells in the design are transformed into an instance of a flip-flop or latch with asynchronous set and clear inputs, as necessary, and additional combinational logic to create the necessary synchronous functionality. Only the flip-flop/latch instances can be moved during retiming. They will be classified according to their synchronous set, clear, and enable functionality.

Selecting the **dont_retime** value specifies that asynchronous sequential cells will not be moved during retiming. Their mapping might still be changed to a different flip-flop from the technology library. The **dont_touch** attributes and retiming transformation attributes set on individual sequential cells override the value set in this option. To set retiming transform attributes, use the **set_transform_for_retimings** command. The default value for this option is *multiclass*.

-check_design

Indicates that additional information about the design is to be displayed before and after retiming. This information includes the number of cells in different categories (for example, hierarchy cells with **dont_touch** attributes or non-movable sequential cells) and more detailed information about the selection of the preferred flip-flop or latch. Use this information to help in troubleshooting if retiming does not show the expected results.

-verbose

Indicates that the explicit names of the cells are to be displayed along with the number of cells in each category for most categories of the **-check_design** option. The explicit naming of cells can help to locate a problem; however, the lists of output names might be long. This option can be used only with the **-check_design** option.

-print_critical_loop

Indicates that the critical loop of the design, as seen during retiming, is to be displayed. The critical loop is defined as the sequence of directly-connected combinational and sequential cells whose total combinational delay divided by the number of registers in the loop has a higher value than any other loop in the design. The critical loop limits the minimum clock period that can be achieved by retiming. Use this option to help troubleshoot problem areas of the design if the intended clock period cannot be achieved with the given number of sequential cells in the design. If you are pipelining a data path, you might need to add pipeline stages in the HDL code.

-clock clock_name

Specifies the name of the clock whose sequential cells are to be retimed. The clock must not be a virtual clock; it must have a associated clock port. The name of the clock is either the name specified in the **create_clock** command or the name of the clock port, if the **create_clock** command had no name specified. The registers of the clock are all sequential cells that are triggered by this clock. The connection from the clock port to the sequential cell can be through clock gating cells, buffer cells and inverter cells. If the **-clock** option is specified and edge-triggered registers are retimed, registers of other clocks are not retimed. If level-sensitive latches are retimed and the **-clock** option is specified, the latches driven by this clock as well as those driven by other clocks needed to complete a two-phase clock system are retimed. If edge-triggered registers are retimed, only registers triggered by one specific edge of the clock are retimed. By default the registers triggered by the rising edge are retimed. A different edge can be specified using the **-edge** option.

-edge rise | fall

Specifies whether the registers triggered by the rising or the falling edge of the clock are to be retimed. This option can only be used together with the **-clock** option. When level-sensitive latches are retimed this option does not matter.

-latch

Specifies that level-sensitive latches are to be retimed instead of edge-triggered sequential cells (flip-flops). If this option is used the edge-triggered sequential cells in the design will not be moved. In order to be able to retime latches they must be driven by a symmetrical two-phase clocks system. Latches that are used to prevent glitches in gated clocks will not be moved, even if the **-latch** option is used. These latches are in the fanin of clock-gating cells.

-justification_effort low | medium | high

Specifies the justification effort level that is to be used during backward justification of registers. You can specify a value of low, medium, or high. Specifying low ensures that justification terminates very quickly, but the QoR may be bad. Specifying medium provides good QoR with considerable runtime. Specifying high provides the best QoR without any regard for runtime. The default value for this option is medium.

-delay_threshold target_clock_period

Instructs *Design Compiler* to improve paths with delays less than worst delay as given in critical loop report. *Design Compiler* makes additional retiming passes until all such paths are optimized to operate at given target clock period.

DESCRIPTION

This command sets the **optimize_registers** attribute on the specified design or on the current design, so that the **compile** command automatically invokes **optimize_registers** to retime the design during optimization. If you specify any of the new options, then **compile** invokes **optimize_registers** with the new options. The DC Ultra **optimize_registers** command moves registers in a design across combinational logic to achieve a target clock period, then minimizes the registers while maintaining that clock period. The **optimize_registers** attribute is particularly useful for creating embedded dc_shell compilation scripts for HDL descriptions that are to be transformed to DesignWare synthetic library components.

For more information about retiming during optimization, see the *Design Compiler* documentation.

To remove **optimize_registers** use the **remove_attribute** command. You can achieve the same effect by setting the **optimize_registers** attribute to false; execute **set_optimize_registers false**. The **reset_design** command removes all attributes, including **optimize_registers**.

Licensing during compile when using the **optimize_registers** attribute can be controlled by using the **compile_retime_license_behavior** dc_shell variable.

The **optimize_registers** attribute can also be used to direct *Design Compiler* to optimize subcritical paths using delay threshold optimization. Subcritical paths are paths that operate at delays less than the final worst critical delay provided by retiming. Threshold optimization techniques can be used to balance delays on paths with positive slacks. The **optimize_registers** attribute uses the target clock period specified by **-delay_threshold** and performs multiple passes of min-period retiming on paths that operate at delays less than the worst delay but greater than the target clock period.

EXAMPLES

In the following example, **optimize_registers** is enabled on the TEST design:

```
prompt> set_optimize_registers -design TEST
```

In the following example, **optimize_registers** is enabled on the current design and disabled on the OLD design:

```
prompt> read TEST
prompt> set_optimize_registers
```

```
prompt> set_optimize_registers false -design OLD
```

In the following example, **optimize_registers** is enabled on the TEST design with the **-minimum_period_only** option. This means that when compile automatically calls **optimize_registers** under the hood, it invokes **optimize_registers** with **-minimum_period_only**.

```
prompt> set_optimize_registers -design TEST -minimum_period_only
```

set_output_clock_port_type

Specifies the output clock port as a data port or a clock port.

SYNTAX

```
status set_output_clock_port_type
  -data | -clock
  port_list
```

Data Types

port_list list

ARGUMENTS

-data

Specifies the port type as data. You must specify either the **-data** or the **-clock** option; they are mutually exclusive. The default type is data.

-clock

Specifies the port type as clock. You must specify either the **-data** or **-clock** option; they are mutually exclusive.

port_list

Specifies the ports to which the port type is assigned.

DESCRIPTION

This command specifies the type of output port.

An output clock port is the port that the clock can reach. An output clock port can drive either clock pins or data pins. The tool cannot determine the type of pin to which the output clock port will be connected. You must specify either **-data** or **-clock** as the port type. By default, all output clock ports will be treated as data ports.

Note that even if the port type is set to clock, the output delay will still be honored, which may impact the timing result. For this reason, it is considered best practice not to set output delay on an output clock port, if the port has already been set as clock port.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies the port named OUT1 as a clock port:

```
prompt> set_output_clock_port_type -clock OUT1
```

set_output_delay

Sets output delay on pins or output ports relative to a clock signal.

SYNTAX

```
status set_output_delay
  delay_value
  [-reference_pin pin_port_name]
  [-clock clock_name [-clock_fall] [-level_sensitive]]
  [-network_latency_included]
  [-source_latency_included]
  [-rise]
  [-fall]
  [-max]
  [-min]
  [-add_delay]
  [-group_path group_name]
  port_pin_list
```

Data Types

<i>delay_value</i>	float
<i>clock_name</i>	string or collection
<i>group_name</i>	string
<i>port_pin_list</i>	list

ARGUMENTS

delay_value

Specifies the path delay. The *delay_value* must be in units consistent with the technology library used during optimization. The *delay_value* represents the amount of time that the signal is required before a clock edge. For maximum output delay, this usually represents a combinational path delay to a register plus the library setup time of that register. For minimum output delay, this value is usually the shortest path delay to a register minus the library hold time.

-reference_pin *pin_port_name*

Specifies the clock pin or port to which the specified delay is related. If you use this option, and if propagated clocking is being used, the delay value is related to the arrival time at the specified reference pin, which is clock source latency plus its network latency from the clock source to this reference pin. The options *-network_latency_included* and *-source_latency_included* cannot be used at the same time as the *-reference_pin* option. For ideal clock network, only source latency is applied.

The pin specified with the *-reference_pin* option should be a leaf pin or port in a clock network, in the direct or transitive fanout of a clock source specified with the *-clock* option. If multiple clocks reach the port or pin where you are setting the input delay, and if the *-clock* option is not used, the command considers all of the clocks.

-clock *clock_name*

Specifies the clock to which the specified delay is related. If *-clock_fall* is used, **-clock *clock_name*** must be specified. If **-clock** is not specified, the delay is relative to time zero for combinational designs. For sequential designs, the delay is considered relative to

a new clock with period determined by considering the sequential cells in the transitive fanout of each port.

The clock can be either a string or collection of one object.

-clock_fall

Specifies that the delay is relative to the falling edge of the clock. If **-clock** is specified, the default is the rising edge.

-level_sensitive

Specifies that the destination of the delay is a level-sensitive latch. This allows the tool to derive setup and hold relationship for paths to this port as if it were a level-sensitive latch. If **-level_sensitive** is not used, the output delay is treated as if it were a path to a flip-flop.

-network_latency_included

Specifies that the clock network latency should not be added to the output delay value. If this option is not specified, the clock network latency of the related clock is added to the output delay value. It has no effect if the clock is propagated or the output delay is not specified with respect to any clock.

-source_latency_included

Specifies that the clock source latency should not be added to the output delay value. If this option is not specified, the clock source latency of the related clock is added to the output delay value. It has no effect if the output delay is not specified with respect to any clock.

-rise

Specifies that *delay_value* refers to a rising transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, then rising and falling delays are assumed to be equal.

-fall

Specifies that *delay_value* refers to a falling transition on specified ports of the current design. If neither **-rise** nor **-fall** is specified, then rising and falling delays are assumed to be equal.

-max

Specifies that *delay_value* refers to the longest path. If neither **-max** nor **-min** is specified, maximum and minimum output delays are assumed to be equal.

-min

Specifies that *delay_value* refers to the shortest path. If neither **-max** nor **-min** is specified, maximum and minimum output delays are assumed to be equal.

-add_delay

Specifies whether to add delay information to the existing output delay, or to overwrite. The **-add_delay** option enables you to capture information about multiple paths leading from an output port that are relative to different clocks or clock edges.

For example, the following command removes all other maximum rise output delay from **OUT1**, since **-add_delay** is not specified. Other output delay with a different clock or with **clock_fall** is removed.

```
prompt> set_output_delay 5.0 -max -rise -clock phi1 {OUT1}
```

In the following example, **-add_delay** is specified:

```
prompt> set_output_delay 5.0 -max -rise -clock phi1 \
    -add_delay {Z}
```

If there is an output maximum rise delay for **Z** relative to the clock **phi1** rising edge, the larger value is used. The smaller value does not result in critical timing for maximum delay. For minimum delay, the smaller value is used. If there is maximum rise output delay relative to a different clock or different edge of the same clock, it remains with the new delay.

-group_path group_name

Specifies that paths ending at the specified ports or pins are added into the named group. If the group does not already exist, it is

created. This is equivalent to specifying the following command in addition to **set_output_delay**:

```
prompt> group_path -name group_name -to port_pin_list
```

If **-group_path** is not specified, the existing path grouping is not changed.

port_pin_list

A list of output port or internal pin names in the current design to which *delay_value* is assigned. If more than one object is specified, the objects are enclosed in double quotation marks ("") or in braces ({}). If output delay is specified on a pin, the cell of the pin is set to size only to leave room for compile applying sizing on it.

DESCRIPTION

This command sets output path delay values for the current design. Used with the **set_load** and **set_driving_cell** commands, the input and output delays characterize the operating environment of the current design.

The **set_output_delay** command sets output path delays on output ports relative to a clock edge. Output ports are assumed to have no output delay unless specified. For inout (bidirectional) ports, you can specify the path delays for both input and output modes.

To describe a path delay to a level-sensitive latch, use the **-level_sensitive** option. If the latch is positive-enabled, set the output delay relative to the rising clock edge. If the latch is negative-enabled, set the output delay relative to the falling clock edge. If time is being borrowed at that latch, subtract that time borrowed from the path delay to the latch when determining output delay.

The **characterize** command automatically sets input and output delay, drive, and load values based on the environment of a cell instance.

The tool adds input delay to path delay for paths starting at primary inputs and output delay for paths ending at primary outputs.

The **-group_path** option modifies the path grouping. Path grouping affects the maximum delay cost function. The worst violator within each group adds to the cost. For optimization, grouping some paths separately may improve their delay cost, but it may also increase design area and compile time.

Use **report_port** to list output delays associated with ports. To list output delays of internal pins, use **report_design**. Use **report_path_group** to list the path groups which are defined.

Use **remove_output_delay** or **reset_design** to remove output delay values. To modify paths grouped with the **-group_path** option, use the **group_path** command to place the paths in another group or the default group.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets an output delay of 1.7 relative to the rising edge of CLK1 for all output ports in the design.

```
prompt> set_output_delay 1.7 -clock [get_clocks CLK1] \
           [all_outputs]
```

The following example sets the input and output delays for the INOUT1 bidirectional port. The input signal arrives at INOUT1 2.5 units after the falling edge of CLK1. The output signal is required at INOUT1 at 1.4 units before the rising edge of CLK2.

```
prompt> set_input_delay 2.5 -clock CLK1 -clock_fall {INOUT1}
prompt> set_output_delay 1.4 -clock CLK2 {INOUT1}
```

In the following example, there are three paths from the OUT1 output port. One path is relative to the rising edge of CLK1. Another path is relative to the falling edge of CLK1. The third path is relative to the falling edge of CLK2. The **-add_delay** option is used to

indicate that new output delay information will not cause old information to be removed.

```
prompt> set_output_delay 2.2 -max -clock CLK1 \
           -add_delay {OUT1}
prompt> set_output_delay 1.7 -max -clock CLK1 \
           -clock_fall -add_delay {OUT1}
prompt> set_output_delay 4.3 -max -clock CLK2 \
           -clock_fall -add_delay {OUT1}
```

The following example specifies two maximum delays and two minimum delays for the Z port using the **-add_delay** option. Since the information is relative to the same clock and clock edge, only the largest of the maximum values (5.0) and the smallest of the minimum values (1.1) are maintained. If the **-add_delay** option is not used, the new information overwrites the old information.

```
prompt> set_output_delay 3.4 -max -clock CLK1 \
           -add_delay {Z}
prompt> set_output_delay 5.0 -max -clock CLK1 \
           -add_delay {Z}
prompt> set_output_delay 1.1 -min -clock CLK1 \
           -add_delay {Z}
prompt> set_output_delay 1.3 -min -clock CLK1 \
           -add_delay {Z}
```

The following example uses the **-group_path** option to add ports into a named group. Without this option, paths to these ports are included in the CLK group.

```
prompt> set_output_delay 4.5 -max -clock CLK \
           -group_path busA {busA[*]}
```

set_partial_on_translation

Defines the translation of PARTIAL_ON to FULL_ON or OFF for purposes of evaluating the power state of supply sets and power domains.

SYNTAX

```
status set_partial_on_translation
  [default_translation]
  [-full_on_tools {tools}]
  [-off_tools {tools}]
```

Data Types

<i>default_translation</i>	string
<i>tools</i>	list

ARGUMENTS

default_translation

Specifies the default translation for unlisted tools. Valid values are FULL_ON, OFF and UNDETERMINED.

-full_on_tools {*tools*}

Specifies the tools in which PARTIAL_ON is translated to FULL_ON. The tool names are determined by simulation tool and implementation tool doesn't need to do any tool name check for the specified value.

-off_tools {*tools*}

Specifies the tools in which PARTIAL_ON is translated to OFF. The tool names are determined by simulation tool and implementation tool doesn't need to do any tool name check for the specified value.

DESCRIPTION

This command defines the translation of PARTIAL_ON to FULL_ON or OFF for purposes of evaluating the power state of supply sets and power domains. This command does not affect implementation and is intended to be used by simulation tools, to read and write transparently.

EXAMPLES

The following example sets the partial_on_translation to FULL_ON for the *Design-Compiler* tool.

```
prompt> set_partial_on_translation OFF \
           -full_on_tools {Design-Compiler}

prompt> add_power_state FULL_ON \
           -off_tools {OTHER-TOOL}
```

SEE ALSO

[create_power_switch\(2\)](#)

set_path_margin

Specifies a margin to adjust required times for specified paths in the current design.

SYNTAX

```
status set_path_margin
  margin_value
  [-rise | -fall]
  [-setup | -hold]
  [-from from_list
   | -rise_from rise_from_list
   | -fall_from fall_from_list]
  [-through through_list]
  [-rise_through rise_through_list]
  [-fall_through fall_through_list]
  [-to to_list
   | -rise_to rise_to_list
   | -fall_to fall_to_list]
  [-reset_path]
```

Data Types

<i>margin_value</i>	float
<i>from_list</i>	list
<i>rise_from_list</i>	list
<i>fall_from_list</i>	list
<i>through_list</i>	list
<i>rise_through_list</i>	list
<i>fall_through_list</i>	list
<i>to_list</i>	list
<i>rise_to_list</i>	list
<i>fall_to_list</i>	list

ARGUMENTS

margin_value

Specifies the value of the margin by which the required time is adjusted for the specified paths. A positive value results in a more restrictive or tighter check. A negative value results in a less restrictive or looser check. The value must be specified in the same time units as those of the technology library used during optimization.

-rise | -fall

Applies the timing adjustment only to paths having a rising signal or only to paths having a falling signal at the path endpoint. By default, paths having either a rising or falling signal at the path endpoint are adjusted.

-setup | -hold

Applies the timing adjustment to only setup or only hold timing constraints for the specified paths. By default, both setup and hold constraints are adjusted.

-from *from_list*

Specifies a list of path startpoints (port, pin, clock, or cell names) of the current design. If you specify a clock, all path startpoints related to that clock are affected. If you specify a cell name, one path startpoint on that cell is affected. All paths from these startpoints to the endpoints in the *to_list* are adjusted by the *margin_value*. If you don't specify *to_list*, all paths from *from_list* are affected. This list cannot include output ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}).

-rise_from *rise_from_list*

Same as the **-from** option, except that the path must rise from the objects specified. If a clock object is specified, this option selects startpoints clocked by the named clock, but only the paths launched by rising edge of the clock at the clock source, taking into account any logical inversions along the clock path. You can use only one of **-from**, **-rise_from**, and **-fall_from**.

-fall_from *fall_from_list*

Same as the **-rise_from** option, except that the path must fall from the objects specified.

-through *through_list*

Determines a list of path throughpoints (port, pin, or leaf cell names) of the current design. The margin value applies only to paths that pass through one of the points in the *through_list*. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify the **-through** option multiple times, the margin values apply to paths that pass through a member of each *through_list* in the order in which the lists were given. In other words, the path must first pass through a member of the first *through_list*, then through a member of the second list, and so on, for every through list specified. If you use the **-through** option in combination with the **-from** or **-to** option, the margin adjustment applies only if the **-from** or **-to** conditions are satisfied and the **-through** conditions are satisfied.

-rise_through *rise_through_list*

Same as the **-through** option, but applies only to paths with a rising transition at the specified objects. You can specify **-rise_through** more than once in a single command invocation as with the **-through** option.

-fall_through *fall_through_list*

Same as the **-through** option, but applies only to paths with a falling transition at the specified objects. You can specify **-fall_through** more than once in a single command invocation as with the **-through** option.

-to *to_list*

Specifies a list of path endpoints (port, clock, cell, or pin names) of the current design. All paths to the endpoints in the *to_list* are adjusted by *margin_value*. If you don't specify a *from_list*, all paths to *to_list* are affected. This list cannot include input ports. If you include more than one object, you must enclose the objects in quotation marks ("") or braces ({}). If you specify a cell, one path endpoint on that cell is affected. If you specify a clock, all path endpoints related to that clock are affected.

-rise_to *rise_to_list*

Same as the **-to** option, but applies only to paths rising at the endpoint. If a clock object is specified, this option selects endpoints clocked by the named clock, but only the paths captured by rising edge of the clock at clock source, taking into account any logical inversions along the clock path.

-fall_to *fall_to_list*

Same as the **-rise_to** option, but applies only to paths falling at the endpoint.

You can use no more than one of **-to**, **-rise_to**, and **-fall_to**.

-reset_path

Removes existing point-to-point exception information on the specified paths. Only information of the same rise/fall setup/hold type is reset. This is equivalent to using the **reset_path** command with similar options before executing the **set_path_margin** command.

DESCRIPTION

This command adjusts the data required time for specified paths by a specified amount, *margin_value*. The required time for any startpoint in *from_list* to any endpoint in *to_list* is adjusted by *margin_value*. A positive margin value results in a more restrictive or tighter check, whereas a negative margin value results in a less restrictive or looser check. Based on the type of timing constraint, either setup or hold, the margin value is either subtracted from or added to the default data required time.

The **set_path_margin** command is a point-to-point timing exception command; that is, it adjusts the required time of the path and therefore the endpoint slack for the timing paths.

Other point-to-point timing exception commands include the **set_multicycle_path**, **set_min_delay**, **set_false_path**, and **set_max_delay** commands.

If a path satisfies multiple timing exceptions, the following rules are applied to determine which exceptions take effect.

Rules referring to **-from** apply equally to **-rise_from** and **-fall_from**, and similarly for the rise and fall options of **-through** and **-to**.

1. If one exception is **set_false_path**, and the other is **set_path_margin**, then **set_false_paths** takes precedence.
2. If one exception is **set_path_margin** and the other is **set_max_delay**, **set_min_delay**, or **set_multicycle_path**, no conflict occurs and both constraints are honored.
3. If one exception has a **-from pin** or **-from cell** and the other does not, the former takes precedence.
4. If one exception has a **-to pin** or **-to cell** and the other does not, the former takes precedence.
5. If one exception has any **-through** points and the other does not, the former takes precedence.
6. If one exception has a **-from clock** and the other does not, the former takes precedence.
7. If one exception has a **-to clock** and the other does not, the former takes precedence.
8. If you apply **set_endpoint_margin** on an endpoint and also a **set_path_margin** on the same endpoint, then the endpoint required time is adjusted for both the values.

Note: Specifying a **path_margin** for a pin that is not a path endpoint places a **size_only** attribute on that cell.

Use the **report_timing_requirements** command to list the **path_margin**, **max_delay**, **min_delay**, **multicycle_path**, and **false_path** information for the design.

To undo the effects of the **set_path_margin**, use the **reset_path** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example adjusts the required time to a port named Y by 10 units. The adjustment results in a more restrictive, tighter timing constraint because the margin value is positive.

```
prompt> set_path_margin 10.0 -to {Y}
```

The following example specifies that the required time of all paths from cell ff1a or ff1b that pass through cell u1 and end at cell ff2e are to be adjusted by 15.0 units.

```
prompt> set_path_margin 15.0 -from {ff1a ff1b} -through {u1} -to {ff2e}
```

The following example shows how to specify that all paths to endpoints clocked by PHI2 are to be adjusted by 8.5 units.

```
prompt> set_path_margin 8.5 -to [get_clocks PHI2]
```

The following example specifies that all timing paths from pin ff1/CP to pin ff2/D that rise through at least one of pins U1/Z and U2/Z and fall through at least one of pins U3/Z and U4/C are to be adjusted by 8.0 units.

```
prompt> set_path_margin 8.0 -from {ff1/CP} -to {ff2/D} \
           -rise_through {U1/Z U2/Z} -fall_through {U3/Z U4/C}
```

set_pg_pin_model

Defines the power and ground pins for a library cell.

SYNTAX

```
status set_pg_pin_model
  cell_name
  [-pg_pin_name pin_names]
  [-pg_voltage_name voltage_names]
  [-pg_pin_type pin_types]
  [-pg_pin_direction pin_directions]
  [-pg_physical_connection physical_connections]
  [-pg_related_bias_pin related_bias_pins]
```

Data Types

<i>cell_name</i>	string
<i>pin_names</i>	list
<i>voltage_names</i>	list
<i>pin_types</i>	list
<i>pin_directions</i>	list
<i>physical_connections</i>	list
<i>related_bias_pins</i>	list

ARGUMENTS

cell_name

Specifies the name of the library cell for which to define the power and ground pins.

-pg_pin_name *pin_names*

Specifies the names of the power and ground pins of the library cell.

-pg_voltage_name *voltage_names*

Specifies the voltage name of the corresponding power or ground pin of the library cell. The voltage names are defined in the library voltage map.

There must be a one-to-one correspondence between the voltage names specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_pin_type *pin_types*

Specifies the pin type for each pin specified in the **-pg_pin_name** option. Valid values are primary_power, primary_ground, backup_power, backup_ground, internal_power, internal_ground, pwell, nwell, deeppwell, and deepnwell.

There must be a one-to-one correspondence between the pin types specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_pin_direction *pin_directions*

Specifies the direction for each pin specified in the **-pg_pin_name** option. Valid values are input, output, inout, and internal.

There must be a one-to-one correspondence between the pin directions specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_physical_connection *physical_connections*

Specifies the type of physical connection used for each pin specified in the **-pg_pin_name** option. Valid values are device_layer and routing_pin.

There must be a one-to-one correspondence between the connection types specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_related_bias_pin *related_bias_pins*

Specifies the related bias pin for each pin specified in the **-pg_pin_name** option.

There must be a one-to-one correspondence between the related bias pins specified in this option and the pins specified in the **-pg_pin_name** option.

DESCRIPTION

The **set_pg_pin_model** command defines the power and ground pins for a library cell. If the power or ground pin already exists, the new specification overrides the old one. Otherwise, new power and ground pins are created for the library cell.

EXAMPLES

The following example defines the power and ground pins for the library cells whose name starts with LVLH.

```
prompt> set_pg_pin_model LVLH* -pg_pin_name {VDD VSS} \
    -pg_voltage_name {VDDL VSS} \
    -pg_pin_type {primary_power primary_ground}
```

set_physical_hierarchy

Sets a list of cells to be physical hierarchies. This command is supported only in Design Compiler topographical mode.

SYNTAX

```
status set_physical_hierarchy  
      object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies the list of hierarchical cells to be set as a physical hierarchy.

DESCRIPTION

The **set_physical_hierarchy** command sets cells in the object list as physical hierarchies. By default, a physical hierarchy has the **dont_touch** attribute.

EXAMPLES

The following example sets the HIER_1 hierarchical cell to be a physical hierarchy:

```
prompt> set_physical_hierarchy HIER_1
```

SEE ALSO

`get_physical_hierarchy(2)`
`set_cell_location(2)`

set_pin_access_optimization_options

Sets the library cells with easy pin access and difficult pin access for pin access optimization. This command is supported only in topographical mode.

SYNTAX

```
status set_pin_access_optimization_options
  [-easy_pin_access_libcells library_cells]
  [-hard_pin_access_libcells library_cells]
  [-default]
```

Data Types

library_cells list or collection

ARGUMENTS

-easy_pin_access_libcells *library_cells*

Specifies the library cell(s) which have easy pin access and should be considered for swapping into the design.

The library cells must exist in the reference library list. One can specify library cells by name, such as "mylib/AN2", or by collections, such as "[get_lib_cells */AN2]". Wildcards can also be used and are expanded according to the library cells in memory at the time the command is issued.

-hard_pin_access_libcells *library_cells*

Specifies the library cell(s) which have difficult pin access and should be considered for swapping out from the design.

The library cells must exist in the reference library list. One can specify library cells by name, such as "mylib/AN2", or by collections, such as "[get_lib_cells */AN2]". Wildcards can also be used and are expanded according to the library cells in memory at the time the command is issued.

-default

Clears all the options set by previous **set_pin_access_optimization** commands and falls back to the conventional implementation.

DESCRIPTION

The **set_pin_access_optimization_options** command sets the library cells with easy pin access and difficult pin access for pin access optimization (PAO).

PAO engine swaps out the cells with difficult pin access from high-utilization regions of the design, and swaps in the equivalent cells with easy pin access in their place.

This command only takes effect when the high pin density cell optimization is enabled. PAO options specified by the user as

argument(s) to this command have precedence over the conventional PAO implementation.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the library cells with difficult pin access.

```
prompt> set_pin_access_optimization_options \
    -hard_pin_access_libcells AN*
```

The following example sets the library cells with difficult as well as easy pin access.

```
prompt> set_pin_access_optimization_options \
    -hard_pin_access_libcells [get_lib_cells */AOI*] \
    -easy_pin_access_libcells [get_lib_cells lib1/EEQ*]
```

SEE ALSO

[compile_high_pin_density_cell_optimization\(3\)](#)

set_pin_model

Specifies the related power and ground pins for a library cell.

SYNTAX

```
status set_pin_model
  cell_name
  [-pins pin_names]
  [-related_power_pin pin_names]
  [-related_ground_pin pin_names]
  [-related_bias_pin pin_names]
  [-power_down_function functions]
```

Data Types

```
cell_name  string
pin_names  list
functions  list
```

ARGUMENTS

cell_name

Specifies the name of the library cell for which to define the related power and ground pins.

-pins pin_names

Specifies the names of the pins for which you are defining the related power and ground pins.

-related_power_pin pin_names

Specifies the related power pin for each pin specified in the ***-pins*** option.

There must be a one-to-one correspondence between the power pins specified in this option and the pins specified in the ***-pins*** option.

-related_ground_pin pin_names

Specifies the related ground pin for each pin specified in the ***-pins*** option.

There must be a one-to-one correspondence between the ground pins specified in this option and the pins specified in the ***-pins*** option.

-related_bias_pin pin_names

Specifies the related bias pin for each pin specified in the ***-pins*** option.

There must be a one-to-one correspondence between the bias pins specified in this option and the pins specified in the ***-pins*** option.

-power_down_function functions

Specifies the power-down function for each pin specified in the **-pins** option.

There must be a one-to-one correspondence between the function specified in this option and the pins specified in the **-pins** option.

DESCRIPTION

The **set_pin_model** command defines the related power pin, related ground pin, and related bias pin for the specified library cell pins. If the related pin is already defined, the new specification overrides the old one.

EXAMPLES

The following example defines the pin model for the RETN and RETNOUT pins of the library cells that match the pattern *DRFF*.

```
prompt> set_pin_model *DRFF* -pins {RETN RETNOUT} \
    -related_power_pin VDDG \
    -related_ground_pin VSSG
```

The following example defines the pin model for the SLEEPOUT pin of the library cells that match the pattern HEAD*.

```
prompt> set_pin_model HEAD* -pins {SLEEPOUT} \
    -power_down_function "!VDDG + VSS"
```

SEE ALSO

`set_voltage_model(2)`
`set_pg_pin_model(2)`
`report_lib(2)`
`check_library(2)`

set_pin_name_synonym

Defines synonyms for pin names.

SYNTAX

```
status set_pin_name_synonym
  [-full_name]
  [-force]
  pin_name_synonym
  pin_name
```

Data Types

```
pin_name_synonym  string
pin_name          string
```

ARGUMENTS

-full_name

Indicates that a pin name synonym is a full name synonym.

-force

Overwrites the existing pin name synonym if a conflict occurs.

pin_name_synonym

Specifies a pin name synonym string for *pin_name*. This argument is required.

pin_name

Specifies a pin name string for which the synonym is defined. This argument is required.

DESCRIPTION

This command defines pin name synonyms, which are supported in pin object queries.

The *pin_name_synonym* is an alternative pin name for a pin object. For example, if the U1/U2/data_in name is defined as the synonym for the U1/U2/D pin, pin query commands can find the pin object named *U1/U2/D* when the commands could not find the pin with the given name *U1/U2/data_in*.

Pin name synonyms are only applicable to pins on leaf-level sequential cells. This feature can also be applicable to physical and logic library pin names.

The tool supports two types of pin name synonyms: full name synonyms and simple name synonyms. The **set_pin_name_synonym**

command defines simple name synonyms unless the **-full_name** option is used. When defining a full name synonym, you specify the full hierarchical name for the pin object in both the *pin_name_synonym* and *pin_name* fields. Pin query commands use full name synonyms exactly as they are defined. Simple name synonym definitions use short names for pin objects. For library pin, only the simple name is needed. Pin query commands use a simple pin name synonym to construct a full pin name during a synonym-based pin object search.

You can get full name and simple name synonyms for pin objects by querying the **full_name** and **name** attributes for pin objects.

Wildcards and regular expressions are not supported in pin name synonym definitions. Simple name synonyms do not support the forward slash (/) since it is considered a hierarchical separator.

When you use the pin name synonyms for pin queries, the full name synonym, when applicable, supersedes the simple name synonym.

EXAMPLES

The following examples use **set_pin_name_synonym** to define pin name synonyms and show how **get_pins** command uses the synonyms:

```
prompt> set_pin_name_synonym SYN_CD CD
1

prompt> set_pin_name_synonym -full_name \
    this/is/a/synonym mid1/FJK2SP_at_mid/TI
1

prompt> set_pin_name_synonym -full_name \
    mid1/FJK2SP_at_mid/J mid2/bot2/LSR0P_at_bot/Q
1
```

SEE ALSO

[remove_pin_name_synonym\(2\)](#)
[report_pin_name_synonym\(2\)](#)

set_pin_physical_constraints

Sets physical constraints for pin instances.

SYNTAX

```
status set_pin_physical_constraints
  objects
    | -pin_name pin_name [-cell cell_name]
    | -nets nets [-cell cell_name]
    [-layers layers]
    [-width pin_width]
    [-depth pin_depth]
    [-side side_number]
    [-offset offset_distance]
    [-order order_number]
    [-pin_spacing spacing]
    [-exclude_sides exclude_side_numbers]
    [-off_edge center | location | auto]
    [-location point]
```

Data Types

<i>objects</i>	collection
<i>pin_name</i>	string
<i>cell_name</i>	string
<i>nets</i>	collection
<i>layers</i>	list
<i>pin_width</i>	float
<i>pin_depth</i>	float
<i>side_number</i>	integer
<i>offset_distance</i>	float
<i>order_number</i>	integer
<i>spacing</i>	integer
<i>exclude_side_numbers</i>	list of integers

ARGUMENTS

objects

Specifies the pins to which the specified constraints are applied. In most cases, you can specify multiple objects. However, if you specify the **-order** option, you can specify only a single pin.

The *objects* argument, **-pin_name** option, and **-nets** option are mutually exclusive. You must specify the pins by using only one of these arguments.

In Design Compiler Topographical mode, only port objects are supported.

-pin_name *pin_name*

In Design Compiler Topographical mode, the command issues an error to indicate that the option is not supported.

-cell *cell_name*

In Design Compiler Topographical mode, the command issues an error to indicate that the option is not supported.

-nets *nets*

In Design Compiler Topographical mode, the command issues an error to indicate that the option is not supported.

-layers *layers*

In Design Compiler Topographical mode, if you specify one layer, the command places the pin on that layer. If you specify more than one layer, the command issues an error to indicate that multiple layers are not supported.

-width *pin_width*

Specifies the pin width in microns. If the specified width constraint is smaller than the minimum width given in the library, the minimum width is applied (unless otherwise noted). The default is 0.

-depth *pin_depth*

Specifies the depth in microns. If the depth constraint specified is smaller than minLength defined in the tech file, then the value of minLength will be honored. If minArea is also defined in the tech file, then the value of pin depth times pin width should also honor minArea. The default is 0.

-side *side_number*

Specifies the block side on which the pin must be placed so that it abuts the specified die edge.

The side number is a positive integer that starts from 1. Given any shape (rectangular or rectilinear), the lower left-most vertical edge is the starting edge (side number 1). The side number of the next edge, going clockwise, is 2, and so on. You can specify a value of 0 to indicate no side constraint.

-offset *offset_distance*

Specifies the distance in microns that the pins must be offset from the starting point of the specific edge. The offset is the distance to the edge of the pin. For a horizontal edge, the starting point is the left vertex of the edge. For a vertical edge, the starting point is the lower vertex of the edge. You must specify a positive floating point value for the offset distance.

-order *order_number*

Specifies the relative placement order for the specified pin. The order number must be a positive integer. A smaller order number specifies a more left side placement on a horizontal placement edge, and a more bottom side placement on a vertical placement edge. An order number of 0 specifies that the pin has no order constraint. Order-constrained pins can be interleaved by other pins. Constraints specified by the **-order** option do not apply to feedthrough pins. The default order number is 0.

-pin_spacing *spacing*

Specifies the minimum number of wire tracks between adjacent pins or between a pin and a preroute wire that cuts across a soft macro or plan group edge in the normal direction. Note that pins that are created are always snapped to wire tracks. The default minimum pin-to-pin spacing is one wire track.

-exclude_sides *exclude_side_numbers*

Specifies the soft macro edges on which pins cannot be placed. The argument is a string consisting of a number or a set of numbers separated by commas. Each number corresponds to a macro or plan group edge. The lower leftmost vertical edge is numbered 1 (one). Other edges are numbered according to their order of traversal in the clockwise direction starting from edge 1. If there are multiple leftmost edges then the edge 1 is the lowest leftmost edge. For example, to exclude sides 2, 4, and 6, enter

`-exclude_sides {2,4,6}`

-off_edge *center | location | auto*

Specifies that the pin is placed off-edge. By default, pins are placed on-edge. The **center**, **location** or **auto** keyword specifies how the pin is placed. You must specify only one keyword.

- **center**

When you specify **-off_edge center**, the pin is placed at the center of the cell.

- **location**

In Design Compiler Topographical mode, the command issues an error to indicate that the location value is not supported.

- **auto**

When you specify **-off_edge auto**, you must create a pin guide that is associated with this pin. The pin guide must be in the center of the block boundary. The pin is placed at the optimal position guided by the pin guide. If you do not provide a pin guide, the pins are placed in the center of the cell, the result is the same as if you specified **-off_edge center**.

-location *point*

In Design Compiler Topographical mode, the command issues an error to indicate that the option is not supported.

DESCRIPTION

This command sets physical constraints, such as layer and width, on the specified pins. The constraints you specify are saved when the design is saved.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies physical constraints on a pin.

```
prompt> set_pin_physical_constraints [get_port "Reset"] \
-layers {M2} \
-width 0.28 -depth 0.28 -side 1 -offset 5
```

SEE ALSO

set_pipeline_scan_data_configuration

Specifies the pipelined scan data configuration for the design.

SYNTAX

```
int set_pipeline_scan_data_configuration
  [-head_pipeline_clock clock_name]
  [-tail_pipeline_clock clock_name]
  [-head_pipeline_stages total_depth]
  [-tail_pipeline_stages total_depth]
  [-head_shared_pipeline_stages shared_top_level_depth]
  [-tail_shared_pipeline_stages shared_top_level_depth]
  [-head_scan_flop true | false]
```

Data Types

<i>clock_name</i>	string
<i>total_depth</i>	integer
<i>shared_top_level_depth</i>	integer

ARGUMENTS

-head_pipeline_clock *clock_name*

Specifies the shift clock for the head pipeline scan data registers. The specified clock must be previously declared as a scan clock using the **set_dft_signal** command. All head pipeline registers are triggered by the trailing edge of the clock. If no clock is specified, the tool creates and uses a new clock signal.

If you enable beginning-of-chain leading-edge retiming registers using the **set_scan_configuration -add_test_retimings_flops** command with the **begin_only** or **begin_and_end** option values, the head pipeline registers are clocked on the leading clock edge instead.

In an OCC controller flow (DFT-inserted or user-defined), you can specify the name of an ATE clock that is predefined with the **set_dft_signal** command. This specification is mapped to the first-defined OCC-controlled clock associated with that ATE clock during DFT insertion.

-tail_pipeline_clock *clock_name*

Specifies the shift clock for the tail pipeline scan data registers. The specified clock must be previously declared as a scan clock using the **set_dft_signal** command. All tail pipeline registers are triggered by the leading edge of the clock. If no clock is specified, the tool creates and uses a new clock signal.

OCC clock specification is the same as with the **-head_pipeline_clock** option.

-head_pipeline_stages *total_depth*

Specifies the number of head pipeline stages. The default is 1. You can choose not to insert head pipeline stages by specifying a depth of 0.

-tail_pipeline_stages *total_depth*

Specifies the number of tail pipeline stages. The default is 1. You can choose not to insert tail pipeline stages by specifying a depth of 0.

-head_shared_pipeline_stages *shared_top_level_depth*

Specifies the number of top-level shared head pipeline stages to use when shared codec input connections are used for core integration.

When set, the tool uses the specified number of shared pipeline registers along the shared scan input path, then it uses dedicated pipeline registers as needed for the remaining stages to meet the total head pipeline depth target. A value of 0 uses only dedicated top-level stages. The default is to use the largest number of shared top-level stages possible given the constraints, which minimizes the number of dedicated top-level stages.

This option is only used when shared codec input connections are specified with the **-shared_inputs** option of the **set_scan_compression_configuration** command.

-tail_shared_pipeline_stages *shared_top_level_depth*

Specifies the number of top-level shared tail pipeline stages to use when shared codec output connections are used for core integration.

When set, the tool uses the specified number of shared pipeline registers along the shared scan output path, then it uses dedicated pipeline registers as needed for the remaining stages to meet the total tail pipeline depth target. A value of 0 uses only dedicated top-level stages. The default is to use the largest number of shared top-level stages possible given the constraints, which minimizes the number of dedicated top-level stages.

This option is used only when shared codec input connections are specified with the **-shared_inputs** and **-shared_outputs** options of the **set_scan_compression_configuration** command.

-head_scan_flop true | false

When set to **true**, scan-replaced registers are used for the head pipeline stages. The scan data input of each head pipeline scan register is used for the pipeline shift path. The functional data input of each register is driven by that register's output, so that the register holds state during scan capture. The default is **false**, which inserts nonscan head pipeline registers.

[set_scan_compression_configuration\(2\)](#)

set_placement_area

Creates the core placement area. This command is supported only in topographical mode.

SYNTAX

```
int set_placement_area
    -coordinate {X1 Y1 X2 Y2}
    [-fixed | -unfixed]
```

ARGUMENTS

-coordinate {X1 Y1 X2 Y2}

{X1 Y1 X2 Y2} specify the lower left and upper right coordinates of the core area. The coordinates are in microns relative to the chip origin. This options will imply -fixed flag unless -unfixed is used explicitly.

-fixed

Marks the core area to be fixed. The tool should not change the core area.

-unfixed

Reset the fixed flag.

DESCRIPTION

The **set_placement_area** command defines the core placement area for rough placement. This will overwrite the previous core area.

This command can also be used to mark or unmark "fixed_core" attribute which indicate the core area may or may not be changed by the tool.

EXAMPLES

The following example shows how to set the placement area to the rectangle with lower left corner (100,100) and upper right corner (2000,2000).

```
prompt> set_placement_area -coordinate { 100 100 2000 2000}
```

SEE ALSO

set_port_attributes

Sets the specified attributes and their value on the ports.

SYNTAX

status **set_port_attributes**

```
[-ports port_list]
[-elements element_list]
[-exclude_ports port_list]
[-exclude_elements element_list]
[-applies_to inputs | outputs | both]
[-attribute at_name at_value]
[-receiver_supply supply_set_ref]
[-driver_supply supply_set_ref]
[-repeater_supply supply_set_ref]
[-model model_name]
[-feedthrough]
[-unconnected]
[-is_analog]
[-clamp_value clamp_value]
```

Data Types

<i>port_list</i>	list
<i>element_list</i>	list
<i>at_name</i>	string
<i>at_value</i>	string
<i>supply_set_ref</i>	string
<i>model_name</i>	string
<i>clamp_value</i>	string

ARGUMENTS

-ports *port_list*

Specifies the collection of ports on which the attributes must be set. Wildcards are accepted in port names.

-elements *element_list*

Specifies the current scope or list of instance names for whose ports or pins the attributes are applicable. Wildcards are accepted in the instance names.

One of the **-ports** or **-elements** options must be specified for this command.

-exclude_ports *port_list*

Specifies the collection of ports on which the attributes should not be applied.

-exclude_elements *element_list*

Specifies the current scope or list of instance names for whose ports or pins the attributes should not be applied.

-applies_to inputs | outputs | both

Specifies whether the given **set_port_attributes** command applies to all input ports or output ports or both input and output ports of the specified element. The argument must be used in conjunction with the **-elements** argument. The default for this argument is **both**.

-attribute at_name at_value

Specifies the name and value of the attribute to be set on the ports specified by the **-ports** option.

The supported attribute names are as follows:

- **iso_source** (used on elements and signal ports)
- **iso_sink** (used on elements and signal ports)
- **smps_derived** (used on supply ports only)
- **related_supply_default_primary** (used on elements, implies to their ports or pins)
- **repeater_power_net** (used on domain root cells and domain boundary ports/pins)
- **repeater_ground_net** (used on domain root cells and domain boundary ports/pins)
- **UPF_async_clamp_value** (used on ports or elements, implying to their ports or pins)

The supported values are as follows:

- For the **iso_source** and **iso_sink** attributes, the value must be the name of a supply set that is already defined.
- For the **smps_derived** attribute, the value must be **true** or **false**, where **true** implies that the attributed supply port has been derived internally by the tool.
- For the **related_supply_default_primary** attribute, only a Boolean value of **true** is supported.
- For **repeater_power_net** attribute, the value must be a supply net.
- For **repeater_ground_net** attribute, the value must be a supply net.
- For the **UPF_async_clamp_value** attribute, only the values of 0 or 1 are supported.

-receiver_supply supply_set_ref

Specifies the supply for the logic reading the port.

-driver_supply supply_set_ref

Specifies the supply for the logic driving the port.

-repeater_supply supply_set_ref

Specifies the supply used by the repeater driving the port.

-model model_name

Specifies a module or library cell on whose ports the attribute is going to be applied.

-feedthrough

Indicates that the specified ports are connected together internally to form a feedthrough path. The **-feedthrough** option must be used in conjunction with the **-model** and **-ports** options, and is mutually exclusive to the **-unconnected** option.

-unconnected

Indicates that the specified ports are not connected internally. The **-unconnected** option must be used in conjunction with the **-model** and **-ports** options, and is mutually exclusive to the **-feedthrough** option.

-is_analog

Indicates that the specified ports are to be marked as analog. The **-is_analog** option is allowed to be used with or without **-model**.

-clamp_value clamp_value

Specifies the clamp value to be used on ports that have an isolation strategy.

DESCRIPTION

This command sets the attributes and their value on a list of ports specified by the **-ports** option or on a list of instances specified by the **-elements** option.

Specifying more than one **-attribute** option is supported only for repeater supply net attributes.

Except for repeater supply net attributes, all other attributes can be set multiple times on the same ports. The last value specified is considered.

If an attribute is defined with both the **-ports** and **-elements** options, the one specified with the **-ports** option has precedence over the one specified with the **-elements** option regardless of the order in which they are specified.

The **iso_source** attribute can only be specified on an input port of the design. It specifies the outside source supply to be used to determine if an isolation strategy with the source or **diff_supply_only** options should insert an isolation cell.

The **iso_sink** attribute can only be specified on an output port of the design. It specifies the outside sink supply to be used to determine if an isolation strategy with the sink or **diff_supply_only** options should insert an isolation cell.

The **related_supply_default_primary** attribute can only be used with the **-elements** option and can be set on cell instances. For ports without the **set_related_supply_net** setting, the tool assumes the primary supply of the ports' domain is the default supply. This assumption can cause equivalence failure when the netlist and the UPF file is verified with RTL and UPF. Setting this attribute with **-elements** as {} helps avoid the equivalence failure. The tool passes this setting to the UPF file, thus making sure the equivalence tool also sees the same assumption as synthesis tool. If this attribute is not set, the **compile_ultra** command warns the possible synthesis and equivalence check mismatch, on finding any ports without the **set_related_supply_net** setting.

The **repeater_power_net** and **repeater_ground_net** attributes must be specified together in a single **set_port_attributes** command. These attributes cannot be specified on the input ports of the top domain and output pins of the macro domain. It is an error to apply these attributes on ports/pins of direction inout. These attributes are not allowed to be specified with the **-repeater_supply** option.

The **-receiver_supply** and **-driver_supply** options can be used on the top-level ports, the design, hard macro cells or black box cells and their pins. The black box/hard macro cell must be the root cell of a power domain. In all other cases, the command reports and ignores such objects. The supply of the visible logic specified by these options is preserved.

The **-receiver_supply** and **-driver_supply** options have higher precedence than the **related_supply_net** attribute. You cannot use the **set_related_supply_net** command on ports that have the **-receiver_supply** or **-driver_supply** setting.

The **-driver_supply** option is applied to the input ports only if the supply voltage (if already specified for the supply using the **set_voltage** command) matches the voltage of the driving cell (as specified by the **set_driving_cell** command for the input port). It is an error if the voltages do not match, and the command ignores the ports that do not meet the voltage compliance check.

For inout ports, **-receiver_supply** and **-driver_supply**, if both are specified, must be electrically equivalent. If only one of them is specified, the other supply will be assumed to be the same.

The **-repeater_supply** option can be specified on any domain root cells or boundary pins except input ports of the top domain and output pins of the macro domain. It is an error to use the **-repeater_supply** option on ports/pins of direction inout. This option is not allowed to be specified with **repeater_power_net** and **repeater_ground_net** attributes.

The **-clamp_value** option can be specified on any-**ports** or **-elements** where an isolation strategy can be applied. It specifies the clamp value that should be used when isolating the referenced ports/elements. Supported values are **0**, **1** and **latch**. In case of multiples instances of the same command, but with a different **-clamp_value** value, the last setting is preserved.

The **-literal_supply** option can be applied to the input pins of macro cells, top-level output ports and hierarchical cells and their pins. In case of multiples instances of the command in the same port, but with a different **-literal_supply** value, the highest precedence setting

is preserved. If settings with the same precedence are applied, the last one is preserved.

The **-model** option can only be used with the **-feedthrough** or **-unconnected** or **-is_analog** or **-attribute function** options. Otherwise, it is an error.

When using the **-feedthrough** or **-unconnected** options, the model referenced with the **-model** option must be either a library cell that is a PAD or MACRO, or a module that is a black box.

One of the **-attribute**, **-driver_supply**, **-receiver_supply**, **-repeater_supply**, **-feedthrough**, **-unconnected**, **-clamp_value** or **-literal_supply** options is required for this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **snps_derived** attribute to **true** on the power_port and ground_port ports in the block named instA.

```
prompt> set_port_attributes \
  -ports {instA/power_port instA/ground_port} \
  -attribute snps_derived true
1
```

The following examples set the **iso_source** and **iso_sink** attributes on the input and output ports respectively.

```
prompt> set_port_attributes -ports {in1 in2} -attribute iso_source SS1
prompt> set_port_attributes -ports {out1 out2} -attribute iso_sink SS2
```

The following example sets the **related_supply_default_primary** attribute on the design element corresponding to the current scope represented by the dot.

```
prompt> set_port_attributes -elements {.} \
  -attribute related_supply_default_primary true
Information: Resolving '.' to the current scope 'top'.
```

The following example sets the **related_supply_default_primary** attribute on the cell instances U1 and U2/U3.

```
prompt> set_port_attributes -elements {U1 U2/U3} \
  -attribute related_supply_default_primary true
```

The following example sets the **repeater_power_net** and the **repeater_ground_net** attributes on the cell instances U1 which must be a power domain root cell.

```
prompt> set_port_attributes -elements {U1} \
  -attribute repeater_power_net VDD -attribute repeater_ground_net VSS
```

The following example sets the repeater supply attribute on the boundaries of the top power domain.

```
prompt> set_port_attributes -elements {.} \
  -repeater_supply SS1 -applies_to both
Information: Resolving '.' to the current scope 'top'.
```

The following example shows the error message when multiple **-attribute** options are used with attributes other than repeater supply net attributes.

```
prompt> set_port_attributes -ports {in1 out1} \
  -attribute iso_source SS1 -attribute iso_sink SS2
Error: Attribute format is not acceptable: Multiple -attribute are allowed only
for repeater supply net attributes. (UPF-210)

prompt> set_port_attributes -ports {in1 out1} \
```

```
-attribute repeater_power_net VDD -attribute iso_sink SS2
```

Error: Attribute format is not acceptable: Dissimilar attributes specified. (UPF-210)

The following example sets the receiver and driver supply attributes for the ports of the design element corresponding to the current scope. The current scope in the following examples is that of the design 'top'.

```
prompt> set_port_attributes -elements {.} \
-receiver_supply SS1 -applies_to outputs
```

Information: Resolving '.' to the current scope 'top'.

```
prompt> set_port_attributes -elements {.} \
-driver_supply SS1 -applies_to inputs
```

Information: Resolving '.' to the current scope 'top'.

The following example issues UPF-231 warning message when you set the driver supply attribute on a hierarchical cell u1.

```
prompt> set_scope u1
prompt> set_port_attributes -elements {.} \
-receiver_supply SS1 -applies_to outputs
```

Information: Resolving '.' to the current scope 'u1'.

Warning: Invalid object(s) specified for '-receiver_supply/-driver_supply' attribute.

Reason: Only the top design, or black box is allowed.

Ignoring 1 invalid object(s) {u1}. (UPF-231)

The following example sets the **UPF_async_clamp_value** attribute on the pin of the element **U1**.

```
prompt> set_port_attributes -elements {U1} -attribute UPF_async_clamp_value 0
```

The following example creates a feedthrough path between two pins of a library cell

```
prompt> set_port_attributes -model {macro_lib_cell} -ports {in out} -feedthrough
```

The following example marks a pin as internally unconnected on a library cell

```
prompt> set_port_attributes -model {macro_lib_cell} -ports {unused} -unconnected
```

The following example sets the clamp value on a hierarchical instance's input pins and then changes the setting on a specific pin.

```
prompt> set_port_attributes -elements {hierarchy_name} -clamp_value 0 -applies_to inputs
prompt> set_port_attributes -ports {hierarchy_name/input_port} -clamp_value 1
```

The following example sets the clamp value on a hierarchical pin and the overrides it with a different clamp value.

```
prompt> set_port_attributes -ports {hierarchy_name/input_port} -clamp_value 1
prompt> set_port_attributes -ports {hierarchy_name/input_port} -clamp_value 0
```

```
prompt> set_port_attributes -ports {macro_cell/in} -literal_supply MACRO_SS1
prompt> set_port_attributes -elements { . } -literal_supply {VDDtop VSStop} -applies_to outputs
```

The following example sets **is_analog** attribute on a hierarchical pin.

```
prompt> set_port_attributes -ports {hierarchy_name/input_port} -is_analog
```

The following example sets **is_analog** attribute on a model pin.

```
prompt> set_port_attributes -model {macro_lib_cell} -ports {in out} -is_analog
```

The following examples set **is_analog** attribute on a hierarchical pin with **-model** specified.

```
prompt> set_port_attributes -model {mid} -ports {in out} -is_analog
```

```
prompt> set_port_attributes -model {.} -ports {in out} -is_analog
```

set_port_fanout_number

Sets the number of external fanout points driven by specified ports in the current design.

SYNTAX

```
status set_port_fanout_number
    fanout_number
    port_list
```

Data Types

```
fanout_number   float
port_list       list
```

ARGUMENTS

fanout_number

Specifies the number of external fanout points driven by the ports in *port_list*. Use this command only with ports. An error message occurs if *port_list* contains any nets. The input value is interpreted as an integer, non-integer values are truncated, and the integer portion is used as the fanout number.

port_list

Specifies a list of ports in the current design whose fanout numbers are to be set.

DESCRIPTION

This command sets the **fanout** attribute on specified ports in the current design. The fanout attribute sets the number of external fanout points driven by each port. This information is used to calculate an external wire load value for the corresponding port. The external wire load value is then added to the wire load of the net connected to the port. Setting this value to *0* when the driver of the port has no other internal fanout causes the net driving the port to be treated as unconnected, so it may be skipped for DRC.

Use the **report_port** command to view the load values on ports.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following sequence of commands describes the external fanout of an output port:

```
prompt> set_port_fanout_number 5 [get_ports O1]  
prompt> set_wire_load_model [get_ports O1] \  
"default_wl"
```

load_of(2)
remove_attribute(2)
report_port(2)
reset_design(2)
set_drive(2)
set_load(2)
target_library(3)

set_port_location

Annotates the specified top-level port with x- and y-coordinates and layer geometry, which the tool uses when running the **reoptimize_design** command.

SYNTAX

```
status set_port_location
  [-coordinate {x y}]
  [-layer_name layer_name]
  [-layer_area {lx ly ux uy}]
  [-append]
  port_name
```

Data Types

<i>x</i>	float
<i>y</i>	float
<i>layer_name</i>	string
<i>lx</i>	float
<i>ly</i>	float
<i>ux</i>	float
<i>uy</i>	float
<i>port_name</i>	string

ARGUMENTS

-coordinate {*x y*}

Specifies the absolute location, in microns, of the x- and y-coordinates of the port.

-layer_name *layer_name*

Specifies the layer name of the top-level design port whose layer geometry is to be annotated.

-layer_area {*lx ly ux uy*}

Specifies the layer geometry of the port, in microns.

-append

Appends the location of port shapes to the same port. If this option is omitted, the location provided by the command overwrites the existing location.

port_name

Specifies the name of the top-level design port whose location is to be annotated.

DESCRIPTION

This command annotates the port location on the specified port. Executing this command without coordinates resets the port location. You can also set the port layer geometry by specifying layer name and layer area coordinates.

The location of the port specified with this command takes precedence over any annotation from a PDEF file using the **read_pdef** or **read_clusters** command. However, if the port location is reset by executing the **set_port_location** command without the x- or y-coordinates, any annotation from the PDEF file is used during optimization.

Layer area geometry is relative to the port origin.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example annotates port Z, a top-level port in the current design, with the location at 100, 5000.

```
prompt> set_port_location -coord {100 5000} Z
```

The following example resets the location of port Z. The tool uses physical information from any PDEF file to determine the location of port Z.

```
prompt> set_port_location Z
```

The following example sets the layer geometry of rectangle 10*20 of port Z.

```
prompt> set_port_location -layer_name METAL1 \
-layer_area {-5 -10 5 10} Z
```

SEE ALSO

set_port_side

Specifies the port side constraints for core generation. This command is supported only in topographical mode.

SYNTAX

```
int set_port_side  
    port_list  
    -side {l | r | b | t | number}
```

Data Types

port_list list

ARGUMENTS

port_list

Specifies the list of ports that this command applies to.

-side {l | r | b | t | number}

Specifies the side to which the ports should be snapped. For a rectangular core outline, specify one of the following values: **l** (left), **t** (top), **b** (bottom), and **r** (right). For a rectilinear core outline, specify the edge number as specified by points on the rectilinear outline.

By default, there is no side constraint on the ports, and they are snapped to the nearest side of the block.

DESCRIPTION

The command **set_port_side** specifies the port side constraints for ports. The constraints will be used to generate a coarse floorplan during synthesis.

If the port side constraints are provided, the ports will be snapped to the specified side. Otherwise, in default, the ports will be snapped to the side nearest to the port location assigned by the coarse placer.

Note that if ports with side constraints also have locations constraints set by **set_port_location**, the location constraints have higher priority during synthesis and side information will be ignored. In this case, the side information will be neither reported by **report_physical_constraints** nor written out by **write_physical_constraints**.

Use this command after loading the physical library and design, but before running synthesis commands.

If the core outline is provided then you can use the edge number as constraints in this command. Please see example below.

EXAMPLES

The following example shows how to constrain the ports clk and reset to be snapped to the left side of the block.

```
prompt> set_port_side {clk reset}-side left
```

The following example shows how to constraint the port on the right lower edge of the L - shaped rectilinear outline

```
prompt>set_rectilinear_outline -coordinate { 0 0 100 0 100 50 50 50 50 100 0 100}
```

```
prompt> set_port_side {ABC}-side 2
```

SEE ALSO

[set_port_location\(2\)](#)
[report_physical_constraints\(2\)](#)
[write_physical_constraints\(2\)](#)

set_power_clock_scaling

Specify clock scaling for power analysis.

SYNTAX

```
int set_power_clock_scaling  
  [-period period_value]  
  [-ratio ratio_value]  
  [clock_objects]
```

Data Types

<i>period_value</i>	float
<i>ratio_value</i>	float

ARGUMENTS

-period *period_value*

Specify the period of clock which is used in simulation.

-ratio *ratio_value*

Specify the clock ratio (period_used_in_SAIF / period_used_in_SDC).

clock_objects

Specify a list of clocks in the design.

DESCRIPTION

Clock frequency used in Switching Activity Interchange Format (SAIF) files, from logic simulation, for functional verification can differ from the clock frequency used in Synopsys Design Constraints (SDC) file for timing and power analysis. This command tells Design Compiler what frequency is used in logic simulation so that Design Compiler can scale dynamic power numbers properly.

To enable this feature, set the **power_enable_clock_scaling** variable to *true*.

The *clock_objects* option in this command is a list of clocks in the design that have the specified period or ratio values used in simulation for SAIF generation. Here the ratio is defined as period-in-simulation / period-in-analysis. The command can be used multiple times, once for each clock. If the same clock is used more than once, a warning message is issued and the clock specified last takes effect. The *-period* and *-ratio* options cannot be used simultaneously. If no clock object is specified, only the ratio option is allowed and the ratio value is applied to all the nets/pins/ports that have related clock whose scaling factor undefined or do not have a related clock.

The tool only scales the switching activities from the SAIF file and activities that are propagated or implied. The command returns 1 on success and 0 on failure.

Note that the scaling result is accumulated since the scaled switching activities in design are saved. For example, if a net has an original toggle rate 1.0 and the *-ratio* option of the **set_power_clock_scaling** command is set to 0.1, the 1st scaling results in the net's toggle rate to 0.1 (the original toggle rate 1.0 is replaced), the second scaling results in 0.01, and so on. To come back to the original toggle rates, you have to use the **reset_switching_activity** command and read the SAIF file again.

Abstract blocks are ignored for clock frequency scaling.

The clock scaling is done only for averaged power.

EXAMPLES

A sample script is listed below. In this case, duration logic simulation the SAIF file mac.saif is generated with clock period 24, so you use **set_power_clock_scaling -period 24 [get_clock clk]**, and you specify SDC clock in mac.sdc (it could be period 12, for example). **report_power** will report the power consumption when the design is operated at SDC clock period 12, rather than logic simulation clock period 24.

```
read_sdc ..//src/hdl/gate/mac.sdc
read_parasitics -format spef ..//src/annotate/mac.spef
read_saif -input "..//sim/mac.saif" -instance "tb/macinst"

set power_enable_clock_scaling TRUE
set_power_clock_scaling -period 24 [get_clock clk]
report_power
```

The following sample script shows the usage of *-period* and *-ratio* options. In the below case, all the nets/pins/ports related to the clock specified are scaled to the value defined with *-period* option. The scaling ratio of 2 is only applied to nets/pins/ports that have related clock whose scaling factor undefined or do not have an related clock.

```
set power_enable_clock_scaling TRUE
set_power_clock_scaling -period 24 [get_clock clk]
report_power
set_power_clock_scaling -ratio 2
repor_power
```

SEE ALSO

[power_enable_clock_scaling\(3\)](#)

set_power_derate

Sets power derating factors on different power components for either the current design, a list of cells, library cells or all cells in a power group in the current design.

SYNTAX

```
status set_power_derate
  [-scenarios scenario_list]
  [-leakage]
  [-switching]
  [-internal]
  [-groups group_names]
  derate_value
  [object_list]
```

Data Types

<i>scenario_list</i>	list
<i>group_names</i>	list
<i>derate_value</i>	float
<i>object_list</i>	list

ARGUMENTS

-scenarios *scenario_list*

Indicates the scenario for which the derate_value is applied. If no scenario is specified the current_scenario is used.

-leakage

Indicates that the derate_value specified should be applied to leakage power only.

-switching

Indicates that the derate_value specified should be applied to switching power only.

-internal

Indicates that the derate_value specified should be applied to internal power only.

-groups *group_names*

Specifies the power group to which the derate_value is applied. The derate_value applies directly to each cell object in the power group. Note groups and object_list are mutually exclusive option.

derate_value

Specifies the power derating factor that is applied to the specified power components as a scalar multiplicative factor.

object_list

Specifies current design or a list of cells or library cells to which the specified power derating factor is applied. Note groups and object_list are mutually exclusive option.

DESCRIPTION

Sets power derating factors on different power components for either the current design, a list of cells, or library cells in the current design. If no object or power group is specified, the power derating factor is set on the current design. The power derating factors are used as a scalar multiplicative factor in power calculation.

Power derating factors affect power analysis results in power reports and power attributes. Power analysis results are multiplied by the derating factors. If power derating factors are not specified, the value of 1.0 is assumed.

If the `set_power_derate` command is used with the `-leakage`, `-internal` or `-switching`, the specified power derating factor is only applied to leakage, internal or switching power accordingly. If none of `-leakage`, `-internal` or `-switching` is specified the power derating factor applies to all power components, which includes internal, switching, and leakage power. First set a generic power derating factor that applies to all power components, and then refine it by setting specific power derating factors for particular power components on particular design objects.

The `object_list` option can be used to set power specific derating factors on instances (cells or library cells) in the design. On each instance the `-switching`, `-internal`, and `-leakage` options can be used in the same way as previously described to specify exactly how the derating factors should be applied to each instance in the object list.

When applying power derating factors the following priority is used (in decreasing order of precedence):

- 1) Leaf Cell or Power Group
- 2) Hierarchical Cell
- 3) Library Cell
- 4) Design

When power derating factors are being applied for a cell the tool first checks if they have been set for the cell itself. It then checks if it has been set for any of the cells hierarchical parents. If no derate factors are found, it checks for the library cell and after that it uses the factors set globally on the design.

Use the `-groups` option to set specific derating factors on all the cell objects in particular power groups. Power group can be user generated or default, such as `clock_network`, `memory`, `register`. They are considered as a collection of leaf and hierarchical cells. If a derate factor is set on a power group, the specified derating factors are applied to all cell objects in the power group.

Power derating factors affect power values shown in power reports. The intended usage mode of this command is to first set global or default derates on the design. Then use the `object_list` option to set specific derate values for cells or library cells in the design. To set derates globally on the design simply issue the command with no object list specified.

To set derating values back to the default use the `reset_power_derate` command.

Multicorner-Multimode Support

EXAMPLES

The following example sets a power derating factor of value 0.95 on all cells in the design for the scenario SCN1.

```
prompt> set_power_derate -scenario SCN1 0.95
```

The following example sets switching power derate and internal power derate to 0.9

```
prompt> set_power_derate 0.9 -switching -internal
```

The following example sets the power derating factors to 0.5 for all power components on the memory power group

```
prompt> set_power_derate 0.5 -groups { memory }
```

The following example sets a leakage power derating factor of 1.1 on all instances of library cell IV in the library MY_LIB

```
prompt> set_power_derate -leakage 1.1 [get_lib_cells MY_LIB/IV]
```

Assuming that cell, "inv" is a particular instantiation of MY_LIB/IV in the design the following command overwrites the power derating factor for the instance "inv" only

```
prompt> set_power_derate -leakage 1.05 [get_cells inv]
```

SEE ALSO

[report_power_derate\(2\)](#)

set_power_guide

Sets an existing exclusive move bound as a power guide or power well. This power guide is used as an always-on power guide.

SYNTAX

```
status set_power_guide
  -name exclusive_movebound_name
  [-guard_band_x horizontal_guard_band_width]
  [-guard_band_y vertical_guard_band_width]
```

Data Types

<i>exclusive_movebound_name</i>	string
<i>horizontal_guard_band_width</i>	integer
<i>vertical_guard_band_width</i>	integer

ARGUMENTS

-name *exclusive_movebound_name*

Specifies the name of an existing exclusive move bound that needs to be set as a power guide or power well.

-guard_band_x *horizontal_guard_band_width*

Facilitates obtaining an integral width for the guard band in the horizontal direction.

-guard_band_y *vertical_guard_band_width*

Facilitates obtaining an integral width for the guard band in the vertical direction.

DESCRIPTION

This command sets an existing exclusive move bound as a power guide. Currently this command is used only for setting an exclusive move bound as an always-on power guide or power well.

The always-on power guides in shutdown voltage areas are used for placing regular cells on the always-on paths so that those cells become always-on.

If no voltage areas exist in the design, you cannot set an exclusive move bound set as a power guide. In a design with voltage area, if an exclusive move bound is in the default voltage area and is set as a power guide, addition or removal of a voltage area might result in incorrect inclusion or exclusion of power guides. You should set power guides only after the design is fixed with respect to the voltage areas in it.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows a flow using the **set_power_guide** command. In this flow, the AO_WELL exclusive move bound physically belongs to the VA_SHUTDN voltage area and is set as an always-on power guide.

```
prompt> create_bounds -name AO_WELL -coordinate {10 10 20 20} \
    -exclusive [get_cells A_INST]
prompt> create_voltage_area -name VA_SHUTDN -coordinate {5 5 30 30}
prompt> set_power_guide -name AO_WELL
```

SEE ALSO

[create_bounds\(2\)](#)
[create_voltage_area\(2\)](#)
[unset_power_guide\(2\)](#)

set_power_prediction

Sets the power prediction mode for **compile_ultra** or **compile_ultra -incremental**. This command is supported only in topographical mode.

SYNTAX

```
int set_power_prediction  
    [true | false]  
    [-ct_references lib_cell_list]
```

ARGUMENTS

true | false

When **true**, sets the power prediction mode. When **false**, turns off the power prediction mode. When no argument is given, **true** is assumed.

-ct_references lib_cell_list

Restricts the list of library cells that can be used for clock tree estimation.

DESCRIPTION

In power prediction mode, **compile_ultra** or **compile_ultra -incremental** tries to correlate the post-synthesis power numbers to that at the end of place and route. Along with improved correlation for power consumption of design components, it predicts the power consumption of missing elements in the design such as clock trees. By using the **-ct_references** switch, the clock tree estimation step can be customized by specifying specific buffers and/or inverters that would be used in real clock tree synthesis.

In power prediction mode, using **report_power** after **compile_ultra** reports the correlated power. Currently the different switches of **report_power** are not supported.

The power prediction mode setting is saved into the design.

EXAMPLES

The following example sets the power prediction optimization mode and checks out the DC Ultra license.

```
prompt> set_power_prediction  
Information: Power prediction mode successfully set. (UIO-67)  
1  
prompt> compile_ultra  
prompt> report_power
```

The following example resets the power prediction mode.

```
prompt> set_power_prediction false
Information: Power prediction mode successfully reset. (UIO-71)
```

The following example shows how to account for power of DFT logic.

```
prompt> insert_dft
prompt> set_power_prediction
prompt> compile_ultra -incremental
prompt> report_power
```

SEE ALSO

[compile_ultra\(2\)](#)
[report_power\(2\)](#)

set_power_switch_cell

Defines the specified library cells as power-switch cells.

SYNTAX

```
status set_power_switch_cell
  cell_name
  [-cell_type coarse_grain | fine_grain]
  [-is_macro]
  [-switch_pin pin_name]
  [-pg_pin {pin_name switch_function pg_function}]
```

Data Types

<i>cell_name</i>	string
<i>pin_name</i>	string
<i>switch_function</i>	string
<i>pg_function</i>	string

ARGUMENTS

cell_name

Specifies the name of the library cell to be defined as a power-switch cell.

-cell_type coarse_grain | fine_grain

Specifies the type of the power-switch cell. The type can be either coarse_grain or fine_grain.

-switch_pin *pin_name*

Specifies the switch pin of the power-switch cell.

-pg_pin {*pin_name* switch_function *pg_function*}

Specifies the power or ground pin of the power-switch cell.

DESCRIPTION

The **set_power_switch_cell** command sets the specified library cells as power-switch cells.

EXAMPLES

In the following example, the library cells whose names starts with FOOT are set as course-grain power-switch cells.

```
prompt> set_power_switch_cell FOOT* -cell_type coarse_grain \
           -switch_pin SLEEPN -pg_pin {VSS !SLEEPN VSS}
```

SEE ALSO

`report_lib(2)`
`check_library(2)`

set_prefer

Sets the **preferred** attribute on the specified library cells.

SYNTAX

```
status set_prefer
  [-min]
  cell_list
```

Data Types

cell_list list

ARGUMENTS

-min

Specifies that the library cells are preferred during hold violation (minimum path) fixing.

cell_list

Specifies the cells on which to set the **preferred** attribute. Cell names must contain a library prefix. If you specify more than one cell name, enclose the list using quotation marks ("") or braces ({}).

DESCRIPTION

The **set_prefer** command sets the **preferred** attribute on the specified library cells. The cells must be in one of the target libraries or in a library already loaded into memory. If this attribute exists on a library cell, optimization uses the library cell before other cells in the target library that implement the same function.

Note that the effect of the **preferred** attribute might not be noticeable during optimization because nonpreferred cells can be chosen to help meet constraints.

If you use the **-min** option, the specified library cells are preferred during hold violation fixing. Only buffers and inverters, which are used to fix hold violations, should be included in the cell list. Including cells with any other functionality in the list with the **-min** option has no impact on the optimization engine. You should be careful when using this option, because the preferred cells are used for minimum path fixing, even if it results in a worse area or cell count solution.

If you use the **set_fix_hold_options -preferred_buffer** command together with the **set_prefer -min** command, the **dont_use** attribute on the specified library cell is ignored during hold violation fixing, but is honored by other optimization engines.

The **set_prefer** command affects only the version of the library that is currently loaded into memory and has no effect on the version that exists on disk. However, if the library is written using the **write_lib** command, the **preferred** attribute is also written, which causes the cells to be permanently preferred.

To remove the **preferred** attribute, use the **remove_attribute** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command specifies that the GA and GB cells from the tech_lib library be preferred during optimization.

```
prompt> set_prefer {tech_lib/GA tech_lib/GB}
```

The following command specifies that the GA and GB cells are preferred during hold fixing (dont_use ignored), and are not used by other optimization engines (dont_use honored).

```
prompt> set_dont_use {tech_lib/GA tech_lib/GB}
prompt> set_prefer -min {tech_lib/GA tech_lib/GB}
prompt> set_fix_hold_options -preferred_buffer
```

SEE ALSO

[report_lib\(2\)](#)
[translate\(2\)](#)
[target_library\(3\)](#)

set_preferred_routing_direction

Sets the preferred routing direction for the specified routing layers.

SYNTAX

```
string set_preferred_routing_direction  
-layers list_of_layers  
-direction horizontal | vertical
```

ARGUMENTS

-layers *list_of_layers*

Specify the list/collection of layer(s) for which the preferred routing directions is to be set.

-direction horizontal | vertical

Specify the preferred routing direction. The allowed values are: horizontal, vertical, h, v, HORIZONTAL, VERTICAL, H, V. Specify any one.

DESCRIPTION

The set_preferred_routing_direction command is used to set the preferred direction for the specified routing layers. This command will be useful in overriding the default layer directions specified in the library itself or even the design. The setting of layer direction done through this command will become specific to this design only.

Note: The command will issue suitable warnings whenever adjacent layers have the same direction after the execution of the command.

Note: This command overrides the preferred direction specified in the reference libraries and saves the user setting as persistent data (will be written when user saves the design) in the design database.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example assigns layers "m1" & "m2" the direction horizontal.

```
prompt> set_preferred_routing_direction \  
-layers {m1 m2} -direction horizontal
```

SEE ALSO

`remove_preferred_routing_direction(2)`
`report_preferred_routing_direction(2)`

set_preferred_scenario

Sets the preferred scenario.

SYNTAX

```
status set_preferred_scenario  
[scenario_name]
```

Data Types

scenario_name string

ARGUMENTS

scenario_name

Specifies the preferred scenario name. When specified, the scenario must be an active scenario. If not specified, the preferred scenario is reset.

DESCRIPTION

The **set_preferred_scenario** command sets the preferred scenario used for multimode or multicorner optimization. When a scenario is specified as preferred, the scenario is treated as the most constraining scenario. The preferred scenario must be an active scenario or the tool generates an error. When no scenario name is specified, the preferred scenario is reset.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following command set the s1 scenario as the preferred scenario:

```
prompt> set_preferred_scenario s1  
Preferred scenario is set to s1.  
1
```

SEE ALSO

`create_scenario(2)`
`compile_ultra(2)`
`set_active_scenarios(2)`

set_preserve_clock_gate

Sets the **pwr_cg_preservation_type** attribute on clock-gating objects.

SYNTAX

```
status set_preserve_clock_gate
  cell_collection
  [-dont_modify_fanout]
  [-dont_modify_enable]
```

Data Types

cell_collection collection

ARGUMENTS

cell_collection

Specifies the list of cells on which the **pwr_cg_preservation_type** attribute is to be set.

-dont_modify_fanout

Forbids the modification of the fanout for the specified clock gating cells.

-dont_modify_enable

Forbids the modification of the enable function for the specified clock gating cells.

DESCRIPTION

This command sets the **pwr_cg_preservation_type** attribute on clock-gating cells.

The **pwr_cg_preservation_type** attribute ensures a clock-gating element is preserved by the tool, unless there is a conflict with other features. This implies that the tool avoids removing the preserved object. Also, if the tool needs to merge two clock-gating objects (to consolidate fanout) and one of them has the **pwr_cg_preservation_type** attribute, it remains in the design after merging.

You can control which kinds of optimizations are allowed on a clock-gating cell by using the flags *-dont_modify_fanout* and *-dont_modify_enable*.

If the option *-dont_modify_fanout* is used, the tool is not allowed to add, remove, or replace the registers and clock gates that are directly driven by the specified clock-gating cells.

Similarly, if the option *-dont_modify_enable* is used, the tool is not allowed to modify the Boolean function corresponding to the enable signal of the specified clock-gating cells.

The possible values that can be assigned to **pwr_cg_preservation_type** are:

preserve (no flag is used)
dont_modify_fanout (only the *-dont_modify_fanout* flag was used)
dont_modify_enable (only the *-dont_modify_enable* flag was used)
unmodifiable (both flags were used)
unmodifiable_read_only (only set by the **identify_clock_gating** command)

If the **pwr_cg_preservation_type** attribute is set on a non-clock-gating element, it is silently ignored by the tool.

If you want to change the current value of **pwr_cg_preservation_type** of a clock-gating cell, you can use again the **set_preserve_clock_gate** command and assign the needed flags.

Use the **report_attribute** command to verify if a clock-gating element has the **pwr_cg_preservation_type** attribute and which value it contains.

You can alternatively use the **set_attribute** command to set the **pwr_cg_preservation_type** attribute on a clock-gating cell. The attribute can only be set to these values: **preserve**, **dont_modify_fanout**, **dont_modify_enable** and **unmodifiable**.

Use the **remove_attribute** command to remove the **pwr_cg_preservation_type** attribute from a clock-gating cell.

NOTE: The **identify_clock_gating** command automatically sets the **pwr_cg_preservation_type** attribute on the clock-gating cells explicitly identified by using the **-gating_elements** option. You are not allowed to remove the **pwr_cg_preservation_type** attribute if the manually identified clock-gating cells do not have the characteristics of a clock gate that can be inserted by the tool.

EXAMPLES

The following example shows the typical flow for using the **set_preserve_clock_gate** command to preserve a user-instantiated clock-gating object, called `user_cg1`. This assigns the **preserve** value:

```
prompt> read_verilog mapped_design.v
prompt> current_design top
prompt> link
prompt> create_clock clk

prompt> identify_clock_gating
prompt> set_preserve_clock_gate user_cg1
```

The following example shows how to preserve a user-instantiated clock-gating object and not allow the modification of its fanout. This assigns the **dont_modify_fanout** value:

```
prompt> identify_clock_gating
prompt> set_preserve_clock_gate user_cg1 -dont_modify_fanout
```

The following example shows how to preserve a user-instantiated clock-gating object and not allow the modification of its enable function. This assigns the **dont_modify_enable** value:

```
prompt> identify_clock_gating
prompt> set_preserve_clock_gate user_cg1 -dont_modify_enable
```

The following example shows how to preserve a user-instantiated clock-gating object and neither allow the modification of its fanout nor its enable function. This assigns the **unmodifiable** value:

```
prompt> identify_clock_gating
prompt> set_preserve_clock_gate user_cg1 -dont_modify_fanout -dont_modify_enable
```

SEE ALSO

[identify_clock_gating\(2\)](#)

```
remove_attribute(2)
report_attribute(2)
set_attribute(2)
set_clock_gating_style(2)
```

set_propagated_clock

Specifies propagated (rather than ideal) clock latency for listed objects.

SYNTAX

```
status set_propagated_clock  
      object_list
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of clocks, ports, or pins on which to apply propagated clocking.

DESCRIPTION

This command specifies that delays be propagated through the clock network to determine latency at register clock pins, including the delay resulting from parasitic capacitance and resistance. If propagated clocking is not specified, the tool uses ideal clocking by default.

Ideal clocking means clock networks have a specified latency (from the **set_clock_latency** command), or zero latency by default. Latency is the amount of time a clock signal takes to be propagated from the ideal waveform origin point to the clock pin of the sequential device.

Propagated clock latency is used for after final clock tree generation and layout. Ideal clock latency specifies a prelayout estimate of the clock tree delay.

If you apply the **set_propagated_clock** command to pins or ports, it affects all register clock pins in the transitive fanout of the specified pins or ports.

To undo the effects of the **set_propagated_clock** command, use the **remove_propagated_clock** command or the **set_clock_latency** command to specify the ideal latency.

To report propagated clock attributes on clocks, use the **report_clock -skew** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

This example specifies the usage of propagated clock latency for all clocks in the design.

```
prompt> set_propagated_clock [all_clocks]
```

SEE ALSO

```
remove_propagated_clock(2)
set_clock_latency(2)
report_clock(2)
set_input_delay(2)
create_clock(2)
```

set_qor_strategy

Applies or reports optimization metrics and application settings for the current design.

SYNTAX

```
status set_qor_strategy
  [-output file_name]
  [-report_only]
  [-diff_only]
  -stage {synthesis}
  -metric {timing total_power timing_total_power}
  [-reduced_effort]
```

Data Types

file_name string

ARGUMENTS

-output *file_name*

Specifies the name of the output file name for writing the application variables.

-report_only

Writes out the application variables and settings to console in tabular format.

-diff_only

Writes out the application options to the console in tabular format for application options that are not set to their target settings.

-stage {synthesis}

Specifies the stage name. Valid stage names is "synthesis"

-metric {timing total_power timing_total_power}

Specify one of these metrics to use when configuring application variables. Valid metric names are, "timing", "total_power" and "timing_total_power".

DESCRIPTION

This command applies metric-specific settings to the current design. It sets the application variables at synthesis stage for better performance in terms of one of the following metrics: timing, total_power, timing_total_power By default, the command applies the application variable settings to the design based on the **-metric** options, and sets the metric_target attribute on the block.

Use the **-output file_name** or **-report_only** options to preview the application variable settings before applying them to the design. The **-output file_name** option writes the application variable settings as Tcl commands which can be applied by using the **source** command. The **-report_only** option writes out the application option settings to the console.

EXAMPLES

The following example writes the application variable settings to the console, but does not change the application variable settings, for the "timing" metric and the "synthesis" stage.

```
prompt> set_qor_strategy -metric timing -stage synthesis -report_only
Metric(s) : timing
+-----+-----+-----+-----+
| Option Name | Metric Group | Tool | Current | Target |
|           | Default   | Setting | Setting |
+-----+-----+-----+-----+
| compile_timing_high_effort | timing | false | false | true |
| psynopt_tns_high_effort   | timing | false | false | true |
...
...
```

The following example applies the application variable settings to timing target metric for synthesis stage.

```
prompt> set_qor_strategy -stage synthesis -metric {timing}
prompt> compile_ultra
```

SEE ALSO

[set_hpc_options\(2\)](#)

set_qtm_global_parameter

Sets a global parameter for quick timing models (QTMs).

SYNTAX

```
status set_qtm_global_parameter
  [-param parameter]
  [-lib_cell lib_cell]
  [-pin pin_name]
  [-clock pin_name]
  [-value parameter_value]
```

Data Types

<i>parameter</i>	string
<i>lib_cell</i>	string
<i>pin_name</i>	string
<i>parameter_value</i>	float

ARGUMENTS

-param *parameter*

Specifies the global parameter to set. The global parameter can be **setup**, **hold**, or **clk_to_output**.

-lib_cell *lib_cell*

Specifies the lib_cell you want to use to mimic the global parameter.

-pin *pin_name*

Specifies the related pin for the global parameter if you are using the **-lib_cell** option to mimic the behavior. If the parameter is **setup** or **hold**, this pin must be an input pin. If the parameter is **clk_to_output**, this pin must be an output pin. If you do not use this option, QTM uses the first constrained pin that it encounters for assigning the **setup** or **hold** parameter. The tool uses the first output pin which has an edge delay arc coming into it for assigning the **clk_to_output** parameter.

-clock *pin_name*

Specifies the constraining pin when you specify the **-param setup** option or the **-param hold** option. This option specifies the launch pin when you specify the **-param clk_to_output** option.

-value *parameter_value*

Specifies the value of the global parameter in time units.

DESCRIPTION

This command sets the value of a desired quick timing model global parameter. The global parameter can be either setup time, hold time, or clk_to_output delay. These parameters specify the global parameter which is added to the timing arcs. The quick timing model setup arc is added to the global setup time to determine the total setup time. The quick timing model hold arc is added to the global hold time to determine the total hold time. The quick timing model edge triggered delay arc is added to the global clk_to_output time to determine the total delay.

You can specify the global parameters of the sequential element by specifying a cell in the library with the **-lib_cell** option. You can also provide the actual value by using the **-value** option. If you specify the **-lib_cell** option, you can specify the clock pin and the input pin name. If you do not specify the clock and input pins, the tool chooses the first setup, hold, or clk_to_output arc that is encountered based on which parameter is being set. If you specify only the **-clock** option, the tool chooses the first setup, hold, or clk_to_output arc (depending on the global parameter) from that clock pin. If you specify only the **-pin** option, the tool chooses the first setup, hold, or clk_to_output arc (depending on the type of global parameter) arriving at the pin.

To display information about the current quick timing model, use the **report_qtm_model** command.

For a basic description of quick timing model, see the **create_qtm_model** man page. For a more detailed description about quick timing model, see the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

Some of the following examples use the **set_qtm_global_parameter** command with the **-lib_cell** option. When you use the **-lib_cell** option, you must also load the technology library and use the **set_qtm_technology** command as shown in the following example:

```
prompt> read_db my_technology_library.db  
prompt> set_qtm_technology -library my_technology_library
```

The following example sets the global setup time equivalent to the setup time of the DFF1 cell.

```
prompt> set_qtm_global_parameter -param setup -lib_cell DFF1
```

The following example sets the global hold time equivalent to the setup time of pin D of the DFF1 cell.

```
prompt> set_qtm_global_parameter -param setup -lib_cell DFF1 -pin D
```

The following example sets the global clk_to_out time to be 1.5 time units.

```
prompt> set_qtm_global_parameter -param clk_to_output -value 1.5
```

`create_qtm_path_type(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`

set_qtm_port_drive

Sets the drive on quick timing model (QTM) ports.

SYNTAX

```
status set_qtm_port_drive
  [-type drive_type]
  [-value drive_value]
  [-input_transition_rise rtrans]
  [-input_transition_fall ftrans]
  port_list
```

Data Types

<i>drive_type</i>	string
<i>drive_value</i>	float
<i>rtrans</i>	float
<i>ftrans</i>	float
<i>port_list</i>	collection

ARGUMENTS

-type *drive_type*

Specifies the global *drive_type* parameter.

To define the drive types, use the **create_qtm_drive_type** command.

-value *drive_value*

Specifies the drive value in drive resistance units.

-input_transition_rise *rtrans*

Specifies the input rising transition time associated with the input pin of the specified drive type to compute the delay for the drive arc for this port. If you do not include this option, the delay table for the rising input of the drive arc is loaded from the library as-is.

Use the **-input_transition_rise** and **-input_transition_fall** options to capture the transition time associated with the input pin defined for the referenced drive type. This can result in more accurate information on the transition time and delay time for the drive arc defined for this port.

-input_transition_fall *ftrans*

Specifies the input falling transition time associated with the input pin of the specified drive type to compute the delay for the drive arc for this port. If you do not include this option, the delay table for the falling input of the drive arc is loaded from the library as-is.

port_list

Specifies the input or inout ports on which to set the attribute. Each element in the list is either a collection of QTM ports or a pattern that matches QTM ports.

DESCRIPTION

This command sets the drive of an output port of a QTM model. There are two methods for setting the drive:

1. If you have defined drive types, use one of the global *drive_type* parameters.
2. Define the drive in drive resistance units.

To show information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTMs, see the **create_qtm_model** man page. For a more detailed description about QTMs, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command sets the drive of output port OUT1 to be of drive type drive1.

```
prompt> set_qtm_port_drive -type drive1 OUT1
```

The following command sets the drive of the output port OUT2 to be 5 drive units.

```
prompt> set_qtm_port_drive -value 5.0 OUT2
```

SEE ALSO

`create_qtm_drive_type(2)`
`create_qtm_model(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`set_qtm_port_load(2)`

set_qtm_port_load

Sets the load on quick timing model (QTM) ports.

SYNTAX

```
status set_qtm_port_load
  [-type load_type]
  [-factor multiplication_factor]
  [-value load_value]
  port_list
```

Data Types

<i>load_type</i>	string
<i>multiplication_factor</i>	float
<i>load_value</i>	float
<i>port_list</i>	collection

ARGUMENTS

-type *load_type*

Specifies the global **load_type** parameter.

To define the load types, use the **create_qtm_load_type** command.

-factor *multiplication_factor*

Specifies the multiplication factor for the load type to set the load on the QTM port.

-value *load_value*

Specifies the load value in the capacitance units.

port_list

Specifies the input or inout ports on which to set the attribute. Each element in the list is either a collection of QTM ports or a pattern that matches QTM ports.

DESCRIPTION

This command sets the load of an input port of a QTM model. There are two methods for setting the load:

1. If you have load types defined, use the global *load_type* parameter along with a multiplication factor.
2. Define the load in terms of the capacitance units.

To show information about the current QTM model, use the **report_qtm_model** command.

For a basic description about QTMs, see the **create_qtm_model** man page. For a more detailed description about QTMs, see the *IC Compiler Design Planning User Guide*.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following command sets the load on IN1 to be 2 times the global load_type load1.

```
prompt> set_qtm_port_load -type load1 -factor 2 IN1
```

The following command sets the load on IN2 to be 4.5 capacitance units.

```
prompt> set_qtm_port_load -value 4.5 IN2
```

SEE ALSO

`create_qtm_load_type(2)`
`create_qtm_model(2)`
`report_qtm_model(2)`
`save_qtm_model(2)`
`set_qtm_port_drive(2)`

set_qtm_technology

Sets quick timing model technology variables.

SYNTAX

```
string set_qtm_technology
[-library name]
[-max_transition max_trans_value]
[-min_transition min_trans_value]
[-max_capacitance max_cap_value]
[-min_capacitance min_cap_value]
[-wire_load_model wlm_name]
[-operating_condition opcond_name]
[-process process_value]
[-voltage voltage_value]
[-temperature temperature_value]
```

Data Types

<i>name</i>	string
<i>max_trans_value</i>	float
<i>min_trans_value</i>	float
<i>max_cap_value</i>	float
<i>min_cap_value</i>	float
<i>wlm_name</i>	string
<i>opcond_name</i>	string
<i>process_value</i>	float
<i>voltage_value</i>	float
<i>temperature_value</i>	float

ARGUMENTS

-library *name*

Specifies the library name for using library elements to define global parameters. The library is the timing library in the Synopsys database (.db) file, not the Milkyway reference or design library. Substitute the string value you want for *name*.

-max_transition *max_trans_value*

Specifies the maximum transition value to use. You must express it in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then you must express *max_transition_value* in nanoseconds. Substitute the float value you want for *max_trans_value*.

-min_transition *min_trans_value*

Specifies the minimum transition value to use. You must express it in units consistent with those in the technology library used during optimization. For example, if the library specifies drive values in kilohms and load values in picofarads, then you must express *min_transition_value* in nanoseconds. Substitute the float value you want for *min_trans_value*.

-max_capacitance *max_cap_value*

Specifies the maximum value to use for capacitance. You must express it in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then you must express *max_cap_value* in picofarads. Substitute the float value you want for *max_cap_value*.

-min_capacitance *min_cap_value*

Specifies the minimum value to use for capacitance. You must express it in units consistent with the technology library used during optimization. For example, if the library specifies capacitance values in picofarads, then you must express *min_cap_value* in picofarads. Substitute the float value you want for *min_cap_value*.

-wire_load_model *wlm_name*

Specifies the wire load model to use when calculating delays. Substitute the string value you want for *wlm_name*.

-operating_condition *opcond_name*

Specifies the default operating condition name for the quick timing model in a multicorner, multimode (MCMM) design. Must be specified together with -process, -voltage, and -temperature.

-process *process_value*

Specifies the process scaling factor for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**. Allowed values are 0.0 through 100.0.

-voltage *voltage_value*

Specifies the voltage value, in Volts, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**.

-temperature *temperature_value*

Specifies the temperature value, in degrees Celsius, for the default operating condition of the quick timing model in an MCMM design. When you want to use any of the following options, you must use all of them: **-operating_condition**, **-process**, **-voltage**, and **-temperature**.

DESCRIPTION

This command sets various quick timing model technology parameters. You can use the **-library** option to define path types, drive types, and load types, or if you set the other global parameters in terms of library cells. Before setting the library, you ensure that it is loaded.

If you have set the wire load model, the path type delays are calculated by using that wire load model.

You can use the **report_qtm_model** command to show information about the current quick timing model.

For a basic description of quick timing models, see the **create_qtm_model** man page. For a more detailed description of quick timing models, see *Creating Quick Timing Models for Black Boxes* in *IC Compiler User Guide: Design Planning Contents*

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets the library to the name my_lib.

```
prompt> read_lib my_lib.db
```

```
#my_lib.db contain the library my_lib  
prompt> set_qtm_technology -library my_lib
```

The following command sets the wire_load_model to wlm1.

```
prompt> set_qtm_technology -wire_load_model wlm1
```

SEE ALSO

```
create_qtm_model(2)  
report_qtm_model(2)  
save_qtm_model(2)
```

set_query_rules

Defines rules for rule-based query.

SYNTAX

```
status set_query_rules
[-hierarchical_separators separator_list]
[-bus_name_notations bus_name_list]
[-class class_list]
[-regsub regsub]
[-regsub_cumulative]
[-wildcard]
[-suffix suffix_list]
[-verbose]
[-nocase]
[-reset]
[-show]
```

Data Types

<i>separator_list</i>	list
<i>bus_name_list</i>	list
<i>class_list</i>	list
<i>regsub</i>	list
<i>suffix_list</i>	list

ARGUMENTS

-hierarchical_separators *separator_list*

Specifies a list of equivalent hierarchy separators in object names. There must be at least two elements in the list. The default list is {/_ .}. The elements are preferably all single character, although at most one multi-character element is allowed. No more than one alphabetical character a-z or A-Z is allowed as a hierarchical separator. The single alphabetical character element is also mutually-exclusive with the multi-character element. The following special characters are not supported as hierarchy separators nor they are allowed as one of the characters for the multi-character hierarchy separator: 0-9, "*", "?", "\", "+", "^", "[", "]", "(", ")", "<", ">", and '{', '}'.

-bus_name_notations *bus_name_list*

Specifies a list of equivalent bus name notations in object names. There must be at least two elements in the list, and the list element must be of two characters exactly. The first character of the element is the opening bus name character, and the second character is the closing bus name character. The default list is {[] __ ()}. No more than one matching pair of alphabetical characters a-z or A-Z is allowed as bus name notations. The following characters are not supported as opening or closing bus name characters: 0-9, "*", "?", "\", "+", "^", and '/'. Bracketed bus notations must be paired. For example, "[]" are not properly paired brackets; therefore, it is not supported. For non-bracket bus name notations, the opening and closing bus name character must be the same. For example, "-_" is not a supported bus name notation.

-class *class_list*

Specifies a list of object class names for which the query rules are applied. The following object classes are supported: cell, port, pin, net, power_domain, supply_net, supply_set, supply_port, and power_switch. By default, they are all enabled; however, you can

specify a subset of them.

-regsub regsub

Specifies a list of options for the **regsub** Tcl command. Each list should include three string elements {{switches} {match_regex} {substitution_exp}}. The query uses the **-regsub** option to evaluate the object name and pattern strings during the matching process.

The **-regsub** option can be specified multiple times in one **set_query_rules** command. When multiple **-regsub** options are used, the **-regsub** options are applied to the leaf object name and pattern in the order you specify.

The **-regsub** option is only applicable to pin, port, net, and leaf cells. If **-regsub** is used without other query rules, the default values for the other options are still used. To save runtime, use this option only if the existing rule-based matching scheme fails to match an object.

In addition to the Tcl built-in options for the **regsub** command, the following options are supported:

- **-class** specifies a single object class name, such as cell, port, pin, or net. The **-class** option makes the **-regsub** query rule object specific. The object class specific **-regsub** rule is preferred to the legacy global **-regsub** rule. The latter has been deprecated. For backward compatibility purposes, the global **-regsub** query rule is automatically converted to the class specific rules for the port, pin, and net classes, but not for the cell class.
- **-cumulative** specifies that the multiple **-regsub** rules for the same object class are executed with cumulative effect so that the subsequent **-regsub** rule is applied to the outputs of the object name and pattern string from the previous **-regsub** rules. After this option is used for an object class with the **-regsub** option, all the **-regsub** rules for that object class will have the cumulative option. The legacy global switch **-regsub_cumulative** is deprecated and is automatically converted to the class specific **-cumulative** option for the port, pin, and net classes, but not for the cell class.

-regsub_cumulative

This option is deprecated. For backward compatibility, it is automatically converted to the class specific **-cumulative** option for the port, pin, and net classes, but not for the cell class.

-wildcard

Enables wildcard support in rule-based matching. Be aware that this option might match more objects after ungrouping and **change_names**.

-suffix suffix_list

Enables the suffix name rule. Only the predefined suffix *_reg* and *_tri* are supported. Suffix *_reg* is only applicable to register cells. When enabled, a cell name pattern such as "U4" would match register cell named "U4_reg". Suffix *_tri* is only applicable to tristate cells. When enabled, a cell name pattern such as "U8" would match tristate cell object named "U8_tri".

-verbose

Prints messages indicating the object is matched using query rules.

-nocase

Enables case-insensitive rule-based matching. This is the preferred way of enabling case-insensitive rule-based matching.

-reset

Resets query rules to the program default.

-show

Shows the current definition of the query rules. If used with other options, the new query rules will be set first and then displayed.

DESCRIPTION

The **set_query_rules** command allows you to define query rules for some applications, such as **extract_physical_constraints** to

guide the object queries with query rules. The purpose of the rule-based matching is to resolve the naming differences that are often due to ungrouping and **change_names** command activity. The hierarchy separators and bus names are typical sources of the naming differences.

When a list of characters is defined as equivalent in terms of hierarchy separator, the object query uses the equivalence when matching the objects in the in-memory netlist. For example, if the list {/ _} is defined as equivalent hierarchy separators, the cell named "a.b_c/d_e" is matched with name string "a/b_c.d/e" provided in the Tcl scripts or in the DEF files.

When a list of bus notations is defined as equivalent in terms of bus names, the object query uses the equivalence when matching the objects in the in-memory netlist. For example, if the list {[] __} is defined as equivalent bus notations, the cell named "a[4][5]" is matched with the name string "a_4__5_" provided in the Tcl scripts or DEF files.

When the **-regsub** rules are specified, the Tcl **regsub** command applies the rules to both the object name and the pattern string for rule-based matching if the other rule-based matching scheme fails to match an object.

Be cautious about enabling wildcard support in a rule-based match because the wildcard match might give you more matches than you want.

Use the **-reset** option to reset the query rules to the program default. Use **-show** to report the current query rules. When **-show** is used with other options, the new rules are set first and then reported.

The **-nocase** option of command **set_query_rules** is the preferred way of enabling case-insensitive rule-based matching, although global variable **find_ignore_case** variable is honored. For runtime reasons, avoid using the **-nocase** option in query commands such as **get_cells** or **get_pins**.

The **set_query_rules** command can be issued multiple times. Unless the **-show** option is used alone, the new rules always overwrite the previous rule settings.

Be cautious when defining and enabling query rules. To save runtime, do not use unnecessary query rules.

Rule-based matching is enabled by the **enable_rule_based_query** variable. The default or user-defined query rules are effective for object queries only when the **enable_rule_based_query** variable is set to **true**. Runtime for rule-based matching could be much slower. Rule-based matching should be disabled once it is no longer needed. By default, rule-based matching is off.

EXAMPLES

```
# Show program default.

set_ref_libs

Sets the reference library list on a library.

SYNTAX

```
status set_ref_libs
[-library name]
[-ref_libs {paths}]
[-use_technology_lib tech_lib_name]
[-add path]
[-before path]
[-remove path]
[-clear]
[-rebind]
```

ARGUMENTS

-library *name*

Which library to set the reference library list. The library must be open. If no library is specified, the *current_lib* is used.

-ref_libs {*paths*}

A list of reference library paths to set on this library.

-use_technology_lib *tech_lib_name*

Specify one library on the ref_lib list as a dedicated technology library. To be used in combination with the -ref_libs option. It is an error if the specified technology library does not have a technology section.

-add *path*

Adds path to the end of the library's reference library list.

-before *path*

Places the path before the named _path in the reference library list.

-remove *path*

Remove the named path from the library reference list. This also marks all open blocks of the library as needed to be bound.

-clear

Remove all paths from the reference library list. This also marks all open blocks of the library as needed to be bound.

-rebind

Rebind each reference library path to libraries currently loaded in memory using the search_path.

DESCRIPTION

The **set_ref_libs** command modifies the list of libraries searched for design objects referenced from this library. This is a list of paths used in conjunction with the library's parent directory, and the *search_path* to find libraries. Paths may be library names, partial paths to libraries, or full path names. If it is a partial path, it is resolved using the current *search_path* setting, except when the partial path is relative, path that starts with "./" or "../", in which case it is resolved relative to the parent directory of the library.

The library's reference library path list can be set with the *-ref_libs* option directly. Alternatively, it can also be automatically created and set by specifying physical source data with the *-ref_libs* option. The supported physical source data includes frame libraries, LEF files and Milkyway libraries. When physical source data is specified with *-ref_libs* option, it will create reference libraries according to these physical source data and the *link_library* setting. The created reference libraries will be put in the directory indicated by the *lib.auto_reflibs.output_dir* app option. The *lib.auto_reflibs.setup_script* app option can be used to point to a tcl script with customized settings for the reference library creation. Please refer to the man pages of these app variables and options for the detailed information about how to use them.

When the reference library list is set, each path is bound to a currently open library on the search path with that name. This binding is recreated when the library is re-opened in a later session. If the *search_path* is changed, the bindings can be updated with *set_ref_libs -rebind*.

Note that rebinding the reference library list with *-rebind* does not affect the bindings of any blocks in memory. Block references within a design can be rebound with *link_block -rebind*.

The list of *ref_libs* on a library can be retrieved with the *get_attribute* command.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example sets two reference libraries on the current library, adds a third path, then removes one path.

```
prompt> set_ref_libs -ref_libs {r4000 macros/TSMC24}
r4000 macros/TSMC24
prompt> set_ref_libs -add r6000 -before TSMC24
r4000 r6000 macros/TSMC24
prompt> set_ref_libs -remove r4000

set_register_merging

Sets the **register_merging** attribute on the specified cells or designs, allowing register merging optimization on the objects.

SYNTAX

```
status set_register_merging  
    obj_list  
    [true | false]
```

Data Types

obj_list list

ARGUMENTS

obj_list

Specifies a list of cell or design names for which you enable register merging optimization. Cell names in *obj_list* must be from the current design. If you specify multiple objects, they must be enclosed in quotation marks ("") or braces ({}).

true | false

Specifies the value with which you set the **register_merging** attribute. When you set this option to **true** (the default), register merging is enabled on the specified objects (cells or designs).

Register merging is performed on the specified objects only if the **compile_enable_register_merging** variable is set to **true**.

If the option is set to **false** on the following objects: - Design: Disables register merging on the whole design. - Instance: Disables register merging on the whole instance.

DESCRIPTION

The **set_register_merging** command sets the **register_merging** attribute on the specified *obj_list*. This attribute is used to specify the cells or designs to be optimized using register merging.

If a cell with a specified name is found in the current design, the **register_merging** attribute is set to the specified value in the cell. If no cell with a specified name is found, the tool searches for a design and the attribute is set for the design.

EXAMPLES

The following example shows how to enable register merging optimization during optimization for the sequential cells U0 and U1 and how to disable register merging for the U2 cell:

```
prompt> set_register_merging {U0 U1} TRUE
prompt> set_register_merging U2 FALSE
```

`compile(2)`
`get_attribute(2)`
`remove_attribute(2)`
`compile_enable_register_merging(3)`
`compile_enable_register_merging_with_exceptions(3)`

set_register_replication

Sets the **register_replication** attribute on the specified sequential cells, thus allowing register replication on the objects.

SYNTAX

```
int set_register_replication
  [-max_fanout max_fanout_value]
  [-num_copies copy_value]
  [-include_fanin_logic cell]
  [-include_fanout_logic cell]
  [-driven_by_original_register end_points_list]
  object_list
```

Data Types

<i>max_fanout_value</i>	integer
<i>copy_value</i>	integer
<i>cell</i>	string
<i>end_points_list</i>	list
<i>object_list</i>	list

ARGUMENTS

-max_fanout *max_fanout_value*

Specifies the maximum fanout of the register after the replication.

-num_copies *copy_value*

Specifies the number of copies for the specified register is replicated.

-include_fanin_logic *cell*

Specifies the combinational cell in the fanin of the register for a path replication.

-include_fanout_logic *cell*

Specifies the combinational cell in the fanout of the register for a path replication.

-driven_by_original_register *end_points_list*

Specifies the endpoints cells (registers or primary output ports) that should remain connected to the original register.

object_list

Specifies the set of registers to replicate.

DESCRIPTION

Sets the **register_replication** attribute on *object_list*. This attribute is used to specify how many copies of the sequential cells are replicated. When you specify the **-num_copies** option, the **register_replication** attribute value is the value of the **-num_copies** option. Otherwise, it is the value of the **-max_fanout** option.

The **-include_fanin_logic** option can be used to replicate a path. A single object is specified for the option and denotes the start of the path. Only a single object can be specified in the **object_list** when **-include_fanin_logic** option is used.

The **-include_fanout_logic** option can be used to replicate paths from a set of registers to a specific cell (choke point). A single object is specified for the option and denotes the end of the paths. Multiple registers can be specified in the **object_list** when **-include_fanout_logic** option is used. There must be an unique path from each register of the set to the choke point cell. The replication would be completed as a single action for the given registers.

The **-driven_by_original_register** option can be used to keep specified endpoints cells connected to the original register when replicating registers.

If a sequential cell with a specified name is found in the *current design*, the **register_replication** attribute is set to the specified value in the cell.

EXAMPLES

The following example shows how to replicate sequential cell U0 three times and how to replicate sequential cell U1 so that its fanout is less than or equal to four.

```
prompt> set_register_replication -num_copies 3 U0
prompt> set_register_replication -max_fanout 4 U1
```

The following example shows how to get an additional copy of the path from the U1 cell to the A_reg register, which lies in the fanin of the register:

```
prompt> set_register_replication -num_copies 2 A_reg -include_fanin_logic U1
```

The following example shows how to get an additional copy of the paths from A_reg B_reg registers to the choke point cell U1, which lies in the fanout of the registers:

```
prompt> set_register_replication -num_copies 2 {A_reg B_reg} -include_fanout_logic U1
```

The following example shows how to use the **-driven_by_original_register** option. The r3_reg, r2_reg, and r1_reg registers are in the transitive fanout of the reg_1_reg original register. The 3 registers remain connected to the original register after replication.

```
prompt> set_register_replication -num_copies 2 reg_1_reg \
    -driven_by_original_register {r3_reg r2_reg r1_reg}
```

The following example shows how to use the **-driven_by_original_register** option. The op_1 and op_2 output ports are in the transitive fanout of the reg_1_reg original register. The 2 output ports remain connected to the original register after replication.

```
prompt> set_register_replication -num_copies 2 reg_1_reg \
    -driven_by_original_register {op_1 op_2}
```

SEE ALSO

compile(2)

```
find(2)
get_attribute(2)
remove_attribute(2)
```

set_register_type

Sets the **latch_type** or **flip_flop_type** attributes on designs or cell instances, to specify which sequential cells from the target library are to be used by the **compile** command.

SYNTAX

```
int set_register_type
    -latch example_latch -exact |
    -flip_flop example_flip_flop [-exact]
    [cell_or_design_list]
```

Data Types

<i>example_latch</i>	string
<i>example_flip_flop</i>	string
<i>cell_or_design_list</i>	list

ARGUMENTS

-latch *example_latch*

Specifies a latch to be used by the **compile** command as the default latch type.

You can specify both **-latch** and **-flip-flop**, but you must specify at least one.

-exact

Instructs the **compile** command to make an exact mapping to the specified *example_latch* or *example_flip-flop*, if possible.

This argument is required when using the **-latch** argument.

-flip_flop *example_flip_flop*

Specifies a flip-flop from the target library to be used by the **compile** command as the default flip-flop type. the *example_flip_flop*, if possible. This argument sets the **default_flip_flop_type** or **default_flip_flop_type_exact** attribute to the *example_flip_flop* on all designs in *cell_or_design_list*; and the **flip_flop_type** or **flip_flop_type_exact** attribute to the *example_flip_flop* on all cells in *cell_or_design_list*.

You can specify both **-latch** and **-flip-flop**, but you must specify at least one.

cell_or_design_list

Specifies a list of cells or designs in which to use the latch or flip-flop. The default is the current design.

DESCRIPTION

Specifies latch or flip-flop type information for the **compile** command to use, by setting appropriate attributes on the designs or cell instances. For designs, specifying **-flip_flop** without **-exact**, sets the **default_flip_flop_type** attribute to *example_flip_flop*, indicating to use it as the default flip-flop type for those designs. And specifying **-exact -flip_flop** sets the **default_flip_flop_type_exact** attribute to *example_flip_flop*, indicating to use it as the exact default flip-flop for those designs.

For example, to set the default flip-flop type for a design to be a D flip-flop, specify the name of any D flip-flop in the target library as the *example_flip_flop*, without **-exact**. If you specify **-exact**, the *example_flip_flop* is interpreted as the exact flip-flop to use.

Similarly, for cell instances, specifying **-flip_flop** without **-exact** sets the **flip_flop_type** attribute to *example_flip_flop*, indicating that it is to be used as the specific flip-flop type for those cells. And specifying **-exact -flip_flop** sets the **flip_flop_type_exact** attribute to *example_flip_flop*, indicating that it is to be used as the exact flip-flop for those cells.

When specifying a latch, you must always use the **-exact** option, so the *example_latch* is always the exact latch used as the default latch for designs and as the specific latch for cells. The **default_latch_type_exact** attribute is set to the specified latch on designs, and the **latch_type_exact** attribute is set to the specified latch on cells.

There are no **latch_type** or **default_latch_type** attributes.

The mapping process for flip-flops and latches consists of two steps:

1. Sequential gates are mapped to an initial latch or flip-flop from the target library. The **compile** command attempts to convert flip-flops or latches tagged by **set_register_type** to the specified flip-flop or latch type. Untagged sequential components are mapped to the default latch or flip-flop type if specified. In the absence of attributes on a design, or a sequential cell instance to control the mapping, the smallest area-cost flip-flop or latch is chosen.
2. If a flip-flop is not specified with the **-exact** option, the tool attempts to individually remap it to a lower-cost component from the target library. If **compile** cannot use the sequential component specified, or if no default flip-flop or latch is specified, **compile** maps these cells into the smallest sequential component possible.

A cell instance can have either latch or flip-flop attributes, but not both. Only latch cells can have latch attributes, and only flip-flop cells can have flip-flop attributes. Designs can have both latch and flip-flop attributes, because these attributes designate the default latch type (for latches in the design) and the default flip-flop type (for flip-flops in the design).

Unmapped sequential components can result when the **translate** command cannot find a close match for a flip-flop or latch in the new target library, or when latches or flip-flops are added to a design by HDL Compiler, VHDL Compiler, or state-machine software.

The **set_register_type** command constrains the mapping process. It does not constrain scan replacement in **insert_dft** or in **compile**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the default flip-flop type for the current design to a D flip-flop, and that one example of a D flip-flop in the current library is the component *DFLOP*. This sets the **default_flip_flop_type** attribute to *DFLOP* on the current design. As a result, the default flip-flop used in mapping components that are not otherwise tagged is a D flip-flop.

```
prompt> set_register_type -flip_flop DFLOP
```

The following example sets the default flip-flop type for the current design exactly to the *DFLOP* cell. This sets the **default_flip_flop_type_exact** attribute to *DFLOP* on the current design. As a result, the default flip-flop used in mapping components that are not otherwise tagged is *DFLOP*.

```
prompt> set_register_type -exact -flip_flop DFLOP
```

The following example sets the default latch type for *FOO* and *BAR* designs to exactly a *DLATCH* gate. The **compile** command attempts to map all unmapped latches in these designs to *DLATCH*. This sets the **default_latch_type_exact** attribute to *DLATCH* on the *FOO* and *BAR* designs. The presence of this attribute indicates that an exact mapping is to be attempted for the *DLATCH* latch on the untagged cells in the *FOO* and *BAR* designs. Sequential types for latches must always be set as exact.

```
prompt> set_register_type -exact -latch DLATCH {FOO, BAR}
```

The following example maps a group of cell instances exactly to the *DLATCH* latch. This sets the **latch_type_exact** attribute on the *U1*, *U2*, and *U3* cell instances to the name *DLATCH*.

```
prompt> set_register_type -exact -latch DLATCH {U1, U2, U3}
```

The following example specifies the exact default latch type for the current design as *DLATCH* and the exact default flip-flop type as *DFLOP*. This sets the **default_latch_type_exact** attribute to the name *DLATCH* and the **default_flip_flop_type_exact** attribute to the name *DFLOP* on the current design so that **compile** can map otherwise untagged components in the design. You must use **-exact** when you specify both **-latch** and **-flip_flop** in the same command.

```
prompt> set_register_type -exact -latch DLATCH -flip_flop DFLOP
```

set_related_supply_net

Associates a supply net to the port of the design or the pin of a cell.

SYNTAX

```
status set_related_supply_net
  [supply_net_name]
  [-object_list objects]
  [-reset]
  [-ground ground_net_name]
  [-power power_net_name]
```

Data Types

<i>supply_net_name</i>	string
<i>objects</i>	list
<i>ground_net_name</i>	string
<i>power_net_name</i>	string

ARGUMENTS

supply_net_name

Specifies the name of the power net. This is deprecated and supported for backward compatibility only. New scripts should specify the power net using the **-power** option.

-object_list *objects*

Specifies the list of ports (pins) to be associated with power/ground nets or reset. If this option is not specified, all the ports are considered.

-reset

Resets the related power and ground nets of the ports (pins) specified in *object_list*. This cannot be used with the **-power** or **-ground** options.

-ground *ground_net_name*

Specifies the name of the ground net.

-power *power_net_name*

Specifies the name of the power net.

DESCRIPTION

This command is used to associate supply nets with design ports or leaf pins. The tool uses this information for constraining and checking the design. The level-shifter insertion tool also uses supply nets to determine if level shifter is required between a port (pin) and the logic connected to the port (pin).

The supply net is associated with the input ports only if the supply voltage (if already specified for the supply using the **set_voltage** command) matches with the voltage of the driving cell (as specified by the **set_driving_cell** command for the input port). The command issues an error when the voltages do not match. The command also neglects ports that do not meet the voltage matching criteria.

This command cannot be used on ports that have driver or receiver supply port attributes. The driver and receiver supply port attributes have higher precedence than the **related_supply_net** attribute; therefore, this command will not set the **related_supply_net** attribute on such ports and issues an information message.

If this command is not specified, the tool assumes that ports are externally connected to the primary supply net of the domain of the top design.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the VDD_EXT power net and the VSS_EXT ground net with the INPUT port.

```
prompt> set_related_supply_net -object_list [get_ports INPUT] \
-power VDD_EXT -ground VSS_EXT
```

The following example resets the power net and ground net on all ports.

```
prompt> set_related_supply_net -reset
```

SEE ALSO

[get_ports\(2\)](#)
[set_port_attributes\(2\)](#)

set_repeater

Defines the UPF repeater strategy for the power domains in the design.

SYNTAX

```
status set_repeater
  repeater_strategy_name
  -domain power_domain
  [-repeater_supply repeater_supply_set]
  [-applies_to inputs | outputs | both]
  [-applies_to_boundary upper | lower | both]
  [-elements objects]
  [-exclude_elements exclude_objects]
  [-name_prefix prefix]
  [-name_suffix suffix]
  [-update]
```

Data Types

<i>repeater_strategy_name</i>	string
<i>power_domain</i>	string
<i>repeater_supply_set</i>	string
<i>objects</i>	list
<i>exclude_objects</i>	list
<i>prefix</i>	string
<i>suffix</i>	string

ARGUMENTS

repeater_strategy_name

Specifies the name of the UPF repeater strategy. The name of the repeater strategy should be unique within the specified power domain.

-domain power_domain

Specifies the name of the power domain to which this UPF repeater strategy will be applied.

-repeater_supply repeater_supply_set

Specifies the supply set whose power and ground functions are to be used as the repeater power and ground nets respectively.

-applies_to inputs | outputs | both

Specifies whether the given **set_repeater** command applies to all inputs or outputs or both types of ports of the power domain.

-applies_to_boundary upper | lower | both

Specifies explicitly whether to apply the strategy to upper boundaries(lowConns) only, to lower boundaries(highConns) only, or to both upper and lower boundaries of the power domain.

The default is

upper

- if the power domain does not have lower_domain_boundary attribute OR
- if the power domain lower_domain_boundary attribute set to FALSE

both

- if the power domain lower_domain_boundary attribute set to TRUE

-elements objects

Specifies the objects to which this UPF repeater strategy will be applied. The objects can be pins of the root cells of the power domain or top level ports or root cells of the power domain.

-exclude_elements exclude_objects

Specifies the objects to which this UPF repeater strategy won't be applied. The objects can be pins of the root cells of the power domain or top level ports or root cells of the power domain.

-name_prefix prefix

Specifies the prefix to use for the repeater cell names.

-name_suffix suffix

Specifies the suffix to use for the repeater cell names.

-update

Indicates that this command adds *elements* or *exclude_elements* for a previous command with the same *strategy_name* and *domain_name* and executed in the same scope.

With the **-update** option, the command only accepts **-elements** or **-excluded_elements**, and the required option *strategy_name* and **-domain**. If other options are specified with **-update**, the command will error out.

DESCRIPTION

This command defines the UPF repeater strategy for the ports of the specified power domain.

If the **-elements** and **-applies_to** options are not specified, then the repeater strategy will be applied to all ports of the power domain.

If **-repeater_supply** is not specified, then the command will error out.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF repeater strategy for all output ports at upper boundaries of the specified power domain PD1.

```
prompt> set_repeater repeater_1 -domain PD1 \
    -repeater_supply PD1.primary -applies_to output \
    -applies_to_boundary upper \
```

The following example shows how to define a UPF repeater strategy for specific ports of the specified power domain:

```
prompt> set_repeater repeater_2 -domain PD1 \
    -repeater_supply rptr_supply_set \
```

-elements inst/special_port

The following example shows how to define a UPF repeater strategy using **-exclude_elements**:

```
prompt> set_repeater repeater_3 -domain PD1 \
           -repeater_supply rptr_supply_set \
           -elements inst \
           -exclude_elements inst/special_port
```

SEE ALSO

[set_port_attributes\(2\)](#)

set_replace_clock_gates

Set directives for clock gate replacement. Forces the enabling or disabling of clock gate replacement for specified combinational cells in the current design. Also sets the edge type for modules or black-box cells that otherwise could not be replaced. The cells are replaced by executing the **replace_clock_gates** command.

SYNTAX

```
int set_replace_clock_gates
  [-include_cells cell_list]
  [-exclude_cells cell_list]
  [-rising_edge_clock pin_list]
  [-falling_edge_clock pin_list]
  [-undo object_list]
```

Data Types

<i>cell_list</i>	list
<i>pin_list</i>	list
<i>object_list</i>	list

ARGUMENTS

-include_cells *cell_list*

Specifies a list of cells in the current design to be included for clock gate replacement. A cell cannot be on more than one of the **-include_cells**, **-exclude_cells**, and **-undo** lists.

-exclude_cells *cell_list*

Specifies a list of cells in the current design to be excluded from clock gate replacement. A cell cannot be on more than one of the **-include_cells**, **-exclude_cells**, and **-undo** lists.

-rising_edge_clock *pin_list*

Specifies a list of pins or ports in the current design to be recognized as a positive edge triggered clock pin during clock gate replacement. A (corresponding) port cannot be on more than one of the **-rising_edge_clock**, **-falling_edge_clock**, and **-undo** lists.

-falling_edge_clock *pin_list*

Specifies a list of pins or ports in the current design to be recognized as a negative edge triggered clock pin during clock gate replacement. A (corresponding) port cannot be on more than one of the **-rising_edge_clock**, **-falling_edge_clock**, and **-undo** lists.

-undo *object_list*

Specifies a list of pins, ports or cells in the current design for which the previous specification to **set_replace_clock_gates** is to be undone. A cell cannot be on more than one of the **-include_cells**, **-exclude_cells**, and **-undo** lists, while a (corresponding) port cannot be on more than one of the **-rising_edge_clock**, **-falling_edge_clock**, and **-undo** lists.

DESCRIPTION

This command specifies combinational cells for which clock gate replacement is to be either enabled or disabled. By default, all combinational cells on the clock paths that are not buffers or inverters are considered for clock gate replacement. Cells on the **-exclude** lists will not be replaced with Power Compiler clock-gating cells, regardless of any previous specifications. If cells are specified on the **-include** lists, only those cells are considered for replacement.

This command is also used to specify the edge type of clock ports for modules or black-box cells that otherwise could not be clock gated by applying clock gate replacement to manually inserted clock gating cells. clock gated otherwise. One of the conditions for clock gate replacement is that the fanout of the manually inserted clock gate should drive only registers that are triggered by the same clock edge. If the fanout contains a black-box cell or sequential cell for which the edge type cannot be identified, or if the edge type is not compatible with the registers in the fanout of the gating cell, it is possible to override the edge detection mechanism used by **replace_clock_gates**.

The same port cannot be specified as rising_edge and falling_edge at the same time. If an instance pin is specified, the corresponding design port is used instead, since the edge type property is design specific.

You must run **set_replace_clock_edges** before issuing \freplace_clock_gates; the specifications persist during all subsequent executions of **replace_clock_gates**. Use the **-undo** option to remove the effect of an earlier invocation of **set_replace_clock_gates**.

EXAMPLES

The following example excludes the manually inserted clock-gating cells named **C12** and **C13** in the current design. All other cells are still considered for clock gate replacement.

```
prompt> set_replace_clock_gates -exclude_cells { C12 C13 }
```

The following example includes the cell named **C71** in the subdesign *MID*, so that only this cell is considered for clock gate replacement at that level of the hierarchy.

```
prompt> set_replace_clock_gates -include_cells MID/C71
```

The following example sets the edge type of clock input **clk** of the black-box instance **RAM_03** in the current design to positive edge triggered.

```
prompt> set_replace_clock_gates -rising_edge_clock RAM_03/clk
```

The following example achieves the same result by specifying the edge type directly on the port of the black-box design.

```
prompt> current_design RAM
prompt> set_replace_clock_gates -rising_edge_clock clk
prompt> current_design top_level
```

SEE ALSO

`report_clock_gating(2)`
`set_clock_gating_style(2)`

set_resistance

Sets the resistance value on nets.

SYNTAX

```
status set_resistance
      value
      [-min] [-max] net_list
```

Data Types

<i>value</i>	float
<i>net_list</i>	list

ARGUMENTS

value

Specifies the resistance value for nets in *net_list*. *value* must be expressed in unit system consistent with what the technology library used during optimization. For example, if the technology library specifies resistance values in ohms, *value* must also be expressed in ohms.

-min

Indicates that the resistance value is to be used for minimum delay analysis. If you do not specify a value for minimum delay analysis, the maximum value is used. If you do not specify a value for maximum delay analysis, the minimum value is ignored. (You cannot annotate only a minimum value.)

-max

Indicates that the resistance value is to be used for maximum delay analysis. If you do not specify **-min** or **-max**, the value is used for both minimum and maximum delay analysis.

net_list

Specifies a list of nets for which the specified resistance values are to be set.

DESCRIPTION

Sets the **ba_net_resistance** attribute, which enables the back-annotation of resistance values on nets in the current design. If the current design is hierarchical, it must have been linked with the **link** command. The specified *value* overrides the internally-estimated net resistance value.

You also can use the **set_resistance** command for nets at lower levels of the design hierarchy. These nets are specified as "BLOCK1/BLOCK2/NET_NAME."

To view resistance values, use the **report_net** command.

To remove a resistance value, use **remove_attribute**. To reset all back-annotated resistance values in a design, use the **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example sets a resistance of 200 units to nets a and b.

```
prompt> set_resistance 200 {a b}
```

This example sets a resistance of 300 units on net U1/U2/NET3.

```
prompt> set_resistance 300 U1/U2/NET3
```

This example removes the back-annotated resistance on net U1/U2/NET3.

```
prompt> remove_attribute [get_nets U1/U2/NET3] ba_net_resistance
```

SEE ALSO

[remove_attribute\(2\)](#)

[report_timing\(2\)](#)
[reset_design\(2\)](#)
[set_drive\(2\)](#)
[target_library\(3\)](#)

set_resource_allocation

Sets the resource_allocation attribute on the current design, specifying the type of resource allocation to be used by compile.

SYNTAX

```
integer set_resource_allocation  
    none | area_only | area_no_tree_balancing | constraint_driven
```

ARGUMENTS

none | area_only | area_no_tree_balancing | constraint_driven

Specifies the allocation type with which the **resource_allocation** attribute is to be set. The type values are as follows:

- **none** directs **compile** to use no resource sharing, so that each operation is implemented with separate circuitry.
 - **area_only** directs **compile** to share operators without considering timing constraints while simultaneously balancing all arithmetic expression trees.
 - **area_no_tree_balancing** directs **compile** to share operators without considering timing constraints and without balancing expression trees.
 - **constraint_driven** (the default) directs **compile** to share resources so that timing constraints are met or not worsened by sharing.
-

DESCRIPTION

This command sets the **resource_allocation** attribute on the current design, specifying the type of resource allocation to be used by **compile**. The **synthetic_library** variable must be set for resource sharing to take affect. This command has no effect in **compile_ultra**.

If **resource_allocation** is not set, then the value of the **hlo_resource_allocation** environment variable is used. The default value for the variable is **constraint_driven**. By default, **compile** shares resources so that timing constraints are met or not worsened. Setting the **resource_allocation** attribute overrides the value of **hlo_resource_allocation** for the current design.

Use the **remove_attribute** command to undo this command.

EXAMPLES

The following example sets the **resource_allocation** attribute to **area_only** on the design named TEST:

```
prompt> current_design TEST
```

```
prompt> set_resource_allocation area_only
```

The following example removes the **resource_allocation** attribute from the current design:

```
prompt> remove_attribute current_design resource_allocation
```

SEE ALSO

[compile\(2\)](#)
[get_attribute\(2\)](#)
[remove_attribute\(2\)](#)
[hlo_resource_allocation\(3\)](#)
[synthetic_library\(3\)](#)

set_retention

Defines the UPF retention strategy for the power domains in the design.

SYNTAX

```
status set_retention
  retention_strategy
  -domain power_domain
  [-retention_power_net retention_power_net]
  [-retention_ground_net retention_ground_net]
  [-retention_supply retention_supply_set]
  [-no_retention]
  [-elements objects]
  [-save_condition {boolean_function}]
  [-restore_condition {boolean_function}]
  [-retention_condition {boolean_function}]
  [-exclude_elements objects]
  [-save_signal {save_signal save_sense}]
  [-restore_signal {restore_signal restore_sense}]
  [-update]
  [-use_retention_as_primary]
```

Data Types

retention_strategy	string
power_domain	string
retention_power_net	string
retention_ground_net	string
objects	list
boolean_function	string
save_signal	string
save_sense	high low
restore_signal	string
restore_sense	high low

ARGUMENTS

retention_strategy

Specifies the name of the UPF retention strategy. The name of the retention strategy must be unique within the specified power domain.

-domain power_domain

Specifies the name of the power domain to which this UPF retention strategy should be applied.

-retention_power_net retention_power_net

Specifies the retention power net for the retention cells that are in this UPF retention strategy.

-retention_ground_net *retention_ground_net*

Specifies the retention ground net for the retention cells that are in this UPF retention strategy.

-retention_supply *retention_supply_set*

Specifies the supply set whose power and ground function associations should to be used as the retention power and retention ground nets respectively. It is mutually exclusive with the **-retention_power_net** and the **-retention_ground_net** options. This option is supported with UPF 3.0 standard.

-no_retention

Specifies that the objects in the power domain do not have retention.

-elements *objects*

Specifies the objects to which this UPF retention strategy applies. The objects can be hierarchical cells, leaf cells, HDL blocks, register signals of a Verilog always block, or the name of a list of retention elements.

-save_condition {*boolean_function*}

This option controls the saving of the current register's value in the retention register's shadow latch.

-restore_condition {*boolean_function*}

The restore_condition controls the restoration of the value from the register's shadow latch to the register.

-retention_condition {*boolean_function*}

The retention_condition controls the preservation of the saved value in the shadow register.

-exclude_elements *objects*

Excludes the listed objects from the strategy in this power domain. The objects can be hierarchical cells, leaf cells, HDL blocks, register signals of a Verilog always block, or the name of a list of retention elements.

-save_signal {*save_signal* *save_sense*}

Specifies the name and active logic state of an existing port, pin, or net that controls saving data into the retention elements before power-down. The logic state can be either **low** or **high**.

-restore_signal {*restore_signal* *restore_sense*}

Specifies the name and active logic state of an existing port, pin, or net that controls restoring data from the retention elements after power-up. The logic state can be either **low** or **high**.

-update

Updates the specification of an existing UPF retention strategy. This option can only update the element list of the strategy.

-use_retention_as_primary

When specified, tool must map the elements of this retention strategy to retention library cell whose output pin is related to retention supply.

In the absence of this option, tool will map the elements of this retention strategy to a retention library cell whose output is related to the primary of the domain.

DESCRIPTION

If the **-no_retention** option is not used, this command defines the UPF retention strategy on the specified power domain, to map the unmapped sequential cells to retention cells.

If the **-no_retention** is used, unmapped sequential cells are mapped to cells that do not have retention functionality. This option is useful for excluding descendant cells from a different retention strategy applied to a hierarchical cell.

If the **-elements** option is not specified, the retention strategy is applied to all the unmapped sequential cells in the power domain. If the **-elements** is specified, the UPF retention strategy is applied to all the unmapped sequential cells that are under the objects from **-elements**.

If neither the **-retention_supply** argument nor **-retention_power_net** or **-retention_ground_net** is specified, the retention power and ground nets are automatically set to the power and ground functions of the **default_retention** supply set handle of the power domain, for which the strategy is being defined.

The **-exclude_elements** list explicitly identifies a set of sequential cells to which this strategy does not apply. The exclude_list might contain hierarchical cells, leaf cells, HDL blocks, register signals of a Verilog always block, or the name of a list of retention elements in the specified domain.

This command specifies the save and restore signals and logical senses of those signals for a specified retention strategy. You can specify each control signal as a port, pin, or net. A port or pin has priority over an identically named net.

The retention signal need not exist in the logical hierarchy where the retention cells are be inserted. The synthesis or implementation tool can perform port-punching to make the connection. Port-punching means automatically creating a port to make a connection from one hierarchical level to the next.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a UPF retention strategy in the specified power domain PD1. Power domain PD1 is defined on instance shutdown_inst.

```
prompt> set_retention retention_1 \
    -domain PD1 \
    -retention_power_net PN1 B \
    -retention_ground_net GN1
```

The following example shows how to define a UPF retention strategy in the objects under the specified power domain:

```
prompt> set_retention retention_2 \
    -domain PD1 \
    -retention_power_net PN1 \
    -retention_ground_net GN1 \
    -elements shutdown_inst/mid_inst
```

The following example shows how to define a UPF retention strategy that excludes register R_reg from retention of its parent cell:

```
prompt> set_retention retention_3 \
    -domain PD1 \
    -no_retention \
    -elements shutdown_inst/mid_inst/R_reg
```

The following example shows how to define a UPF retention strategy using a supply set:

```
prompt> set_retention retention_2 -domain PD1 \
    -retention_supply ret_supply_set \
    -elements shutdown_inst/mid_inst/R_reg
```

The following example shows how a UPF retention strategy can be defined without using a supply set or supply nets.

```
prompt> set_retention retention_2 -domain PD1 \
    -elements shutdown_inst/mid_inst/R_reg
```

The following example shows how to define a UPF retention strategy with the save/restore/retention conditions:

```
prompt> set_retention retention_3 -domain PD1 \
    -elements shutdown_inst/mid_inst/R_reg \
    -save_condition {save_net&&restore_net} \
    -restore_condition {!restore_net} \
    -retention_condition {save_net||restore_net}
```

In the following example, suppose there is a RTL which results in registers with the names mygenblk[0].myblk.myreg_reg and mygenblk[1].myblk.myreg_reg:

```
4 generate for (i=0; i < 2; i = i + 1 ) begin : mygenblk
5   always @(posedge clk or negedge rst) begin : myblk
6     reg myreg;
7     if( !rst ) begin
8       qout = 0;
9       myreg = 0;
10    end
11   else begin
12     qout = myreg;
13     myreg = datain;
14   end
15 end
16 end endgenerate
```

The following example shows how to define a UPF retention strategy for registers using the HDL block name or register signal name:

```
prompt> set_retention retention_4 -domain PD1 \
    -elements mygenblk[*]
prompt> set_retention retention_5 -domain PD1 \
    -elements mygenblk[*].myblk
prompt> set_retention retention_6 -domain PD1 \
    -elements mygenblk[*].myblk.myreg
```

The following example shows how to specify save and restore signals in the **set_retention** command:

```
prompt> set_retention retention_4 -domain PD1 \
    -save_signal {sleep high} \
    -restore_signal {wake_up low} \
    -elements mygenblk[*]
```

The following example shows how to update a UPF retention strategy with new elements:

```
prompt> set_retention retention_1 -domain PD1 \
    -elements {mid_inst_1}
prompt> set_retention retention_1 -domain PD1 \
    -elements {mid_inst_2} -update
```

The following example shows how to exclude a retention cell from the strategy:

```
prompt> set_retention retention_1 -domain PD1 \
    -elements {mid_inst_1}
prompt> set_retention retention_1 -domain PD1 \
    -exclude_elements {mid_inst_1/reg} -update
```

set_retention_elements(2)
```

set_retention_cell

Sets the specified library cells as retention cells.

SYNTAX

```
status set_retention_cell
  cell_name
  [-cell_type retention_type]
  [-retention_pin {pin_name pin_type disable_value}]
```

Data Types

<i>cell_name</i>	string
<i>retention_type</i>	string
<i>pin_name</i>	string
<i>pin_type</i>	string
<i>disable_value</i>	Boolean

ARGUMENTS

cell_name

Specifies the name of the library cell to be defined as a retention cell.

-cell_type *retention_type*

Specifies the type of the retention cell.

-retention_pin {*pin_name* *pin_type* *disable_value*}

Defines the retention pin of the library cell. The valid values for the *pin_type* argument are restore, save, and save_restore. The value values for the *disable_value* argument are 0 and 1.

DESCRIPTION

The **set_retention_cell** command sets the specified library cells as retention cells. You can also specify the retention pin and retention cell type for the retention cell.

EXAMPLES

The following example sets all library cells whose name matches *DRFF* as DRFF retention cells. The retention pin, RETN, is a save-

restore pin and is disabled by a logic 1 value.

```
prompt> set_retention_cell *DRFF* -cell_type DRFF \
           -retention_pin {RETN save_restore 1}
```

SEE ALSO

[report_lib\(2\)](#)
[check_library\(2\)](#)

set_retention_control

Defines the UPF retention control signals for a retention strategy.

SYNTAX

```
status set_retention_control
  retention_strategy
  -domain power_domain
  -save_signal {save_signal save_sense}
  -restore_signal {restore_signal restore_sense}
  [-assert_r_mutex {net_name sense}]
  [-assert_s_mutex {net_name sense}]
  [-assert_rs_mutex {net_name sense}]
```

Data Types

<i>retention_strategy</i>	string
<i>power_domain</i>	string
<i>save_signal</i>	string
<i>save_sense</i>	high low
<i>restore_signal</i>	string
<i>restore_sense</i>	high low
<i>net_name</i>	string
<i>sense</i>	high low

ARGUMENTS

retention_strategy

Specifies the UPF retention strategy name. The retention strategy should already be defined using the **set_retention** command.

-domain *power_domain*

Specifies the power domain where this UPF retention strategy is applied.

-save_signal {*save_signal* *save_sense*}

Specifies an existing port, pin, or net in the design used to save data into the shadow register before power-down; and the logic state of the signal, either **low** or **high**, that causes this action to be taken.

-restore_signal {*restore_signal* *restore_sense*}

Specifies an existing port, pin, or net in the design used to restore data from the shadow register before power-up; and the logic state of the signal, either **low** or **high**, that causes this action to be taken.

-assert_r_mutex {*net_name* *sense*}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the restore signal.

-assert_s_mutex {*net_name* *sense*}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the save signal.

-assert_rs_mutex {net_name sense}

Creates an assertion, which the verification tools can trigger, when the specified RTL signal is active simultaneously with the save or restore signals. If the signal name and value are not specified, it indicates the save and restore signals are mutually exclusive.

DESCRIPTION

This command specifies the save and restore signals and logical senses of those signals for a specified retention strategy. You can specify each control signal as a port, pin, or net. A port or pin has priority over an identically named net.

The retention signal need not exist in the logical hierarchy where the retention cells are be inserted; the synthesis or implementation tool can perform port-punching as needed to make the connection. Port-punching means automatically creating a port to make a connection from one hierarchical level to the next. These punched ports are not considered for isolation or level-shifting, even though after the port creation, these ports reside within the coverage of an isolation or level-shifter strategy. Existing ports, even if they reside on an always-on path, are isolated and level-shifted according to the applicable isolation and level-shifter strategy.

The **-assert_r_mutex**, **-assert_s_mutex**, and **-assert_rs_mutex** options create assertions, which can be used as triggers by the verification and simulation tools. They are read by synthesis and implementation tools, but they are not used by these tools and are not written out by the **save_upf** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define the retention control signals for the retention strategy retention_1 of the power domain PD1.

```
prompt> set_retention_control retention_1 \
-domain PD1 \
-save_signal {sleep high} \
-restore_signal {wake_up low}
```

When the signal called sleep goes high, it saves the data in the retention register for entry into the power-down state. Upon exit from the power-down state, when the signal called wake_up goes low, it restores the data to the retention register. Each signal name can be port, pin, or net.

The following example shows how to define the assertion options for the retention strategy retention_2 of the power domain PD1.

```
prompt> set_retention_control retention_2 \
-domain PD1 \
-save_signal {sleep high} \
-restore_signal {wake_up low} \
-assert_r_mutex {wake_up high} \
-assert_s_mutex {sleep low} \
-assert_rs_mutex {wake_up low}
```

The following example shows how to define the assertion options when the save signal and restore signal are mutually exclusive.

```
prompt> set_retention_control retention_3 \
-domain PD1 \
-save_signal {sleep high} \
-restore_signal {wake_up low} \
```

-assert_rs_mutex {}

SEE ALSO

`map_retention_cell(2)`
`set_retention(2)`

set_retention_control_pins

Converts the retention register library cell attributes in the old library format to the ones that can be used in \$retain flow. The \$retain flow requires retention register library cells to have new retention cell attributes, which is different from the original power gating flow.

SYNTAX

```
status set_retention_control_pins
  [-type style]
  [-power_pin_index power_pin
   | -library_pin library_pin_name]
  [-is_save_pin
   | -is_restore_pin
   | -is_save_restore_pin]
  lib_or_lib_cell_list
```

Data Types

<i>style</i>	string
<i>power_pin</i>	string
<i>library_pin_name</i>	string
<i>lib_or_lib_cell_list</i>	string

ARGUMENTS

-type *style*

Specifies the retention register style.

-power_pin_index *power_pin*

Specifies the power pin index number of the old retention register library pin.

-library_pin *library_pin_name*

Specifies the name of the library pin of the old retention register cell.

-is_save_pin

Assigns the specified power pin index or library pin as a SAVE pin.

-is_restore_pin

Assigns the specified power pin index or library pin as a RESTORE pin.

-is_save_restore_pin

Assigns the specified power pin index or library pin as a SAVE_RESTORE pin.

lib_or_lib_cell_list

Specifies the retention register cell library or a list of library cells to which the new attributes are applied.

DESCRIPTION

The \$retain flow requires retention register library cells to have new retention cell attributes, which is different from the original power gating flow. This command converts the retention register library cell attributes in the old library format to the ones that can be used in \$retain flow.

EXAMPLES

The command should be specified before running the **compile** command. The following example sets the new attributes to the list of specified library cells:

```
prompt>set retain_cell_CLK_LOW_lat \
[get_lib_cell GS60_W_125_1.08_CORE_RET_SNPM.db/RTCLLAH*]

prompt>set retain_cell_CLK_LOW_reg \
[get_lib_cell GS60_W_125_1.08_CORE_NSFLOP_RET_SNPM.db/RTCLDFF*]

prompt>set_retention_control_pins -type CLK_LOW \
-power_pin_index 1 -is_save_pin $retain_cell_CLK_LOW_lat

prompt>set_retention_control_pins -type CLK_LOW -power_pin_index 2 \
-is_restore_pin $retain_cell_CLK_LOW_lat

prompt>set_retention_control_pins -type CLK_LOW -power_pin_index 1 \
-is_save_pin $retain_cell_CLK_LOW_reg

prompt>set_retention_control_pins -type CLK_LOW -power_pin_index 2 \
-is_restore_pin $retain_cell_CLK_LOW_reg
```

SEE ALSO

[set_retention_control_pins\(2\)](#)

set_retention_elements

Creates a named list of elements that can be used in the set_retention command.

SYNTAX

```
status set_retention_elements
      retention_list_name
      -elements objects
```

Data Types

```
retention_list_name   string
objects           list
```

ARGUMENTS

retention_list_name

Specifies name of the retention element list. The name must be unique within the current scope.

-elements *objects*

Specifies the objects that belong to the retention element list. The objects can be hierarchical cells, leaf cells, HDL blocks, or register signals of a Verilog always block. The objects list can include dot ".".

DESCRIPTION

Creates a named list of elements at the current scope. Elements must adhere to the following rules:

- It is an error if an element belonging to the retention element list is not retained when any element in the same list is retained.
- It is an error if an element belonging to the retention element list is not retained when any element in the same power domain extent is retained.
- It is an error to specify **no_retention** constraints on an element belonging to the retention element list.

If dot "." is in the element list, then all the elements in the current scope should adhere to the previously mentioned rules.

NOTE: Specifying **set_retention_elements** does not mandate retaining the elements.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to define a retention element list.

```
prompt> set_retention_elements RET_LIST1 \
-elements shutdown_inst/mid_inst
```

ARGUMENTS

-reroute_clock_shapes true | false

Specifies whether the router can reroute fixed clock wires and vias.

The default is **false**.

-reroute_user_shapes true | false

Specifies whether the router can reroute user-created wires and vias.

The default is **false**.

-plan_group_aware off | all_routing | top_level_routing_only

Specifies whether the plan-group constraints are obeyed during global routing. This parameter does not affect track assignment or detail routing.

The definition for each mode is

- **off** (the default)

The global router ignores plan groups and routes the design flat.

- **all_routing**

The global router routes all nets and preserves the hierarchy and pin constraints for the pin-cutting flow.

- **top_level_routing_only**

The global router preserves the hierarchy and pin constraints, but it ignores intraplan group nets and routes only those nets that have top-level connections. This mode saves CPU time, but might be less accurate because it ignores the congestion due to intraplan group nets.

When you specify a mode other than **off**, the global router gives priority to clock net routing. During floorplanning, you might want to route the clocks flat to generate clock pins on the module boundaries. You should buffer these clocks later in the flow. The clock nets are routed before any other nets so that their pin placement has priority over normal signal pins. Timing and cross talk optimization are not supported when plan group aware routing is active. The "comb" topology for clocks is also unsupported in plan group aware routing.

-reshield_modified_nets off | reshield | unshield

Specifies whether to automatically unshield or reshield modified shielded nets during routing.

The definition for each mode is

- **off** (the default)

The router does not unshield or reshield modified shielded nets.

- **reshield**

The router unshields modified shielded nets, automatically reshields them, and then reconnects the floating shielding. If the router cannot reconnect the floating shielding, it removes it. Shielded nets might have been modified by routing or outside of routing by manual editing, route optimization, and other commands.

- **unshield**

The router deletes existing shielding that is associated with modified shielded nets and reconnects the floating shielding if necessary. The nets might be reshielded at a later stage.

-child_process_net_threshold int

Specifies the minimum number of nets to trigger a separate router process.

The default is -1, which means that the tool decides when to trigger a separate router process based on the number of nets in the design and the peak memory of the parent process when the routing command is run.

-verbose_level int

Sets the verbosity level for the routing log file.

The value range is from 0 to 2.

The default is 0.

-clock_topology normal | comb

Specifies the clock routing topology. Valid values are

- **normal** (default)

Use normal routing for clock nets.

- **comb**

Use comb routing for clock nets with a mesh or trunk.

-comb_distance int

Specifies the number of global routing cells within which to connect clock pins to the clock mesh.

The range is from 0 to 10.

The default is 2.

-pg_shield_distance_threshold distance

Specifies the distance threshold in microns for the router to consider the existing power and ground structure as shielding when calculating the shielding ratio. When a PG wire is within the specified distance, it is counted as a shielding wire.

Note that this option does not change the routing behavior. It affects only the shielding ratio report generated by the **create_zrt_shield** and **report_zrt_shield** commands.

The default distance is 0, which means that the router determines the distance threshold.

-connect_floating_shapes true | false

Specifies whether the router should connect just the pins or the pins and all floating shapes.

When **false** (the default), the router connects just the pins. The router might use the floating shapes; however, it does not have to connect the floating shapes.

When **true**, the router connects the pins and all floating shapes.

-allow_pg_as_shield true | false

Specifies whether the router should treat power and ground nets as shields.

When **true** (the default), the router treats power and ground nets as shields and does not reserve additional space around the nets to be shielded.

If set to **false**, the router tries to reserve space around the nets to be shielded if they are close to a power or ground net.

Note that this option changes the routing behavior.

-rc_driven_setup_effort_level off | low | medium | high

Enables the router to automatically bias layer preference based on RC values for better setup timing.

The default setting is **medium**.

This option takes effect only if timing-driven routing is enabled.

-read_user_metal_blockage_layer true | false

Specifies how the router treats shapes on metal blockage layers.

When **false** (the default), the shapes are ignored.

When **true**, the shapes are honored.

-wide_macro_pin_as_fat_wire true | false

Specifies whether a wide macro pin or pad pin should have an implicit depth the same as its width.

The default value is **false**.

-route_top_boundary_mode stay_half_min_space_inside | stay_inside | ignore

Controls the routing behavior near the top boundary.

The definition for each mode is

- **stay_half_min_space_inside**

The routing must be inside the boundary by half of the minimum spacing.

- **stay_inside** (the default)

The routing must be inside or abut the boundary.

- **ignore**

Wires can extend outside the boundary.

-standard_cell_blockage_as_thin true | false

Specifies whether to treat wide blockages in standard cells as thin wires.

The default is **false**.

-freeze_layer_by_layer_name {{layer true | false}...}

Controls whether routing layers are frozen to prevent them from changing during routing. You must specify the routing layers by using the layer names in the technology file.

This option can be set only after the cell is open.

When **false** (the default), the layer is not frozen.

When **true**, the layer is frozen.

-freeze_via_to_frozen_layer_by_layer_name {{layer true | false}...}

Controls the treatment of vias that touch the specified frozen layers on one side. You must specify the routing layers by using the layer names in the technology file. The specified layers should be frozen layers.

By default, all the frozen layers are set as false, which indicates that the vias whose surroundings on a frozen layer are enclosed by other metal shapes can be removed or rerouted as long as they do not make a change on the frozen metal layer. Special vias such as H-shape vias are not removed or rerouted even though they do not change the frozen metal layer.

When you set this option to **true** on one or more frozen layers, the vias adjacent to these frozen layers are frozen and cannot be changed. Note that no change is allowed on a cut layer adjacent to two frozen metal layers.

-forbid_new_metal_by_layer_name {{layer true | false}...}

Controls whether ECO routing (the **route_zrt_eco** command) can remove, but not add, metal on the specified layers. You must specify the routing layers by using the layer names in the technology file.

Note that for all other routing commands, this option acts the same as the **-freeze_layer_by_layer_name** option and controls whether routing cannot add or remove metal on the specified layers.

When **false** (the default), the router can add or remove metal from the layer.

When **true**, the ECO router can remove, but not add, metal from the layer. The ECO router can remove metal if it is dangling or is not fully contained within fixed user shapes, such as pins. All other routing phases cannot add or remove metal from the layer. If the router adds metal on the layer, and that metal is not fully contained within a fixed user shape, the router reports a "Forbidden metal" DRC violation.

You would use this option if you want to essentially freeze a layer when running core commands, such as **route_opt**, but give the router the flexibility to remove some shapes during ECO routing. If a layer is frozen with the **-freeze_layer_by_layer_name** option, the router cannot touch any shapes, which can result in dangling wires and unfixable shorts if the placement changes during ECO. The **-forbid_new_metal_by_layer_name** option gives the router the flexibility to remove such shapes while otherwise treating the layer as frozen.

If you specify both the **-freeze_layer_by_layer_name** and **-forbid_new_metal_by_layer_name** options, the stricter **-freeze_layer_by_layer_name** option takes precedence.

This option can be set only after the cell is open.

-global_max_layer_mode soft | allow_pin_connection | hard

Controls the application of the maximum routing layer constraint set for the design. This global constraint is set by using the **set_ignored_layers** command.

The definition for each mode is

- **soft** (the default)

Routing above the maximum layer is discouraged, but not disallowed. DRC violations are not flagged on any metal above the maximum layer.

- **allow_pin_connection**

Routing is allowed above the maximum layer only for pin connections. DRC violations are flagged on metal above the maximum layer if the metal is not along a path that connects to a pin. DRC violations are flagged on metal above the maximum layer if the metal is along a path that connects to a pin and the path is long. A path is considered long by the detail router if its length exceeds approximately 10 average track pitches. A path is considered long by the **verify_zrt_route** command if its length exceeds approximately 15 average track pitches.

- **hard**

No routing can occur above the maximum layer. DRC violations are flagged on metal above the maximum layer.

Note that the **-number_of_vias_over_global_max_layer** option can relax the maximum layer constraint, but only for vias.

-global_min_layer_mode soft | allow_pin_connection | hard

Controls the application of the minimum routing layer constraint for the design. This global constraint is set by using the **set_ignored_layers** command.

The definition for each mode is

- **soft** (the default)
Routing below the minimum layer is discouraged, but not disallowed. DRC violations are not flagged on any metal below the minimum layer.
- **allow_pin_connection**
Routing is allowed below the minimum layer only for pin connections. DRC violations are flagged on metal below the minimum layer if the metal is not along a path that connects to a pin. DRC violations are flagged on metal below the minimum layer if the metal is along a path that connects to a pin and the path is long. A path is considered long by the detail router if its length exceeds approximately 10 average track pitches. A path is considered long by the **verify_zrt_route** command if its length exceeds approximately 15 average track pitches.
- **hard**
No routing can occur below the minimum layer. DRC violations are flagged on metal below the minimum layer.

Note that the **-number_of_vias_under_global_min_layer** option can relax the minimum layer constraint, but only for vias.

-ignore_var_spacing_to_blockage true | false

Controls whether the spacing defined in a nondefault routing rule is ignored against blockages.

The default is **false**.

-ignore_var_spacing_to_pg true | false

Controls whether the spacing defined in a nondefault routing rule is ignored against all wires on power and ground nets.

The default is **false**.

-ignore_var_spacing_to_shield true | false

Controls whether the spacing defined in a nondefault routing rule is ignored against shield wires on power and ground nets.

The default is **true**.

This option has no effect if the **-ignore_var_spacing_to_pg** option is **true**.

-min_edge_offset_for_macro_pin_connection_by_layer_name {{layer offset}...}

Specifies the minimum edge offset for macro pin connections for one or more metal layers. The minimum edge for macro pin connection rule enforces exactly aligned connections between metal wires and macro pins where they connect. If the macro pin and wire have different widths, the short edges resulting at the connection point must have at least the specified length.

The settings specified in this option override the **minEdgeOffsetForMacroPinConnection** values specified in the Layer section of the technology file for the specified layers. The technology file values are used for any layers not specified in this option.

-net_max_layer_mode soft | allow_pin_connection | hard

Defines the default mode for the net-based maximum routing layer constraints set by the **set_net_routing_layer_constraints** command. This setting applies only to nets whose maximum routing layer mode is not set by the **set_net_routing_layer_constraints -max_layer_mode** command option.

The definition for each mode is

- **soft**
Routing above the maximum layer is discouraged, but not disallowed. DRC violations are not flagged on any metal above the maximum layer.
- **allow_pin_connection**
Routing is allowed above the maximum layer only for pin connections. DRC violations are flagged on metal above the maximum layer if the metal is not along a path that connects to a pin. DRC violations are flagged on metal above the maximum layer if the metal is along a path that connects to a pin and the path is long. A path is considered long by the detail

router if its length exceeds approximately 10 average track pitches. A path is considered long by the **verify_zrt_route** command if its length exceeds approximately 15 average track pitches.

- **hard** (the default)

No routing can occur above the maximum layer. DRC violations are flagged on metal above the maximum layer.

Note that the **-number_of_vias_over_net_max_layer** option can relax the maximum layer constraint, but only for vias.

-net_min_layer_mode soft | allow_pin_connection | hard

Defines the default mode for the net-based minimum routing layer constraints set by the **set_net_routing_layer_constraints** command. This setting applies only to nets whose minimum routing layer mode is not set by the **set_net_routing_layer_constraints -min_layer_mode** command option.

The definition for each mode is

- **soft** (the default)

Routing below the minimum layer is discouraged, but not disallowed. DRC violations are not flagged on any metal below the minimum layer.

- **allow_pin_connection**

Routing is allowed below the minimum layer only for pin connections. DRC violations are flagged on metal below the minimum layer if the metal is not along a path that connects to a pin. DRC violations are flagged on metal below the minimum layer if the metal is along a path that connects to a pin and the path is long. A path is considered long by the detail router if its length exceeds approximately 10 average track pitches. A path is considered long by the **verify_zrt_route** command if its length exceeds approximately 15 average track pitches.

- **hard**

No routing can occur below the minimum layer. DRC violations are flagged on metal below the minimum layer.

Note that the **-number_of_vias_under_net_min_layer** option can relax the minimum layer constraint, but only for vias.

-net_max_layer_mode_soft_cost low | medium | high

Defines the default cost for routing above the net-based maximum routing layer when using the soft maximum layer mode. This setting applies only to nets whose soft mode maximum routing layer cost is not set by the **set_net_routing_layer_constraints -max_layer_mode_soft_cost** command option.

The default is **medium**.

-net_min_layer_mode_soft_cost low | medium | high

Defines the default cost for routing below the net-based minimum routing layer when using the soft minimum layer mode. This setting applies only to nets whose soft mode minimum routing layer cost is not set by the **set_net_routing_layer_constraints -min_layer_mode_soft_cost** command option.

The default is **medium**.

-extra_preferred_direction_wire_cost_multiplier_by_layer_name {{layer multiplier}...}

Specifies the cost multiplier for routing in the preferred direction for the specified metal layers. You must specify the metal layers by using the layer names in the technology file.

The multiplier value must be between 0.0 and 20.0; it affects the routing cost in the preferred direction as follows:

$$\text{cost} = \text{baseCost} * (1 + \text{multiplier})$$

The default is 0.0.

You can set this option only after opening the top-level design.

-extra_nonpreferred_direction_wire_cost_multiplier_by_layer_name {{layer multiplier}...}

Specifies the cost multiplier for routing in the nonpreferred direction for the specified metal layers. You must specify the metal layers by using the layer names in the technology file.

The multiplier value must be between 0.0 and 20.0; it affects the routing cost in the nonpreferred direction as follows:

```
cost = baseCost * (1 + multiplier)
```

The default is 0.0.

Note that specifying large values can prevent nonpreferred direction routing. If you require nonpreferred direction routing, you should use smaller values.

You can set this option only after opening the top-level design.

-extra_via_cost_multiplier_by_layer_name {{layer multiplier}...}

Specifies the cost multiplier for vias on the specified via layers. You must specify the via layers by using the layer names in the technology file.

The multiplier value must be between 0.0 and 20.0; it affects the via cost as follows:

```
viaCost = baseViaCost * (1 + multiplier)
```

The default is 0.0.

You can set this option only after opening the top-level design.

-extra_via_off_grid_cost_multiplier_by_layer_name {{layer multiplier}...}

Specifies the cost multiplier for vias that are off grid with respect to the specified metal layers. You must specify the metal layers by using the layer names in the technology file.

The multiplier value must be between 0.0 and 20.0; it affects the via cost on the via layers adjacent to the specified metal layers as follows:

```
viaCost = baseViaCost * (1 + multiplier)
```

The default is 0.0.

You can set this option only after opening the top-level design.

-number_of_vias_over_global_max_layer int

Allows the router to use stacked vias to access pins or fixed routes above the global maximum layer. If the global maximum layer mode is set to **soft**, this option is ignored, because in that case access above the maximum layer is allowed.

The value range is between 0 and 15. This value specifies the number of via layers that may be legally traversed to access a pin. For example, if the max layer is M6 and a value of 2 is given, a violation will not be flagged on vias on M6->M7 and M7->M8 if these vias are needed to access pins on layers above the max layer.

The default is 1.

-number_of_vias_under_global_min_layer int

Allows the router to use stacked vias to access pins or fixed routes below the global minimum layer. If the global minimum layer mode is set to **soft**, this option is ignored, because in that case access below the minimum layer is allowed.

The value range is between 0 and 15. This value specifies the number of via layers that may be legally traversed to access a pin. For example, if the min layer is M2 and a value of 1 is given, a violation will not be flagged on any vias on M1->M2 if these vias are needed to access pins on M1.

The default is 1.

-number_of_vias_over_net_max_layer int

Allows the router to use stacked vias to access pins or fixed routes above the net-specific maximum layer. If the net-specific maximum layer mode is set to **soft**, this option is ignored, because in that case access above the maximum layer is allowed.

The value range is between 0 and 15. This value specifies the number of via layers that may be legally traversed to access a pin. For example, if the max layer is M6 and a value of 2 is given, a violation will not be flagged on vias on M6->M7 and M7->M8 if these vias are needed to access pins on layers above the max layer.

The default is 1.

-number_of_vias_under_net_min_layer int

Allows the router to use stacked vias to access pins or fixed routes below the net-specific minimum layer. If the net-specific minimum layer mode is set to **soft**, this option is ignored, because in that case access below the minimum layer is allowed.

The value range is between 0 and 15. For example, if the min layer is M2 and a value of 1 is given, a violation will not be flagged on any vias on M1->M2 if these vias are needed to access pins on M1.

The default is 1.

-via_array_mode off | swap | rotate | all

Specifies the types of rotated via arrays that can be used during signal routing and redundant via insertion when using the default routing rules.

The definition for each mode is

- **off**
Do not rotate or swap via arrays.
- **swap**
Use 1 x N and N x 1 via arrays as rotated equivalent vias.
- **rotate**
Rotate line via arrays instead of swapping row and column numbers.
- **all** (the default)
Use all four possible via arrays.

-post_detail_route_redundant_via_insertion off | low | medium | high

Enables automatic redundant via insertion after each detail routing step.

The default setting is **off**.

If the value is set to **low**, **medium**, or **high**, the tool performs redundant via insertion after each detail routing change, including initial detail routing, ECO routing, and incremental routing. Enabling this option keeps the redundant vias in the design up-to-date with routing changes. The **low**, **medium**, or **high** setting specifies the effort level used for redundant via insertion.

-post_incremental_detail_route_fix_soft_violations true | false

Enables automatic optimization of soft rules that are fixable postroute, after the incremental routing step.

The default setting is **false**.

-concurrent_redundant_via_mode off | reserve_space | insert_at_high_cost

Specifies the concurrent redundant via insertion mode for initial routing.

The valid modes are

- **off** (the default)
Concurrent redundant via insertion is turned off.
- **reserve_space**
Concurrent redundant via insertion reserves space for redundant vias but does not instantiate them. The space reservation is done by generating internal soft rules for redundant vias and performing soft-rule-based optimization. The actual instantiation is done later by explicitly calling the **insert_zrt_redundant_vias** command or by setting the **-post_detail_route_redundant_via_insertion** common Zroute option to a value other than **off**.
- **insert_at_high_cost**
Concurrent redundant via insertion creates hard design rules for redundant vias and tries to insert them. Use this mode if only you need a nearly 100 percent conversion rate. It can lead to very long runtimes if the design is congested or the technology parameters are not friendly to redundant via insertion. This mode should be used with caution.

-concurrent_redundant_via_effort_level low | medium | high

Specifies the effort level for the concurrent redundant via insertion flow.

The default effort level is **low**. The higher effort levels result in a better redundant via conversion rate at the expense of runtime.

This option takes effect only if the **-concurrent_redundant_via_mode** option is set to a value other than **off**.

-eco_route_concurrent_redundant_via_mode off | reserve_space

Specifies the concurrent redundant via insertion mode for ECO routing.

The definition for each mode is

- **off** (the default)
Concurrent redundant via insertion is turned off.
- **reserve_space**
Concurrent redundant via insertion reserves space for redundant vias in ECO routing but does not instantiate them. The space reservation is done by generating internal soft rules for redundant vias and performing soft-rule-based optimization. The actual instantiation is done later by explicitly calling the **insert_zrt_redundant_vias** command or by setting the **-post_detail_route_redundant_via_insertion** common Zroute option to a value other than **off**.

-eco_route_concurrent_redundant_via_effort_level low | medium | high

Specifies the effort level for the concurrent redundant via insertion flow in ECO routing.

The default effort level is **low**. The higher effort levels result in a better redundant via conversion rate at the expense of runtime.

This option takes effect only if the **-eco_concurrent_redundant_via_mode** option is set to a value other than **off**.

-rotate_default_vias true | false

Specifies whether the router can rotate default vias.

The default is **true**.

-route_soft_rule_effort_level off | min | low | medium | high

Specifies the effort level for rip up and reroute to fix soft rule design rule violations.

The definition for each effort level is

- **off**
Does not perform rip up and reroute passes to resolve soft rule design rule violations.
- **min**
Uses the smallest number of rip up and reroute passes to resolve soft rule design rule violations.
- **low**
Uses a small number of rip up and reroute passes to resolve soft rule design rule violations.
- **medium** (the default)
Uses a medium number of rip up and reroute passes to resolve soft rule design rule violations.
- **high**
Treats soft rule design rule violations the same as regular design rule violations during rip up and reroute.

-post_detail_route_fix_soft_violations true | false

Enables automatic optimization of soft rules that are fixable postroute, after the detail routing step.

The default setting is **false**.

-post_eco_route_fix_soft_violations true | false

Enables automatic optimization of soft rules that are fixable postroute, after the ECO routing step.

The default setting is **false**.

-post_group_route_fix_soft_violations true | false

Enables automatic optimization of soft rules that are fixable postroute, after the group routing step.

The default setting is **false**.

-routing_rule_effort_level {{rule {layer {effort_list}}...}...}

Specifies detailed, layer-by-layer effort levels on the various spacings of soft nondefault routing rules. For each nondefault routing rule, you can specify the effort for each spacing value defined for a layer. The rule name corresponds to a previously defined nondefault routing rule. For each layer defined in the **-spacings** option of the **define_routing_rule** command, you specify the effort level for each of the spacings defined for that layer.

The definition for each effort level is

- **low**
Uses a small number of rip up and reroute passes to resolve soft rule design rule violations.
- **med**
Uses a medium number of rip up and reroute passes to resolve soft rule design rule violations.
- **high**
Treats soft rule design rule violations the same as regular design rule violations during rip up and reroute.

For example, suppose you have defined the following two soft routing rules:

```
define_routing_rule soft_rule_1 \
    -spacings {M1 {0.12 0.24 } \
        M2 {0.14 0.28 } \
        M3 {0.14 0.28 } \
        M4 {0.14 0.28 } \
        M5 {0.14 0.28 }} \
    -spacing_weights {M1 {1 0.9 } \
        M2 {1 0.9 } \
        M3 {1 0.9 } \
        M4 {1 0.9 } \
        M5 {1 0.9 }}

define_routing_rule soft_rule_2 \
    -spacings {M1 {0.24 0.36} \
        M2 {0.28 0.42} \
        M3 {0.28 0.42} \
        M4 {0.28 0.42} \
        M5 {0.28 0.42}} \
    -spacing_weights {M1 {0.9 0.8} \
        M2 {0.9 0.8} \
        M3 {0.9 0.8} \
        M4 {0.9 0.8} \
        M5 {0.9 0.8}}
```

You would specify the detailed effort levels for these rules as shown in the following example:

```
set_route_zrt_common_options \
    -routing_rule_effort_level \
    { {soft_rule_1 { {M1 {high med}} \
        {M2 {high med}} \
        {M3 {high med}} \
        {M4 {high med}} \
        {M5 {high med}} \
    } } \
    {soft_rule_2 { {M1 {high med}} \
        {M2 {low high}} \
        {M3 {med high}} \
        {M4 {med high}} \
        {M5 {high high}} \
    } } }
```

}

-soft_rule_weight_to_effort_level_map {{weight_level} {effort_level}}...}

Specifies a global mapping from soft weight level to soft effort level.

The weight level must be one of the following values: low, medium, or high.

The effort level must be one of the following values: off, low, medium, or high.

The definition for each effort level is

- **off** (the default)
Does not perform rip up and reroute passes to resolve soft rule design rule violations.
- **low**
Uses a small number of rip up and reroute passes to resolve soft rule design rule violations.
- **medium**
Uses a medium number of rip up and reroute passes to resolve soft rule design rule violations.
- **high**
Treats soft rule design rule violations the same as regular design rule violations during rip up and reroute.

This mapping is applied whenever soft rules are defined using the **-spacing_weight_levels** option of the **define_routing_rule command**.

Each weight level should appear only once in the map.

The following mappings are not allowed:

- Low weight with medium effort
- Low weight with high effort

For example, suppose you have defined the following mapping:

```
set_route_zrt_common_options \
-soft_rule_weight_to_effort_map \
{ {low low}
  {medium medium}
  {high medium} }
```

This means that

- Soft rules with low weight should use low effort.
- Soft rules with medium weight should use medium effort.
- Soft rules with high weight should use medium effort.

-enforce_voltage_areas off | strict | relaxed

Specifies the level of enforcement of voltage areas.

The definition for each mode is

- **off**
Voltage area constraints are turned off for routing.
- **strict**
Uses strict voltage area constraints for routing.
- **relaxed** (the default)
Uses relaxed voltage area constraints for routing.

-voltage_area_weight {{voltage_area_name} {weight}}...}

Specifies the degree to which routing is discouraged in non-native voltage areas for a given net. Valid weight values are **low**,

medium, and **high**.

The native voltage areas for a net are the voltage areas that contain the ports connected to the net. The router always prefers to route a net in its native voltage area. When the router must route in non-native voltage areas, the higher the weight of the voltage area, the more the router tries to avoid routing in that voltage area.

If you do not specify a weight for a voltage area, it is assigned a default weight of **medium**.

This option is honored only if the **-enforce_voltage_areas** option is set to a value other than **off**.

-single_connection_to_pins connection_mode

Specifies whether the router can connect to a pin only once.

Valid values are **off**, **standard_cell_pins**, **macro_cell_pins**, **top_cell_pins**, **standard_and_macro_cell_pins**, **standard_and_top_cell_pins**, **macro_and_top_cell_pins**, **standard_and_macro_and_pad_cell_pins**, and **all_pins**. If the value is **off**, the router is allowed to connect to a pin any number of times. If the value is **all_pins**, all the pins in the design have the single-connection constraint and the router can connect to any pin only once. The other values specify the subset of pins that have the single-connection constraint.

The default is **off**, except for nets that use a nondefault width routing rule. For those nets, the value is always **all_pins**.

-mark_clock_nets_minor_change true | false

Controls whether changes on clock tree nets are limited during routing.

When **true** (the default), the router can make only limited changes to nets marked as clock tree nets in the database.

When **false**, nets marked as clock tree nets in the database are routed normally (the router can make any changes to these nets).

-track_auto_fill true | false

Specifies whether to fill empty space with routing tracks.

The default is **true**.

-tie_off_mode all | rail_only

Controls whether the router can connect tie-off nets to any power or ground (PG) structures, such as straps, rails, or pins, or only to a PG rail.

The definition for each mode is

- **all** (the default)
Tie-off nets can be connected to any PG structures.
- **rail_only**
Tie-off nets can be connected only to a PG rail.

-connect_within_pins_by_layer_name {{layer mode}...}

Specifies, for each layer, whether to connect to pins by using vias or wires contained within the pin shapes. You must specify the routing layers by using the layer names in the technology file.

This option can be set only when the top cell is open.

The valid mode values are

- **off** (the default)
Connect by using wires or vias anywhere on the pins.
- **via_standard_cell_pins**
Connect to standard cell pins by using vias contained within the pin shapes.
- **via_wire_standard_cell_pins**
Connect to standard cell pins by using vias and wires contained within the pin shapes.
- **via_all_pins**
Connect to any pins by using vias contained within the pin shapes.

- via_wire_all_pins**

Connect to any pin by using vias and wires contained within the pin shapes.

-number_of_secondary_pg_pin_connections int

Specifies the maximum number of secondary power and ground (PG) pins in a cluster.

The definition of a cluster is a set of connected secondary PG pins. Each cluster has one connection with a PG strap or ring. If the value is larger than 0, a cluster should not contain more than the specified number of secondary PG pins.

By default, the setting is 0, which means that there is no maximum.

-separate_tie_off_from_secondary_pg true | false

Specifies whether to separate the tie-off connections from the secondary PG power connections.

By default (**false**), tie-off connections and secondary PG power connections are considered the same nets, so nondefault routing rules, minimum and maximum layer constraints, and other constraints on the net apply to both tie-off connections and secondary PG power connections.

When you separate the tie-off connections from the secondary PG power connections by setting this option to **true**, you can apply nondefault routing rules, minimum and maximum layer constraints, and other constraints only to the secondary PG power connections.

-default true | false

If **true**, this option resets all options to their default values.

The default is **false**.

-shielding_nets pg_net_names

Specifies the power and ground nets to be used for shielding by the **create_zrt_shield** command.

When routing signal nets, if the **-allow_pg_as_shield** option is **true** (the default), the router tries to route the shielded nets adjacent to any of the specified power and ground nets while considering other routing metrics such as congestion and wire length.

If the **-allow_pg_as_shield** option is **false**, this option has no effect.

If you do not specify this option, by default, the **create_zrt_shield** command uses the ground net for shielding.

You can also specify the power or ground net used for shielding by using the **-with_ground** option with the **create_zrt_shield** command; however, this option supports only a single power or ground net.

If you specify both the **-shielding_nets** option and the **create_zrt_shield -with_ground** option, the tool issues a warning message and uses the **-shielding_nets** setting.

-report_local_double_pattern_odd_cycles true | false

Controls whether local double pattern odd cycles are reported.

For double-patterning technology designs, a mask is split into two masks for lithography success. To check whether a mask can be split into two masks, the tool creates double-pattern links between any two polygons whose distance is smaller than the double-pattern spacing defined in technology file. A cycle is formed when a set of polygons is connected in a ring topology by double-pattern links.

A double-pattern odd cycle is a cycle that consists of an odd number of double-pattern links. Double-pattern odd cycles must be avoided or fixed because they prevent the mask from splitting into two masks. A local double-pattern odd cycle is a double-pattern odd cycle that is contained in a bounding box that is 20 global routing cells high by 20 global routing cells wide.

By default (**false**), Zroute does not report local double-pattern odd cycles.

When this option is **true**, Zroute reports local double-pattern odd cycles that are caused by signal detail routes. Zroute does not report local double-pattern cycles that contain only shapes that cannot be changed by Zroute. For example, Zroute does not report a local double-pattern odd cycle that contains only PG preroutes, pins, and standard-cell obstacles.

To check for local double-pattern odd cycles, use the **verify_zrt_route** command. This command guarantees the reporting of local double-pattern odd cycles when this option is **true**. Note that the **route_zrt_detail** command and other routing commands do not

guarantee the reporting of double-pattern odd cycles.

-wire_on_grid_by_layer_name {{layer true | false}...}

Controls whether wires must be routed on-grid. This option controls the same functionality as the **onGrid** attribute for a metal layer in the technology file.

If you use this option, the tool ignores all **onGrid** or **onWireTrack** attributes defined in the technology file (both for metal layers and via layers). The default setting for any unspecified **onGrid** attributes is **false**; therefore, on-grid routing is required only for the metal layers specified with a setting of **true** in this option and via layers specified with a setting of **true** in the **-via_on_grid_by_layer_name** option.

-via_on_grid_by_layer_name {{layer true | false}...}

Controls whether the vias and their associated via enclosures must be routed on-grid. This option controls the same functionality as the **onGrid** attribute for a via layer in the technology file.

If you use this option, the tool ignores all **onGrid** or **onWireTrack** attributes defined in the technology file (both for metal layers and via layers). The default setting for any unspecified **onGrid** attributes is **false**; therefore, on-grid routing is required only for the via layers specified with a setting of **true** in this option and metal layers specified with a setting of **true** in the **-wire_on_grid_by_layer_name** option.

-min_shield_length_by_layer_name {{layer length}...}

Specifies the minimum shielded length in microns on each layer for the router to skip shielding the net wires with lengths less than these values. Since these wires are always unshielded, after shield creation of the net, when reporting shielding ratio in **create_zrt_shield** and **report_zrt_shield** commands, these wires are not counted.

The default length for each layer is 4-layer-pitch. Using -1 could set it back to the default value while a layer value has been set.

DESCRIPTION

The **set_route_zrt_common_options** command sets Zroute options that are common to global routing, track assignment, and detail routing. The settings are saved with the design.

Note:

Hardcoded layer name strings are no longer supported. If the option settings saved with a design use hardcoded layer name strings, these option settings are not honored. You must reset these options using the layer names from the technology file instead of the hardcoded layer name strings.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-enforce_voltage_areas** option to **off**.

```
prompt> set_route_zrt_common_options -enforce_voltage_areas off
```

The following example sets the **-threshold_noise_ratio** option to 0.2.

```
prompt> set_route_zrt_common_options -threshold_noise_ratio 0.2
```

The following example sets the **-freeze_layer_by_layer_name** option to **true** for m3 and m4. Here "m3" and "m4" are the layer names in the technology file for metal3 and metal4.

```
prompt> set_route_zrt_common_options \
    -freeze_layer_by_layer_name {{m3 true} {m4 true}}
```

The following example sets the **-clock_topology** option to **comb**.

```
prompt> set_route_zrt_common_options -clock_topology comb
```

The following example sets the extra via cost multiplier to 0.5 on the VIA12 layer and to 1.5 on the VIA23 layer.

```
prompt> set_route_zrt_common_options \
    -extra_via_cost_multiplier_by_layer_name {{VIA12 0.5} {VIA23 1.5}}
```

If the technology file defines the VIA12 via layer between the M1 and M2 metal layers and the VIA23 via layer between the M2 and M3 metal layers, the following example sets the extra off-grid via cost multiplier on the VIA12 and VIA23 layers to 0.5. Note that you specify the metal layer, but the multiplier is set on the adjacent via layers.

```
prompt> set_route_zrt_common_options \
    -extra_via_off_grid_cost_multiplier_by_layer_name {{M2 0.5}}
```

set_route_zrt_global_options

Sets the options for Zroute global routing.

SYNTAX

```
status set_route_zrt_global_options
[-exclude_blocked_gcells_from_congestion_report true | false]
[-layer_based_congestion_map true | false]
[-timing_driven true | false]
[-timing_driven_effort_level low | medium | high]
[-crosstalk_driven true | false]
[-double_pattern_utilization_by_layer_name {{layer int}...}]
[-effort minimum | low | medium | high | ultra]
[-force_full_effort true | false]
[-extra_blocked_layer_utilization_reduction int]
[-macro_boundary_track_utilization int]
[-macro_boundary_width int]
[-macro_corner_track_utilization int]
[-voltage_area_corner_track_utilization int]
[-default true | false]
[-auto_gcell true | false]
```

Data Types

int integer

ARGUMENTS

-exclude_blocked_gcells_from_congestion_report true | false

Controls whether blocked global routing cells (gcells) are included in the overflow percentage calculation.

By default (**false**), the total number of global routing cells is used to calculate the overflow percentages in the congestion report.

If the option is set to **true**, the overflow percentage calculation excludes the global routing cells that are blocked for routing. In cases where the global router has to route through blocked global routing cells to find a solution, those global routing cells are counted in the overflow number, but not in the total number.

-layer_based_congestion_map true | false

Controls whether layer-based congestion maps are created.

By default (**true**), both layer-based and aggregate congestion maps are created.

If the option is set to **false**, only an aggregate congestion map is created to reduce the storage requirements.

-timing_driven true | false

Enables (true) or disables (false) timing-driven global routing.

The default is false.

-timing_driven_effort_level low | medium | high

Specifies the effort level for the timing-driven flow. The effort levels trade off between timing QoR and DRC convergence, with the high effort level emphasizing timing QoR and the low effort level emphasizing DRC convergence.

This option takes effect only if the **-timing_driven** option is set to **true**.

The default is **high**.

-crosstalk_driven true | false

Enables (true) or disables (false) crosstalk-driven global routing.

The default is **false**.

-double_pattern_utilization_by_layer_name {{layer int}...}

Specifies the double pattern (DPT) utilization percentage for each layer. Specify the layers by using the layer names from the technology file.

The range for the utilization percentage is from 0 to 100.

The default is 80 for M1 and M2, 85 for M3, and 90 for any higher DPT layers. The value is 100 for non-DPT layers.

-effort minimum | low | medium | high | ultra

Specifies the global routing effort.

Valid values are

- **minimum**

Very fast run time. Runs a maximum of two phases.

- **low**

Fast run time. Runs a maximum of three phases.

- **medium** (default)

Medium run time. Runs a maximum of four phases.

- **high**

Slow run time, but better quality of results. Runs a maximum of five phases.

- **ultra**

Slower run time. Use on really congested designs. Runs a maximum of seven phases.

-force_full_effort true | false

Forces the maximum number of phases specified by the **-effort** option to try to achieve better results with longer runtime.

By default (**false**), the global router might stop before the maximum number of iterations, based on the incremental congestion reduction.

If set to **true**, the global router always performs the maximum number of routing phases, based on the specified effort level. For example, if this option is set to **true** and the **-effort** option is set to **high**, the global router always runs five routing phases.

-extra_blocked_layer_utilization_reduction int

Specifies the percentage of additional utilization to be reduced for areas where either the upper or lower layer is blocked and switching to the opposite layer would take more than one track resource.

The range is from 0 to 100.

The default is 0.

-macro_boundary_track_utilization int

Specifies the percentage of tracks to be used along macro boundaries.

The range is from 0 to 100.

The default is 100.

-macro_boundary_width *int*

Specifies the width of the macro boundary in terms of global route cells.
The range is from 0 to 10.

The default is 5.

-macro_corner_track_utilization *int*

Specifies the percentage of tracks to be used along macro corners.
The range is from 0 to 100.

The default is 100.

-voltage_area_corner_track_utilization *int*

Specifies the percentage of tracks to be used in the region within five global routing cells of a voltage area corner.

A smaller utilization reduces the number of global routes that can go through a global routing cell by artificially setting the congestion in that area higher. If the neighboring global routing cells have lower congestion, the routing might be pushed to them; however, this is a function of many other metrics in the global router.

This option has an effect only if the **enforce_voltage_areas** common route option is set to **strict**.

The range is from 0 to 100.

The default is 100.

-default true | false

Resets all options to their default values when set to true.

The default is false.

-auto_gcell true | false

When set to true, automatically increases gCell size when cell row height is too small. This option is default off as it is recommended for lower technology nodes.

The default is false.

DESCRIPTION

The **set_route_zrt_global_options** command sets the options for Zroute global routing. These settings affect all commands that perform Zroute global routing.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the **-timing_driven** option to **true**.

```
prompt> set_route_zrt_global_options -timing_driven true
```

The following example sets the **-double_pattern_utilization_by_layer_name** option on M1, M2, and M5.

```
prompt> set_route_zrt_global_options \
    -double_pattern_utilization_by_layer_name { {M1 85} {M2 85} {M5 70} }
```

The following example sets the **-auto_gcell** option to true.

```
prompt> set_route_zrt_global_options -auto_gcell true
```

SEE ALSO

[report_route_zrt_global_options\(2\)](#)

set_rp_group_options

Sets relative placement group attributes on the specified relative placement groups.

SYNTAX

```
collection set_rp_group_options
  rp_groups
    [-alignment bottom-left | bottom-pin | bottom-right]
    [-pin_align_name pin_name]
    [-utilization percentage]

    [-y_offset float]
    [-group_orient default | N | FN | S | FS]
    [-cell_orient_opt]
    [-auto_blockage]
    [-disable_buffering]
    [-cts_option fixed_placement | size_only]
    [-route_opt_option fixed_placement | in_place_size_only]
    [-psynopt_option fixed_placement | size_only | all_optimization]
    [-move_effort low | medium | high]
    [-allow_keepout_over_tapcell false | true]
    [-allow_non_rp_cells]
    [-place_around_fixed_cells standard | physical_only | all | none]
    [-anchor_corner bottom-left | bottom-right | top-left | top-right | rp-location [-anchor_row integer] [-anchor_column integer]]
    [-placement_type bit_slice | compression | vertical_compression]
    [-ignore_rows ignore_row_names_list]
    [-max_rp_width float]
    [-max_rp_height float]
```

Data Types

<i>rp_groups</i>	list or collection
<i>pin_name</i>	string
<i>percentage</i>	float
<i>float</i>	percentage
<i>ignore_row_names_list</i>	list of strings

ARGUMENTS

rp_groups

Specifies the relative placement groups for which you want to change the attributes. This is a required argument.

-alignment bottom-left | bottom-pin | bottom-right

Specifies the default alignment method to use when placing leaf cells and relative placement groups in the specified relative placement groups. If you do not specify this option, the tool uses bottom-left alignment.

You can override the default alignment method for a specific leaf cell or relative placement group when you add it to a relative

placement group (by using the **add_to_rp_group** command).

-pin_align_name pin_name

Specifies the default alignment pin for the specified relative placement groups. During placement, the tool uses the alignment pin's location to align the cells within a column when you use the bottom-pin alignment type.

You can override the alignment pin for a specific leaf cell when you add the cell to the group (by using the **add_to_rp_group** command).

-utilization percentage

Specifies the utilization percentage to use for placement of the specified relative placement groups. Utilization is represented as a floating-point number between 0.0 (representing 0%) and 1.0 (the default, representing 100%).

-ignore

Indicates that the tool is to ignore the specified relative placement groups during placement and not treat them as relative placement groups. Instead, the tool places all of the group's parts individually, as it would normally do when there is no relative placement.

-x_offset float

Specifies a left coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area for top-level relative placement group. It is ignored for a lower-level relative placement group. Specifying only an x-offset allows a group to slide in the y-direction.

-y_offset float

Specifies a lower coordinate (anchor) for the group, in microns, relative to the lower-left corner in the core area for top-level relative placement group. It is ignored for a lower-level relative placement group. Specifying only a y-offset allows a group to slide in the x-direction.

-group_orient default | N | FN | S | FS

Specifies the orientation of a relative placement group.

If this value is not specified or is specified as **default** for any relative placement group, the tool chooses a suitable orientation for that relative placement group.

-cell_orient_opt

Applies automatic orientation on the cells in a relative placement group for optimizing wirelength.

-auto_blockage

Disallows buffer insertion inside the area of relative placement groups.

-disable_buffering

Disallows buffer insertion on nets within relative placement groups.

-cts_option fixed_placement | size_only

Specifies how to treat the cells in the relative placement group during clock tree synthesis and clock tree optimization.

If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during **compile_clock_tree**, **optimize_clock_tree**, and **clock_opt** activity and cannot be sized or moved.

If you specify **size_only**, the cells in the relative placement group can only be sized. This option is applies to the **compile_clock_tree**, **optimize_clock_tree**, and **clock_opt** commands.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-route_opt_option fixed_placement | in_place_size_only

Specifies how to treat the cells in the relative placement group during **route_opt** and **psynopt on_route**.

If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during the **route_opt** and **psynopt -on_route** commands and cannot be sized or moved.

If you specify **in_place_size_only**, sizing changes are constrained for minimal engineering change order (ECO) placement changes. For example, a cell is sized to improve timing or design rule costs only if the newly-sized cell can fit into any available space adjacent to the original cell location. The resulting transformation is verified to ensure it is legal.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-psynopt_option fixed_placement | size_only | all_optimization

Specifies how to treat the cells in the relative placement group during **psynopt** and **place_opt**.

If you specify **fixed_placement**, the cells in the relative placement group are treated as fixed during physical optimization and cannot be sized or moved. This value is not recommended for **place_opt**.

If you specify **size_only**, the cells in the relative placement group can only be sized.

If you specify **all_optimization**, all the preroute optimization capabilities can be applied to cells in the relative placement group. This might result in losing some cells from the relative placement group because cells can be decomposed or deleted from the netlist.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups. The top-level value is propagated to the hierarchical relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-move_effort low | medium | high

Controls the extent to which a relative placement group can be moved from its initial location to preserve the relative placement without violating relative placement constraints.

The size of the region searched for placement of a relative placement group is progressively reduced as you reduce the effort from high to medium to low.

Coarse placement estimates an initial location for every top-level relative placement group. If those groups are placed at the same locations returned by coarse placement, the relative placement groups might need to be broken, which would violate the relative placement constraints for those groups.

Specifying high effort allows the higher movement of a relative placement group from its initial location in search of a location compared to low and medium effort, to maintain the relative placement constraints and potentially avoid breaking the relative placement group. The tradeoff for maintaining the relative placement group is a potential loss of QoR, because the group is moved from the location initially determined by coarse placement.

Specifying low effort indicates that the relative placement group is placed as close as possible to the initial location returned by coarse placement. The tradeoff for maintaining the location is a higher potential for breaking the relative placement groups and violating the relative placement constraints for some relative placement groups.

This option is not supported in Design Compiler topographical mode and will be ignored.

-allow_keepout_over_tapcell false | true

Specifies that the hard keepout in the relative placement group should be overlapped with tap cells if needed. By default, the value is false.

This option is not supported in Design Compiler topographical mode and will be ignored.

-allow_non_rp_cells

Specifies to allow nonrelative placement cells in the unused area of relative placement groups during **place_opt** and **refine_placement**.

-place_around_fixed_cells standard | physical_only | all | none

Specifies how to treat fixed cells in the floorplan during legalization of relative placement groups.

If you specify **standard**, the relative placement groups are legalized around fixed standard cells and the legalization engine avoids fixed physical-only cells.

If you specify **physical_only**, the relative placement groups are legalized around fixed physical-only cells, and the legalization engine avoids fixed standard cells.

If you specify **all**, the relative placement groups are legalized around both fixed standard and fixed physical-only cells.

If you specify **none**, the legalization engine avoids both fixed standard and fixed physical-only cells during legalization of relative placement groups.

The default of the option is **all**.

This option applies to top-level relative placement groups only and is ignored for hierarchical relative placement groups.

-anchor_corner bottom-left | bottom-right | top-left | top-right | rp-location

Specifies the corner for the anchor point that is set by using the **-x_offset** and **-y_offset** options.

If you specify **bottom-left** (the default), the anchor point corner is the lower-left corner of the relative placement group.

If you specify **bottom-right**, the anchor point corner is the lower-right corner of the relative placement group.

If you specify **top-left**, the anchor point corner is the upper-left corner of the relative placement group.

If you specify **top-right**, the anchor point corner is the upper-right corner of the relative placement group.

If you specify **rp-location**, the anchor point corner is the starting location of object at the row and column specified by the **-anchor_row** and **-anchor_column** options. When you specify **rp-location**, the **-anchor_row** and **-anchor_col** options are required and the specified location must not be empty.

This option applies to top-level relative placement groups only and is ignored for hierarchical relative placement groups. When you specify **-anchor_corner bottom-right**, the relative placement group is anchored at the bottom-right corner at the specified x- and y-coordinates during legalization.

When many blockages are present, a slight deviation from the anchor point might occur.

-anchor_row integer

Specifies the row of the object for which the **-anchor_corner rp-location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp-location** option and is not accepted for other values of the **-anchor_corner** option.

-anchor_column integer

Specifies the column of the object for which the **-anchor_corner rp-location** option is specified.

Note that this option is applicable only to the **-anchor_corner rp-location** and is not accepted for other values of the **-anchor_corner** option.

-placement_type bit_slice | compression | vertical_compression

Specifies how to place cells in relative placement groups. The default is **bit_slice**.

When you specify the **bit_slice** keyword, the next row starts after the tallest object in the row and the next column starts after the widest object in the column. Both the row and column alignments are preserved.

When you specify the **vertical_compression** keyword, columns are compressed such that no gap is between leaf cells, lower-level hierarchical relative placement groups, and keepouts in a column. Row alignment is not preserved.

When you specify the **compression** keyword, rows are compressed such that no gap is between leaf cells, lower-level hierarchical relative placement groups, and keepouts in a row. Column alignment is not preserved. If you set the **-alignment** option to **bottom-right** or **bottom-pin** and set this option to **compression**, then **compression** is ignored and **alignment** is respected.

If both the **-utilization** and **-placement_type compression** options are specified, the utilization constraints are observed with gaps

between leaf elements in a relative placement row.

The setting of this option does not propagate to child relative placement groups.

-ignore_rows *ignore_row_names_list*

Specifies the site rows that must be ignored for the relative placement group cells.

To ignore site rows during relative placement, you must first define the **rp_ignore_row_name** attribute on the site rows to be ignored. The *ignore_row_names_list* argument is a list that includes the **rp_ignore_row_name** attribute value for each site row to be ignored.

This option applies only to top-level relative placement groups and is ignored for hierarchical relative placement groups.

-max_rp_width *float*

Specifies the maximum allowable width in microns for the top-level relative placement groups. It is ignored for the lower-level relative placement groups. If you specify this option, the tool tries to restrict the width of the top-level relative placement groups to the specified maximum value during **psynopt**, **place_opt** and **route_opt**.

-max_rp_height *float*

Specifies the maximum allowable height in microns for the top-level relative placement groups. It is ignored for the lower-level relative placement groups. If you specify this option, the tool tries to restrict the height of the top-level relative placement groups to the specified maximum value during **psynopt**, **place_opt** and **route_opt**.

DESCRIPTION

The **set_rp_group_options** command sets the attributes of the specified relative placement groups. The same attributes can be set during the creation of the relative placement groups by using the **create_rp_group** command. This command is supported only for designs that do not contain multiply-instantiated designs.

This command returns a collection containing the relative placement groups for which the attributes have changed. If attributes have not changed for any object, the empty string is returned.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **set_rp_group_options** command to change the attributes for a relative placement group.

```
prompt> set_rp_group_options ripple::grp_ripple \
    -utilization 0.95 -ignore
{ripple::grp_ripple}

prompt> define_user_attribute \
    -type string -class site_row rp_ignore_row_name
prompt> set_attribute [get_site_rows STD_ROW_112] \
    rp_ignore_row_name clock
prompt> set_rp_group_options d::rp -ignore_rows {clock}
```

`write_rp_groups(2)`

set_rtl_load

Sets an RTL load value for capacitance and resistance on pins, ports, and nets.

SYNTAX

```
status set_rtl_load
  [-min]
  [-max]
  pin_net_list
  [-capacitance cvalue]
  [-resistance rvalue]
```

Data Types

<i>pin_net_list</i>	list
<i>cvalue</i>	float
<i>rvalue</i>	float

ARGUMENTS

-min

Specifies that the load value is to be used for minimum delay analysis. If no minimum load value is specified, the maximum value is used. If neither **-min** nor **-max** are specified, the load values are used for both minimum and maximum delay calculations.

-max

Specifies that the load value is to be used for maximum delay analysis. If no value is specified for maximum analysis on a net, the minimum value is used. If neither **-min** nor **-max** are specified, the load values are used for both minimum and maximum delay calculations.

pin_net_list

Specifies a list of ports, pins, and nets in the current design on which the RTL loads are set.

-capacitance *cvalue*

Specifies the capacitance value with which to set the RTL load value on the pins, ports, and nets contained in *pin_net_list*. The *cvalue* must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies capacitance values in picofarads, *cvalue* must also be expressed in picofarads. If *cvalue* is not specified, it remains unchanged from any previous setting. If *cvalue* is never set, the value defaults to zero. You must specify either **-capacitance** or **-resistance**, and you can specify both.

When *cvalue* is set on a net, the capacitance is split equally among the sticky pins of that net. For more information about sticky pins, see the "Sticky Pins and RTL Load on Nets" subsection below.

-resistance *rvalue*

Specifies the resistance value with which to set the RTL load value on the ports, nets, or pins contained in *pin_net_list*. The *rvalue* must be expressed in units consistent with the technology library used during optimization. For example, if the technology library specifies resistance values in Kohms, *rvalue* must also be expressed in Kohms. If *rvalue* is not specified, it remains unchanged

from any previous setting. If *rvalue* is never set, the value is calculated based on the specified capacitance value. For more information, see the "Calculation of Wire Delays and Capacitances" subsection below. You must specify either **-capacitance** or **-resistance**, and you can specify both.

When *rvalue* is set on a net, the resistance value is assigned to all sticky pins of that net. This is not the same method used to distribute *cvalue* on a net. For more information about sticky pins, see the "Sticky Pins and RTL Load on Nets" subsection below.

DESCRIPTION

The **set_rtl_load** command overrides the calculation of wire characteristics during RTL level synthesis and other early phases of synthesis. By default, the **compile** command uses wire load models (WLMs) to calculate both the total capacitance and the time-of-flight delay of a wire. When **set_rtl_load** values are specified for particular pins, ports, or nets, the default WLM calculation is replaced by a detailed RC calculation.

Apply **set_rtl_load** only to sticky pins, or nets attached to sticky pins. For information about sticky pins, see the "Sticky Pins and RTL Load on Nets" subsection below.

The **set_rtl_load** command values are ignored during the later stages of synthesis that include the **reoptimize_design** command, because the placement-based wire capacitance and delay calculations of these commands are more accurate than the **set_rtl_load** values.

Sticky Pins and RTL Load on Nets

Annotating capacitance and resistance values on a design at the RTL level can be difficult. The objects to which you want to annotate might not exist before the first compile. Moreover, compile optimization could change or delete an object you want to annotate. The **set_rtl_load** command circumvents this problem by defining the concept of "sticky pins". Sticky pins are pins (or ports) of your design that are guaranteed to be persistent throughout the early stages of optimization. Therefore, annotated capacitance and resistance can stick to these pins and not be lost. You can apply **set_rtl_load** only to sticky pins.

A sticky pin is defined as one of the following:

- A top-level port of your design
- A pin of a hierarchical block
- A pin of a cell marked with the **dont_touch** attribute
- A pin of a cell marked with the **size_only** attribute
- A pin of a black-box cell (has a 'b' attribute **inreport_cell**)
- A pin connected to a net marked with the **dont_touch** attribute.

Applying **set_rtl_load** to a net is shorthand for applying **set_rtl_load** to the sticky pins of the net. For example, consider a net that is connected to a top-level port, the pin of a RAM that is a black box, two hierarchical pins, and two leaf cells that are not marked with the **dont_touch** attribute. This net is connected to four sticky pins and two non-sticky pins. If the specified RTL load capacitance for the net is 4, the capacitance is distributed equally, with 1 to each of the four sticky pins.

If an RTL load resistance is specified for the net, that resistance is assigned to each of the four sticky pins. For example, if the specified resistance is 3, each of the sticky pins is assigned an RTL load resistance of 3.

If you want more detailed control of the assignment of RTL load capacitance and resistance on a net, assign values to each pin individually.

Calculation of Wire Delays and Capacitances

When **set_rtl_load** is in use, wire load models are switched off for the annotated wire. Instead, the values are calculated with a hybrid of annotated RTL loads and wire load models.

The total capacitance of a wire is needed in the delay calculation of the wire's driving cell. The wire capacitance is calculated as the sum of all annotated RTL load capacitances of the wire, plus an extra capacitance to account for the wiring required to connect to any nonannotated pin. For the example net with four annotated sticky pins, two hierarchy blocks, and two other leaf pins, the wire's total capacitance is the sum of the following:

- The total annotated RTL load capacitance on the four sticky pins
- The WLM calculation of the wire capacitance needed to connect the two nonsticky pins
- The WLM calculation of the wire capacitance needed to connect any nonannotated pins within the subhierarchy of the top-level block.

One implication of the method by which capacitances are calculated is that setting an RTL load capacitance is not strictly an additive process. If a net's capacitance as calculated by wire load models is 2.0, and you set an RTL load capacitance of 1.0 on the net, the resulting capacitance could be more or less than 3.0. If you intend to use **set_rtl_load** to obtain a particular fixed capacitive value, see the "Layout-based Annotation" subsection below.

The time-of-flight delay on a wire that has RTL loads is calculated in two phases: first, an RC network that represents the wire is built; second, Elmore delay calculation is applied to the RC network. The RC network is built as follows:

- Any leaf-level pin or top-level port that has an annotated RTL load is given an RC segment that is connected to that pin or port. The capacitance and resistance values of the RC segment are taken from the **set_rtl_load** values.
- Any hierarchy pin that has an annotated RTL load is given an RC segment. The capacitance and resistance values of the RC segment are taken from the **set_rtl_load** values. Wire segments within the hierarchy block are placed on one side of the pin's RC segment. Wire segments outside the hierarchy block are placed on the other side of the pin's RC segment. In this way, annotated hierarchy pins segment the wire into two parts.
- Any leaf-level pin that does not have an annotated RTL load is connected into the RC network at the appropriate hierarchy level. The capacitance and resistance of the connection is calculated using the wire load model for that hierarchy level. For example, if 3 nonannotated pins are connected to the network at the top level, the connection capacitance and resistance are calculated using the top-level wire load model for 3 connections.

Default Resistance Values

It is not necessary to specify resistance values directly to the **set_rtl_load** command. Instead, **set_rtl_load** can calculate the resistance value as a constant factor times capacitance. You determine the constant factor by setting the **rtl_load_resistance_factor** variable to the required value. The default is 0.0. For example, if you set the **rtl_load_resistance_factor** variable to 0.5, specify the RTL load capacitance of a pin as 4, and do not specify the RTL load resistance, **set_rtl_load** calculates the RTL load resistance to be 2. The factor is applied to each annotated pin of a net individually, not to the net's capacitance as a whole. The default library units are used throughout.

Reporting and Resetting RTL Load Values

Use one of the following to display a report of the current value of RTL load values on cells or nets:

```
prompt> report_cell -connections cells
prompt> report_net -connections -verbose nets
```

Use the **write_rtl_load** command to display all RTL load information in the current design.

Remove RTL load annotations using the **remove_rtl_load** command. The **reset_design** command removes all attributes from a design, including load annotations placed by **set_rtl_load**.

Layout-based Annotation

RTL loads are intended to be used for annotation of physical interconnect information, such as RC values derived from top-level floorplans. Unlike the traditional layout-based annotation commands (**set_load** for nets, **read_sdf** and **set_annotated_delay**), RTL loads can be used at the RTL level and for preplaced designs. However, RTL loads are not a replacement for the traditional layout-based commands. The **reoptimize_design** command has sophisticated algorithms to incrementally update annotated capacitances and delays from the traditional layout-based commands as layout-based optimization proceeds. RTL load values are fixed. Thus, in the **reoptimize_design** and **report_timing** commands, annotations from **set_load** for nets, **read_sdf** and **set_annotated_delay** override any calculation based on RTL loads.

It is possible that your design methodology can generate early place and route results that are available before your RTL synthesis is finalized. Use current information from the layout to obtain RTL load annotation for the next pass of RTL synthesis using the **calculate_rtl_load** command. The **calculate_rtl_load** command converts back-annotated layout information from **set_load** for nets, **read_sdf**, and **set_annotated_delay** to RTL load values suitable for RTL level optimization. A typical sequence of commands is shown in the following script example:

```
/* Load your currently placed netlist */
read my_netlist.db
/* Annotate capacitance and delay information from placement */
read_sdf my_delays.sdf
include my_set_load_info.scr

/* Generate RTL load information for selected nets
 * and save the result
 */
calculate_rtl_load -cap -delay [get_nets *]
calculate_rtl_load -cap -delay [get_pins my_ram/*]
write_rtl_load -output my_rtl_load.scr

/* Apply the RTL loads to the RTL design and compile */
remove_design -designs
read my_rtl.db
include my_rtl_load.scr
compile
```

For more information, see the man page for the **calculate_rtl_load** command.

There are some caveats associated with the use of **calculate_rtl_load**. Use **set_rtl_load** and **calculate_rtl_load** only on nets that are predictably long. This includes nets that cross between floorplan blocks or nets that connect to large macro blocks. Do not use **set_rtl_load** and **calculate_rtl_load** for nets that occur deep in a physical hierarchy. Unlike the traditional layout-based annotation commands, which are kept up-to-date by **reoptimize_design**, RTL loads do not change if the layout changes. Deep in the physical hierarchy, a net that is long in one iteration of placement is not guaranteed to be long in the next iteration. Synthesis results could degrade if unreliable RTL loads are annotated onto the design.

EXAMPLES

The following example sets an RTL load capacitance of 4 on each of the specified pins and ports. The RTL load resistance is left as its default value.

```
prompt> set_rtl_load -cap 4 {my_port my_ram/ADDR[*]}
```

The following example sets maximum and minimum RTL load values on a pin:

```
prompt> set_rtl_load -max -cap 4 -res 0.5 my_hier/SIG1
```

```
prompt> set_rtl_load -min -cap 3 -res 0.0 my_hier/SIG1
```

The following example splits an RTL load capacitance of 4 across the sticky pins of a net, then assigns a resistance of 0.5 to each sticky pin.

```
prompt> set_rtl_load -cap 4 my_hier/net1
```

```
prompt> set_rtl_load -res 0.5 my_hier/net1
```

set_safety_core_rule

Associates the cores with the rule.

SYNTAX

```
status set_safety_core_rule
    -rule rule_name
    -error_signal pin_or_port
    [-split_pins pin_names]
    -cores core_list
```

Data Types

<i>pin_or_port</i>	object
<i>pin_names</i>	list
<i>core_list</i>	collection

ARGUMENTS

-rule *rule_name*

Specifies the name safety_core_rule to apply to the cores. This must be an existing and valid rule name.

-error_signal *pin_or_port*

An existing pin or port in the design to which the error signal generated from voting logic should be tied. Either a hierarchical or leaf-level pin or an output port can be specified, but it must exist in the design.

-split_pins *pin_names*

Specifies the pin names which should be split so as to be a part of different branches of high-fanout tree.

-cores *core_list*

Explicitly specifies the core on which the rule should be applied.

DESCRIPTION

Sets the safety_core_rule on all the specified cores. If a specified core already has another rule associated with it, that core is skipped and the original rule remains applied to it.

EXAMPLES

The following example creates an association of a rule with cores & pins.

```
prompt> set_safety_core_rule -rule rule1 \
    -cores {core1 core2}
```

The following example associates cores and specifies an error port

```
prompt> set_safety_core_rule -rule rule2 \
    -cores {coreA coreB} -error_signal [get_ports Err_out]
```

SEE ALSO

[create_safety_core_rule\(2\)](#)
[get_safety_core_rules\(2\)](#)

set_safety_error_code_rule

Associates the rule with one set of data bits.

SYNTAX

```
status set_safety_error_code_rule
  -rule safety_error_code_rule
  -data pins_or_ports
  [-error_signal pin_or_port]
  [-clock pin_or_port]
  [-correction_signal pin_or_port]
  [-requirement_id requirement_id_string]
  [-checkbits cell_or_port_list]
  [-enable pin_or_port]
```

Data Types

<i>safety_error_code_rule</i>	string
<i>pins_or_ports</i>	collection
<i>pin_or_port</i>	string

ARGUMENTS

-rule *safety_error_code_rule*

Specifies the safety_error_code_rule to apply to the data bits. This must be an existing and valid rule name. This is mandatory.

-data *pins_or_ports*

Specifies the collection of pins or ports of data signal on which the safety error code rule should be applied. This is mandatory.

-error_signal *pin_or_port*

Specifies the existing pin or port in the design to which the decoder error output is connected to. This can be specified for all types, when mode is decode or encode_decode.

DESCRIPTION

This command sets the safety error code rule on one set of data bits. This command should be run after the design is linked, and before executing the synthesis optimization flow (compile_fusion command). The synthesis code honors and processes the association of the rule on the data signal and adds encoder or decoder and related circuit for the given data signal, thereby creating a safety error code group.

This command should be called one time for each set of data bits on which the safety mechanism is to be applied. This command supports undo or redo operations.

The command shows error, if the *data* pins or ports list is empty. The command shows error, if any of the *data* pins or ports already associated with safety error code rules. In the list all elements should be either pin or port, combination of pins and ports in the list is not allowed.

EXAMPLES

The following example creates an association of a rule with data pins

```
prompt> set_safety_error_code_rule -rule rule1 \
           -data {cell_1/pin1 cell_1/pin2 cell_1/pin3 cell_1/pin4}
```

The following example sets a safety error code rule and specifies an error signal for creation

```
prompt> set_safety_error_code_rule -rule rule1 \
           -data {cell_3/pin1 cell_3/pin2 cell_3/pin3 cell_3/pin4} -error_signal {err_port}
```

SEE ALSO

[get_safety_error_code_rules\(2\)](#)
[remove_safety_error_code_rules\(2\)](#)

set_safety_logic_port_map

Set the port map on safety logic module.

SYNTAX

```
status set_safety_logic_port_map
  -module module to set the port map on
  -voting voting pin
  -error error pin
  [-input string_list]
```

Data Types

<i>module</i>	list of lib_cell
<i>voting</i>	string
<i>error</i>	string

ARGUMENTS

-module *module* to set the port map on

Specifies the modules that the port map is set on.

DESCRIPTION

Specifies the port map on the modules.

EXAMPLES

The following example creates port map on the specified modules

```
prompt> set_safety_logic_port_map -module {VOTE2} \
  -input {in1 in2} -output o -error o
```

SEE ALSO

```
report_safety_logic_port_map(2)
set_safety_register_rule(2)
```

set_safety_register_rule

Associates the registers with the rules.

SYNTAX

```
status set_safety_register_rule
  -rule safety_register_rule_name
  -registers registers
  -error_signal error_signal_pin
  [-target]
```

Data Types

<i>safety_register_rule_name</i>	string
<i>registers</i>	collection

ARGUMENTS

-rule *safety_register_rule_name*

Specifies the name of safety_register_rule to apply to the registers. This must be an existing and valid rule name.

-registers *registers*

Explicitly specifies the register(s) or the output pin of the registers on which the constraint should be applied. The safety register rule can be set on either the register cells or the output pin of the multibit register cell. But you can not set on both the register cell and the output pin of the register cell.

-error_signal *error_signal_pin*

This option can be an input pin of an error handler logic inside the design or input port of an error handler hierarchy inside the design. This option is mandatory with the 'dule_mode' safety register rule, it is optional for 'triple_mode'. When provided, error detection logic will be implemented (along with the regular voting logic) in triple_mode.

Explicitly specifies the register(s) on which the constraint should be applied.

DESCRIPTION

Sets the safety_register_rule on all the specified registers. If a specified register already has another rule associated with it, that register will be skipped and the original rule will remain applied to it.

EXAMPLES

The following example creates an association of a rule with registers.

```
prompt> set_safety_register_rule -rule rule1 \
           -registers {flop1 flop2 flop3 flop4}
```

SEE ALSO

`create_safety_register_rule(2)`
`get_safety_register_rules(2)`
`write_safety_register_data(2)`

set_scaling_lib_group

Specifies the scaling library group (previously defined by the **define_scaling_lib_group** command) to use for the current design or a subdesign.

SYNTAX

```
status set_scaling_lib_group
  [-min min_group]
  [-max max_group]
  [-object_list objects]
  [group]
```

Data Types

<i>min_group</i>	string
<i>max_group</i>	string
<i>objects</i>	collection
<i>group</i>	string

ARGUMENTS

-min *min_group*

Specifies the scaling library group to use for minimum delay analysis. If you do not specify a scaling library group for minimum delay analysis, the maximum group is used. The **-min** option cannot be used without the **-max** option. If neither of these options are specified, the library group applies to both minimum and maximum delay analysis.

-max *max_group*

Specifies the scaling library group to use for maximum delay analysis. If this option is not specified, the scaling group is used for both maximum and minimum delay analysis.

-object_list *objects*

Specifies the cells or top-level ports on which to apply the scaling library group. If you do not use this option, the scaling library group applies to the top-level design. This option accepts both leaf-level cells and hierarchical blocks.

group

Specifies the scaling library group to use for both maximum and minimum delay analysis.

DESCRIPTION

The **set_scaling_lib_group** command set a scaling library group on the specified design objects. The tool performs interpolation between libraries in this group for voltage, temperature, or both voltage and temperature. You can set scaling library for maximum, minimum, or both maximum and minimum delay analysis. You can set multiple scaling library groups on an object.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example defines a scaling library group named g1 and applies it to the top/inv cell.

```
prompt> define_scaling_lib_group -name g1 { 0.9.db 1.1.db 1.3.db }
prompt> set_scaling_lib_group -object_list top/inv g1
```

SEE ALSO

[define_scaling_lib_group\(2\)](#)
[remove_scaling_lib_group\(2\)](#)
[create_scenario\(2\)](#)
[set_operating_conditions\(2\)](#)

set_scan_compression_configuration

Specifies the scan compression configuration for the design.

SYNTAX

```
status set_scan_compression_configuration
  [-chain_count chain_count
   | -max_length max_chain_length
   | -minimum_compression compression_factor]
  [-xtolerance high | default]
  [-synchronize_chains none | all | tail | head]
  [-compressor_pipeline false | true]
  [-serialize chip_level | core_level | none]
  [-integration_only true | false]
  [-hybrid true | false]
  [-force_diagnosis true | false]
  [-static_x_chain_isolation true | false]
  [-inputs number_of_inputs]
  [-outputs number_of_outputs]
  [-base_mode base_mode_name]
  [-test_mode scan_compression_mode_name]
  [-min_power false | true]
  [-shared_inputs number_of_shared_inputs]
  [-shared_outputs number_of_shared_outputs]
  [-identical_cores core_list]
  [-scramble_identical_outputs true | false]
  [-shared_block_select false | true]
  [-shared_codec_controls false | true]
  [-shift_power_groups false | true]
  [-shift_power_chain_length chain_length
   | -shift_power_chain_ratio chain_ratio]
  [-shift_power_clock clock_name]
  [-shift_power_disable test_control_name]
  [-location compressor_decompressor_location]
```

Data Types

<i>chain_count</i>	integer
<i>max_chain_length</i>	integer
<i>compression_factor</i>	integer
<i>number_of_inputs</i>	integer
<i>number_of_outputs</i>	integer
<i>base_mode_name</i>	string
<i>scan_compression_mode_name</i>	string
<i>number_of_shared_inputs</i>	integer
<i>number_of_shared_outputs</i>	integer
<i>core_list</i>	string
<i>chain_length</i>	integer
<i>chain_ratio</i>	integer
<i>clock_name</i>	string
<i>test_control_name</i>	string
<i>compressor_decompressor_location</i>	string

ARGUMENTS

-chain_count *chain_count*

Specifies the number of compressed scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-max_length *max_chain_length*

Specifies the maximum allowed length of the compressed scan chains. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-minimum_compression *compression_factor*

Specifies the minimum required amount of compression, relative to the underlying standard scan base mode chain count. This is a relative method of specifying the compressed scan chain count. The standard scan chains are subdivided into compressed scan chains according to this ratio, along with a 20 percent pattern inflation factor to account for compression overhead:

```
num_compressed_chains =  
    num_standard_chains * compression_factor * 1.2
```

The minimum value is 2. The default is 10. See the DESCRIPTION section for more information.

-xtolerance *high | default*

Enables the insertion of fully X-tolerant scan compression structures when the value is set to **high**. When set to **default** (the default), the tool does not insert fully X-tolerant scan compression structures.

For information on high X-tolerance scan-in and scan-out pin requirements, see the TEST-1722 man page.

-synchronize_chains *none | all | tail | head*

Specifies the shift state of all compression mode chains. The values are as follows:

- **head** specifies that the first shift state of all compression mode chains are synchronized to the same clock edge.
- **tail** specifies that the last shift state of all compression mode chains are synchronized to the same clock edge.
- **all** specifies that both the first and the last shift states of all the compression mode chains are synchronized.
- **none** (the default behavior) specifies that no synchronization is performed.

-compressor_pipeline *false | true*

Enables compressor input pipelining.

This option enables pipeline registers at the compressor inputs (between the compressed scan chains and the compressor logic). These pipeline registers can push any partial-cycle paths and long routes to the input side of these pipeline registers so that a full clock cycle is available for the compressor XOR logic.

This feature requires that tail scan data pipelining registers also be used, which are enabled by the **-tail_pipeline_stages** option of the **set_pipeline_scan_data_configuration** command. The compressor pipeline registers do not count against the tail scan data pipeline register depth.

The default is **false**, which disables the feature.

-serialize *chip_level | core_level | none*

This option enables the insertion of the serializer when the value is set to **chip_level** or **core_level**. The value **chip_level** inserts both the serializer and the serializer clock controller at the top level. The value **core_level** inserts the serializer but not the clock controller, and should be specified in hierarchical adaptive-scan synthesis (HASS) flows. The value **none**, which is the default, inserts neither the serializer nor the clock controller.

-integration_only *true | false*

Enables scan compression integration. The design must have cores that have scan compression structures inserted. This feature integrates the cores at the chip level by connecting the test signals to chip-level ports and creating a chip-level test protocol. The default of this option is **false**.

This option is mutually exclusive with the **-hybrid** option.

-hybrid true | false

When set to **true**, turns on the hybrid flow. This enables insertion of scan compression logic at the chip level along with integration of cores with scan compression structures in one pass. The default of this option is **false**.

This option is mutually exclusive with the **-integration_only** option.

-force_diagnosis true | false

When set to **true**, issues an error if a compressor cannot be built with full diagnosis capabilities. The default of this option is **false**.

-static_x_chain_isolation true | false

When set to **true**, specifies that cells that frequently capture X values are to be isolated into separate scan chains, called X chains. These X chains are observed only in direct observability modes and excluded from the full observation mode. The default of this option is **false**.

This feature requires that the following options also be set:

```
set_dft_drc_configuration -static_x_analysis enable
set_scan_compression_configuration -xtolerance high
```

-inputs number_of_inputs

Specifies the number of scan inputs to load scan data for scan compression. The tool reuses the scan inputs from the underlying standard scan base mode before creating new scan inputs. The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-outputs number_of_outputs

Specifies the number of scan outputs to observe scan data for scan compression. The tool reuses the scan outputs from the underlying standard scan base mode before creating new scan outputs. The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-base_mode base_mode_name

Specifies the standard scan base mode that is to be associated with the scan compression mode indicated by the **-test_mode** option. The default is **Internal_scan**.

-test_mode scan_compression_mode_name

Specifies the scan compression test mode to which the specification applies. The default is **all_dft**, except when **define_test_mode** is used. In this case, the default is the value of the last **test_mode** defined.

-min_power false | true

When set to **true**, specifies that compressor inputs are to be gated for power saving. The **insert_dft** command creates the compressor logic such that it is active only during scan shift in that compression mode. The compressor logic is inactive during scan capture in that mode, during other test modes, and during mission mode. This eliminates power consumption due to switching activity in the compressor during functional operation (which is at-speed rather than at test clock frequencies). The default of this option is **false**.

-shared_inputs number_of_shared_inputs

Specifies the number of top-level scan inputs to share across all codecs in a HASS or Hybrid integration flow. The minimum allowed value is the widest input width across all codecs. The maximum allowed value is the sum of all codec input widths, which disables codec I/O sharing. By default, codec I/O sharing is disabled.

If high X-tolerance is used, additional scan inputs are required. The number of additional scan-in pins is equal to log2 of the number of shared codecs, rounded up to the next integer value.

-shared_outputs number_of_shared_outputs

Specifies the number of top-level scan outputs to share across all codecs in a HASS or Hybrid integration flow. The minimum allowed value is the widest output width across all codecs. The maximum allowed value is the sum of all codec output widths, which disables output sharing. By default, the outputs are fully shared when codec I/O sharing is enabled by the **-shared_inputs** option.

The **-shared_outputs** option by itself does not enable codec I/O sharing; the feature is only enabled if the **-shared_inputs** option is also specified.

-identical_cores core_list

Specifies the list of identical core instances in the current design. This information allows the shared codec I/O feature to optimize their scan-in and scan-out connections for improved diagnosability. Wildcards and collections are supported.

If you have multiple groups of identical cores, provide all of them as a flat list; the tool determines the grouping automatically by comparing their codec and compressed scan chain characteristics.

This option requires that shared codec I/O be enabled with the **-shared_inputs** option.

-scramble_identical_outputs true | false

When set to **true**, the tool creates nonidentical (scrambled) connections for identical cores, which improves the diagnosability of identical cores. By default, the tool creates identical output connections for identical cores.

This option requires that identical cores be defined with the **-identical_cores** option.

-shared_block_select false | true

Specifies whether to use shared or dedicated block-select signal connections for identical shared-I/O cores that have dedicated outputs.

When set to **true**, the tool uses shared block-select connections for the cores. The default is **false**, which uses dedicated (separate) block-select signals for the cores.

Enabling this option requires the following:

- Shared codec I/O is enabled with the **-shared_inputs** option.
- The cores contain shared-I/O codecs with high X-tolerance, such that the core has one or more block-select signals.
- All cores in the current design or partition are identical instances of this core, specified with the **-identical_cores** option.
- Dedicated (unshared) outputs are used for the cores, specified with the **-shared_outputs** option.

-shared_codec_controls false | true

When set to **true**, the tool adds gating logic at the inputs of the output sharing compressor to selectively disable shared codecs from being observed. You can then use the **-disable_codecs** option of the **write_test_protocol** command to write a test protocol that excludes one or more codecs.

If you are using IEEE 1500 test-mode control, the **write_test_protocol** command automatically creates a test protocol that disables the codecs. Otherwise, you are responsible for test protocol and/or netlist modifications to disable the codecs.

The default is **false**, which does not add any gating logic.

This option requires that shared codec I/O be enabled with the **-shared_inputs** option.

-shift_power_groups false | true

Enables the shift power groups feature. This feature implements a shift power control chain that allows ATPG to selectively gate groups of compressed chains for shift power reduction. The gated chains still shift, but they shift constant (non-toggling) values into the chains, which reduces toggle activity.

When this feature is enabled, the following options are also required:

- **-shift_power_chain_length** or **-shift_power_chain_ratio**
- **-shift_power_clock**

The default is **false**, which does not implement the control chain or gating logic.

-shift_power_chain_length *chain_length*

Specifies the length of the shift power control (SPC) chain. This value directly controls the number of compressed chain groups.

Use this option to keep the length of the SPC chain constant as the compression architecture changes.

-shift_power_chain_ratio *chain_ratio*

Specifies the ratio of compressed chains to each shift power control (SPC) register. This value directly controls the number of compressed chains in each group.

Use this option to keep the group size constant as the compression architecture changes.

-shift_power_clock *clock_name*

Specifies the clock to use for the shift power control chain. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. This option is required when using shift power groups.

-shift_power_disable *test_control_name*

Specifies the signal that, when asserted to its active value, disables the shift power logic. The specified signal must be previously declared as a TestControl signal using the **set_dft_signal** command. By default, the shift power logic is always active and no shift power disabling logic is implemented.

-location *compressor_decompressor_location*

Specifies the instance name in which the compressor and decompressor will be instantiated. The instance name cannot be a library cell, a black-box CTL model, or a black box.

DESCRIPTION

The **set_scan_compression_configuration** command allows you to specify certain DFTMAX insertion parameters prior to using the **insert_dft** command. The parameters include scan chain specifications such as compressed scan chain count, the number of scan-in and scan-out pins, the X-tolerance capabilities, and core integration strategies.

There are three related options to control the number of compressed scan chains. Only one option can take effect at a time. They are, in order of highest precedence first:

- **-max_length**
- **-chain_count**
- **-minimum_compression**

You can use these options to directly or indirectly specify the scan compression ratio for your design. If none of these options are specified, a minimum compression value of 10 (relative to the underlying standard scan chain count) is used. The maximum compressed chain count is 32000.

If you are using high X-tolerance, the maximum compressed chain count might be lower. For more information, see the TEST-1722 man page.

There are five related options to configure the shared codec I/O feature. They are:

- **-shared_inputs**
- **-shared_outputs**
- **-identical_cores**
- **-scramble_identical_outputs**
- **-shared_codec_controls**

There are five related options to configure shift power groups. They are:

- **-shift_power_groups**
 - **-shift_power_chain_length**
 - **-shift_power_chain_ratio**
 - **-shift_power_clock**
 - **-shift_power_disable**
-

set_scan_configuration

Specifies the scan chain design.

SYNTAX

```
int set_scan_configuration
  [-max_length max_chain_length
   | -exact_length chain_length
   | -chain_count chain_count
   | -count_per_domain chain_count]
  [-add_lockup true | false]
  [-clock_mixing no_mix | mix_edges | mix_clocks | mix_clocks_not_edges]
  [-add_test_retiming_flops begin_and_end | begin_only | end_only | none]
  [-create_dedicated_scan_out_ports true | false]

Data Types

<i>max_chain_length</i>	integer
<i>chain_length</i>	integer
<i>chain_count</i>	integer
<i>pin_count</i>	integer
<i>exclude_list</i>	list
<i>max_scan_cells</i>	integer

ARGUMENTS

-max_length *max_chain_length*

Specifies the maximum allowed length of the scan chains. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-exact_length chain_length

Specifies a positive integer that indicates the exact chain length. **insert_dft** builds, as much as possible, scan chains with the specified length. See the DESCRIPTION section for more information.

-chain_count chain_count

Specifies the number of scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-count_per_domain chain_count

Specifies a positive integer for the number of chains that **insert_dft** is to build per clock domain. See the DESCRIPTION section for more information.

-add_lockup true | false

When set to its default of **true**, inserts lockup latches (synchronization element) between clock domain boundaries on scan chains. To disable synchronization element insertion, set this option to **false**. If the scan specification does not mix clocks on chains, **insert_dft** ignores this option.

-clock_mixing no_mix | mix_edges | mix_clocks | mix_clocks_not_edges

Specifies whether the **insert_dft** command can include cells from different clock domains in the same scan chain. The following allowed values control the clocking of cells in scan chains to be inserted by the **insert_dft** command:

- **no_mix** (the default)
Cells must be clocked by the same edge of the same clock.
- **mix_edges**
Cells must be clocked by the same clock, but the clock edges can be different.
- **mix_clocks_not_edges**
Cells must be clocked by the same clock edge, but the clocks can be different.
- **mix_clocks**
Cells can be clocked by different clocks and different clock edges.

-add_test_retimig_flops begin_and_end | begin_only | end_only | none

Specifies whether the **insert_dft** command can insert leading edge retiming lockup flip-flops to scan chains clocked with trailing edge scan elements. If a scan chain contains only leading edge scan elements, a retiming lockup flip-flop is not inserted. The following allowed values control the lockup flip-flop insertion by the **insert_dft** command:

- **begin_and_end**
Retiming lockup flip-flops are added to the scan chain beginning and end.
- **begin_only**
Retiming lockup flip-flop is added only to the scan chain beginning.
- **end_only**
Retiming lockup flip-flop is added only to the scan chain end.
- **none** (the default)
No retiming flip-flop is inserted.

-create_dedicated_scan_out_ports true | false

When set to **true**, instructs **insert_dft** to implement dedicated scan-out signal ports on the current design. When set to **false** (the default), **insert_dft** uses mission-mode ports as scan-out ports whenever possible.

-internal_clocks none | single | multi

This option applies only to the multiplexed flip-flop scan style; it is ignored for other scan styles.

The **-internal_clocks** option can be set to the following values:

- **single**

The **insert_dft** command treats internal clock network regions driven by any combinational gate, including buffers and inverters, as separate clocks for the purposes of scan chain architecture.

- **none**

The **insert_dft** command does not perform internal clock analysis. This is the default.

- **multi**

The **insert_dft** command treats internal clock network regions driven by multiple-input gates, such as MUX cells, as separate clocks for the purposes of scan chain architecture. Buffers and inverters are transparent for the analysis.

Integrated clock-gating cells are transparent for the determination of internal clocks.

The **-internal_clocks** setting is common to all test modes. As a result, this option can be specified only if the **-test_mode** option value is set to 'all'. Otherwise, the tool issues a warning message, ignores the **-internal_clocks** option, and processes the remaining **set_scan_configuration** options.

-insert_terminal_lockup true | false

When set to **true**, inserts synchronization element at the end of scan chains. The default is **false**. This option applies only to the multiplexed flip-flop scan style; it is ignored for other scan styles.

-lockup_type latch | flip_flop

Selects the type of synchronization element used in the scan chain. The default lock-up type is a level-sensitive latch. If you choose **flip_flop** as the lock-up type, an edge-triggered flip-flop is used as the synchronization element. You can use this option in conjunction with the **-add_lockup** option or **-insert_terminal_lockup** options.

-mix_internal_clock_driver true | false

When set to **true**, **insert_dft** allows mixing in a scan chain of any internal clocks that are derived from a single external clock pin. This capability can only be activated when the clock mixing scan configuration is either **no_mix** or **mix_edges**.

-preserve_multibit_segment false | true

Specifies whether to treat sequential multibit components as scan segments. A multibit component is a group of cells with identical functionality, inferred from RTL code or created by the **create_multibit** command. Depending on tool configuration and design constraints, synthesis implements a multibit component using multibit cells or single-bit cells.

When this option is set to the default of **false**, the **insert_dft** command treats the cells inside a multibit component as discrete sequential cells that can be reordered, split up, and rebalanced across scan chains as needed. Note that this does not affect the functional behavior of a multibit component as used by synthesis.

When this option is set to **true**, the **insert_dft** command treats each sequential multibit component as a scan segment. As a result, the cells inside a multibit component cannot be separated for length-balancing purposes. You can report the multibit scan segments that will be used by using the **preview_dft -show {segments}** command.

To report the multibit components identified by synthesis, use the **report_multibit** command.

-style multiplexed_flip_flop | clocked_scan | lssd | combinational | scan_enabled_lssd | none

Identifies the scan style. Select **none** if you have not selected a scan style for the design. By default, **insert_dft** uses the scan style value specified by environment variable **test_default_scan_style**.

-shared_scan_in_pin_count

Specifies the number of scan-in pins to be shared between chains. The pins will be shared between chains which do not have a scan-in pin assigned to them. If there are existing scan-in pins in the design that are not already assigned to any chain, they will be used. If there are no existing pins that can be used, new pins are created and shared between the chains.

-exclude_elements exclude_list

Specifies the list or collection of design objects to exclude from scan chain insertion. You can specify leaf cells, hierarchical cells, or scan segment names. If hierarchical cells are specified, the specification applies to all sequential cells inside those cells.

Specification of scan segment names results in spurious UID-95 warnings, which can be ignored.

This option causes the specified cells to be excluded from scan stitching by the **insert_dft** command. It does not prevent the specified cells from being scan-replaced by the **compile -scan**, **compile_ultra -scan**, or **insert_dft** commands, and it does not cause excluded test-ready cells to be unscanned by the **insert_dft** command. To prevent cells from being scan-replaced, use the **set_scan_element false** command.

This option is cumulative with other previously specified **-exclude_elements** lists. Refer to the example at the end of this man page. Wildcards and collections are supported.

This option does not affect DFT connections to clock-gating cell test pins; use the **set_dft_clock_gating_configuration -exclude_elements** command instead.

-voltage_mixing true | false

When set to **true**, allows scan elements from different voltage domains into the same scan chain. This requires you to insert level shifters after scan insertion is complete. The default is **false**.

-power_domain_mixing true | false

When set to **true**, allows scan elements from different power domains into the same scan chain. The default is **false**.

-test_mode mode_name

Indicates which test mode the scan configuration applies to. The default is the last test mode specified with the **current_test_mode** command, or the last test mode created by **define_test_mode** if no current test mode has been set.

-domain_based_scan_enable true | false

When set to **true**, **insert_dft** creates one scan-enable signal per clock domain. This process is independent of the value of the **-clock_mixing** option. The default is **false**.

This option is intended to be used to create a core that can use pipelined scan-enable signals at a higher integration level.

To make domain-specific scan-enable connections for a subset of clocks instead of all clocks, use the **set_dft_signal -type ScanEnable -connect_to <clock>** command instead.

-reuse_mv_cells true | false

Specifies whether **insert_dft** should reuse existing level shifters, isolation cells, and enabled level shifters if they are on the scan path. When set to **true** (the default), **insert_dft** will attempt to reuse these cells to avoid creating dedicated test ports and additional multivoltage cells. When set to **false**, **insert_dft** will always create new multivoltage cells, creating new test ports as needed.

-pipeline_scan_enable true | false

When set to **true**, **insert_dft** creates a scan-enable pipelining stage for each scan-enable signal. The default is **false**.

-pipeline_fanout_limit max_scan_cells

When set to a positive integer value, **insert_dft** creates each scan-enable signal so that the number of flip-flops driven by the same scan-enable signal does not exceed the value. This option only takes effect if the **-pipeline_scan_enable** or **-domain_based_scan_enable** option (or both) is set to **true**. The default is to not apply a limit.

-create_test_clocks_by_system_clock_domain true | false

When **true**, **insert_dft** creates dedicated test clocks (for example, `test_scan_clock_a`) according to different system clocks. Thus, scan cells that have different system clocks have different test clocks. When **false** (the default), **insert_dft** creates test clocks without considering system clocks.

-replace true | false

When **true** (the default), **insert_dft** replaces sequential cells with scan cells, if the sequential cells are not violated by scan design rule checking. To disable scan replacement, set this option to **false**.

-hierarchical_isolation true | false

When **true**, **insert_dft** builds hierarchical isolation logic, so that dedicated subdesign scan-out signals are gated by the design scan-enable signal. This prevents long top-level scanout nets from toggling during functional operation. When **false** (the default), **insert_dft** does not add hierarchical isolation logic.

When this option is set to **true**, you cannot disable the use of shared subdesign scan-out signals by setting the **test_dedicated_subdesign_scan_outs** variable to **true**.

DESCRIPTION

There are four related options to control the number of scan chains. Only one option can take effect at a time. They are, in order of highest precedence first:

- **-max_length**
- **-exact_length**
- **-chain_count** or **-count_per_domain**

You can use these options to directly or indirectly specify the scan chain configuration for your design. If none of these options are specified, the tool builds the minimum number of scan chains consistent with the clock mixing constraints.

The following option controls clock domain identification:

-internal_clocks single | none | multi

Clocks driven by separate top-level input ports are always considered to be separate clocks for scan chain routing. The **-internal_clocks** option controls whether regions of the same clock signal, driven by multi-input combinational gates, should also be treated as separate clock domains. For designs where the entire clock tree is balanced through these multi-input combinational gates, you can specify a value of **none** to treat the entire clock port fanout as a single clock domain. For designs where clock latencies might differ in the fanout of each multi-input gate, it is recommended that you specify a value of **multi** to treat these regions as separate clock domains.

The following options control how separate clock domains can be mixed during scan chain routing:

-clock_mixing no_mix | mix_edges | mix_clocks | mix_clocks_not_edges
-mix_internal_clock_driver true | false

The **-clock_mixing** option allows you to control two independent aspects of mixing: whether separate clock domains can be mixed together on the same scan chain, and whether scan cells clocked by different clock edge polarities can be mixed together on the same scan chain. Four possible values allow all four combinations of these two aspects to be specified. When separate clock domain mixing is disabled by specifying a **-clock_mixing** value of **no_mix** or **mix_edges**, the **-mix_internal_clock_driver** option can be used to allow only separate clock domains driven by the same input port (such as those created with the **-internal_clocks** option) to be mixed.

For all possible clock domain mixing configurations, lockup latches are inserted between the separate clock domains when they are mixed on the same scan chain.

EXAMPLES

The following example allows DFT Compiler to establish the maximum sequential length of scan chains (30 in this example):

```
prompt> set_scan_configuration -max_length 30
```

The following example demonstrates how a mix of object types can be provided to the **set_scan_configuration** command. In this example, the **-exclude_elements** option takes **s2/ff1** which is a cell name, **s1/***, which is a wild card representation, **s0/1** which is a segment name, **\$foo** which is a collection, and **U5** which is a design instance name.

```
prompt> set foo [get_cell s4/*]
```

```
prompt> set_scan_config -exclude_elements \
[list s2/ff1 s1/* s0/1 $foo U5]
```

The following example allows DFT Compiler to mix scan cells in the same scan chain when a clock passes through multi-input combinational cells. Lockup latches will be inserted between scan cells driven by different multi-input combinational cells. Scan cells driven by separate clock input ports will not be mixed.

```
prompt> set_scan_configuration -internal_clocks multi
prompt> set_scan_configuration -clock_mixing no_mix
prompt> set_scan_configuration -mix_internal_clock_driver true
```

`insert_dft(2)`
`preview_dft(2)`

set_scan_element

Sets the **scan_element** attribute on specified design objects, to determine whether scan replacement replaces them with scan cells.

SYNTAX

```
int set_scan_element  
    true | false  
    cell_design_ref_list
```

Data Types

cell_design_ref_list list

ARGUMENTS

true | false

The Boolean value with which to set the **scan_element** attribute on the *cell_design_ref_list*. If **true**, (the default), the specified objects are replaced by sequential cells in the design. When **false**, scan replacement is disabled.

cell_design_ref_list

A list of design objects for scan replacement. Objects must be of the following *sequential* types:

- cells (such as flip-flops and latches)
- hierarchical cells (containing flip-flops or latches)
- references
- library cells
- designs

Wildcards and collections are supported.

DESCRIPTION

Sets the **scan_element** attribute to **true** on objects in *cell_design_ref_list*, indicating that scan replacement is to replace them with equivalent scan cells and make them part of the scan path. This command affects scan replacement performed by the **insert_dft**, **compile -scan**, and **compile_ultra -scan** commands.

The default attribute value is **true**, which replaces all nonviolated sequential cells with equivalent scan cells for full scan designs. It is only necessary to explicitly set this value to **true** if you are altering the attribute value of a cell whose attribute was previously set to **false**.

Nonscan sequential cells determined to be violations by the **dft_drc** command are not scan-replaced, even if their **scan_element** attribute is set to **true**.

Sequential cells with the **scan_element** attribute set to **false** are not to be replaced by equivalent scan cells. If the attribute is applied

before the first test-ready compile, the cells are never scan-replaced. If the attribute is set to **false** after a previous test-ready compile, the following behaviors apply:

- Subsequent test-ready compile commands will not unscan them.
- In wireload mode, the **insert_dft** command will unscan them (unless the **set_dft_insertion_configuration -synthesis_optimization** option is set to **none**).
- In topographical mode, the **insert_dft** command will keep the cells scan-replaced (to minimize layout disturbance) but will not include them on scan chains.

If the library has no nonscan cells, then scan cells with deasserted test pin connections are used. For hierarchical cells, the **scan_element** attribute value applies to all sequential leaf cells within the hierarchical cell. For references, library cells, or designs, the **scan_element** attribute value applies to the instances of these objects, or to the sequential leaf cells within the hierarchy of the instances. The effects of the **scan_element** attribute are applied hierarchically in a design. The value of the **scan_element** attribute on a lower-level object in the design takes precedence over the value of the **scan_element** attribute on a higher level object in the design. For example, if the value of the **scan_element** attribute on a higher-level object in the hierarchy is **false** and the value of the **scan_element** attribute on a sequential element inside the higher-level object is **true**, the sequential element is scan replaced. The **scan_element** attribute value on a cell instance takes precedence over the **scan_element** value on the reference for that cell. The **scan_element** attribute value on a library cell is treated as a technology limitation and cannot be overwritten in any way. The **set_scan_element** command supports full instance-based specification. However, the **scan_element** attributes on instances are specific to the current design. For example, if you start with a lower-level design, use the **set_scan_element** command to put **scan_element** attributes on instances in this context, and change the current design to a higher-level design, the **scan_element** attributes are no longer visible at the higher level. To remove individual **scan_element** attributes, use the **remove_attribute** command. To remove all attributes, use the **reset_design** command. To disable scan connections for CTL-modeled custom scan cells that do not use the synthesis-based scan replacement flow, use the **set_scan_configuration -exclude** command instead. This command does not affect DFT connections to clock-gating cell test pins; use the **set_dft_clock_gating_configuration -exclude_elements** command instead.

EXAMPLES

The following example specifies that the **insert_dft** command is not to scan replace three sequential cells in the current design.

```
prompt> set_scan_element false {U3_1 U3_2 U3_3}
```

The following example specifies that the **insert_dft** command is to scan replace every instance of cell DFF in the current design.

```
prompt> set_scan_element true [get_references DFF]
```

The following example specifies that the **insert_dft** command is not to scan replace instances of library cell DLATCH.

```
prompt> set_scan_element false tech_lib/DLATCH
```

The following example specifies that the **insert_dft** command is not to scan replace instances of design REGFILE (sequential cells within REGFILE are not to be replaced by equivalent scan cells).

```
prompt> set_scan_element false [get_designs REGFILE]
```

set_scan_group

Specifies an unordered group of cells that are not yet connected, but should be kept together within a scan chain. Also identifies existing logic in the current design that is to be designated as a scan segment.

SYNTAX

```
status set_scan_group
  scan_group_name
  [-access signal_type_pin_pairs]
  [-include_elements object_list]
  [-serial_routed false | true]
  [-lockup_exists false | true]
  [-segment_length length_of_virtual_segment]
  [-clock top_level_clock_port]
  [-edge rising | falling]
  [-class occ | wrapper | input_wrapper | output_wrapper]
```

Data Types

scan_group_name string

ARGUMENTS

scan_group_name

Specifies the name of the scan group. The scan group must be uniquely identified as a design object. The name of the scan group name must also be unique.

-access signal_type_pin_pairs

Lists ordered pairs, each consisting of a scan signal type and a design pin, indicating how the **insert_dft** command is to access the scan group. Valid signal types are ScanClock, ScanMasterClock, ScanSlaveClock, ScanEnable, ScanDataIn, and ScanDataOut. Validation ensures that specified signal types are consistent with the design scan style. Note that this list is mandatory when the **-serial_routed** option is set to **true**. This option is not supported when **-serial_routed** is set to **false**.

-include_elements object_list

Specifies a list of scan group components.

If the **-serial_routed** option is set to **false**, the list is unordered, and you can specify sequential cells, segment names, and design instances. Collections are supported.

If the **-serial_routed** option is set to **true**, the list is ordered, and you can specify only sequential cells. Collections are not supported for serially routed lists.

-serial_routed false | true

Identifies whether the scan group is composed of serially routed sequential cells or that you are specifying an unordered group of sequential cells. The default is **false**.

-lockup_exists false | true

Identifies whether the serially routed scan group has a lock-up latch at the end. The default is **false**.

This option can be used only when the **-serial_routed** option is set to **true**.

-segment_length length_of_virtual_segment

Specifies the length of the virtual scan segment. This option can be used only when **-serial_routed** is set to **true**. With this option, you must also use **-access** to specify the correct input and output access pins, and use **-clock** for top-level clock specifications with respect to this segment.

-clock top_level_clock_port

Specifies the top level clock port or pin associated with the virtual scan segment.

-edge rising | falling

Specifies the edge of the clock associated with the virtual scan segment. The scan architect uses this information for architecting the scan chains.

-class occ | wrapper | input_wrapper | output_wrapper

Specifies the class of the scan group.

The **occ** keyword specifies that the scan group describes an on-chip clocking (OCC) clock chain segment. Scan groups of **-class occ** are used only during OCC flows.

The **wrapper** keyword specifies that the scan group describes a wrapper chain segment. Scan groups of **-class wrapper** are used only during core wrapping flows.

The **input_wrapper** keyword specifies that the scan group describes an input wrapper chain segment. Scan groups of **-class input_wrapper** are used only during core wrapping flows.

The **output_wrapper** keyword specifies that the scan group describes an output wrapper chain segment. Scan groups of **-class output_wrapper** are used only during core wrapping flows.

DESCRIPTION

The **set_scan_group** command identifies existing logic in the current design that is to be designated as a scan group. Scan groups implement scan in a particular scan style. DFT Compiler can include scan groups in scan chains by connecting their access pins (when serially routed), or maintain the cells' grouping without assuming they are serially connected to each other. The **insert_dft** command does not scan-replace scan group members explicitly.

When the **-serial_routed** option is set to **true**, the **set_scan_group** command allocates sequential cells to scan groups and identifies design pins as scan group access pins with particular scan signal-type semantics. The **set_scan_configuration** command used with the **-style** option determines the scan group scan styles.

The **set_scan_group** command options are not incremental. A **set_scan_group** option that specifies a scan group name overwrites any previous **set_scan_group** command specification of the same name and scan style.

The **set_scan_group** command accepts a list of members. By default, the list of members is unordered and not serially connected. This list must be ordered when **-serial_routed** is set to **true**.

The scan group members should belong to the same clock domain and same edge. If the scan group is provided with elements from a different clock domain, an error message is displayed during scan architecting and the scan group specification is discarded.

The **set_scan_group** command does not accept collections as input.

The **set_scan_group** command accepts design instances as scan group members. It adds every scannable cell in the design instance to the scan group at the specified position, in alphanumeric order. This specification is valid only when **-serial_routed** is set to **false**.

The **-segment_length** option specifies the length of the virtual scan segment. Virtual segments are segments for which you specify the scan segment input and the scan segment output using the **-access** option, and the scan segment clock association using **-clock**.

option. If you do not specify the **-include_elements** option but you want specify the length of a segment, use the **-segment_length** option. The tool connects only to the hookup points during scan chain construction and does not trace within the hookup points (or virtual scan segment). The segment length you provide is considered for top-level scan chain balancing.

Note that the post-DFT DRC and SCANDEF generation support is not available when virtual scan segments are present in the scan chain.

The **-clock** option specifies the top-level clock that drives the virtual scan segment. If you specify the **-segment_length** option, you must also specify a valid **-clock** specification.

Ensure that the clock name specified as part of the **-clock** option is already defined using the **set_dft_signal** command. Alternatively, run the **set_scan_group** command after creating the test protocol and inferring the clocks and asynchronous signals.

The **-edge** option specifies the controlling edge of the clock with respect to the virtual scan segment. The controlling edge is specified as **rising** or **falling**. The default is **rising**.

When the **-access** option is used, the access pin signal types must be consistent with the segment scan style. Access pin directions must be consistent with their signal types. Access pins cannot be associated with more than one signal type. Scan groups cannot have more than one ScanDataIn or ScanDataOut access pin. Scan groups cannot contain duplicate members; sequential cells cannot belong to more than one scan group. Scan group members cannot also belong to scan chains. In other words, a sequential cell element that belongs to a scan group cannot be specified as part of the **set_scan_path** command.

A scan group does not accept another scan group as a member; nested scan groups are not supported.

Valid scan group error messages are TEST-400 and TEST-700. TEST-400 is displayed when scan group elements belong to more than one clock domain or have the same clock domain but a different edge. TEST-700 is displayed when scan group elements have a nonexistent element specified as part of the scan group specification.

Use the **preview_dft** command with the **-bsd** option set to all to review your scan group specifications. Use the **remove_scan_group** command with *scan_group_name* argument to delete an existing scan group specification.

EXAMPLES

The following example identifies an embedded shift register in the multiplexed flip-flop scan style. This specification can be completed in a single **set_scan_group** command by including the identification of the ScanEnable access pin in the first **-access** option specification.

```
prompt> set_scan_group my_shift_reg \
    -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
    -include_elements [list P/B/U7 P/B/U8 P/B/U9] \
    -serial_routed true

prompt> set_scan_group my_unconnected_group \
    -include_elements [list U1 U2]
```

The following is an example of a virtual scan segment controlled by the rising edge of the clock tck:

```
prompt> set_scan_group virtual_scan_segment \
    -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
    -segment_length 20 \
    -clock tck \
    -edge rising \
    -serial_routed true
```

The following is an example of a virtual scan segment controlled by the falling edge of the clock tck:

```
prompt> set_scan_group virtual_scan_segment \
    -access [list ScanDataIn P/B/U7/si ScanDataOut P/B/U9/QN] \
    -segment_length 20 \
    -clock tck \
    -edge falling \
```

-serial_routed true

SEE ALSO

`insert_dft(2)`
`preview_dft(2)`
`remove_scan_group(2)`

set_scan_link

Declares a scan link for the current design.

SYNTAX

```
int set_scan_link  
    scan_link_name Wire | Lockup  
    [-test_mode mode_name]
```

Data Types

scan_link_name string

ARGUMENTS

scan_link_name

Specifies the name of the scan link. Substitute the name you want for *scan_link_name*.

-test_mode *mode_name*

Specifies the test mode for the specification. The default is current mode.

DESCRIPTION

Declares a scan link for the current design. Scan links connect scan cells, scan segments, and scan ports within scan chains. DFT Compiler supports scan links that are implemented as wires (type Wire) and scan-out lock-up latches (type Lockup).

This command reserves words for particular types of scan links. Use these words within **set_scan_path** commands to specify scan links of various types. You can use scan links to insert lock-up latches at specific scan chain locations and correct timing problems. You can also use wire scan links to override the automated insertion of lock-up latches. The **scan_link_name** option must uniquely identify the scan link as a design object.

You can use the **-test_mode** option to specify the test mode.

To review your scan link specifications, use the **preview_dft** command with the **-show** option set to **cells**. To create scan links and add them to the current design, use the **insert_dft** command. To delete scan link specifications, use the **remove_scan_link** command.

The **set_scan_link** command does not invalidate **dft_drc** modeling information.

EXAMPLES

The following example declares a lock-up latch named a_lckup in Internal_scan mode and uses it to resynchronize the scan outputs of the elements named A and F of chain chain3.

```
prompt> current_design WC66
prompt> set_scan_link a_lckup Lockup -test_mode Internal_scan
prompt> set_scan_path chain3 {A a_lckup B C D E F a_lckup G}
prompt> insert_dft
```

ARGUMENTS

scan_chain_name

Specifies a name for the scan chain being specified.

-ordered_elements *ordered_list*

Specifies an ordered list of scan chain elements to be included in the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards are supported, but collections are not.

-head_elements *head_list*

Specifies an ordered list of scan chain elements to be placed at the beginning of the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards are supported, but collections are not.

-tail_elements *tail_list*

Specifies an ordered list of scan chain elements to be placed at the end of the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards are supported, but collections are not.

-include_elements *include_list*

Specifies a list of scan chain elements to be included in the scan chain. Unlike an ordered list, the scan architect is free to place them anywhere in the scan chain. This list can include names of sequential cells, design instances, scan segments, and scan links. The input is accepted as a simple list. Wildcards are supported, but collections are not.

-infer_dft_signals

Specifies that the **set_scan_path** command automatically infers the ScanDataIn, ScanDataOut, and ScanEnable DFT signals that are normally specified using the **set_dft_signal** command. This option is only applicable when you are using this command in a scan extraction flow.

Note that if you use this option, and you later use the **remove_scan_path** command to remove scan paths, the signals that were inferred are not removed. You must use the **remove_dft_signal** command to explicitly remove these DFT signals.

-dedicated_scan_out true | false

Forces the use of a dedicated scan-out port, which allows the **insert_dft** command to reuse a functional output port driven by this scan chain as a scan-out port. When this option is set to **true**, the **set_scan_path** command always uses a dedicated scan-out port for this scan chain.

-complete true | false

Indicates whether **insert_dft** can add components to a specified scan chain. When **true**, **insert_dft** does not add any other scan cells to this scan chain and treats it as a complete scan chain. When **false** (the default), **insert_dft** can add more scan cells to this specification to balance scan chains. The new scan cells are embedded at the beginning of the scan chain (after any **-head_elements** scan cells).

-exact_length *length*

Specifies that **insert_dft** command should build the *scan_chain_name* scan chain with the exact sequential length indicated by *length*. The value must be a positive integer. If the specification cannot be met due to other scan requirements, the tool generates a warning stating that the specified scan chain requirements cannot be honored, and then it proceeds with normal scan architecting.

If you specify **-class bsd**, this option allows you to specify the length of the boundary-scan test data register being specified.

This option is not used when describing the length of an existing segment by specifying the list of elements.

-bsd_style global | synchronous | asynchronous

Specifies the boundary-scan style for a user-defined test data register (UTDR) definition. The default is **global**, which uses the

global style specified by the **-style** option of the **set_bsd_configuration** command.

-insert_terminal_lockup true | false

Specifies a lock-up latch to be associated at the end of the scan chain. Scan architect takes the user-defined lock-up latch specification into consideration while building scan chains.

-scan_master_clock clock_name

Specifies a clock to be associated with a scan chain. The scan architect takes the user-defined clock domain into consideration while building scan chains. The clock edge is determined by the **-edge** option, which defaults to rising-edge scan cells.

If the same clock edge specification applies to more than one scan chain specification, the scan architect attempts to balance the clock domain elements across the scan chains.

-edge rising | falling

Specifies the edge of the scan_master_clock associated with the scan chain. The scan architect includes only the elements controlled by the specified edge of the scan_master_clock in the scan chain. The default is **rising**.

-scan_slave_clock clock_name

Specifies a clock to be associated with a scan chain. The scan architect takes the user-defined clock domain into consideration while building scan chains.

-scan_enable port_name

Specifies a scan enable to be associated with a scan chain. The scan architect takes the specified scan-enable port into consideration while allocating a scan-enable signal to the scan chain. The specified scan-enable port is dedicated to the scan chain; it will not be used to drive scan enable pins of flip-flops in other chains. If the internal pins flow is enabled using the **set_dft_drc_configuration** command, a hookup pin can be specified as a scan-enable signal for a scan chain.

When you specify **-class wrapper**, the specified port name can be a wrapper shift enable signal.

-scan_data_in port_name

Specifies a scan-in port to be associated with a scan chain. The scan architect takes the user-defined scan-in port into consideration while building scan chains. If the internal pins flow is enabled using the **set_dft_drc_configuration** command, a hookup pin can be specified as a scan-in signal for a scan chain.

-scan_data_out port_name

Specifies a scan-out port to be associated with a scan chain. The scan architect takes the user-defined scan-out port into consideration while building scan chains. If the internal pins flow is enabled using the **set_dft_drc_configuration** command, a hookup pin can be specified as a scan-out signal for a scan chain.

-test_mode mode_name

Indicates the test mode to which the scan path constraint applies. The default is the current test mode, if user-defined test modes have been created, or the Internal_scan mode if no test modes have been created.

Note that unlike most commands, the **set_scan_path** command does not apply a global specification to all test modes when the **-test_mode** option is omitted and no current test mode has been defined. To apply a scan path specification to all test modes, you must explicitly specify the **-test_mode all** option.

-view view_name

Indicates the view to which the specification applies. The following views are valid:

- **existing_dft** indicates that the specification refers to the existing usage of a scan chain. Use this when working with DFT-inserted designs. For example, to describe to the tool that chain A is being used, enter the following:

```
set_scan_path C1 -view existing_dft -ordered_elements {reg0 reg1 reg2}
```

- **spec** (default) indicates that the specification refers to scan chains that the tool will create during DFT insertion. This is used when preparing a design for DFT insertion. For example, to prescribe to the tool that a scan chain A must be created in a certain way, you would do the following

set_scan_path C1 -view spec -ordered_elements {reg0 reg1 reg2}
-class scan | wrapper | bsd | occ | spc | ieee_1500 | ieee_1500_ring | pco_wrapper

Specifies the class of the scan chain. The allowed values are:

- **scan** (default) specifies that the chain is a scan chain. Chains of class **scan** are used only during scan insertion.
- **wrapper** specifies that the chain is a wrapper chain of a wrapped core. Chains of class **wrapper** are used only during core wrapping insertion.
- **bsd** specifies that the chain is a BSR chain or a BSD register. Chains and registers of class **bsd** are used only during BSD insertion.
- **occ** specifies that the chain is a clock chain for an on-chip clocking (OCC) controller. Chains of class **occ** are used only in an OCC flow.
- **spc** specifies that the chain is a shift power control (SPC) chain, used by the shift power groups feature. Chains of class **spc** are used only when the SPC feature is enabled.
- **ieee_1500** specifies that the chain is an IEEE 1500 register or is accessed by the IEEE 1500 controller. Chains and registers of class **ieee_1500** are used only when describing IEEE 1500 logic.
- **ieee_1500_ring** specifies that the chain describes an IEEE 1500 ring. Chains of class **ieee_1500_ring** are used only when describing IEEE 1500 logic.
- **pco_wrapper** specifies that the chain is to be the control chain in a power controller override (PCO) flow. Chains of class **pco_wrapper** must be defined as **-view spec**. The specifications can include scan-in and scan-out ports but cannot include any scan cell elements.

Scan chains defined as a certain class automatically include elements of that class, unless limited or explicitly specified by other options of this command. The exceptions are the **occ** and **spc** classes, which require the scan elements to be explicitly specified if cores containing **occ** or **spc** chains are present.

-opcode opcode_value

Specifies the value that, when loaded into the IEEE 1500 wrapper instruction register (WIR), selects the data register being defined by the current command. The *opcode_value* is a binary string.

The default is to choose any suitable available encoding. This option is only valid for IEEE 1500 data register definitions. It requires that the **-class ieee_1500** option also be used.

-init_data init_value

Specifies a user-defined test data register (UTDR) initialization value associated with the current **set_scan_path** specification. The *init_value* argument is a binary string.

With **-class bsd**, the option specifies the value to be loaded into the UTDR described by the current **set_scan_path** command when an IEEE 1149.1 instruction is loaded for test-mode control.

With **-class ieee_1500_ring**, the option specifies the value to be loaded into the ring selection UTDR to select the ring described by the current **set_scan_path** command.

Other **-class** values are not supported.

This option is used only by the SHS and DFTMAX interoperability flow.

-hookup hookup_pin_list

Specifies the hookup pin names associated with the scan chain. The *hookup_pin_list* can contain hierarchical pin names or pin objects.

These pin names are used in defining a boundary-scan register (of class **bsd**). The signal types for these pins are specified using *set_dft_signal* command. This list of pins, along with the *set_dft_signal* signal definitions, defines the hookups needed for the boundary-scan register.

By default, capture and update clock pins of the boundary-scan test data register are not gated, which means the pins are always driven by TCK. This behavior is controlled by the **test_bsd_synthesis_gated_tck** variable. For more information, see the man

page.

There is no default for this option.

-input_wrapper_cells_only enable | disable

Specifies whether or not only input wrapper cells should be used in the chain. This option is specific to chains of class **wrapper**.

The default for this option is **disable**.

-output_wrapper_cells_only enable | disable

Specifies whether or not only output wrapper cells should be used in the chain. This option is specific to chains of class **wrapper**.

The default for this option is **disable**.

-pipeline_head_registers scan_chain_element_names

Specifies an ordered list of existing head pipelined scan data registers, starting from the scan-in port. In regular scan mode, the scan data goes through these elements after the scan-in port and before the first scan cell of the specified scan chain. In compressed scan mode, the scan data goes through these elements after the scan-in port and before the adaptive scan decompressor. These elements are automatically excluded from scan architecting. This ordered list must only include instance names of sequential cells. If the scan-in port attached to the scan chain does not have a hookup pin specified, the last element that is specified drives the scan chain using the first output pin found for that cell. The input is accepted as a simple list. Wildcards and collections are not supported.

-pipeline_tail_registers scan_chain_element_names

Specifies an ordered list of existing tail pipelined scan data registers, ending at the scan-out port. In regular mode scan, the scan data goes through these elements after the last scan cell of the specified scan chain and before the scan output port. In compressed scan mode, the scan data goes through these elements after the adaptive scan compressor output and before the scan output port. These elements are automatically excluded from scan architecting. This ordered list must only include instance names of sequential cells. If the scan output port attached to the scan chain does not have a hookup pin specified, the first element that is listed observes the scan chain using the first usable input pin found for that cell. The input is accepted as a simple list. Wildcards and collections are not supported.

DESCRIPTION

This command specifies a scan chain for the current design. The command allocates scan cells, scan segments, and scan links to scan chains, and specifies scan chain orderings. The **set_scan_configuration** command **-style** option determines the chain scan style. It can be used either to describe the existing usage or to prescribe the usage during implementation.

Scan chain elements cannot belong to more than one chain. When **set_scan_path** options conflict, the most recent command overrides the previous command.

The **set_scan_path** options are not incremental. A **set_scan_path** option specified for a given chain name overwrites any previous **set_scan_path** option previously applied to that same chain name.

The **set_scan_path** command accepts design instances as scan chain elements. When specified, they include every scannable cell in the design instance.

Scan segments can be subdesign scan chains. Suppose the hierarchical design instance *instance_name* has a scan chain of **report_dft**. The **-scan_path** option reports as "Complete scan chain #n." You can include this subdesign scan chain in a scan chain by referring to it as *instance_name/n*.

Scan chain orderings must satisfy clock domain constraints asserted by using the **set_scan_configuration** command with the **-clock_mixing** option. The **insert_dft** command resynchronizes nonfunctional scan chains by using lockup latches. DFT Compiler reorders nonfunctional scan chains if you disable lockup latch insertion by using the **set_scan_configuration** command with the **-add_lockup** option.

The **set_scan_path** command does not invalidate **dft_drc** modeling information.

Use the **report_scan_path** command to review your scan chain specification. Use the **insert_dft** command to implement the scan chain. Use the **remove_scan_path** command to delete scan chain specifications.

In the case of multimode scan insertion, if you have previously defined several test modes using the **create_test_schedule** or **define_test_mode** command, the default **set_scan_path** command is not associated with any mode and is not honored. Use the **-test_mode** option to specify the test mode to which you want your scan path constraint to apply.

When using this command in a scan extraction flow, either specify the existing DFT signals using the **set_dft_signal -view existing** command prior to running the **set_scan_path** command, or use **set_scan_path** with the **-infer_dft_signals** option to infer these signals.

To define an existing IEEE 1500 register, specify **-class ieee_1500** and specify the ordered list of register cells with the **-ordered_elements** option. The following scan path names are special values that represent part of the IEEE 1500 architecture:

- **WIR** - wrapper instruction register
- **WBY** - wrapper bypass register

Other scan path names represent user-defined core data registers (CDRs). A user-defined CDR serves as the test-mode control data register (TMCDR) unless the WIR is used directly for test-mode control. For non-WIR register definitions, you can define the WIR opcode that enables the register by using the **-opcode** option.

In a boundary-scan flow, to define a user-defined test data register (UTDR) accessed by the TAP controller, specify **-class bsd** and specify the register access pins using **-hookup**. You must also specify the signal types of the hookup pins by using the **set_dft_signal** command.

EXAMPLES

The following example defines a complete scan chain named C1, consisting of sequential cells A, B, and C in reverse alphanumeric order.

```
prompt> current_design WC66
prompt> set_scan_path C1 -include_elements {C B A} -complete true
```

The following example shows how you can use wildcards to specify design objects by converting a collection to a name list:

```
prompt> set_scan_path C1 -include_elements \
    [get_object_names [get_cells {*cache*reg*}]]
```

The following example shows how to use the **-head_elements**, **-tail_elements**, and **-include_elements** options to specify that the elements from the U4 instance are at the beginning of the chain and the elements from the U5 instance are at the end of the chain. The elements from U3 are ordered and scan architect does not change the order of the elements in this instance during architecting. The **-include_elements** option ensures that the U2/2 segment is included somewhere in scan chain 1.

```
prompt> set_scan_path C1 -view spec -head_elements {U4} \
    -include_elements {U2/2} -ordered_elements {U3} \
    -tail_elements {U5}
```

The following example shows how to build scan chains with user-defined sequential lengths and/or clocks in a design with 25 scan cells, 10 of which belong to clock domain A and 15 of which belong to clock domain B. This builds C1 with 7 sequential elements clocked with A, C2 with 15 sequential elements clocked with B and a tool-named chain with the 3 remaining elements clocked with A.

```
prompt> set_scan_configuration -clock_mixing no_mix
prompt> set_scan_path C1 -exact_length 7 -clock A
prompt> set_scan_path C2 -scan_master_clock B
```

The following examples show how to use the **-edge** option along with the **-scan_master_clock** option. First, the \fbset_scan_path command assigns all elements controlled by the rising edge of the clk1 clock to C1, and then assigns all elements controlled by the falling edge of the clk1 clock to C2.

Consider **set_scan_path** specifications for C3 and C4 below. If there are 10 elements controlled by the rising edge of clock clk2, then C3 and C4 will get 5 elements each.

```

prompt> set_scan_path C1 -view spec -scan_master_clock clk1 -edge rising
prompt> set_scan_path C2 -view spec -scan_master_clock clk1 -edge falling

prompt> set_scan_path C3 -view spec -scan_master_clock clk2 -edge rising
prompt> set_scan_path C4 -view spec -scan_master_clock clk2 -edge rising

```

The following example shows how to specify the DFT signals and scan path for a design with existing scan chains:

```

prompt> set_dft_signal -view existing_dft \
    -type ScanDataIn -port test_si
prompt> set_dft_signal -view existing_dft \
    -type ScanDataOut -port test_so
prompt> set_dft_signal -view existing_dft \
    -type ScanEnable -port test_se
prompt> set_dft_signal -view existing_dft \
    -type MasterClock -port test_clk -timing {45 55}
prompt> set_dft_signal -view existing_dft \
    -type ScanMasterClock -port test_clk -timing {45 55}
prompt> set_scan_path C1 -view existing_dft \
    -scan_data_in test_si -scan_data_out test_so -scan_enable test_se

```

The following example shows how to specify a scan path such that the first cell of the scan chain is connected to the output of pipeline register head_reg_2 and the last cell of the scan chain is connected to the input of pipeline register tail_reg.

```

prompt> set_scan_path C1 -view spec \
    -pipeline_head_registers {head_reg_1 head_reg_2} \
    -pipeline_tail_registers {tail_reg}

```

The following example shows how to specify a scan path for a design with existing scan chains, using the **set_scan_path -infer_dft_signals** option to infer the existing DFT signals:

```

prompt> set_scan_path C1 -view existing_dft -infer_dft_signals

```

The following example shows how to specify a boundary-scan register (BSR) chain for use with boundary-scan insertion. In this example, in1, in2, en, out1, out2 are ports of the current design.

```

prompt> set_scan_path -class bsd C_BSR -view spec \
    -ordered_elements {in1 in2 en out1 out2}

```

The following example shows how to specify a short BSR chain for use with boundary-scan synthesis. In this example, in1, in2 are the ports of the current design.

```

prompt> set_scan_path -class bsd C_SHORT_BSR -view spec \
    -ordered_elements {in1 in2}

```

The following example defines a set of existing, preconnected IEEE 1500 registers in the design:

```

prompt> set_scan_path WIR -class ieee_1500 -view existing_dft -test_mode all \
    -ordered_elements {WIR_reg[1] WIR_reg[0]}
prompt> set_scan_path WDR -class ieee_1500 -view existing_dft -test_mode all \
    -opcode 000001 -ordered_elements {TMCDR_reg[1] TMCDR_reg[0]}
prompt> define_test_mode WS_BYPASS -usage wrp_bypass \
    -encoding {WIR_reg[1] 1 WIR_reg[0] 1}
prompt> set_scan_path WBY -class ieee_1500 -view existing_dft -test_mode WS_BYPASS \
    -ordered_elements {WBY_reg}

```

The following example shows how to specify a user-defined test data register (UTDR) for use with boundary-scan synthesis. Here, I1/si, I1/so, I1/se, I1/clk, I1/inst_en are active-high access pins of the UTDR that are to be hooked up to boundary-scan logic during boundary-scan insertion. Pin I1/reset is an active-low access pin; note that it is excluded from the **set_scan_path** hookup pin list.

```

prompt> set_dft_signal -type tdi      -view spec -hookup_pin I1/si
prompt> set_dft_signal -type tdo      -view spec -hookup_pin I1/so
prompt> set_dft_signal -type bsd_shift_en -view spec -hookup_pin I1/se
prompt> set_dft_signal -type capture_clk -view spec -hookup_pin I1/clk
prompt> set_dft_signal -type inst_enable -view spec -hookup_pin I1/inst_en
prompt> set_dft_signal -type bsd_reset -view spec -hookup_pin I1/reset \

```

```
-active_state 0
prompt> set_scan_path -class bsd MY_USER_REG -view spec -exact_length 10 \
    -hookup {l1/si l1/so l1/se l1/clk l1/inst_en}
```

set_scan_register_type

Specifies a list of scan sequential cells from the target library that are to be used by **insert_dft** or **compile -scan** when scan replacing designs or cell instances.

SYNTAX

```
int set_scan_register_type
  [-exact]
  [-type example_scan_seq_cell_list]
  [cell_or_design_list]
```

Data Types

example_scan_seq_cell_list list
cell_or_design_list list

ARGUMENTS

-exact

If specified, indicates that the *example_scan_seq_cell_list* is to be honored even during backend delay and area optimization done by **insert_dft** or by subsequent synthesis operations (for example, **compile -incremental**). If **-exact** is not specified, backend optimization can optimize scan cell instances to use scan cells that are not in the *example_scan_seq_cell_list*.

-type *example_scan_seq_cell_list*

Specifies a list of scan sequential cells from the target library, to be used by **insert_dft** or **compile -scan** as the scan equivalent for the current design or for sequential cells in the *cell_or_design_list* during scan replacement.

cell_or_design_list

Specifies a list of sequential nonscan cells or designs that are to be replaced by the scan cells in *example_scan_seq_cell_list* during scan replacement. The default is the current design.

DESCRIPTION

The **set_scan_register_type** command specifies a list of scan sequential cells from the target library to be used by **insert_dft** or **compile -scan** as the scan equivalents for specified nonscan sequential cells during scan replacement.

To determine the current settings resulting from previous use of the **set_scan_register_type** command, execute **report_test -register**. To remove **set_scan_register_type** settings currently in effect, execute **remove_scan_register_type**.

Specifying **-exact** indicates that only cells from the **-type** list can be used as a scan replacements for those cells, even during scan optimization.

To effectively use the **set_scan_register_type** command, it is important to understand the scan insertion process. The process of

mapping sequential cells into scan flip-flops and latches consists of three steps:

1. The **compile -scan** command maps each sequential cell in the generic design description into an initial nonscan latch or flip-flop from the target library. Non-scan sequential cells are mapped to an initial latch or flip-flop from the target library. In the absence of any **set_scan_register_type** specification, the smallest area-cost flip-flop or latch is chosen. For a design or cell instance that has a **set_scan_register_type** setting in effect, the nonscan equivalent of a scan cell in the *example_scan_seq_cell_list* is chosen.
2. The **compile -scan** or **insert_dft** command replaces the nonscan sequential cells with scan sequential cells, using only the scan cells specified by the **set_scan_register_type** command, where applicable. If **compile -scan** or **insert_dft** is unable to use a scan cell from the *example_scan_seq_cell_list*, it uses the best possible matching scan cell from the target library and issues a warning.
3. If non mapping was possible with fun-id. The scan replacement table specified using **set_scan_replacement** is searched for a one-to-one mapping for the design's scan style.
4. If the **-exact** option is not used in the **set_scan_register_type** command, **compile -scan** or **insert_dft** attempts to remap each scan sequential cell into another component from the target library to optimize the delay or area characteristics of the circuit. If the **-exact** option is used, optimization is restricted to using the scan cells in the *example_scan_seq_cell_list*.

EXAMPLES

In the following example, the scan register type for the current design is to be SDFLOP in the target library. (The DFLOP is a non-scan equivalent of this SDFLOP.) During scan replacement, the scan sequential cell used is SDFLOP, but during scan cell optimization, other scan cells from the target library could be used.

```
prompt> set_scan_register_type -type SDFLOP
```

In the following example, the scan register type for the current design is to be SDFLOP, and this cell is to be used as an exact scan replacement. During scan replacement, the scan sequential cell used is SDFLOP, and remains so during scan cell optimization.

```
prompt> set_scan_register_type -exact -type SDFLOP
```

The following example indicates that the scan register type for the current design is to be from the list of cells SD1FLOP SD2FLOP. During scan replacement, the scan sequential cell used is either an SD1FLOP or an SD2FLOP.

```
prompt> set_scan_register_type -type {SD1FLOP SD2FLOP}
```

`target_library(3)`

set_scan_replacement

Specifies a table of one-to-one mappings of flip-flops to their equivalent scan flip-flops from the target library that are to be used by **insert_dft** when scan replacing cell instances.

Note that as of 2006.06-SP1, **compile -scan** and **compile_ultra -scan** map to scan cells directly, rather than doing scan replacement. So, this command has no effect on **compile -scan** and **compile_ultra -scan**.

SYNTAX

```
status set_scan_replacement
[-nonscan non_scan_seq_cell_list]
[-lssd lssd_rep_cell]
[-multiplexed_flip_flop muxed_scan_cell]
[-clocked_scan clocked_scan_cell]
[-combinational combinational_scan_cell]
[-scan_enabled_lssd scan_enabled_lssd_cell]
```

Data Types

<i>non_scan_seq_cell_list</i>	list
<i>lssd_rep_cell</i>	string
<i>muxed_scan_cell</i>	string
<i>clocked_scan_cell</i>	string
<i>combinational_scan_cell</i>	string
<i>scan_enabled_lssd_cell</i>	string

ARGUMENTS

-nonscan *non_scan_seq_cell_list*

Specifies the set of cells for which a scan replacement is specified using the **set_scan_replacement** command.

-lssd *lssd_rep_cell*

Specifies the scan replacement flip-flop for all flip-flops specified in the **-nonscan** option in the LSSD scan methodology.

-multiplexed_flip_flop *muxed_scan_cell*

Specifies the scan replacement flip-flop for all flip-flops specified in the **-nonscan** option in the multiplexed flip-flop scan methodology.

-clocked_scan *clocked_scan_cell*

Specifies the scan replacement flip-flop for all flip-flops specified in the **-nonscan** option in the clocked-scan methodology.

-combinational *combinational_scan_cell*

Specifies the scan replacement flip-flop for all flip-flops specified in the **-nonscan** option in the combinational scan methodology.

-scan_enabled_lssd *scan_enabled_lssd_cell*

Specifies the scan replacement flip-flop for all flip-flops specified in the **-nonscan** option in the scan-enabled LSSD scan methodology.

DESCRIPTION

The **set_scan_replacement** command indicates that the instances of cells in *non_scan_seq_cell_list* for the **-nonscan** option will be replaced by the corresponding scan cell specified in each of the scan style options.

The flip-flops specified in all options except **nonscan** must be valid scan cells for the corresponding scan methodology.

The **set_scan_replacement** command can be used to specify a one-to-one mapping of nonscan flip-flops to corresponding scan flip-flops for each scan methodology.

The **insert_dft** command uses this mapping table to do scan replacement. If the mapping is not a valid scan cell for the corresponding scan methodology, **insert_dft** will reject the mapping and use other mapping methods, such as function ID or Boolean matching. Boolean matching can be time consuming, but ensures that a scan flip-flop that satisfies the design constraints is selected.

This mapping does not ensure that the design constraints are met before mapping. This command should be used only when you are sure that your constraints will be met by this mapping.

EXAMPLES

In the following example, all instances of FD1 will be replaced by the scan flip-flop FD1S in the multiplexed scan style:

```
prompt> set_scan_replacement -nonscan FD1 -multiplexed_flop_flop FD1S
```

In the following example, the instances of FD1, FD2 and FD3 will be replaced by FDLS in the LSSD scan methodology:

```
prompt> set_scan_replacement -nonscan {FD1 FD2 FD3} -lssd FDLS
```

set_scan_skew_group

Defines a scan skew group of scan cells, which might have a different clock latency characteristic than other parts of the design.

SYNTAX

```
status set_scan_skew_group  
  scan_skew_group_name  
  -include_elements object_list
```

Data Types

```
  scan_skew_group_name  string  
  object_list           list
```

ARGUMENTS

scan_skew_group_name

Specifies the name of the scan skew group to define.

A scan skew group is referenced by name. You can use any name, as long as it has not previously been used to define another scan skew group. Scan skew group names are used by the **report_scan_skew_group**, **remove_scan_skew_group**, and **preview_dft** commands.

-include_elements object_list

Specifies the cells to include in the scan skew group. The object list can contain leaf cells, hierarchical cells, and CTL-modeled cells. Hierarchical cells include all scan cells in their hierarchy. CTL-modeled cells include all their scan segments. Wildcards and collections are supported.

DESCRIPTION

You can use scan skew groups to provide manual guidance for lock-up latch insertion. A scan skew group is a group of scan cells that might have a different clock latency characteristic than other parts of the design. The DFT architect treats the scan skew group as if it were a unique clock domain.

Scan skew groups override the normal scan clock domain identification behaviors such as

- Scan clock name
- The **-internal_clocks** option of the **set_scan_configuration** command
- The **-mix_internal_clock_driver** option of the **set_scan_configuration** command

If clock mixing is disabled, the cells in a scan skew group are not mixed in the same scan chain as other scan cells. If clock mixing is enabled, the cells in a scan skew group can be mixed in the same scan chain as other scan cells, with lock-up latches inserted as

needed.

EXAMPLES

The following example defines a scan skew group for a particular design register:

```
prompt> set_scan_skew_group MY_GROUP \
           -include {CONFIG_reg[*]}
```

SEE ALSO

`remove_scan_skew_group(2)`
`report_scan_skew_group(2)`

set_scan_state

Sets the scan state status for the current db design.

SYNTAX

```
int set_scan_state  
    unknown | test_ready | scan_existing
```

ARGUMENTS

DESCRIPTION

This command sets the scan state status for the current design. Valid values are **unknown** (the scan state of the design is unknown), **test_ready** (the design is scan-replaced), and **scan_existing** (the design is scan-inserted).

Use this command only on a design that has been scan-replaced using, for example, **compile -scan**, so that the Q outputs of scan flip-flops are connected to the scan inputs and the scan enable pins are connected to logic zero. If there are nonscan elements in the design, use **set_scan_element false** to identify them.

This command can modify the netlist in memory if synchronous-logic shift register reidentification is enabled. For details, see the man page for the **compile_seqmap_identify_shift_registers_with_synchronous_logic_ascii** variable.

EXAMPLES

The following example illustrates setting the **test_ready** scan state status for the current design.

```
prompt> set_scan_state test_ready
```

`set_scan_configuration(2)`
`set_scan_element(2)`
`set_scan_path(2)`

set_scan_suppress_toggling

Specifies how the **insert_dft** command should insert gating at scanflip-flop functional outputs to suppress downstream toggling activity during scan shift.

SYNTAX

```
status set_scan_suppress_toggling
  [-selection_method manual | auto | mixed]
  [-include_elements cell_design_ref_list]
  [-exclude_elements cell_design_ref_list]
  [-min_slack minimum_timing_slack_after_gating]
  [-ignore_timing_impact true | false]
  [-total_percentage_gating percentage_value]
```

Data Types

<i>cell_design_ref_list</i>	list
<i>minimum_timing_slack_after_gating</i>	float
<i>percentage_value</i>	float

ARGUMENTS

-selection_method manual | auto | mixed

Specifies the scan flip-flop selection method used by the **insert_dft** command. The default is **manual** which applies gating only for objects manually specified with the **-include_elements** option. The **auto** value enables automatic selection of flip-flops for gating using power-based heuristics. The "mixed" value enables a combined approach, allowing the manual specification to be supplemented with automatic selection by the tool.

-include_elements cell_design_ref_list

Specifies leaf cells, hierarchical cells, or designs that should be gated. Hierarchical cells and designs implicitly include all leaf scan cells within the block or design.

Wildcards and collections are supported.

-exclude_elements cell_design_ref_list

Specifies leaf cells, hierarchical cells, or designs that should be excluded from gating. Hierarchical cells and designs implicitly include all leaf scan cells within the block or design.

Wildcards and collections are supported.

-min_slack minimum_timing_slack_after_gating

Specifies the required minimum slack value after gating is added. Valid values are between 0 and 1000. The default is 0, which means the slack should not be negative after gating is added. This option is ignored if **-ignore_timing_impact true** has been specified.

-ignore_timing_impact true | false

Indicates whether slack should be ignored when determining which scan cells will be gated. The default is false.

-total_percentage_gating percentage_value

Specifies the target percentage of scan flip-flops to be automatically selected for gating when the **-selection_method** option is set to **auto** or **mixed**. The default for this option is 5.

DESCRIPTION

During scan testing, when scan data shifts through the scan chains, the scan flip-flop functional output pins are toggling. This causes switching activity in downstream functional logic, which can increase the power dissipation during scan shift.

To reduce power consumption, the **insert_dft** command can insert gating logic which suppresses the switching activity of selected scan flop functional output pins when the scan enable signal is asserted. The method used to select functional output gating locations is configured with the **set_scan_suppress_toggling** command.

The **-selection_method** option specifies the method used to select scan cells for gating. The default is **manual** which applies gating only for objects manually specified with the **-include_elements** option. If no **set_scan_suppress_toggling** command has been specified, the default behavior is that no scan cells are gated because no flip-flops have been manually specified.

When the **-selection_method** option is set to **auto**, scan cells are automatically selected for gating using propagated power analysis to maximize the power savings. The desired percentage of gated scan flops is specified with the **-total_percentage_gating** option. A percentage value between 5% and 30% is typically specified. Tradeoffs between test mode power consumption, functional power consumption, and functional timing must be considered when choosing a gating percentage value. As the gating percentage value is increased, leakage power increases, and the potential for layout congestion and timing closure difficulty increases. While considering timing and power tradeoffs, you should also consider that TetraMAX ATPG has several power-aware algorithms that seek to reduce shift and capture flop toggle rates during the ATPG process.

Setting the **-selection_method** option to **mixed** enables a combined approach, allowing the manual specification to be supplemented with automatic selection by the tool. All flip-flops specified with the **-include_elements** option are gated, even if the **-total_percentage_gating** target is exceeded. If the **-total_percentage_gating** target is not met by the manually specified flip-flops, additional flip-flops are selected automatically to meet the goal.

When the **-selection_method** option is set to **manual** or **mixed**, the set of manually-selected scan cells for output gating is specified with the **-include_elements** option. The **-include_elements** option is not supported in the **auto** selection mode.

Specific scan cells can be excluded from output gating with the **-exclude_elements** option. This option is supported for all selection methods.

By default, output gating is only inserted at a functional output if the resulting slack would be nonnegative. If a higher positive slack threshold is desired for selection, it can be specified with the **-min_slack** option. Alternatively, the slack requirement can be disregarded altogether with the **-ignore_timing_impact** option, which allows gating to be inserted even at negative slack functional outputs.

A flip-flop is excluded from output gating if it meets any of the following criteria:

- The flip-flop is manually excluded with the **-exclude_elements** option.
- The flip-flop is part of a shift register segment identified by the **compile_ultra** command.
- In a bottom-up flow, the flip-flop is within a block where test models are used or you have specified a **set_dont_touch** attribute on the block.
- The Q or QN pin of the flip-flop connects only to the scan-in signal. (They can be gated if they are functionally connected.)
- The logic does not meet the minimum slack limit or would not meet the minimum slack limit if gating is inserted.

When the selection mode is set to auto or mixed, the **insert_dft** command reports the number of scan flip-flops selected for gating, the number considered for gating, the number that you manually included, and the number rejected due to timing considerations.

By default, the toggle suppression logic uses the driving scan cell's scan-enable signal. To define a dedicated scan-enable signal for suppression, define the signal using the **-usage scan_toggle** option of the **set_dft_signal** command, as shown in the examples.

Use the **report_scan_suppress_toggling** command to confirm the option settings you specified with the **set_scan_suppress_toggling** command. Use the **remove_scan_suppress_toggling** command to remove the previous toggling suppression settings applied.

EXAMPLES

The following example specifies that the **insert_dft** command should insert power gating on the optimal 10% of scan cell functional output pins:

```
prompt> set_scan_suppress_toggling -selection_method auto -total_percentage_gating 10
```

The following example specifies that the **insert_dft** command should insert power gating on the optimal 20% of scan cell functional output pins, without violating a minimum slack requirement:

```
prompt> set_scan_suppress_toggling -selection_method auto -total_percentage_gating 20 -min_slack 0.5
```

The following example manually specifies that all scan flip-flops in hierarchical cell BLK should be gated by the **insert_dft** command, except for some critical output scan flip-flops which should not be gated:

```
prompt> set_scan_suppress_toggling -include_elements {BLK} -exclude_elements {BLK/OUT_reg*}
```

The following example specifies that the **insert_dft** command should insert power gating on the functional output pins of all valid scan flip-flops within the MULTACCUM design:

```
prompt> set_scan_suppress_toggling -include_elements [get_designs MULTACCUM]
```

The following example shows a usage of mixed selection method:

```
prompt> set_scan_suppress_toggling -selection_method mixed -total_percentage_gating 20 -include_elements [get_designs
```

The following example shows how to create and configure a new SE signal **tog_se**, to be used as exclusive toggling suppression controller for the cell **U1/rst_q1_reg**:

```
prompt> create_port -dir in tog_se  
Creating port 'tog_se' in design 'CORE'  
1
```

```
prompt> set_dft_signal -type ScanEnable -port tog_se -usage scan_toggle  
Accepted dft signal specification for modes: all_dft
```

```
prompt> set_scan_suppress_toggling -include_elements [get_cells U1/rst_q1_reg]  
Accepted set_scan_suppress_toggling specification.  
1
```

set_scenario_options

Sets the scenario options for one or more scenarios.

SYNTAX

```
status set_scenario_options
  [-scenarios scenario_list]
  [-setup true | false]
  [-hold true | false]
  [-leakage_power true | false]
  [-dynamic_power true | false]
  [-cts_mode true | false]
  [-cts_corner min | max | min_max | none]
  [-reset_all true | false]
```

Data Types

scenario_list list

ARGUMENTS

-scenarios *scenario_list*

Specifies the list of scenarios to which to apply the scenario options.

If you do not specify this option, the command applies the scenario options to the current scenario.

-setup true | false

Controls whether the setup (maximum delay) cost is enabled for the specified scenarios.

The default is **true**. When set to **false**, optimization ignores setup violations in the specified scenarios.

-hold true | false

This option is not used by Design Compiler. If the design is saved with this setting, it is saved in the .ddc file and can be used by tools that read the .ddc file later in the flow.

-leakage_power true | false

Controls whether the leakage power cost is enabled for the specified scenarios.

The default is **false**.

If set to **true**, it is incompatible with the %LVT cells constraint (which is scenario independent).

-dynamic_power true | false

If set to true, low power placement must also be enabled (by setting the flag **power_low_power_placement**) to true to be effective. Note that low power placement requires **compile_ultra -spg**.

-cts_mode true | false

This option is not used by Design Compiler. If the design is saved with this setting, it is saved in the .ddc file and can be used by tools that read the .ddc file later in the flow.

-cts_corner min | max | min_max | none

This option is not used by Design Compiler. If the design is saved with this setting, it is saved in the .ddc file and can be used by tools that read the .ddc file later in the flow.

-reset_all true | false

When set to **true**, resets all scenario options to default values. When **false** (the default), the scenario options remain unchanged.

DESCRIPTION

This command sets options to restrict a scenario to be used for specific costs. Combinations of the **-setup**, **-hold**, and **-leakage_power** options can be used to restrict a scenario. All scenario options can be applied to active and inactive scenarios.

Use the **report_scenario_options** command to report the options set by this command.

Multicorner-Multimode Support

By default, this command applies to the current scenario. You can select different scenarios by using the **-scenarios** option.

EXAMPLES

The following example uses the **set_scenario_options** command to restrict the MODE1 scenario for use only for setup timing and uses the **-dynamic_power** option to enable dynamic power optimization.

```
prompt> create_scenario MODE1
Warning: Discarding all scenario specific information previously
defined in this session.
(UID-1008)
Current scenario is: MODE1
1
```

```
prompt> set_scenario_options -setup true \
    -dynamic_power true -leakage_power false
1
```

```
prompt> report_scenario_options
```

```
*****
Report : scenario options
Design : TEST03
Version: C-2009.06
Date  : Wed Mar 19 14:57:08 2008
*****
```

```
Scenario: MODE1 is active.
setup      : false
hold       : true
leakage_power : false
dynamic_power : true
```

SEE ALSO

`set_fix_hold(2)`

set_scope

Specifies the current scope.

SYNTAX

```
string set_scope
      [instance]
```

Data Types

instance string

ARGUMENTS

instance

Specifies the working instance in dc_shell.

- If *instance* is not specified, the tool returns to the current design top instance.
- If *instance* is ".", the tool returns to the working instance.
- If *instance* is "..", the context is moved up one level in the hierarchy of the current design.
- If *instance* begins with "/", the tool returns to the working instance under current design top instance whose name is after the "/". Basically, the "/" in the beginning of instance name is interpreted as design top instance.
- Multiple levels of hierarchy can be traversed in a single call to the **set_scope** command, by separating the cell names with a slash (/).

More complex examples of *instance* arguments are described in the EXAMPLES section below.

DESCRIPTION

The **set_scope** command sets the current scope. Functionally, this command is a subset of the **current_instance** command, but has a different return value. Upon success, the **set_scope** command returns the current scope prior to the execution of this command as a full path string relative to the current design top instance. The command returns a null string upon failure.

The **set_scope** command does not work on leaf cells. If you attempt to run the **set_scope** command on a leaf cell, the tool issues the following error message:

Error: A leaf cell instance A/B/leaf has been specified as the scope. (UPF-012)

It is not allowed for the instance name given with **set_scope** command to navigate outside of design top instance. Consider the following case where mid_inst is both the current scope and design top instance.

```
prompt> set_scope ..//mid_inst
```

Warning: The specified scope navigates outside the current design top instance mid_inst. This is not allowed. (UPF-566)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the scope to the U1/U2 hierarchy, if the U1 cell exists in the current hierarchy and the U2 cell exists in the U1 cell.

```
prompt> set_scope U1/U2
```

The following example sets the scope to two levels of hierarchy above the current instance, and then down one level to the MY_INST cell.

```
prompt> set_scope ../../MY_INST
```

SEE ALSO

`current_design(2)`
`current_instance(2)`
`load_upf(2)`
`apply_power_model(2)`

set_script_runtime_report_mode

Sets or queries the report mode of script runtime.

SYNTAX

```
string set_script_runtime_report_mode
      [mode_name]
```

ARGUMENTS

mode_name

Specifies the name of the new mode. The supported mode names are **off**, **summary**, and **verbose**. If you do not specify a mode name, the command returns the current mode name.

DESCRIPTION

The **set_script_runtime_report_mode** command sets the new mode for script runtime report or queries the current report mode. When the script runtime reporting is turned on, possible runtime saving in the script, such as avoiding unnecessary changes because of the **current_design** command, are reported.

You can use this command in de_shell only.

EXAMPLES

The following examples show how to use the command:

```
prompt> set_script_runtime_report_mode
          off

prompt> set_script_runtime_report_mode verbose
          verbose
```

SEE ALSO

SCR-01(n)
SCR-02(n)

set_security_configuration

Sets the default security configuration for the current design.

SYNTAX

```
status set_security_configuration
  [-logic_lock enable | disable]
  [-obfuscation enable | disable]
  [-watermark enable | disable]
  [-security_lock enable | disable]
  [-id uid_name]
```

ARGUMENTS

-logic_lock enable | disable

Specifies if logic lock insertion is enabled or disabled.

If logic lock insertion is enabled and gate level logic lock configuration is specified, logic lock gates are inserted into the design with **insert_security command**.

-obfuscation enable | disable

Specifies if obfuscation logic insertion is enabled or disabled.

If obfuscation logic insertion is enabled and gate level obfuscation configuration is specified, obfuscation logic is inserted into the design with **insert_security command**.

-watermark enable | disable

Specifies if watermark logic insertion is enabled or disabled.

If watermark logic insertion is enabled and gate level watermark configuration is specified, watermark logic is inserted into the design with **insert_security command**.

-security_lock enable | disable

Specifies if security lock is enabled or disabled.

If security lock is enabled and security lock configuration is specified, security logic is inserted into the design with **insert_security command**.

DESCRIPTION

This command specifies the default security configuration to be used by the **insert_securitycommand**.

Use the **reset_security_configuration** command to reset the current security configuration of the design.

EXAMPLES

The following example specifies that logic lock gates to be inserted into top level module of current design.

```
prompt> set_security_configuration -logic_lock enable \
           -top_module des_unit
Accepted security configuration for design '...'.
1
```

SEE ALSO

[insert_security\(2\)](#)
[reset_security_configuration\(2\)](#)
[report_security_configuration\(2\)](#)

set_security_lock

Sets the default security lock specification for the current design.

SYNTAX

```
status set_security_lock
  [-test_mode_locks test_mode_list]
  [-unlock_patterns test_mode_unlock_pattern_list]
```

Data Types

```
test_mode_list      list
test_mode_unlock_pattern_list  list
```

ARGUMENTS

-test_mode_locks test_mode_list

Specifies list of test mode lock signals which are used to lock test mode/register/sib logic during security logic insertion in **insert_security command**.

These signals should be specified as dft signals of type TestModeLock.

Currently tool supports only ports of current design for these signals.

-unlock_patterns test_mode_unlock_pattern_list

Specifies list of test mode unlock patterns. Here is syntax of test mode unlock pattern :

<test_mode_or_register_name>:<unlock_pattern_value>

where width of <unlock_pattern_value> should match size of test mode lock signals specified with **-test_mode_locks** option.

<unlock_pattern_value> should contain only 0s or 1s.

DESCRIPTION

This command specifies the default security lock specification to be implemented by **insert_security**, **insert_dftcommands**.

Use the **reset_security_lock** command to reset the current security lock specification of the design.

EXAMPLES

The following example specifies that security lock specification to be implemented in security/dft logic insertion.

```
prompt> set_security_lock \
-test_mode_locks { tml1 tml2 tml3 } \
-unlock_patterns { wrp_if:000 wrp_of:000 ScanCompression_mode:000 }
Accepted security lock specification for design '...'.
1
```

[report_security_lock\(2\)](#)
[insert_dft\(2\)](#)

set_self_gating_objects

Forces the enabling or disabling of self-gating for specified objects in the current design, overriding all conditions necessary for automatic self-gating, by the **compile_ultra -self_gating** command. Objects can be of type register, hierarchical cell, power domain or design.

SYNTAX

```
status set_self_gating_objects
  [-force_include object_list]
  [-exclude object_list]
  [-include object_list]
  [-undo object_list]
  [-type cell_type]
```

Data Types

<i>object_list</i>	list
<i>cell_type</i>	string

ARGUMENTS

-force_include *object_list*

Specifies a list of objects in the current design to be self-gated, overriding the conditions set by the **set_self_gating_options** command.

-exclude *object_list*

Specifies a list of objects in the current design to be excluded from self-gating.

-include *object_list*

Specifies a list of objects in the current design for which self-gating should be done as per the options specified by the **set_self_gating_options** command. This is the default for all objects in the design.

-undo *object_list*

Specifies a list of objects in the current design for which the inclusion or exclusion criteria for self-gating should be removed.

-type *cell_type*

This option is only supported in Design Compiler NXT topographical mode. Specifies the type of combinational cell that the tool should insert to compare the input and output data pins of the registers during self-gating insertion. This option must be used with the **-force_include** or **-include** options, and is not allowed if used with the **-exclude** or **-undo** options. The possible values of *cell_type* are: - xor: the tool will use XOR cells. - nand: the tool will use NAND cells. - or: the tool will use OR cells. - auto: the tool will automatically choose the combinational cell for each register.

If not present, this option will be reset to the default value ('xor' in dc_shell and 'auto' in dcnxt_shell) over the given objects. This is of particular relevance when a certain type of compare cell was previously set on a parent hierarchy, since the **-type** option will be overwritten if specified on a register or subdesign.

The *object_lists* are mutually exclusive, that is, an object cannot be specified with more than one of the following options: -**force_include**, **-exclude**, **-include** or **-undo**.

DESCRIPTION

This command specifies the objects on which self-gating is to be either enabled or disabled on its registers, overriding all conditions necessary for automatic self-gating by the **compile_ultra -self_gating** command.

For objects specified with the **-force_include** option, self-gating is performed regardless of the previous specification. Objects specified with the **-exclude** option are excluded from self-gating regardless of the previous specification.

Excluding a self-gated register does not cause the register to be ungated in a incremental call of the **compile_ultra -self_gating** command.

Use the **-include** option to specify that regular self-gating criteria should be used on the specified objects. This option is used to explicitly set an object as included for self-gating when one of its higher hierarchies is forcefully included or excluded. Achieving a donut shaped region, where regular self-gating is performed, in the middle of hierarchies completely excluded or forcefully included.

Use the **-undo** option to remove a previously specified criteria on the specified objects.

You must run the **set_self_gating_objects** command before running the **compile_ultra -self_gating** command. The specifications persists during the subsequent executions of the **compile_ultra -self_gating**.

EXAMPLES

The following example excludes the register bank A_reg in the current design, from self-gating:

```
prompt> set_self_gating_objects -exclude A_reg[*]
```

In the following example, the register bank D_OUT_reg in the MID subdesign, is self-gated overriding the previous specification.

```
prompt> set_self_gating_objects -force_include MID/D_OUT_reg[*]
```

The following example includes and excludes certain registers from self-gating in the ADDER subdesign:

```
prompt> set_self_gating_objects \
    -force_include ADDER/out1_reg[*] \
    -exclude ADDER/out2_reg[*]
```

The following example removes the directive to include and exclude self-gating for the registers in the ADDER subdesign:

```
prompt> set_self_gating_objects \
    -undo {ADDER/out1_reg[*] ADDER/out2_reg[*]}
```

The following example excludes every register present in the ADDER subdesign, except for the out1_reg bank, which is self-gated according to the specified options.

```
prompt> set_self_gating_objects \
    -exclude ADDER \
    -include ADDER/out1_reg[*]
```

The following example states that self-gating must be performed on the mid subdesign following the options specified by the **set_self_gating_options** command, and using NAND combinational cells as comparators.

```
prompt> set_self_gating_objects \
    -include mid \
    -type nand
```

In the following example, the register bank q_reg in the mid subdesign is self-gated overriding the previous specification. Note that the type of compare cell to be used is not given, so this register bank will be self-gated using the default compare cell (unlike the other registers of the mid subdesign, which will be self-gated using NAND cells according to the previous example).

```
prompt> set_self_gating_objects \
           -force_include mid/q_reg
```

SEE ALSO

```
compile_ultra(2)
set_self_gating_options(2)
report_self_gating(2)
set_clock_gating_objects(2)
```

set_self_gating_options

Sets the self-gating options for the self-gate insertion. This command is supported only in topographical mode.

SYNTAX

```
status set_self_gating_options
  [-min_fanout min_fanout_count]
  [-max_fanout max_fanout_count]
  [-min_bitwidth min_bitwidth_count]
  [-max_bitwidth max_bitwidth_count]
  [-interaction_with_clock_gating none | insert | merge]
```

Data Types

<i>min_fanout_count</i>	integer
<i>max_fanout_count</i>	integer
<i>min_bitwidth_count</i>	integer
<i>max_bitwidth_count</i>	integer

ARGUMENTS

-min_fanout *min_fanout_count*

This option is deprecated; instead, use "-min_bitwidth". Specifies the minimum bitwidth of a single self-gating cell.

-max_fanout *max_fanout_count*

This option is deprecated; instead, use "-max_bitwidth". Specifies the maximum bitwidth of a single self-gating cell.

-min_bitwidth *min_bitwidth_count*

Specifies the minimum bitwidth of a single self-gating cell. This setting is optional, and if not set it defaults to 4.

-max_bitwidth *max_bitwidth_count*

Specifies the maximum bitwidth of a single self-gating cell. This setting is optional, and if not set it defaults to 8.

-interaction_with_clock_gating none | insert | merge

Specifies the interaction between the self-gates to be inserted and traditional clock-gates. By default, value **insert** is assumed.

The value **none** prevents the tool from inserting self-gates on already clock-gated registers.

The value **insert** directs the tool to insert self-gates on already clock-gated registers.

The value **merge** directs the tool to insert self-gates on already clock-gated registers and merges the clock gates and the self-gates.

Merging can happen only if the clock gate and the self-gate are in the same hierarchy, have the same operating condition, and have the same test enable signal. Merging can happen during the first **compile_ultra** command or during an incremental compile execution, in which cases self-gate insertion and clock-gate merging are performed at the same time. To do this, specify the **set_clock_gating_options -interaction_with_clock_gating merge** command before any **compile_ultra -self_gating** command.

DESCRIPTION

This command sets the self-gating options to be used for self-gating with the **compile_ultra -self_gating** command.

The self-gating options specifies the following aspects of self-gating:

- Conditions when self-gating is applied
 - Interaction with traditional clock-gating elements
-

EXAMPLES

Default values are assumed for all unspecified options. In particular, option values from previous self-gating options settings are not stored.

The following example sets the self-gating options such that each self-gate is inserted to gate at least 2 and at most 10 bit-widths that belong to single-bit and/or multibit registers:

```
prompt> set_self_gating_options -min_bitwidth 2 -max_bitwidth 10
```

The following example sets the self-gating options such that traditional clock gated registers are allowed to be self-gated and, if possible, both gates are merged

```
prompt> set_self_gating_options -interaction_with_clock_gating merge
```

SEE ALSO

[compile_ultra\(2\)](#)

[all_self_gates\(2\)](#)

set_sense

Specifies unateness propagating forward for pins with respect to clock source.

SYNTAX

```
status set_sense
  [-type clock]
  [-positive]
  [-negative]
  [-stop_propagation]
  [-pulse pulse_type]
  [-clocks clock_list]
  pins
  -clock_leaf
```

Data Types

```
pulse_type string
clock_list list
pins list
```

ARGUMENTS

-type *clock*

Currently the sense is only applied to clock networks. If you do not specify this option, the default is **clock**.

-positive

Propagates only the positive unate paths forward from the specified pins.

The **-positive** option is mutually exclusive with the **-negative**, **-pulse**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-negative

Propagates only the negative unate paths forward from the specified pins.

The **-negative** option is mutually exclusive with the **-positive**, **-pulse**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-stop_propagation

Stops propagation of the specified clocks at the specified pins along the clock paths only.

The **-stop_propagation** option is mutually exclusive with the **-positive**, **-negative**, **-logical_stop_propagation**, and **-pulse** options. You must specify one of these options.

-pulse *pulse_type*

Specifies the type of pulse clock that is generated from the specified pins. You must specify one of the following values:

rise_triggered_high_pulse, **rise_triggered_low_pulse**, **fall_triggered_high_pulse**, or **fall_triggered_low_pulse**.

The **-pulse** option is mutually exclusive with the **-positive**, **-negative**, **-logical_stop_propagation**, and **-stop_propagation** options. You must specify one of these options.

-clocks clock_list

Specifies the clocks to which the specified clock sense applies.

If you do not specify this option, the clock sense setting applies to any clock that passes through the specified pins.

pins

Specifies the pins on which to set the clock sense.

DESCRIPTION

This command provides the capability to define the clock sense at nonunate points in the clock network. The command is ignored if it is used on a unate point in the clock network. The specified clock sense propagates forward from the specified pins.

If the **-clocks** option is used, only the specified clocks are considered. Otherwise, all clocks passing through the specified pins are considered.

Warning messages are issued if the specified sense cannot be respected on the specified pins. Hierarchical pins are not supported.

To undo the settings made by the **set_sense** command, use the **remove_sense** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example specifies positive unateness for a pin named XOR/Z with respect to the CLK1 clock:

```
prompt> set_sense -positive -clocks [get_clocks CLK1] XOR/Z
```

The following example specifies a pulse type of **rise_triggered_high_pulse** for all clocks passing through a pin named MUX/Z:

```
prompt> set_sense -pulse rise_triggered_high_pulse MUX/Z
```

SEE ALSO

[remove_sense\(2\)](#)

set_separate_process_options

Sets options that control whether the tool uses separate UNIX processes for extraction, placement, and routing.

SYNTAX

```
status set_separate_process_options  
      [-placement true | false]
```

ARGUMENTS

-placement true | false

Specifies whether placement should use a separate UNIX process.

If true, a separate UNIX process is used.

If false (the default), placement is run within the parent UNIX process.

DESCRIPTION

The **set_separate_process_options** command sets options that control whether the tool uses separate UNIX processes for extraction, placement, and routing. The setting is not saved in database. It is applicable only in the current session and must be reapplied if desired in a new session.

You can use the **report_separate_process_options** command to report the current settings for separate processes.

EXAMPLES

The following example sets the **-placement** option to true to turn on separate processes for placement.

```
prompt> set_separate_process_option -placement true  
1
```

SEE ALSO

[report_separate_process_options\(2\)](#)

set_serialize_configuration

Specifies the serializer configuration for the design.

SYNTAX

```
status set_serialize_configuration
[-inputs number_of_deserializer_inputs]
[-outputs number_of_serializer_outputs]
[-ip_inputs list_core_instance_and_number_of_deserializer_ip_inputs]
[-ip_outputs list_core_instance_and_number_of_serializer_ip_outputs]
[-update_stage true | false]
[-exclude_clocks list_of_clock_names_to_exclude]
[-serializer_clock clock_for_serializer_controller]
[-update_clock clock_for_update_stage_in_load_deserializer]
[-strobe user_defined_signal_for_strobe_in_unload_serializer]
[-wide_duty_cycle true | false]
[-parallel_mode parallel_scan_compression_mode_name]
[-test_mode serial_scan_compression_mode_name]
```

ARGUMENTS

-inputs *number_of_deserializer_inputs*

Specifies the number of inputs used to load scan data in the deserializer for scan compression. The inputs are a subset of the scan inputs used for base mode (reconfigurable scan mode).

The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-outputs *number_of_serializer_outputs*

Specifies the number of outputs used to observe scan data from the serializer for scan compression. The outputs are a subset of the scan outputs used for base mode (reconfigurable scan mode).

The default is equal to the minimum number of chains that DFT would build if scan compression were not enabled.

-ip_inputs *list_core_instance_and_number_of_deserializer_ip_inputs*

In the serializer IP insertion flow, this command accepts a list of pairs of the core instance names and the number of deserializer inputs for the core. The inputs are a subset of the scan inputs used for base mode (reconfigurable scan mode).

The default is null (no value specified). Deserializer IP is inserted only for the DFTMAX cores specified in the list.

-ip_outputs *list_core_instance_and_number_of_serializer_ip_outputs*

In serializer IP insertions flow, this command accepts list of pairs of the core instance names and the number of serializer outputs for the core. The inputs are a subset of the scan outputs used for base mode (reconfigurable scan mode).

The default is null (no value specified). Serializer IP is inserted only for the DFTMAX cores specified in the list.

-update_stage true | false

Adds an update stage to the deserializer.

The default is **false**.

-exclude_clocks *list_of_clock_names_to_exclude*

Specifies the list of clock names to be excluded from gating in the serializer clock controller. The specified clock must be previously declared as a test clock using the **set_dft_signal** command.

The default is null (no value specified).

-serializer_clock *clock_for_serializer_controller*

In hierarchical flows, when **set_scan_compression_configuration -serialize** is set to **core_level**, you can specify the clock to be used for the deserializer-serializer. The specified clock must be previously declared as a test clock using the **set_dft_signal** command.

The default is null (no value specified).

-update_clock *clock_for_update_stage_in_load_deserializer*

In hierarchical flows, when the **set_scan_compression_configuration -serialize** option is set to **core_level**, you can specify the clock to be used for the update stage in the unload deserializer. The specified clock must be previously declared as a test clock using the **set_dft_signal** command.

The default is null (no value specified).

-strobe *user_defined_signal_for_strobe_in_unload_serializer*

In hierarchical flows, when **set_scan_compression_configuration -serialize** is set to **core_level**, you can specify a test data signal to be used for the strobe signal in load serializer. The specified signal must be previously declared as a test data signal using the **set_dft_signal** command.

The default is null (no value specified).

-wide_duty_cycle *true | false*

When set to **true**, the serializer clock controller generates the internally generated scan shift clocks and the update stage clock with a duty cycle closer to 50%, which helps prevent timing issues.

The default is **false**, which generates these clocks by passing through selected high-frequency clock pulses from the clock source.

-parallel_mode *parallel_scan_compression_mode_name*

Specifies the parallel ScanCompression mode that is to be associated with the serial ScanCompression_mode as indicated by the **-test_mode** switch.

The default is null (no value specified).

-test_mode *serial_scan_compression_mode_name*

Specifies the scan compression test mode to be applied to the appropriate parameters of this serializer configuration specification.

The default is **all_dft**, except when **define_test_mode** is used. In this case, the default is the value of the test mode defined last.

DESCRIPTION

The **set_serialize_configuration** command allows you to specify certain DFTMAX insertion parameters prior to using the **insert_dft** command.

The command also enables the configuration of the number of serial scan inputs and serial scan outputs that are to be used for a particular serial scan compression mode. In the serializer IP insertion flows, you can specify the number of serial scan inputs and outputs for every DFTMAX core using the **-ip_inputs** and **-ip_outputs** options.

The other parameters are used to specify the clocks that can be excluded from clock-gating using the **-exclude_clocks** option, as well as the serializer clock in core-level flows using the **-serializer_clock** option.

An update stage can be inserted along with the deserializer to enable fast clocking schemes when the **-update_stage** option is set to **true**. A parallel scan compression mode can be associated with the serial scan compression mode specified by the **-test_mode** option using the **-parallel_mode** option. The parallel mode has direct access to the decompressor-compressor active in the serial scan compression mode.

```

set_size_only

Controls whether the specified leaf cells can only be sized during optimization.

SYNTAX

```
status set_size_only
  [-all_instances]
  object_list
  [true | false]
```

Data Types

object_list collection

ARGUMENTS

-all_instances

Controls how the size-only setting is applied to child instances of multiply instantiated designs.

When you use this option, if a specified cell is in a multiply instantiated instance of a subdesign, the tool applies the size-only setting to the similar cells in all instances of that subdesign.

This is especially useful to avoid changing the current design to issue this command in different designs.

object_list

Specifies the leaf cells on which to apply the size-only setting.

true | false

Specifies the value of the size-only setting.

The default is **true**, so **set_size_only U1** has the same effect as **set_size_only U1 true**.

DESCRIPTION

This command applies size-only settings to the specified leaf cells.

When you apply a size-only setting of **true** to leaf cell, optimization can perform only sizing operations on that cell. A setting of **false** removes the size-only settings for the specified leaf cells.

For example, if apply a size-only setting of **true** to a cell, the tool attempts to optimize this cell by replacing it with a cell of the same function. The size-only setting on a cell does not prevent changes to the net driven by this cell. For example buffers can be added to this net. To prevent changes to the net, use the **set_dont_touch** command to set the **dont_touch** attribute on the net.

To report the size-only settings, use the **report_cell** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example applies a size-only setting of **true** to the cell named U1.

```
prompt> set_size_only U1
```

The following example removes the size-only setting from the cell named U1.

```
prompt> set_size_only U1 false
```

The following example uses the **-all_instances** option.

```
prompt> set_size_only -all_instances mid1/bot1/c1
Information: Set size_only for all instances of cell 'c1'
in subdesign 'bot'. (UID-193)
1
```

set_spfm_loss

Set the spfm loss on the design.

SYNTAX

```
status set_spfm_loss
    |spfm_loss
    -registers cell_or_port_list
```

DESCRIPTION

This command set the spfm loss on the design. The value of the spfm target is between 0.0 to 100.0.

EXAMPLES

The following example set the spfm_loss to be 1.2

```
prompt> set_spfm_loss 1.2
```

SEE ALSO

`create_safety_register_rule(2)`

set_spfm_target

Set the spfm target on the design.

SYNTAX

```
status set_spfm_target
      \!spfm_target
```

DESCRIPTION

This command set the spfm target on the design. The value of the spfm target is between 0.0 to 100.0. Teh spfm_target will trigger automatic inference and creation of safety register.

EXAMPLES

The following example set the spfm_target to be 1.2

```
prompt> set_spfm_target 1.2
```

SEE ALSO

`create_safety_register_rule(2)`

set_streaming_compression_configuration

Specifies the streaming compression configuration for the design.

SYNTAX

```
status set_streaming_compression_configuration
[-compressed_max_length max_chain_length
 | -max_length max_chain_length
 | -chain_count chain_count]
[-inputs number_of_inputs]
[-outputs number_of_outputs]
[-external_clock_chain true | false]
[-test_mode compression_mode_name]
[-base_mode base_mode_name]
[-clock clock_name]
[-decompressor_clock clock_name]
[-compressor_clock clock_name]
[-exclude_clocks clock_name_list]
[-min_power false | true]
[-shift_power_groups false | true]
[-shift_power_chain_length chain_length]
[-shift_power_chain_ratio chain_ratio]
[-shift_power_clock clock_name]
[-shift_power_disable test_control_name]
[configuration_ports Specify_ports_for_multiple_configuration_IP]
```

Data Types

<i>max_chain_length</i>	integer
<i>chain_count</i>	integer
<i>number_of_inputs</i>	integer
<i>number_of_outputs</i>	integer
<i>compression_mode_name</i>	string
<i>base_mode_name</i>	string
<i>clock_name</i>	string
<i>clock_name_list</i>	list
<i>chain_length</i>	integer
<i>chain_ratio</i>	integer
<i>test_control_name</i>	string

ARGUMENTS

-compressed_max_length *max_chain_length*

Specifies the maximum allowed number of shift cycles of the entire scan compression path (from decompressor inputs to compressor outputs). The tool adjusts the codec shift register and compressed chain lengths together to find an optimal architecture that meets this constraint. If unable to do so, the tool issues an error. See the DESCRIPTION section for more information.

This specification applies only to the codec and its compressed chains. External scan constructs, such as scan data pipelining or external chains, are not included.

-max_length *max_chain_length*

Specifies the maximum allowed length of the compressed scan chains only (not including the codec shift registers). The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-chain_count *chain_count*

Specifies the number of compressed scan chains to build. The tool attempts to meet this constraint. If unable to do so, the tool issues a warning. See the DESCRIPTION section for more information.

-inputs *number_of_inputs*

Specifies the number of scan data inputs used to drive the streaming compression decompressor.

-outputs *number_of_outputs*

Specifies the number of scan data outputs used to capture data from the streaming compression compressor.

-external_clock_chain true | false

Controls whether an external on-chip clocking (OCC) chain is created.

When set to **true** (the default), an external clock chain is created.

When set to **false**, the clock chain is driven by the decompressor. In this case, you must have at least two inputs to the streaming compression codec (an **-inputs** value of 2 or more).

-test_mode *compression_mode_name*

Specifies the streaming compression test mode to be applied to the appropriate parameters of this streaming configuration specification.

The default value is **all_dft**, except when **define_test_mode** is used. In this case, the default is the value of the **test_mode** defined last.

-base_mode *base_mode_name*

Specifies the base mode (or Internal_scan mode) that is to be associated with the ScanCompression_mode indicated by the **-test_mode** switch. By default, the value is Internal_scan.

-clock *clock_name*

Specifies the scan clock to be used for the streaming compression codec (compressor and decompressor) to be inserted. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. By default, the tool selects the dominant scan clock, which typically results in the fewest lockup latches at the decompressor outputs and compressor inputs.

In an OCC controller flow (DFT-inserted or user-defined), you can specify the name of an ATE clock that is predefined with the **set_dft_signal** command. This specification is mapped to an OCC controller clock associated with that ATE clock during DFT insertion.

-decompressor_clock *clock_name*

Specifies the scan clock to be used for the streaming decompressor to be inserted. This option is similar to the **-clock** option, but it specifies the clock for the decompressor only. This option takes precedence over the **-clock** option.

-compressor_clock *clock_name*

Specifies the scan clock to be used for the streaming compressor to be inserted. This option is similar to the **-clock** option, but it specifies the clock for the compressor only. This option takes precedence over the **-clock** option.

-exclude_clocks *clock_name_list*

Specifies the list of clock names to be excluded from automatic codec clock selection (when the **-clock** option is not used). The specified clocks must be previously declared as test clocks using the **set_dft_signal** command. The default is an empty list.

-min_power false | true

When set to **true**, specifies that compressor inputs are to be gated for power saving. The **insert_dft** command creates the

compressor logic such that it is active only during scan shift in that compression mode. The compressor logic is inactive during scan capture in that mode, during other test modes, and during mission mode. This eliminates power consumption due to switching activity in the compressor during functional operation (which is at-speed rather than at test clock frequencies). The default of this option is **false**.

-shift_power_groups false | true

Enables the shift power groups feature. This feature implements a shift power control chain that allows ATPG to selectively gate groups of compressed chains for shift power reduction. The gated chains still shift, but they shift constant (non-toggling) values into the chains, which reduces toggle activity.

If the option is set true; DFTMAX Ultra calculates shift power chain length automatically. DFTMAX Ultra calculates SPC length as: Minimum of {number of chains of codec/3, max shift length of chain}.

For a specific SPC length or chain ratio use **-shift_power_chain_length** or **-shift_power_chain_ratio** options.

The default is **false**, which does not implement the control chain or gating logic.

-shift_power_chain_length chain_length

Specifies the length of the shift power control (SPC) chain. This value directly controls the number of compressed chain groups.

Use this option to keep the length of the SPC chain constant as the compression architecture changes.

-shift_power_chain_ratio chain_ratio

Specifies the ratio of compressed chains to each shift power control (SPC) register. This value directly controls the number of compressed chains in each group.

Use this option to keep the group size constant as the compression architecture changes.

-shift_power_clock clock_name

Specifies the clock to use for the shift power control chain. The specified clock must be previously declared as a test clock using the **set_dft_signal** command. By default decompressor clock is selected as shift power clock.

-shift_power_disable test_control_name

Specifies the signal that, when asserted to its active value, disables the shift power logic. The specified signal must be previously declared as a TestControl signal using the **set_dft_signal** command. By default, the shift power logic is always active and no shift power disabling logic is implemented.

DESCRIPTION

The **set_streaming_compression_configuration** command allows you to specify certain streaming compression insertion parameters prior to using the **insert_dft** command.

There are three related options to control the number of compressed scan chains. Only one option can take effect at a time. They are, in order of highest precedence first:

- **-compressed_max_length**
- **-max_length**
- **-chain_count**

The command also enables configuration of the number of scan inputs (using **-inputs**) and scan outputs (using **-outputs**).

By default, the tool selects clocks for the decompressor and compressor that minimize the number of lock-up latches. (For most designs, the decompressor and compressor use the same clock.) You can use the following options to control codec clock selection, in order of highest precedence first:

- **-decompressor_clock, -compressor_clock**

- **-clock**
- **-exclude_clocks** (applies to automatic clock selection)
- Automatic clock selection

There are five related options to configure shift power groups. They are:

- **-shift_power_groups**
- **-shift_power_chain_length**
- **-shift_power_chain_ratio**
- **-shift_power_clock**
- **-shift_power_disable**

set_structure

Sets structure attributes on a design or on a list of designs, to determine how the designs are structured during compile.

SYNTAX

```
status set_structure
  [true | false]
  [-design design_list]
  [-boolean true | false]
  [-boolean_effort low | medium | high]
  [-timing true | false]
```

Data Types

design_list list

ARGUMENTS

true | false

Specifies the value to which the **structure** attribute is to be set. If set to **true** (the default), **compile** adds logic structure to the specified designs by adding intermediate variables factored from the designs' equations.

-design *design_list*

Specifies a list of designs on which the **structure** attribute is to be set. The default value is the current design.

-boolean true | false

Specifies the value to which the **structure_boolean** attribute is to be set. If set to **true**, and if the **structure** attribute is also set to **true**, **compile** uses Boolean (non-algebraic) optimization on the specified designs. The default value is **false**. If **structure** is **false**, **structure_boolean** is ignored.

-boolean_effort low | medium | high

Specifies the value to which the **boolean_effort** attribute is to be set. This attribute specifies the relative amount of CPU time to be spent by Boolean (non-algebraic) optimization during the structuring phase of **compile**. The default value is **low**.

-timing true | false

Specifies the value to which the **structure_timing** attribute is to be set. If **structure** is set to **true**, by default **structure_timing** is also **true**, and **compile** uses timing-driven structuring on the specified designs. Set this attribute to **false** if you do not want timing-driven structuring. If **structure** is **false**, **structure_timing** is ignored.

DESCRIPTION

The **set_structure** command sets structure attributes on a design or on a list of designs, to determine how the designs are structured during **compile**. If **set_structure** is called without a value, by default the design is structured.

This optimization step adds logic structure to a design by adding intermediate variables. The **compile** command searches for subfunctions that can be factored out and evaluates these factors based on the size of the factor and the number of times the factor appears in the design. The subfunctions that most reduce the logic are converted to intermediate variables and factored out of the design's equations. When **structure** is **true**, by default **structure_timing** is also **true**, and timing-driving structuring is automatically done unless **structure_timing** is set to **false**. With **structure** set to **true**, setting **structure_boolean** to **true** enables Boolean (non-algebraic) optimization during structuring. If **structure** is **false**, both **structure_boolean** and **structure_timing** are ignored.

To remove the **structure**, **structure_boolean**, **boolean_effort**, and **structure_timing** attributes, use the **remove_attribute** command. To remove all attributes, use the **reset_design** command.

EXAMPLES

In the following example, structuring, timing-driven structuring, and Boolean optimization are enabled on the design named TEST1 and structuring is disabled on the design named TEST2:

```
prompt> set_structure -design TEST1 -boolean
```

```
prompt> set_structure -design TEST2 false
```

In the following example, structuring is enabled and timing-driven structuring is disabled on the design named ADD1:

```
prompt> set_structure -design ADD1 -timing false
```

In the following example, structuring is disabled for all designs read in memory:

```
prompt> set_structure -design [get_designs *] false
```

set_svf

Generates a Formality setup information file for efficient compare point matching in Formality.

SYNTAX

Boolean **set_svf**
 filename
 [-append]
 [-off]

ARGUMENTS

filename

Names the file into which Formality setup information will be recorded. You must specify a file name unless the -off option is specified.

-append

Appends to the specified file. If another Formality setup verification file is already open then it will be closed before opening the specified file. If -append is not used then **set_svf** will overwrite the named file, if it exists.

-off

Stops recording Formality setup information to the currently-open file. To resume recording into the same file, you must re-issue the **set_svf** command with the -append option.

DESCRIPTION

This command causes Design Compiler to start recording setup information for Formality, the Synopsys formal verification tool. The SVF ("Setup Verification for Formality") file that is produced is used by Formality during the matching step to facilitate the alignment of compare points. By using the automatically-generated SVF file, the user is relieved of the time-consuming and error-prone process of entering the setup information manually.

To record setup information for formal verification products other than Formality, use the **set_vsdc** command, instead.

The SVF file is used to account for name changes that occur during synthesis as a result of running commands such as group, ungroup, uniquify and change_names. Also, certain operations performed by the compile command perform transformations that are recorded in the SVF file.

Further information on SVF files can be found in the Formality User Guide.

Once this command is issued, Design Compiler will begin recording all relevant operations. Because information is buffered internally, the file may not be complete until recording is stopped. Recording is stopped by running "set_svf -off" or by exiting dc_shell. Running **set_svf** with a new file name will write out and close the original SVF file before starting the new one.

The SVF file is stored in encrypted format.

This command returns a Boolean value indicating whether **set_svf** succeeded (true) or not (false).

Formality setup recording might be enabled by default in Design Compiler's system-wide setup file. If so, then the file name used is "default.svf". If you prefer a different file name then you may run **set_svf** in your setup file or script prior to performing any recordable operations. Alternately, you may disable SVF recording completely by running "set_svf -off".

EXAMPLES

The following example shows a typical invocation of the command

```
prompt> set_svf my_design.svf
```

In the following example the Formality setup information is appended to the existing SVF file, barfile.svf.

```
prompt> set_svf -append barfile.svf
```

set_switching_activity

Sets the switching activity annotation on nets, pins, ports and cells of the current design.

SYNTAX

```
status set_switching_activity
[-static_probability static_probability]
[-toggle_rate toggle_rate]
[-state_condition state_condition]
[-path_sources path_sources]
[-rise_ratio rise_ratio]
[-period period_value | -base_clock clock]
[-type object_type_list]
[-hierarchy]
[object_list]
[-verbose]
[-scenarios {scenario_name1 scenario_name2 ... }]
```

Data Types

<i>static_probability</i>	float
<i>toggle_rate</i>	float
<i>state_condition</i>	string
<i>path_sources</i>	list
<i>rise_ratio</i>	float
<i>period_value</i>	float
<i>clock</i>	string
<i>object_type_list</i>	list
<i>object_list</i>	collection

ARGUMENTS

-static_probability *static_probability*

Specifies the static probability value. The static probability is a floating point number between 0.0 and 1.0. It represents the percentage of the time the signal is at logic 1. For example, a static probability value of 0.25 indicates that the signal is at logic 1 for 25% of the time.

-toggle_rate *toggle_rate*

Specifies the toggle rate value. The toggle rate is a positive floating point number that represents the number of 0->1 and 1->0 transitions that the signal makes during a period of time. The period is by default 1 unit and can be specified with the **-period** option. The time unit defined in the library is used as the time unit. Alternatively, a related clock can be annotated using the **-base_clock** argument, and the specified toggle rate will be relative to the related clock period.

-state_condition *state_condition*

Specifies the state condition when annotating state-dependent toggle rates on pins or state-dependent static probabilities on cells. State dependent toggle rates can be annotated when the internal power of the library cell pin is characterized with state-dependent power tables. State-dependent static probabilities can be annotated when the cell leakage power is characterized with state-

dependent power tables. The state condition specified with this argument must be logically equivalent to a state condition in the internal or leakage power characterization.

-path_sources path_sources

Specifies the path sources when annotating path-dependent toggle rates on pins. This can be used when the library cell pin has path-dependent internal power characterization. The path sources specified with this argument must be the same as those in the internal power characterization.

-rise_ratio rise_ratio

Specifies the ratio of rise transitions to total transitions for the specified toggle rate when annotating pins that are characterized with both rise and fall internal power. The *rise_ratio* argument is a floating point number between 0.0 (all transitions are falling) and 1.0 (all transitions are rising). You need to specify a toggle rate in order to use this option. The default value is 0.5.

-period period_value

Specifies the time period for which the number of transitions given in the toggle rate *-toggle_rate* occur. The time units for this value are those specified in the main technology library. When this argument is used, the *-toggle_rate* specified by the **-toggle_rate** argument is divided by the given *-period_value*; The resulting toggle rate is then annotated to the object(s) specified with the **set_switching_activity** command. If the **-period** argument is not specified, a default value of 1.0 is assumed.

-base_clock clock

Specifies a clock to which *toggle_rate* is related. This clock is referred to as the object's related clock. When specified, the related clock is annotated to the design objects, and during power calculations the annotated toggle rate value is divided by the related clock period. The resulting toggle rate is then used for calculating power. The clock period can be changed between different runs of **report_power** and the resulting change in the toggle rate of the design objects will be used automatically without re-annotating the switching activity. You can also specify "*" as the *clock* value of the **-base_clock** argument. This specifies that Power Compiler will infer the related clock on the design object automatically before power calculations.

-type object_type_list

Specifies a list of object types that will be used for implicitly selecting the objects that will be annotated with the specified switching activity information. The *object_type_list* argument can be a list of one or more of the following object types:

- registers** (sequential cell outputs),
- tristates** (tristate cell outputs),
- black_boxes** (black box cell outputs),
- inputs** (input design ports or hierarchical instance pins),
- outputs** (output design ports or hierarchical instance pins),
- inouts** (inout design ports / hierarchical instance pins),
- ports** (design port or hierarchical instance pins),
- nets** (nets),
- regs_on_clocks** *clock_list* (outputs of flip-flops clocked by the clocks in *clock_list*),
- clock_gating_cells** (clock gating cell outputs),
- memory** (memory cell outputs).

When the **-type** argument is used all the objects in the current instance (or current design, if current instance is not set) that satisfy the selection criteria will be annotated with the specified switching activity. If the **registers** or **regs_on_clocks** selection type is used, both the non-inverting (Q) and inverting (QN) sequential cell outputs are annotated. Thenon-inverting outputs are annotated with the specified toggle rate and static probability. The inverting outputs are annotated with the specified toggle rate. The annotated static probability on the inverting outputs is $1.0 - sp_val$ where *sp_val* is the specified static probability. The **regs_on_clocks** selection type needs the argument *clock_list* which is a list of clock names. This selection type selects all the registers that are clocked by a clock whose name is in *clock_list*. A register is clocked by a clock *clk* if the clock pin of the register is in the transitive fanout of the source port or pin of the clock *clk*. Note that although the **registers** selection type applies to both flip-flops and latches, the **regs_on_clock** selection type applies only to flip-flops. Both the **registers** and **regs_on_clocks** selection types exclude clock-gating cells, that might have internal latches and are therefore sequential cells.

Note that the *object_list* argument for explicitly specifying the objects to be annotated, and the **-type** argument for implicitly specifying the objects to be annotated, are mutually exclusive.

-hierarchy

Used with the **-type** argument and specifies that all the objects in all the hierarchy that satisfy the selection criteria will be annotated. When this option is not specified, only the top level objects in the current instance are considered.

object_list

Specifies a list of nets, pins, ports or cells in the current design on which the **-static_probability** and **-toggle_rate** switching activity values are to be set.

Note that the *object_list* argument for explicitly specifying the objects to be annotated.

If the object is a hierarchical cell, it is used with the **-type** argument and specifies that all the objects in the hierarchical cell that satisfy the selection criteria will be annotated.

-verbose

Provides a more verbose output when switching activity is annotated.

DESCRIPTION

This command can be used to annotate design nets, ports, pins and cells with the different kinds of switching activity. These include simple toggle rate and static probability on nets, ports and pins; state and path dependent toggle rates on cell pins, and state dependent static probabilities on cells.

Toggle rates and static probabilities are annotated using the **-toggle_rate** and **-static_probability** arguments respectively. The toggle rate and static probability can be made state dependent by specifying the state condition with the **-state_dep** argument. The toggle rate can be made path dependent by specifying the path sources with the **-path_sources** argument. A related clock can be specified using the **-base_clock** argument. The annotated toggle rate is divided by the related clock period during power calculation to calculate the effective toggle rate. When none of the **-toggle_rate**, **-static_probability** and **-base_clock** arguments are given, then annotated switching activity is removed from the specified objects.

The design objects that will be annotated with switching activity can be specified explicitly and implicitly as a list of objects. The objects can also be specified implicitly by the **-type** and **-hierarchy** arguments.

For statistics on the switching activity annotation on the current design, use the **report_saif** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following **set_switching_activity** command annotates a simple toggle rate value of $33 / 1320 = 0.025$ and a static probability value of 0.015 to all design input ports.

```
prompt> set_switching_activity -toggle_rate 33 -period 1320 \
           -static_probability 0.015 [get_inputs]
```

The following example annotates a toggle rate value of 0.25 and a static probability value of 0.015 to all design input ports. The clock CLK is specified as the related clock for all inputs. When calculating the power, the annotated toggle rate value (0.25) is divided by the related clock period (10) and the resulting toggle rate (0.025) is used.

```
prompt> create_clock CLK -period 10
prompt> set_switching_activity -toggle_rate 0.25 -base_clock CLK \
           -static_probability 0.015 -type inputs
```

The following example annotates state-dependent static probabilities on the cell or1:

```
prompt> set_switching_activity -static_probability 0.10 \
           -state_condition "A & B" [get_cell or1]
prompt> set_switching_activity -static_probability 0.35 \
```

```
-state_condition "A & ! B" [get_cell or1]
prompt> set_switching_activity -static_probability 0.25 \
-state_condition "! A & B" [get_cell or1]
prompt> set_switching_activity -static_probability 0.30 \
-state_condition "! A & ! B" [get_cell or1]
```

The following example annotates simple and path-dependent toggle rates on the Y output pin of the cell xor1:

```
prompt> set_switching_activity -toggle_rate 0.022 \
[get_pin xor1/Y]
prompt> set_switching_activity -toggle_rate 0.020 \
-path "A" [get_pin xor1/Y]
prompt> set_switching_activity -toggle_rate 0.002 \
-path "B" [get_pin xor1/Y]
```

The following example removes the switching annotation from all sequential cell outputs in the current design:

```
prompt> set_switching_activity -type registers -hierarchy
```

The following example annotates switching activity on all the registers in the current design that are clocked by the clk1 or clk2 clocks.

```
prompt> set_switching_activity -toggle_rate 0.1 \
-static_probability 0.5 \
-type {regs_on_clock {clk1 clk2}} -hierarchy
```

The following example annotates all primary inputs with a toggle rate of 0.2, a static probability of 0.5, and a related_clock attribute with a value of "*". When power is calculated during the **report_power** command, the related clocks on the design inputs are inferred automatically and the toggle rate value of 0.2 is scaled by the related clock period.

```
prompt> set_switching_activity -toggle_rate 0.2 \
-static_probability 0.5 -base_clock "*" \
-type inputs
prompt> report_power
```

set_switching_activity_profile

Generates switching activity profiles and sets the profiles on input-bused ports of the current design.

SYNTAX

```
status set_switching_activity_profile
[-uniform {static_probability toggle_rate}]
[-linear {{breakpoint_0 static_probability_0 toggle_rate_0} {breakpoint_1 static_probability_1 toggle_rate_1}}]
[-normal_dist {std_dev temp_corr sample_rate is_signed}]
[-period period_value | -base_clock clock]
[object_list]
[-all_buses]
[-verbose]
```

Data Types

<i>static_probability</i>	float
<i>toggle_rate</i>	float
<i>breakpoint_0</i>	integer
<i>static_probability_0</i>	float
<i>toggle_rate_0</i>	float
<i>breakpoint_1</i>	integer
<i>static_probability_1</i>	float
<i>toggle_rate_1</i>	float
<i>std_dev</i>	float
<i>temp_corr</i>	float
<i>sample_rate</i>	float
<i>is_signed</i>	Boolean
<i>period_value</i>	float
<i>clock</i>	string
<i>object_list</i>	collection

ARGUMENTS

-uniform {*static_probability* *toggle_rate*}

This optional argument sets the same switching activity on all bits of a bus. The static probability is a positive floating-point number between 0.0 and 1.0. It represents the percentage of time that the signal is at logic 1. For example, a static probability value of 0.25 indicates that the signal is at logic 1 for 25 percent of the time. The toggle rate is a positive floating-point number that represents the number of 0->1 and 1->0 transitions that the signal makes during a period of time. The period is, by default, 1 unit and can be specified with the **-period** option. The time unit defined in the library is used as the time unit. Alternatively, a related clock can be annotated using the **-base_clock** option, and the specified toggle rate is relative to the related clock period.

-linear {{*breakpoint_0* *static_probability_0* *toggle_rate_0*} {*breakpoint_1* *static_probability_1* *toggle_rate_1*}}

This optional argument sets a piecewise linear profile on a bus. The *breakpoint_0* is an integer number between the start bit and end bit of the bus. It represents the first bit position of a bus where the *static_probability_0* and *toggle_rate_0* is applied. Similarly with the *breakpoint_1*, it represents the second bit position of a bus where the *static_probability_1* and *toggle_rate_1* is applied. Each bit between *breakpoint_0* and *breakpoint_1* is set to the corresponding static probability and toggle rate that are calculated by the toggle rate values and static probability values on *breakpoint_0* and *breakpoint_1*.

-normal_dist {std_dev temp_corr sample_rate is_signed}

This optional argument generates a piecewise linear profile for the specified signal distribution and sets this profile on a bus. std_dev represents the standard deviation of normal distribution. temp_corr is the word-level temporal correlation. sample_rate is the number of the input value changes during a period. is_signed is a Boolean value to indicate whether inputs are signed or unsigned.

-period period_value

This optional argument specifies the time period for which the number of transitions given in the toggle rate occur. The time units for this value are those specified in the main logic library. When this argument is used, the toggle rate specified is divided by the given "period_value"; the resulting toggle rate is then annotated to the objects specified with the **set_switching_activity_profile** command. If the **-period** argument is not specified, a default of 1.0 is assumed.

-base_clock clock

This optional argument specifies a clock to which the toggle rate is related. This clock is referred to as the object's related clock. When specified, the related clock is annotated to the design objects, and during power calculations the annotated toggle rate value is divided by the related clock period. The resulting toggle rate is then used for calculating power. The clock period can be changed between different runs of "report_power" and the resulting change in the toggle rate of the design objects is used automatically without re-annotating the switching activity. You can also specify "*" as the clock value of the **-base_clock** argument. The "*" specifies that Power Compiler infers the related clock on the design object automatically before power calculations.

object_list

This optional argument specifies a list of input bused ports in the current design on which the switching activity profiles are to be applied. Note that this command only supports in/out bused port. It does not support scalar port types (net, pin and so on). In addition, this command supports partial selection of a bus and a hierarchical bus as an object. The partial selection of a bus is a portion of a full bus. The hierarchical bus indicates a bus not in top-level design, but in a subdesign. The partial selection of a bus string should follow the format bus_name[start_bit:end_bit]. The hierarchical bus string should follow the format cell_name/bus_name. This command also supports use of the wildcard character in the object_list.

-all_buses

This optional argument sets the switching activity profile on all input buses of the current design. Note that **-all_buses** and **object_list** are exclusive options for explicitly specifying the bus to be annotated. Otherwise an error message is issued.

-verbose

This optional argument reports the switching activity profiles that are annotated on the object list.

DESCRIPTION

This command can be used to annotate design input bused ports with different kinds of switching activity profiles, including uniform profiles and piecewise linear profiles.

The **-uniform** option can set the same activity on all bits of a bus. The **-linear** option can set a piecewise linear profile for a bus. The **-normal** option can set a piecewise linear profile on a bus that is calculated from the specified signal distribution.

The design objects that are annotated with the switching activity profiles can be specified explicitly as a list of objects. The objects can also be specified by the **-all_buses** flag option.

For statistics on the switching activity annotation on the current design, use the **report_saif** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following **set_switching_activity_profile** command annotates a simple toggle rate value of $33 / 1320 = 0.025$ and a static probability value of 0.015 to an input bus a. The width of bus a is 8.

```
prompt> set_switching_activity_profile -uniform {0.015 33} \
    -period 1320 a -verbose
```

[reset_switching_activity\(2\)](#)
[report_power\(2\)](#)
[create_clock\(2\)](#)

set_synlib_dont_get_license

Specifies a list of synthetic library part licenses that are not automatically checked out.

SYNTAX

```
int set_synlib_dont_get_license  
    license_list
```

ARGUMENTS

license_list

Lists synthetic library part licenses that are not automatically checked out.

DESCRIPTION

Specifies a list of synthetic library part licenses that are not automatically checked out. By default, all synthetic library part licenses are automatically checked out if there is a possibility that they will be used. Add licenses to this list if they should not be automatically checked out when only the possibility of their use exists. The exception that licenses on this list can be checked out is, but only when read a design that **required** to have these licenses, or when manually requested via the **get_license** command. To determine what licenses are required for reading a design, use **report_design** command.

If all licenses in the list present in the key file, the command sets synlib variable **synlib_dont_get_license** to be the same list of licenses. To determine the current value of **synlib_dont_get_license**, type **list synlib_dont_get_license**.

The **set_synlib_dont_get_license** command fails if any of the license key is mistyped in the command or not present in the key file.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example issues an error message because the license key is mistyped in the command or not present in the key file.

```
prompt> set_synlib_dont_get_license \  
    {"Synlib_advMath" "Synlib_ALU"}  
Warning: Unrecognized key 'Synlib_advMath' found in 'synlib_set_dont_get_license' command. (UISN-30)  
Warning: Unrecognized key 'Synlib_ALU' found in 'synlib_set_dont_get_license' command. (UISN-30)  
0
```

The following example specifies that licenses named DesignWare-Foundation-Ultra and SynLib-AdvMath are not to be automatically checked out.

```
prompt> set_synlib_dont_get_license \
  {DesignWare-Foundation-Ultra SynLib-AdvMath}
{DesignWare-Foundation-Ultra SynLib-AdvMath}
1
```

SEE ALSO

`get_license(2)`

set_tap_elements

Specifies the set of TAP state elements for the boundary-scan TAP controller.

SYNTAX

```
int set_tap_elements  
    -state_cells cell_names
```

Data Types

cell_names list

ARGUMENTS

-state_cells *cell_names*

Specifies the set of TAP state elements *cell_names*.

DESCRIPTION

The **set_tap_elements** command identifies the set of TAP state elements in the boundary-scan TAP controller. The state elements can be specified in any order. A minimum of four state elements are required according to the IEEE 1149.1 standard.

EXAMPLES

The following example specifies four TAP state elements.

```
prompt> set_tap_elements -state_cells {  
    tap/simple/tap_state_reg[1],  
    tap/simple/tap_state_reg[3],  
    tap/simple/tap_state_reg[0],  
    tap/simple/tap_state_reg[2] }
```

set_target_library_subset

Restricts the optimization of a block to a subset of the target libraries.

SYNTAX

```
status set_target_library_subset
[-top | -object_list cells]
[-dont_use lib_cells]
[-use lib_cells]
[-clock_path]
[-only_here lib_cells]
[-milkyway_reflibs milkyway_replib_paths]
[library_file_name_list]
```

Data Types

<i>cells</i>	collection
<i>lib_cells</i>	collection
<i>milkyway_replib_paths</i>	list
<i>library_file_name_list</i>	list

ARGUMENTS

-top

Sets the target library subset on the top-level design, including all cells in the hierarchy.

If you do not specify either this option or the **-object_list** option, the tool uses the **-top** option by default. Specifying both options is also supported.

-object_list *cells*

Specifies the hierarchical cells on which to set the target library subset.

The cells are instances of hierarchical designs, and the subset restriction applies to these instances and their child instances. You cannot specify a target library subset on leaf-level cells.

If you do not specify either this option or the **-object_list** option, the tool uses the **-top** option by default. Specifying both options is also supported.

-dont_use *lib_cells*

Specifies the library cells that cannot be used for optimization within the block. This is in addition to the restrictions imposed by the *library_file_name_list* argument.

You can specify the library cell by name, such as AN2 or mylib/AN2, or by collections, such as [get_lib_cells */AN2]. You can also use wildcards. Wildcards are expanded according to the library cells in memory at the time the command is issued. In all cases, the library name is ignored. For example, the **-dont_use "lib1/AN2"** option restricts the use of all library cells that have the name AN2.

-use *lib_cells*

Specifies library cells that can be used for optimization within the block. This is in addition to the libraries listed in the *library_file_name_list* argument.

The syntax for the **-use** and **-dont_use** options are identical. If a library cell is listed in both the **-use** and **-dont_use** options, the **-use** option overrides the **-dont_use** option. A library cell with the **dont_use** attribute is not used even if it is listed in the **-use** option. To remove the **dont_use** attribute, use the **remove_attribute** command. Otherwise, the tool issues a reminder.

If you specify this option and you do not specify the *library_file_name_list* argument, the *library_file_name_list* argument takes on an empty default value.

-clock_path

When this option is specified, the requested target library subset will apply to cells along any clock path within the specified hierarchies, rather than all cells in these hierarchies. These clock path cells will be mapped using library cells in the subset, but will not be optimized further by Design Compiler.

-only_here lib_cells

Specifies the library cells that can be used for optimization within the specified blocks but cannot be used in other blocks (unless those blocks also list the library cell in an **-only_here** option).

The syntax for the **-only_here** and **-dont_use** options are identical. If a library cell is listed in both the **-only_here** and **-dont_use** options, the **-only_here** option overrides the **-dont_use** option. However, the **-only_here** option does not override the global **dont_use** attribute set by the **set_dont_use** command. Therefore, a library cell with the **dont_use** attribute is not used even if it is listed by the **-only_here** option.

The target library subset report does not show the effects of the global **dont_use** attribute setting. Therefore, you should check for any LIBSETUP-124 messages when you use the **set_target_library_subset** command. To remove a **dont_use** attribute that was set by the **set_dont_use** command, use the **remove_attribute** command. Otherwise, the tool issues a reminder.

-milkyway_reflibs milkyway_reflib_paths

Specifies the Milkyway reference library paths to associate with the identified instances. When you specify multiple reference library paths, enclose them in braces ({}). The list must be a subset of the reference library list for the design.

Design Compiler parses but ignores this option and passes it to the .ddc file or Milkyway database and the **write_script** command.

library_file_name_list

Specifies the libraries that are available to optimize the specified design instances. The list of libraries must be a subset of the libraries specified by the **target_library** variable.

If you do not specify this option, the behavior depends on whether you specify the **-use** option. If you do not specify the **-use** option, all the libraries listed in the **target_library** variable can be used. If you specify the **-use** option, only the cells specified in the **-use** option can be used.

DESCRIPTION

The **set_target_library_subset** command specifies a subset of target libraries that are available for use during the optimization of the specified instances. Usually, a library cell is selected from the libraries specified in the **target_library** variable. The **set_target_library_subset** command allows you to specify or filter the library cells to be used in a particular block.

The subset applies to the specified blocks and their child instances. A subset on a low-level block completely overrides a subset specified at a higher level.

The subset restriction applies only to cells that are created, mapped, or modified during optimization. The subset does not affect any unoptimized portions of the design. Use the **check_target_library_subset -verbose** command to see any cells that are already mapped to the library cells outside their subset.

To remove a target library subset from the design or a design instance, use the **remove_target_library_subset** or **reset_design** command.

As with most design constraints, the subset specifications are tied to the current design. If you change the current design to another level, and you want the subset to affect optimization at that level, you must reapply the **set_target_library_subset** command, or use the **characterize** or **propagate_constraints** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example sets the target libraries for the design to lib1.db and lib2.db but restricts the library cells used in block u1 to the lib2.db library.

```
prompt> set target_library "lib1.db lib2.db"
prompt> set_target_library_subset "lib2.db" -object_list [get_cells u1]
```

The following example restricts the AVOID1 and AVOID2 library cells from use in the u1 and u2 blocks.

```
prompt> set_target_library_subset -object_list "u1 u2" \
-dont_use "AVOID1 AVOID2"
```

The following example restricts the SPECIAL library cell for use only in the u1 and u2 blocks.

```
prompt> set_target_library_subset -object_list "u1 u2" \
-only_here "SPECIAL"
```

The following example has the same result as the previous example. The second **set_target_library_subset** command imposes no restrictions, so the cells from all the libraries specified by the **target_library** variable are allowed in the u1 and u2 blocks, including the SPECIAL library cell.

```
prompt> set_target_library_subset -top -dont_use "SPECIAL"
prompt> set_target_library_subset -object_list "u1 u2"
```

set_technology

Applies technology-node settings to the current design

SYNTAX

```
status set_technology  
  -node node_number
```

Data Types

node_number string

ARGUMENTS

-node *node_number*

Specifies the technology-node settings, such as "7", "12" or "16". You have to specify one of the supported technology node names.

DESCRIPTION

This command applies technology-node settings to the current design. It sets the parameters for placement and route engines to satisfy advanced node design rules. When you use the command, all the technology-node specific controls are applied to the design and the "technology_node" attribute is also set on the design.

It is recommended to use the **set_technology** command at the beginning of the design flow. For example, after you load and link the design, and before place and route.

The settings are persistent and saved in the design database, so you do not have to call this command multiple times in the flow. However, when you move to a newer release, you must use the **set_technology** command again, as the internal settings might get upgraded in the newer release.

You can use this feature in Design Compiler NXT topographical mode.

EXAMPLES

In the following example, the technology-node settings are applied to a design using the 7 nm technology.

```
prompt> set_technology -node 7  
7  
1
```

SEE ALSO

`set_hpc_options(2)`

set_test_assume

Sets the **test_assume** attribute to a logic value to be assumed on specified cell output pins throughout test design rule checking.

SYNTAX

```
integer set_test_assume
    zero_or_one_value
    pin_list
```

Data Types

```
zero_or_one_value   string
pin_list           list
```

ARGUMENTS

zero_or_one_value

Specifies the fixed value of the output pins. To assume a constant value of logic one, *zero_or_one_value* must be "1", "one", or "ONE." To assume a constant value of logic zero, *zero_or_one_value* must be "0", "zero", or "ZERO."

pin_list

Lists the hierarchical pins in the current design for which values are specified. If more than one pin is specified, they must be enclosed in braces ({}).

DESCRIPTION

The **set_test_assume** command sets the **test_assume** attribute to *zero_or_one_value* on the cell output pins on *pin_list*. The **dft_drc** command uses **test_assume** to freeze the assumed value on the specified pins throughout test design rule checking.

Use **set_test_assume** to set conditions that would otherwise be unknown to **dft_drc**, such as the state of a non-scan register, or the output of a RAM. Known values are often applied to the design circuitry to facilitate testing by configuring the design circuitry into the desired test mode. For example, during testing, a state could be preloaded into the non-scan registers of an on-chip test controller. This condition could configure the scan chains in the design to form multiple parallel scan chains. Or, if it is known that prior to testing, all address locations of an on-chip RAM are preloaded with a fixed pattern, this pattern can be assumed at the data output pins of the RAM when testing the surrounding functional logic. You can communicate these preloaded values to the testing software through the **test_assume** attribute.

Note: The specified conditions must exist throughout testing, regardless of other changes in the design state. Otherwise, incorrect design rule checking reports can result. If the assumed state is not attainable or not held throughout the scan test sequence, it is considered best practice to use the initialization protocol to provide initialization vectors that perform the assumed setup, instead of using **set_test_assume**, which could result in errors. The **read_test_protocol -section test_setup** is used to read in this initialization protocol.

Use the **report_test_assume** command to list the **test_assume** attributes on a design.

To remove selected or all **test_assume** attributes from a design, use the **remove_attribute** or **reset_design** command.

EXAMPLES

The following commands specify a fixed internal state to assume for a register in an on-chip test controller:

```
prompt> set_test_assume 0 my_tap/reg3/Q  
prompt> set_test_assume 1 my_tap/reg3/QN
```

The following command specifies that all the data outputs of a RAM cell are fixed throughout testing:

```
prompt> set_test_assume ONE [get_pins h1/ramcell/DOUT*]
```

set_test_point_configuration

Specifies the automatic test point insertion configuration options (deprecated).

SYNTAX

```
status set_test_point_configuration
    -target pattern_reduction | testability
    [-control_signal control_name]
    [-clock_signal clock_name]
    [-clock_type dominant | dedicated]
    [-max_control_points n]
    [-max_observe_points n]
    [-test_points_per_scan_cell n]
    [-power_saving enable | disable]
    [-max_additional_logic_area n]
```

Data Types

<i>control_name</i>	string
<i>clock_name</i>	string
<i>n</i>	integer

ARGUMENTS

-target pattern_reduction | testability

Enables and configures an automatic test point insertion target. This is a required argument. The valid target values are:

- **pattern_reduction** - focuses on pattern count reduction (Test Data Volume Reduction) by inserting only observe test points.
- **testability** - focuses on test coverage improvement by inserting both control and observe points.

The **-target** option specifies which automatic test point insertion target to enable, and it is a required option. The **pattern_reduction** and **testability** targets are mutually exclusive.

-control_signal *control_name*

Specifies the name of the control signal for test points. The signal must have a type of TestMode or IbistEnable. If the control signal is not specified, the test points are controlled by any available signal with the TestMode signal type. If a TestMode signal is not found, DFT Compiler creates a new test-mode signal.

-clock_signal *clock_name*

Specifies the name of the clock signal used for test points when a dedicated test point clock is used. If dedicated test point clocks are enabled with the **-clock_type** option and a clock signal is not specified with this option, DFT Compiler creates a new dedicated test point clock port.

In all flows, you can specify the name of a scan clock signal that is predefined with the **set_dft_signal -type ScanClock** command.

In a DFT-inserted OCC controller flow, you can specify the name of a PLL output pin that is predefined with the **set_dft_signal -type Oscillator** command. This specification is mapped to the corresponding OCC controller clock during DFT insertion.

In an existing OCC controller flow, you can directly specify the name of an output pin of an existing OCC controller that is predefined with the **set_dft_signal -type Oscillator** command.

-clock_type dominant | dedicated

Specifies the clock type to use for control and observe point scan cells. A value of **dominant** clocks the test points with the clock signal that clocks the most sequential cells in the design. A value of **dedicated** uses a separate dedicated test point clock. By default, the clock type is **dominant**.

-max_control_points n

Specifies the maximum number of control test points inserted. The default is 1000.

This option can be used only with the **testability** target.

-max_observe_points n

Specifies the maximum number of observe test points inserted. The default is 1000.

-test_points_per_scan_cell n

Specifies the number of test points of the same type (control or observe test points) that can be shared per scan cell. The valid value range is 1 to 8. By default, eight control test points can share one control scan cell and eight observe test points can share one observe scan cell.

-power_saving enable | disable

Enables the insertion of power-saving logic structures (AND gates) on the observe XOR trees.

-max_additional_logic_area n

Specifies the maximum percentage of area overhead allowed by automatic test point insertion.

DESCRIPTION

Note: this command has been deprecated. Use the **set_testability_configuration** command instead.

The **set_test_point_configuration** command configures the automatic test point insertion. When enabled, the design is analyzed during DFT insertion, and then test points are inserted to improve the testability of the design.

This command configures automatic test point insertion, but does not enable it. To enable automatic test point insertion, enable it with the **set_dft_configuration** command, then configure one or more test point targets with this command:

```
set_dft_configuration -test_points enable  
set_test_point_configuration -target ...  
set_test_point_configuration -target ...
```

You can insert test points at either the RTL or gate level. If you insert observe test points at the RTL level, set the **compile_delete_unloaded_scan_cells** variable to **false** to avoid removing scan cells associated with observe points during compilation.

In order to get the optimum test coverage improvement, both control and observe test points should be inserted by using the **-target testability** option.

EXAMPLES

The following example inserts up to 6 control and up to 1000 (default) observe test points:

```
prompt> set_test_point_configuration -target testability \
-max_control_points 6 \
-clock_type dominant -test_points_per_scan_cell 2
```

The following example inserts up to 6 control and up to 10 observe test points:

```
prompt> set_test_point_configuration -target testability \
-max_control_points 6 -max_observer_points 10 \
-clock_type dominant -test_points_per_scan_cell 2
```

The following example inserts up to 7 observe test points:

```
prompt> set_test_point_configuration -target pattern_reduction \
-max_observe_points 7 \
-clock_type dedicated -test_points_per_scan_cell 3
```

The following example inserts up to 1000 (default) control and 1000 (default) observe test points:

```
prompt> set_test_point_configuration -target testability \
-clock_type dedicated
```

[set_dft_configuration\(2\)](#)

set_test_point_element

Configures the insertion of force, control, and observe user-defined test points.

SYNTAX

```
int set_test_point_element
  list_of_design_pin_objects
  [-type control_0 | control_z0 | control_1 | control_z1 | control_01 | control_z01 | force_0 | force_z0 | force_1 | force_z1 | force_01 | force_z01]
  [-control_signal control_name]
  [-clock_signal clock_name]
  [-source_or_sink source_or_sink_name]
  [-test_point_enable test_point_enable_name]
  [-test_points_per_source_or_sink n]
  [-test_points_per_test_point_enable n]
  [-scan_source_or_sink enable | disable]
  [-scan_test_point_enable enable | disable]
  [-power_saving enable | disable]
```

Data Types

<i>control_name</i>	string
<i>clock_name</i>	string
<i>source_or_sink_name</i>	string
<i>test_point_enable_name</i>	string
<i>n</i>	integer

ARGUMENTS

-type *control_0 | control_z0 | control_1 | control_z1 | control_01 | control_z01 | force_0 | force_z0 | force_1 | force_z1 | force_01 | force_z01 | observe*

| *control_z1 | control_01 | control_z01 | Oforce_0 | force_z0 | force_1 | force_z1 | force_01 | force_z01 | observe*

Specifies the type of test point to insert at each design object in the list. Specify only one type with each invocation of this command. Observe and control test points are not supported with the LSSD scan style.

-control_signal *control_name*

Specifies the name of the existing pin or port control signal that activates the test point. The signal must have a type of TestMode, ScanEnable, or IblastEnable. If no control signal is specified, the test points are controlled by any signal with the TestMode signal type. If no TestMode signal is found, DFT Compiler creates a new TestMode port.

-clock_signal *clock_name*

Specifies the name of the clock signal used to clock any inserted user-defined test point scan registers. If no clock signal is specified, DFT Compiler creates a new clock port.

In all flows, you can specify the name of a scan clock signal that is predefined with the **set_dft_signal -type ScanClock** command.

In a DFT-inserted OCC controller flow, you can specify the name of a PLL output pin that is predefined with the **set_dft_signal -type Oscillator** command. This specification is mapped to the corresponding OCC controller clock during DFT insertion.

In an existing OCC controller flow, you can directly specify the name of an output pin of an existing OCC controller that is predefined with the **set_dft_signal -type Oscillator** command.

-source_or_sink source_or_sink_name

Specifies the name of the source data signal (for control and force test points) or the sink observed data signal (for observe test points). The source or sink signal can be an existing pin or an existing port. This option overrides the normal creation of source or sink scan registers (when **-scan_source_or_sink** is enabled) or source or sink ports (when **-scan_source_or_sink** is disabled).

When a signal is specified with the **-source_or_sink** option, it will be used for all source or sink signal connections for that test point definition, and the **-test_points_per_source_or_sink** sharing value will be ignored.

-test_point_enable test_point_enable_name

Specifies the name of the test point enable signal (for control test points). The enable signal can be an existing pin or an existing port. This option overrides the normal creation of test point enable scan registers (when **-scan_test_point_enable** is enabled) or **test_point_enable** input ports (when **-scan_test_point_enable** is disabled).

When a signal is specified with the **-test_point_enable** option, it will be used for all test point enable signal connections for that test point definition, and the **-test_points_per_test_point_enable** sharing value will be ignored.

-test_points_per_source_or_sink n

Specifies the number of test points that can be shared per source data signal (for control and force test points) or sink observed signal (for observe test points). The source signal can be a source data scan register or a source signal input port. The sink signal can be an observe scan cell or a sink output port.

A range of 1 to 32 can be specified for *n*.

By default, 8 observe test points can share one sink signal and 8 control or force test points can share one source signal.

-test_points_per_test_point_enable n

Specifies the number of test points that can be shared per test point enable signal for control test points. By default, a test point enable signal is used per control test point. This test point signal can be a test point enable scan register or a test point enable input port.

This option is valid only for the control test point types.

-scan_source_or_sink enable | disable

Enables or disables the insertion of control or observe scan registers. When **-scan_source_or_sink** is enabled (which is the default behavior), the source data of the force and control test points come from new source signal scan registers, and data is observed through sink scan registers. When **-scan_source_or_sink** is disabled, the source data of the control and force test points come from a new source signal input ports, and data is observed through new sink output ports.

If the **-source_or_sink** option is specified, this option is ignored.

-scan_test_point_enable enable | disable

Enables or disables the insertion of test point enable scan registers. When **-scan_test_point_enable** is enabled (which is the default behavior), the test point enable signal for the control test points come from new test point enable scan registers. When **-scan_test_point_enable** is disabled, the test point enable signal for the control test points come from a new test point enable signal input port.

If the **-test_point_enable** option is specified, this option is ignored.

-power_saving enable | disable

Specifies the insertion of power saving logic structures (AND gates) on the observe XOR trees.

DESCRIPTION

The **set_test_point_element** command configures the insertion of force, control, and observe user-defined test points. These test points are subsequently modeled by the **preview_dft** command, and inserted by the **insert_dft** command.

This command requires a list of pins or ports where the test points should be inserted. The user-defined test point feature can fix scan rule violations (force test points), reduce test data volume reduction (observe test points) and improve test coverage (control and observe test points).

Force test points are used when a value needs to be forced throughout the entire test session. A force test point is activated when the control signal (normally the TestMode signal) is asserted. The force_0 and force_1 test point types allow a signal to be replaced with a constant 0 or constant 1 value throughout the entire test session. These test point types are useful when a particular signal must be forced to a known value for testability purposes. The force_01 test point type allows a signal to be replaced with a source data value (driven from a scan register, input port, or user-supplied source data signal) throughout the entire test session.

Control test points are used when a hard-to-control signal should be controllable (selectively forced) for some test vectors, but left unaltered for others. This allows the test program to select either the original signal behavior, or the forced behavior, on a vector-by-vector basis. Control test points are typically inserted to increase the fault coverage of the design. A control test point is like a "selectively-activated" force control point. It works the same way, except that an additional test point enable signal, supplied by a scan register, input port, or user-supplied test point enable signal, must also be asserted.

Observe test points are typically inserted at hard-to-observe signals in a design to reduce test data volume or to increase the coverage. An observe test point passively observes a signal, and captures its value in an observe sink data scan register, or a sink data output port. Multiple observed points within a single observe test point definition can share the same sink point by collapsing the observed signals with an XOR observability tree.

Each **set_test_point_element** command describes a unique test point element definition. Signal sharing is not performed between test point element definitions. If test points within a limited geographic region should share the same source, sink, or enable signals, they should all be provided in a single **set_test_point_element** command. If test points across a wide geographic region should not share signals to avoid routing congestion, they should be broken up into localized groups and specified with separate **set_test_point_element** commands.

EXAMPLES

The following example specifies that observe test points be inserted at the specified set of four design pins. Since -**scan_source_or_sink** is enabled by default, **insert_dft** inserts two new observe scan registers to observe the four pins. The first three pins share one observe scan register, and the last pin is observed by a second observe scan register.

```
prompt> set_test_point_element -type observe {U0/Q U1/Q U2/Q U3/Q} \
    -test_points_per_source_or_sink 3 \
    -clock_signal CLK
```

The following example forces the RSTN pin of an analog block to zero during the entire test program, to hold the analog block in a quiet, low-power reset state:

```
prompt> set_test_point_element -type force_0 {U_ANALOG/RSTN}
```

```

Data Types

<i>file_name</i>	string
<i>clock_name</i>	string
<i>control_name</i>	string
<i>n</i>	integer
<i>object_list</i>	list
<i>cell_list</i>	list
<i>coverage_value</i>	float
<i>threshold_value</i>	integer

ARGUMENTS

-target random_resistant | untestable_logic | x_blocking | multicycle_paths | shadow_wrapper | core_wrapper | user

Enables and configures an automatic test point insertion target.

Test points are not inserted for a target until it is enabled by this option. Target lists are supported.

The valid target values are:

- **random_resistant** - inserts **control_0**, **control_1**, and **observe** test points to improve the testability of hard-to-test (random-pattern-resistant) logic.
- **untestable_logic** - inserts **force_01** and **observe** test points to control uncontrollable nets and observe unobservable logic, respectively.
- **x_blocking** - inserts **force_01** test points at unknown-function output pins, such as the output pins of black boxes.
- **multicycle_paths** - inserts capture-blocking logic at endpoints constrained by multicycle paths.
- **shadow_wrapper** - inserts a shadow wrapper around each cell specified with the **isolate_elements** option (**observe** test points at input pins, **force_01** test points at output pins).
- **core_wrapper** - inserts test-point-based core wrapping in the design **force_01** test points at input ports, **observe** test points at output ports).
- **user** - inserts user-supplied test points described in the external file defined by the **-test_point_file** option

If the **-target** option is omitted, the command can only configure the following global (non-target-specific) options:

- **-test_point_file**
- **-clock_signal**
- **-allowed_clock_signals**
- **-disallowed_clock_signals**
- **-control_signal**
- **-test_points_per_scan_cell**
- **-sg_command_file**

-test_point_file *file_name*

Specifies a file that describes test points to insert.

Each line contains three whitespace-separated fields: a user-defined label (can be any string), the test point type keyword, and the net where the test point should be inserted. Any text after the '#' comment character is ignored, whether in-line or on a separate line.

If a test point comes from a SpyGlass run (with an in-line SpyGlass comment), it belongs to that target. Otherwise, it belongs to the **user** target.

Note that file-based test points are not implemented unless the target is enabled (just as with analysis-based test points). For more information, see the DESCRIPTION section.

Supported scopes: global

-only_from_file *false* | *true*

Specifies whether file-based test points should augment or replace analysis-based test points.

When set to **false** (the default) for a target, the tool performs analysis for it, then implements both analysis-based and file-based test points for it.

When set to **true** for a target, the tool does not perform analysis for it; it implements only file-based test points for it. Any options that affect analysis for that target will have no effect.

This option is valid only when the **-test_point_file** option is also set. For more information, see the DESCRIPTION section.

Supported scopes: all targets

-clock_signal *clock_name*

Specifies the name of a previously defined ScanClock signal to use for DFT-inserted test point registers.

The default is to use the dominant clock of the logic surrounding each test point.

Supported scopes: global, all targets

-allowed_clock_signals *clock_list*

specifies the list of a previously defined scanclock signals to use for dft-inserted test point registers.

supported scopes: global, all targets

-disallowed_clock_signals *clock_list*

specifies the list of a previously defined scanclock signals not to be used for dft-inserted test point registers.

supported scopes: global, all targets

-control_signal *control_name*

Specifies the name of control signal to use for enabling test points. The signal must have a type of TestMode or IbistEnable.

The default is to use an available TestMode signal, or if one is not found, to create a new TestMode signal.

Supported scopes: global, all targets

-test_points_per_scan_cell *n*

Specifies the number of test points that can be shared by a single test-point register.

The default is 8.

Supported scopes: global, all targets

-include_elements *object_list*

Specifies hierarchical cells that should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **global, random_resistant, untestable_logic**

-include_fanin_cone *object_list*

Specifies ports or pins whose fanin logic should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **global, random_resistant, untestable_logic**

-include_fanout_cone *object_list*

Specifies ports or pins whose fanout logic should be fixed. Wildcards and collections are supported.

The default is to perform fixing across the entire design.

Supported scopes: **global, random_resistant, untestable_logic**

-exclude_elements *object_list*

Specifies objects that should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **global** (hierarchical cells), **random_resistant** (hierarchical cells), **untestable_logic** (hierarchical cells), **core_wrapper** (ports)

-exclude_fanin_cone *object_list*

Specifies ports or pins whose fanin logic should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **global, random_resistant, untestable_logic**

-exclude_fanout_cone object_list

Specifies ports or pins whose fanout logic should be excluded from fixing. Wildcards and collections are supported.

The default is not to exclude any objects from fixing.

Supported scopes: **global, random_resistant, untestable_logic**

-effort low | medium | high

Specifies the effort level used to compute the optimal test points for hard-to-test logic. Higher effort levels yield more efficient test points, but at the expense of analysis runtime.

The default is **medium**.

Supported scopes: **random_resistant**

-isolate_elements cell_list

Specifies hierarchical, black-box, or CTL-modeled cells to be isolated with atest-point shadow wrapper. Wildcards and collections are supported.

The default is an empty list.

Supported scopes: **shadow_wrapper**

-max_test_points n

Specifies the maximum number of test points to be inserted.

This limit applies to the **global random_resistant** and **untestable_logic** targets. When applied globally, the tool allocates the limit across both targets. You can also apply per-target limits, which takes precedence.

The default is 5% of the register count of the design.

Supported scopes: **global, random_resistant, untestable_logic**

-max_test_point_register_percent test_point_register_percent_value

Specifies the maximum number of test point registers to be inserted be equal to the percent value of total number of registers (only flip-flop) in the design times the test points per scan cell.

This limit applies to the **global, random_resistant** and **untestable_logic** targets. Value per-target takes the precedence over global.

Supported scopes: **global, random_resistant, untestable_logic**

-random_pattern_count n

Specifies the number of random patterns to statistically model when performing random-resistant analysis. Coverage values specified with the **-target_test_coverage** option are interpreted according to this value.

The default is 8000.

Supported scopes: **random_resistant**

-target_test_coverage coverage_value

Specifies the random-pattern target test coverage in percentage points that, when reached, prevents further test points from being generated.

The default is 100.

Supported scopes: **random_resistant**

-reuse_threshold threshold_value

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells when wrapping the design with test points.

The default is 0.

Supported scopes: **core_wrapper**

-depth_threshold threshold_value

Specifies the maximum combinational depth of I/O registers that can be reused as shared wrapper cells when wrapping the design with test points.

The default is 1.

Supported scopes: **core_wrapper**

-sg_command_file file_name

Specifies a file of SpyGlass Tcl commands file to be applied to the test-point analysis.

This options file is an unordered list of SpyGlass Tcl commands that you want to apply. The tool automatically applies the Tcl commands at the proper point in the analysis based on their type (design read, setup, goal definitions, etc.).

Supported scopes: global

DESCRIPTION

The **set_testability_configuration** command enables and configures automatic test-point insertion for one or more targets.

To use this feature, you must first enable the testability DFT client:

prompt> set_dft_configuration -testability enable

Issue this command without the **-target** option to configure global test-point insertion parameters. These global options are noted above.

Issue this command with the **-target** option to configure the specified target(s). Each target supports a particular subset of this command's options, described above. Warning messages are issued if you specify unsupported options for a target.

Specify the global configuration first, followed by the per-target configurations.

The following global options can also be specified per-target, which takes precedence over their global value:

- **-clock_signal**
- **-control_signal**
- **-test_points_per_scan_cell**

By default, analysis-based test points are implemented for a target when it is enabled. If you specify the **-test_point_file** option, any file-based test points are also implemented for that target. To suppress analysis and implement only the file-based test points, set the **-only_from_file** option to **true** for that target.

The following **set_testability_configuration** options can be specified on a per-partition basis:

```
[-target random_resistant | untestable_logic | x_blocking | multicycle_paths | shadow_wrapper | core_wrapper | user]  
[-test_point_types control_0 | control_1 | control | observe | force_01]  
[-clock_signal clock_name]  
[-control_signal control_name]
```

```
[-allowed_clock_signals clock_list]
[-disallowed_clock_signals clock_list]
[-test_points_per_scan_cell n]
[-max_test_points n]
```

EXAMPLES

The following example configures three automatic test-point insertion targets:

```
prompt> # global settings
prompt> set_testability_configuration \
    -test_points_per_scan_cell 20 \
    -control_signal TM_TP

prompt> # target-specific settings
prompt> set_testability_configuration -target random_resistant \
    -random_pattern_count 1000 -target_test_coverage 95

prompt> set_testability_configuration -target {x_blocking core_wrapper}
```

The following example configures insertion of only file-based test points for two targets from a previous SpyGlass run, without rerunning analysis:

```
prompt> # global settings
prompt> set_testability_configuration \
    -control_signal TM_TP \
    -test_point_file spyglass.txt

prompt> # enable targets for file-based insertion only
prompt> set_testability_configuration -only_from_file true \
    -target {random_resistant x_blocking}
```

reset_testability_configuration(2)
run_test_point_analysis(2)
set_dft_configuration(2)
```

set_timing_derate

Sets a derating factor on the current design or specified objects. Derating factors adjust the worst-case calculated delays for a particular operating condition.

SYNTAX

```
status set_timing_derate
      [-rise]
      [-fall]
      [-min]
      [-max]
      [-early]
      [-late]
      [-clock]
      [-data]
      [-net_delay]
      [-cell_delay]
      [-cell_check]
      [-pocvm_guardband]
      [-pocvm_coefficient_scale_factor]
      value
      object_list
```

Data Types

<i>value</i>	float
<i>object_list</i>	list

ARGUMENTS

-rise

Applies the derating value only to the delays of paths that have a rising transition at the specified objects.

-fall

Applies the derating value only to the delays of paths that have a falling transition at the specified objects.

If neither the **-rise** nor **-fall** option is used in the command, the derating value applies to both rise and fall.

-min

Applies the derating value only to the minimum operating condition.

-max

Applies the derating value only to the maximum operating condition.

If neither the **-min** nor **-max** option is used in the command, the derating value applies to both operating conditions.

-early

Applies the derating factor only to minimum delays, which defines how early a signal can arrive. The factor applies to clock path delays in a setup check, and to data path delays in a hold check.

-late

Applies the derating factor only to maximum delays, which defines how late a signal can arrive. The factor applies to data path delays in a setup check, and to clock path delays in a hold check.

If neither the **-early** nor **-late** option is used in the command, the derating value applies to early and late delays.

-clock

Applies the derating value only to elements in the clock network.

-data

Applies the derating value only to elements in the data network.

If neither the **-clock** nor **-data** option is used in the command, the derating value applies to both clock paths and data paths.

-net_delay

Applies the derating value only to net delay, which is the delay from the driver to the receiver of each net. This option cannot be used with an object list. There is only one set of derating values for net delays and they apply to the whole design.

-cell_delay

Applies the derating value only to cell delay, which is the delay from the input to the output of a cell.

-cell_check

Applies the derating value to the setup and hold time requirements of cells: cell setup and cell recovery times for late derating or cell hold and cell removal times for early derating. This option cannot be specified with any of the following options: **-clock**, **-data**, **-cell_delay**, **-net_delay**, **-aocvm_guardband** and **-pocvm_guardband**.

-pocvm_guardband

This option applies only to the parametric on-chip variation (POCV) context. In that context, both the POCV coefficient and the distance-based derating factor (if used) are adjusted by the *value* specified in the command. This option cannot be used together with the **-dynamic** or **-cell_check** option.

-pocvm_coefficient_scale_factor

This option applies only to the parametric on-chip variation (POCV) context. In that context, the POCV coefficient is adjusted by the *value* specified in the command. For example, if the POCV coefficient is 0.05 and the *value* is 1.2, then the coefficient used for POCV analysis is $0.05 \times 1.2 = 0.06$.

value

Specifies the derating value, which must be in the range of 0.1 to 2.0.

object_list

Specifies the leaf cells, instances, or library cells on which to set the derating factor. To ensure that the setting on an instance is preserved during optimization, the tool sets the **size_only** attribute of the instance to **true**.

DESCRIPTION

The **set_timing_derate** command sets derating factors for the current design or specified objects. If a timing derating factor is specified, some or all path delays are multiplied by the derating factor.

Derating factors define the lower and upper ranges of timing delays for a certain operating condition. The derating factor specified with the **-late** option is multiplied by the data path delays for maximum delay (setup) checking and clock path delays for minimum delay

(hold) checking. Conversely, the derating factor specified with the **-early** option is multiplied by the data path delays for hold checking and clock path delays for setup checking.

The **-net_delay**, **-cell_delay**, and **-cell_check** options apply the specified derating value to net delays, cell delays, or cell setup and hold time requirements, respectively. The **-net_delay** option can apply to the whole design only, so it cannot be used with an object list.

If none of these three options is used and an object list is provided, the derating value applies to cell delay only; if no object list is provided, the value applies to both cell delay and net delay.

The setup timing check is calculated using the maximum operating condition. The hold timing check is calculated using the minimum operating condition.

Input delay and ideal clock network latency are not derated.

Multicorner-Multimode Support

This command applies to the current scenario only. By default, when you set timing derating factors on a library cell, the setting is applied to all scenarios. You can control whether timing derating factors on library cells are scenario-specific with the **timing_library_derate_is_scenario_specific** variable. If this variable is **true** when you set the timing derating factor on a library cell, the timing derating factors apply to the current scenario only. For more information, see the man page for the **timing_library_derate_is_scenario_specific** variable.

EXAMPLES

The following example specifies an early derating value of 0.9 and a late derating value of 1.1 for all clock network nets at the maximum operating condition.

```
prompt> set_timing_derate -max -early -net_delay 0.9
prompt> set_timing_derate -max -late -net_delay 1.1
```

The following example specifies an early derating value of 0.8 and a late derating value of 1.2 for leaf cell U1 at the maximum operating condition.

```
prompt> set_timing_derate -max -early 0.8 U1
prompt> set_timing_derate -max -late 1.2 U1
```

The following example specifies an early POCV guardband derating value of 0.8 and a late POCV guard-band derating value of 1.2 for leaf cell U1.

```
prompt> set_timing_derate -pocvm_guardband -early 0.8 U1
prompt> set_timing_derate -pocvm_guardband -late 1.2 U1
```

SEE ALSO

`report_timing_derate(2)`
`report_timing(2)`

set_timing_ranges

Sets timing ranges for the current design.

SYNTAX

```
int set_timing_ranges  
  [timing_ranges]  
  [-library library_name]
```

Data Types

timing_ranges collection
library_name string

ARGUMENTS

timing_ranges

One or two timing ranges to be applied to the current design.

-library *library_name*

Specifies the name of the library that contains definitions of the timing ranges used.

DESCRIPTION

Specifies the names of one or two timing ranges to be used for timing the current design. The specified timing ranges must be defined in *library_name*, or in one of the libraries in the **link_library**. If a **local_link_library** is set on the current design, it is added to the beginning of the **link_library** before the **link_library** is searched. That is, the order for a library search is:

1. *library_name*
2. **local_link_library**
3. **link_library**

Timing ranges define scaling factors that are used to scale timing path totals. You can model operating condition variations using timing ranges, by defining a range of relative slow and fast times.

The *slowest_factor* is the largest value of any of the specified timing ranges. The *fastest_factor* is the smallest value of any of the specified timing ranges. Maximum delays of data paths are scaled by the *slowest_factor*. Minimum delays of data paths are scaled by the *fastest_factor*. Timing ranges do not affect the clock network. The effect of this command can be seen with the **report_timing**, **report_constraint**, and **compile** commands. Timing ranges affect path delays for reports, such as **report_timing** and **report_constraints**, and affect delay cost computation during optimization.

The following is an example of a timing range definition, as it appears in the source text of a library:

```
timing_range("BEST_CASE") {  
    faster_factor : 0.95  
    slower_factor : 0.99  
}
```

The name of this timing range is "BEST_CASE". The fields are defined as follows:

faster_factor

A floating-point number by which arrival times are scaled to model faster times due to environmental variations.

slower_factor

A floating-point number by which arrival times are scaled to model slower times due to environmental variations.

The **report_lib -timing_arcs** command shows the timing ranges that are defined in the technology library.

Each time the **set_timing_ranges** command is used, it overwrites the previous specifications. To remove the timing ranges defined for the current design, use the **set_timing_ranges** command with no parameters, or use the **reset_design** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

To check a library for timing ranges, use the following command:

```
prompt> report_lib test_lib
```

```
Timing ranges:  
Name      Library      slower_factor      faster_factor  
-----  -----  -----  
BEST_CASE   test_lib     0.98          0.96  
WORST_CAS   test_lib     1.1           1.0
```

In the following example, timing ranges from "my_lib.db" for the current design are selected:

```
prompt> read my_lib.db  
prompt> set_timing_ranges WORST_CASE -library my_lib.db
```

The following example specifies two timing ranges for the current design if the **link_library** is "other_lib.db" and there is no **local_link_library** set on the current design:

```
prompt> set_timing_ranges {WORST_CASE BEST_CASE}
```

SEE ALSO

report_timing(2)
reset_design(2)

set_local_link_library(2)

set_tlu_plus_files

Sets the files used for TLUPlus extraction. This command is supported only in topographical mode.

SYNTAX

```
status set_tlu_plus_files
[-max_tluplus max_tluplus_file]
[-min_tluplus min_tluplus_file]
[-max_emulation_tluplus max_emul_file]
[-min_emulation_tluplus min_emul_file]
[-tech2itf_map mapping_file]
```

Data Types

<i>max_tluplus_file</i>	string
<i>min_tluplus_file</i>	string
<i>max_emul_file</i>	string
<i>min_emul_file</i>	string
<i>mapping_file</i>	string

ARGUMENTS

-max_tluplus *max_tluplus_file*

Specifies the name of the TLUPlus file used for maximum condition calculation of resistance and capacitance using TLUPlus.

-min_tluplus *min_tluplus_file*

Specifies the name of the TLUPlus file used for minimum condition calculation of resistance and capacitance using TLUPlus.

-max_emulation_tluplus *max_emul_file*

Specifies the name of the emulation TLUPlus file used for maximum condition calculation of resistance and capacitance using TLUPlus.

-min_emulation_tluplus *min_emul_file*

Specifies the name of the emulation TLUPlus file used for minimum condition calculation of resistance and capacitance using TLUPlus.

-tech2itf_map *mapping_file*

Specifies the name of the file that defines the layer mapping between the technology file and the Interconnect Technology Format (ITF) file. This switch is optional only if the names are the same.

DESCRIPTION

This command specifies the files used for virtual route and postroute extraction using TLUPlus. At a minimum, you must specify the maximum TLUPlus file and the mapping file.

The **-min_tluplus** option is optional and, if specified, the command runs an extraction for the minimum condition, as well.

The file specified by the **-tech2itf_map** option maps the layer names in the technology file to the layer names in the Interconnect Technology Format (ITF) file. The mapping file should contain at least two sections, `conducting_layers` and `via_layers`; the `conducting_layers` section maps a routing layer to a conductor layer in the ITF file and the `via_layers` section maps a contact layer to a via layer in the ITF file. If the layer names are the same in your technology file and ITF file, you do not have to specify this option. If you do not specify this option, the tool assumes that the layer names are the same. Thus, if the names are actually different, an error will occur later in the flow.

You can also use this command to define two (optional) emulation TLUPlus files, which are used to perform emulation metal fill extraction. Emulation TLUPlus files include metal-fill-related information, such as `FILL_RATIO`, `FILL_SPACING`, `FILL_WIDTH`, and `FILL_TYPE`.

If you use the same names in different directories for the maximum and minimum TLUPlus files, they are considered the same file. The file names must be different if the files are not the same.

Note that TLUPlus files are stored as physical attributes of the design. When you use the **import_designs** command, you must set the TLUPlus files after running this command. Designs without a floorplan are considered logical designs. When a logical design is opened, only logical attributes are reloaded. It is important to run the **initialize_floorplan** or **read_def** command with valid floorplan DEF data after you set the TLUPlus files and before you save the design, to ensure that the physical attributes are reloaded when the design is reopened.

You can read nxtgrd files for extraction as an alternative to TLUPlus files. You specify an nxtgrd file the same way you specify a TLUPlus file, by using the **set_tlu_plus_files** command as shown in the following example. In this example, the command sets the `NXTGRD_file_max.nxtgrd` file for the maximum condition calculation of the resistance and capacitance:

```
prompt> set_tlu_plus_files -max_tluplus NXTGRD_file_max.nxtgrd -tech2itf_map design.map
```

You must generate the nxtgrd file using the grdgenxo tool version N-2017.12 or later.

Multicorner-Multimode Support

This command uses information from the current scenario only. If using emulation, it must be set for all scenarios.

EXAMPLES

Assume that the technology file has the following layer definitions:

```
Layer "METAL1" {
    maskName = "metal1"
    ...
}
Layer "VIA1" {
    maskName = "via1"
    ...
}
```

and the Interconnect Technology Format (ITF) file has the following layer definitions:

```
CONDUCTOR metal1 {THICKNESS=0.53 WMIN=0.23 SMIN=0.23 RPSQ=0.078 \
    CAPACITIVE_ONLYETCH=0}
...
VIA via1 {FROM=metal1 TO=metal2 AREA=0.0169 RPV=1.6}
```

In this case, the mapping file would have the following entries:

```
conducting_layers
METAL1 metal1
...
...
```

```
via_layers  
VIA1 via1  
...
```

The following example runs the **set_tlu_plus_files** command.

```
prompt> set_tlu_plus_files -max_tluplus tlu.max \  
-tech2itf_map design.map
```

SEE ALSO

[extract_rc\(2\)](#)
[set_extraction_options\(2\)](#)

set_top_implementation_options

Sets the top-level design options for the linking and optimization of the block's interface logic using transparent interface optimization.

SYNTAX

```
status set_top_implementation_options
  -block_references reference_names
  [-load_logic full_interface | compact_interface]
  [-optimize_block_interface true | false]
  [-optimize_shared_logic true | false]
  [-size_only_mode off | auto | in_place | footprint]
  [-block_update_setup_script file_name]
  [-block_update_cmd_script file_name]
  [-reset]
```

Data Types

<i>reference_names</i>	list
<i>file_name</i>	string

ARGUMENTS

-block_references *reference_names*

Specifies a list of names of the block references that are to be linked with block abstractions. The tool searches the current design library and its reference libraries for the blocks. The tool also searches the link libraries for blocks created in Design Compiler.

This is a required option.

-load_logic full_interface | compact_interface

Specifies the extent of logic to be loaded from the blocks at the top level. The block must already have a block abstraction created by using the **create_block_abstraction** command.

You can control the extent of the logic to load using one of the following settings:

full_interface (the default)

To load the entire block abstraction, consisting of all the interface logic, use the **-load_logic full_interface** option setting. When you load the full interface, the following logic is marked as interface logic:

- All the logic from input ports to registers or output ports
- All the logic to output ports from registers or input ports

compact_interface

To load a compact version of the block abstraction, consisting of only the logic for the timing-critical paths of every input and output, use the **-load_logic compact_interface** option setting.

For compact block abstractions, the following logic is marked as interface logic:

- The logic that belongs to min/max rise/fall from input ports to registers or output ports

- The logic that belongs to min/max rise/fall to output ports from registers or input ports

The following clock-gating circuitry is marked as interface logic whether you load the full interface or the compact interface:

- Any logic in the connection from the master clock to the generated clocks
- The clock trees that drive interface registers, including any logic in the clock tree
- The longest and shortest clock paths from the clock ports
- The side-load cells of all non-ideal and non-DRC disabled nets

When transparent interface optimization is not performed on a block, you can load the block with a compact interface. However, when you perform transparent interface optimization at the top level with the **compile_ultra** command, load the entire block abstraction for the blocks you want to optimize by using the **-load_logic full_interface** option setting.

-optimize_block_interface true | false

Specifies whether the interface logic for the block is optimized during top-level optimization.

By default, this option is set to **false** and the tool optimizes only the top-level logic, and not the interface logic. This option is only supported in Design Compiler in topographical mode for block abstractions that were created by Design Compiler in topographical mode.

-optimize_shared_logic true | false

Specifies whether the shared logic is optimized during interface optimization. The shared logic is defined as the list of cells and nets that are part of the interface timing paths for the block and are also shared with some block-level timing paths that are not visible at the top level.

Enabling this option can potentially disturb block-level register-to-register timing.

This option is applicable only when used with the **-optimize_block_interface** option.

By default, this option is **false** and interface optimization does not optimize the shared logic. This option is only supported in Design Compiler in topographical mode for block abstractions that were created by Design Compiler in topographical mode.

-size_only_mode off | auto | in_place | footprint

This option is currently ignored in Design Compiler because cell sizing is the only optimization that is performed.

-block_update_setup_script file_name

Specifies the setup file to be sourced during the block update of the specified block.

This file is useful for passing any variable settings for the block update phase. The file name should not include relative paths.

-block_update_cmd_script file_name

Specifies the script file with the commands to be run to update the specified block.

If this option is not specified, the tool automatically runs the **extract_rc -estimate** command for the block update.

If this option is specified, the tool sources the specified script file and does not run the **extract_rc -estimate** command. However, the tool still automatically runs **create_block_abstraction** and **write_file** after sourcing the script file.

The file name should not include relative paths.

-reset

Removes the top-level implementation options for the specified blocks.

DESCRIPTION

The **set_top_implementation_options** command sets the top-level implementation options for the specified blocks. Prior to this command, the blocks for which top-level implementation options are specified need to have block abstraction information annotated on them by using the **create_block_abstraction** command.

You must set the top-level implementation options for a block before loading it.

To allow top-level optimization to optimize the interface logic of the blocks, you must ensure the following:

- You are running Design Compiler in topographical mode.
- The block is not multiply instantiated in the design.
- The block abstraction was created using Design Compiler in topographical mode.

The option settings are not stored in the database. You need to specify these settings in every session.

To verify the top-level implementation options that are specified, see the report generated by the **report_top_implementation_options** command.

The following example enables block interface optimization for the blk1 block.

```
prompt> set_top_implementation_options -block_references blk1 \
-optimize_block_interface true
```

The following example resets the top-level implementation options for the blk1 and blk2 blocks.

```
prompt> set_top_implementation_options \
-block_references {blk1 blk2} -reset
```

[report_block_abstraction\(2\)](#)
[report_top_implementation_options\(2\)](#)

set_transform_for_retimining

Sets the **transform_for_retimining** attribute on cells in the current design. This can effect both hierarchical cells and sequential leaf cells.

SYNTAX

```
integer set_transform_for_retimining  
  cell_list  
    multiclass | decompose | dont_retime
```

Data Types

cell_list list

ARGUMENTS

cell_list

Specifies a list of cells on which the **transform_for_retimining** attribute is to be set. If you specify more than one cell name, the names must be enclosed either in quotation marks or in braces ({}).

multiclass | decompose | dont_retime

Specifies the value with which to set the **transform_for_retimining** attribute. There is no default value. One of the values must be specified.

- **multiclass** specifies that the cell will be moved together with any synchronous or asynchronous preset or clear or synchronous load-enable signals.
- **decompose** specifies that synchronous load-enable and synchronous reset logic are made explicit, and only the basic storage register is moved. For example, if a register has a data (D) input, a clock (CLK) input, and a synchronous clear (SD) input with active low polarity and the **transform_for_retimining** attribute is set to *decompose*, it is decomposed into a simple register with D and CLK input and an and gate driving the D input. The inputs of this and gate are the original data net and the synchronous clear net. Only the simple register will be moved for retiming, while the and gate stays in place.
- **dont_retime** specifies that the cell will not be retimed. It may still be mapped to a different library cell during incremental mapping optimizations.

DESCRIPTION

This command sets the **transform_for_retimining** attribute on cells in the current design.

If placed on a sequential, non-hierarchical cell, the attribute determines the way in which this cell will be transformed for retiming.

If you want to disable both retiming and sequential mapping optimizations for a cell, use the **dont_touch** attribute.

If the attribute is set on a hierarchical cell, it applies to all sequential cells in the hierarchy below this cell, unless the attribute is set on a hierarchical cell in between or on the sequential leaf cell itself. Values of the attribute set on lower levels of hierarchy override those set on higher levels.

The attribute does not effect non-sequential non-hierarchical cells.

If the attribute has neither been set on a sequential leaf cell nor on any of its hierarchical parent cells, the transform that is applied to this cell is determined by the corresponding command line option chosen for the **optimize_registers** command, or by the default setting for the retiming command that you are using.

If the **dont_touch** attribute is set to *true* on a cell, the **transform_for_retimining** attribute does not come into effect on this cell or any of its child cells.

Using the attribute can improve timing results at the cost of increased area for certain designs.

To remove the **transform_for_retimining** attribute, use **remove_attribute**.

EXAMPLES

The data inputs of two synchronous clear register cells R_1 and R_2 are connected to the same net, while the synchronous clear inputs are connected to two different and unrelated clear signals. If **optimize_registers** is invoked with the command line option **-sync_trans_multiclass**, it will not move any of these registers backward over the driving cell of the net connected to the data ports, even if it would improve the timing of the design. Setting the **transform_for_retimining** attribute to *decompose* on the register cells allows backward movement to achieve better timing results. However, there are additional gates in the design. Use the following command to achieve this:

```
prompt> set_transform_for_retimining find(cell, {R_1, R_2}) decompose
```

The following command removes the attribute from the two cells:

```
prompt> remove_attribute find(cell, {R_1, R_2}) transform_for_retimining
```

`set_optimize_registers(2)`
`set_dont_touch(2)`

set_unconnected

Lists output ports to be unconnected.

SYNTAX

```
int set_unconnected  
    port_list
```

Data Types

port_list list

ARGUMENTS

port_list

A list of port names in the current design that are to be left unconnected. If more than one port is specified, they must be enclosed either in quotes or in braces ({}).

DESCRIPTION

Assigns an **output_not_used** attribute to ports in *port_list*. This information is used by **compile** to create smaller designs by eliminating logic that drives an unconnected output port and therefore might not need to be maintained during optimization. After a design with an unconnected output port is compiled, the port usually is not driven by anything inside the design.

This attribute can be removed using the **remove_attribute** command.

Note:

The **set_unconnected** command cannot be used on input ports. Input ports can be tied to logic one, logic zero, or don't-care using **set_logic_one**, **set_logic_zero**, and **set_logic_dc**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example specifies that output ports "CARRY_OUT" and "err_1" are not to be used.

```
prompt> set_unconnected {CARRY_OUT err_1}
```

SEE ALSO

`get_attribute(2)`

`reset_design(2)`
`set_logic_one(2)`
`set_logic_zero(2)`
`set_logic_dc(2)`
`simplify_constants(2)`

set_ungroup

Sets the **ungroup** attribute on specified designs, cells, or references, indicating that they are to be ungrouped during **compile**.

SYNTAX

```
int set_ungroup  
    object_list true | false
```

Data Types

object_list list

ARGUMENTS

object_list

Specifies a list of cells, references, or designs to be ungrouped during **compile**.

true | false

The value with which to set the **ungroup** attribute. The default is **true**.

DESCRIPTION

Sets the **ungroup** attribute on the specified objects so that they are ungrouped (collapsed to one design level) before they are optimized. The **compile** command does not ungroup cells or designs with the **dont_touch** attribute.

This attribute is removed with the **remove_attribute** or **reset_design** commands.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the **ungroup** attribute is set on the cell U1.

```
prompt> set_ungroup U1
```

If the **ungroup** attribute is specified on a reference object, cells using that reference are ungrouped during **compile**. In the following example, all the instances of ADDER in the current design are ungrouped.

```
prompt> set_ungroup [get_references ADDER]
```

A design with this attribute is ungrouped whenever **compile** encounters it.

```
prompt> set_ungroup [get_designs ND17]
```

Specifying **set_ungroup false** on a MUX operator sets a `map_only` and `size_only` on the MUX to ensure that the MUX is preserved.

SEE ALSO

`compile(2)`
`current_design(2)`
`remove_attribute(2)`
`reset_design(2)`
`ungroup(2)`
`ungroup_keep_original_design(3)`

set_uninitialized_register_value

Specifies the initial state to be set on uninitialized registers by constant removal engines. Uninitialized registers are registers for which the constant engines could not compute an initial state.

SYNTAX

```
int set_uninitialized_register_value  
  [-value init_value]  
  object_list
```

Data Types

object_list list

ARGUMENTS

-value *init_value*

Specifies the initial state value to be used by the constant engines (0 or 1).

object_list

Specifies the set of registers on which the value will be set as an initial state.

DESCRIPTION

Specifies a constant value (0 or 1) as the initial state for uninitialized registers listed in *object_list*.

EXAMPLES

The following example shows how to specify an initial state on the sequential cell U0.

```
prompt> set_uninitialized_register_value -value 0 U0  
prompt> set_uninitialized_register_value -value 1 U0
```

SEE ALSO

```
compile(2)
find(2)
get_attribute(2)
remove_attribute(2)
```

set_units

Sets the units used for resistance, capacitance, timing, leakage power, current, and voltage. The units must be consistent with the main library units.

SYNTAX

```
string set_units
  [-resistance ohm|kohm|mohm|Mohm|10ohm|100ohm]
  [-capacitance f|ff|pf|nf|uf|mf|10ff|100ff]
  [-time s|fs|ps|ns|us|ms|10ps|100ps]
  [-power w|fw|pw|nw|uw|mw|10uw|100uw|10mw|100mw|10pw|100pw|10nw|100nw]
  [-current A|fA|pA|nA|uA|mA|10uA|100uA|10mA|100mA]
  [-voltage v|fv|pv|nv|uv|mv|10mv|100mv]
```

ARGUMENTS

-resistance ohm|kohm|mohm|Mohm|10ohm|100ohm

Sets the resistance unit.

-capacitance f|ff|pf|nf|uf|mf|10ff|100ff

Sets the capacitance unit.

-time s|fs|ps|ns|us|ms|10ps|100ps

Sets the time unit.

-power w|fw|pw|nw|uw|mw|10uw|100uw|10mw|100mw|10pw|100pw|10nw|100nw

Sets the power unit.

-current A|fA|pA|nA|uA|mA|10uA|100uA|10mA|100mA

Sets the current unit.

-voltage v|fv|pv|nv|uv|mv|10mv|100mv

Sets the voltage unit.

DESCRIPTION

The **set_units** command sets the units for SDC file. The specified units cannot conflict with the main library units; therefore, you should not use the **set_units** command interactively.

When the tool writes an SDC file, the **set_units** command is always written out as the first SDC command. If no units are set, the tool gets the units from the main library (the first link library).

EXAMPLES

The following example specifies the set_units command that is written to the SDC file.

```
prompt> set_units -time ns -resistance kohm -capacitance pf \
-power uW -voltage V -current A
```

SEE ALSO

[report_units\(2\)](#)

set_unloaded_register_removal

Sets an attribute to unloaded register(s) to selectively preserve or optimize it.

SYNTAX

```
status set_unloaded_register_removal
      objects true / false
      [flag]
```

ARGUMENTS

DESCRIPTION

The **set_unloaded_register_removal** command is applied on unloaded sequential cell(s) or hierarchical cell(s) to optimize or preserve it selectively. It set an attribute **remove_unloaded_register** on specified register. The attribute can store true or false based upon your input. **set_unloaded_register_removal** when set to false on objects it sets the attribute **remove_unloaded_register** to value false and does not allow removal of the unloaded register. When the command is set to true on objects it allows optimization of those unloaded registers. You can use the attribute **remove_unloaded_register** to query the unloaded registers which are not removed after compile_ultra. This attribute can be used before compile_ultra to query registers which are to be removed. **set_unloaded_register_removal** honors size_only and issues warning if any register in this category is been set.

EXAMPLES

The following command optimizes register unld_regA:

```
prompt> set_unloaded_register_removal unld_regA true
```

The following command preserves register unld_regB:

```
prompt> set_unloaded_register_removal unld_regB false
```

The following command issues warning OPT-1222 as register unld_sizeonly_regC is size_only:

```
prompt> set_unloaded_register_removal unld_sizeonly_regC false
```

SEE ALSO

set_upf_cell_mismatch

Used to specify relaxations that tool can apply to get a final mapped netlist.

SYNTAX

```
status set_upf_cell_mismatch
  -allow_tlsViolation
  -allow_pvt_mismatch
  -no_unmapped retention | isolation | both
  -reset
```

ARGUMENTS

-allow_tlsViolation

When this option is specified, target library subset constraint may be violated for power management cells (retention, isolation and level shifter). If the tool is not able to map to a cell honoring target library subset, it will attempt to map to a cell violating target library subset constraint.

-allow_pvt_mismatch

When this option is specified, PVT matching may be relaxed for power management cells (retention, isolation and level shifter). Design Compiler will not complain if there is PVT mismatch during linking and mapper may bring in PVT mismatching cells in case matching cells are not available. PVT matching relaxation will eventually relax process, voltage, temperature, rail voltages, target_library_subset and bias requirements. As target_library_subset is also relaxed here, -allow_pvt_mismatch is a superset of -allow_tlsViolation.

-no_unmapped retention | isolation | both

When this option is specified, UPF constraint may be relaxed such that the final netlist will not have any unmapped PM cells.

If the option value is specified as **retention**, then in the absence of a suitable Retention library cell, tool will relax the retention constraint on unmapped sequential element and it will be mapped to non-Retention cell.

If the option value is specified as **isolation**, then in the absence of a suitable Isolation library cell, tool will relax the Isolation constraints specified in the UPF and unmapped isolation cells will be removed from the final netlist.

If the option value is specified as **both**, unmapped isolation cells will be removed and unmapped sequential cells with retention constraints will be mapped to non-retention.

-reset

When this option is specified, all the previously specified relaxations (-allow_tlsViolation, -allow_pvt_mismatch and -no_unmapped) will be reset. The benefit of this option is that once user brings in all the required libraries, the existing relaxations can be reset using this option.

DESCRIPTION

This command allows the user to specify relaxation on target_library_subset, PVT matching and having a netlist free of unmapped PM cells.

This is a cumulative command and user can have multiple specifications.

All the options are optional. If just set_upf_cell_mismatch is specified without any options, then it means all the relaxations are enabled.

This command always applies to the entire current design.

The netlist synthesized with these relaxations might have QoR degradation and verification failures.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify relaxations using set_upf_cell_mismatch command.

```
prompt> set_upf_cell_mismatch -allow_tlsViolation
prompt> set_upf_cell_mismatch -allow_pvtMismatch
```

This command will be interpreted as

```
set_upf_cell_mismatch -allow_tlsViolation -allow_pvtMismatch
```

SEE ALSO

set_upf_query_options

Sets the options for specifying design elements in UPF commands.

SYNTAX

```
status set_upf_query_options
    -bus_struct_mode true | false
```

ARGUMENTS

-bus_struct_mode true | false

Enables bus/struct querying support for the **-elements** option of the **set_retention**, **set_isolation**, and **map_retention_cell** commands. The default behavior is **false**.

DESCRIPTION

The **set_upf_query_options** command sets the mode for specifying bus/struct elements.

When the **-bus_struct_mode** argument is set to **true**, it allows vector elements and struct elements to be referenced by their RTL vector/struct names in the **-elements** option of the **set_retention**, **set_isolation**, and **map_retention_cell** commands.

For example, given an 8-bit register named ROUT:

```
reg [7:0] ROUT;
```

The **set_retention** command can refer to ROUT as follows:

```
prompt> set_retention -elements {ROUT} ...
```

This avoids the use of wildcard characters, which require more runtime resources to process:

```
prompt> set_retention -elements {ROUT*} ...
```

while avoiding the need to enumerate all bits of the register:

```
prompt> set_retention -elements {ROUT_reg[0] ROUT_reg[1] ... ROUT_reg[7]} ...
```

To use this option, the following application variables must be appropriately set prior to reading in RTL:

```
prompt> set_app_var bus_naming_style = "%s[%d]"  (default setting)
prompt> set_app_var hdlin_enable_upf_compatible_naming true
```

Furthermore, this option should only be set to **true** while loading the initial RTL UPF, and set to **false** at other times, as demonstrated in the EXAMPLES section.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows an instance of a user-defined struct, "ip_n", and a 8-bit bused register "rout" that is used in the **-elements** option of **set_retention** command.

```
typedef struct packed {
    logic [7:0] pad;
    logic [7:0] offset;
    logic B;
} user_struct;

module top(..., rout);
    output logic [7:0] rout;
    user_struct IP_N;
    ...
}

prompt> set hdlin_enable_upf_compatible_naming true
prompt> read_sverilog top.sv
prompt> get_cells rout*
{rout_reg[7] rout_reg[6] rout_reg[5] rout_reg[4] rout_reg[3] rout_reg[2] rout_reg[1] rout_reg[0]}
prompt> get_cells ip_n_reg.*
{ip_n_reg.pad[7] ... ip_n_reg.pad[0] ip_n_reg.offset[7] ... ip_n_reg.offset[0] ip_n_reg.B}
prompt> set_upf_query_options -bus_struct_mode true
...
prompt> set_retention -domain TOP -retention_power_net VDD \
    -retention_ground_net VSS -elements {rout} RETN_OUT
prompt> set_retention -domain TOP -retention_power_net VDD \
    -retention_ground_net VSS -elements {ip_n.pad} RETN_IP_N_PAD
...
prompt> set_upf_query_options -bus_struct_mode false
...
```

SEE ALSO

[map_retention_cell\(2\)](#)
[hdlin_enable_upf_compatible_naming\(3\)](#)

set_user_attribute

Sets the value of an attribute on a design or library object.

SYNTAX

```
list set_user_attribute
  object_list
  attribute_name
  attribute_value
  [-bus]
  [-quiet]
```

Data Types

```
object_list      list
attribute_name   string
attribute_value  attribute value
```

ARGUMENTS

object_list

Specifies a list of design or library objects on which the attribute is to be set. For details on searching for design and library names, see the man pages for the **get_designs** and **get_libs commands**.

attribute_name

Specifies the name of the attribute to set.

attribute_value

Specifies the value of the attribute. The data type must be the same as the attribute data type.

-bus

Sets the attribute on the bus as a whole, and not on each individual bus member.

-quiet

Turns off warning messages that would otherwise be issued if the attribute or objects are not found.

DESCRIPTION

The **set_user_attribute** command sets the value of an attribute on an object. It is the same as the **set_attribute** command. See the **set_attribute** command man page for further information.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

`remove_user_attribute(2)`
`set_attribute(2)`
`attributes(3)`

set_user_budget

Sets user budgets or budget ratios.

SYNTAX

```
string set_user_budget
  -from object_list
  -to object_list
  [-percent]
  value
```

Data Types

<i>object_list</i>	list
<i>value</i>	float

ARGUMENTS

-from *object_list*

Indicates the pins or clocks from which the budget is specified.

-to *object_list*

Indicates the pins or clocks to which the budget is specified.

-percent

Indicates the specified budget value is a percentage.

value

Sets the budget value or percentage.

DESCRIPTION

The **set_user_budget** command is used to specify user directives for budget allocation. You can specify budgets as an absolute value or as a percentage of available constraint to be allocated. These directives are honored by budget allocation. If you don't specify user budgets for a budgeted cell, budget allocation is performed automatically.

The objects specified in either the **-from** or **-to** options must be inputs pins or output pins of budgeted cells. User budgets specified for cells which are not ultimately budgeted are ignored.

EXAMPLES

The following command specifies the budget from clock clk1 to the two outputs is 5.0.

```
prompt> set_user_budget -from clk1 -to {I2/out1 I2/out2} 5.0
```

The following command specifies that the budget from the IN input to the Y of I1 should be 70 percent of the path constraint.

```
prompt> set_user_budget -from I1/IN -to I1/Y -percent 70.0
```

SEE ALSO

`dc_allocate_budgets(2)`
`report_path_budget(2)`

set_utilization

Specifies placement utilization constraint for core area. This command is supported only in topographical mode.

SYNTAX

```
int set_utilization  
    util_float
```

Data Types

util_float float

ARGUMENTS

util_float

Specifies target placement utilization for core area. The utilization is defined as standard cell utilization:

$\text{total_standard_cell_area} / (\text{core area} - \text{blockage area} - \text{macro_cell_area})$

Area Definition ---- -----

Core area Core area bounding box

Standard cell sum of fixed and non-fixed area standard cell area

blockage area sum of placement keepout area and filler cell (physical only cell) area

macro_cell area sum of fixed and non-fixed macro cell area

Note: for utilization calculation purpose, we define the macro cell as the cell in the netlist without lib site linked, or the cell width and height is larger than 5 minimum lib site height.

Value for *util_float* is a float number less than 1, for example, 0.85 for 85% utilization. The default value is 0.60.

DESCRIPTION

This command defines design level physical constraint for utilization. The constraint will be used to generate coarse floorplan during synthesis.

Use this command after loading the physical library and design, but before running synthesis.

There are also other commands that set constraints on core area, such as **set_placement_area**, **set_rectilinear_outline** and **set_aspect_ratio**. Among the four commands, **set_placement_area** has the highest priority, while **set_rectilinear_outline** has higher priority than **set_utilization** and **set_aspect_ratio**. This means if the placement area constraint is set by **set_placement_area** or rectilinear outline constraint is set by **set_rectilinear_outline** on the current design, then the utilization constraint will not be used during synthesis. Furthermore, in this case, utilization will be neither reported by the command **report_physical_constraints**, nor

written out by the command **write_physical_constraints**.

EXAMPLES

The following example shows how to set the floorplan utilization to 80%.

```
prompt> set_utilization 0.8
```

SEE ALSO

[set_placement_area\(2\)](#)
[report_physical_constraints\(2\)](#)
[write_physical_constraints\(2\)](#)

set_variation

Used to define tolerance levels of supplies in the design that is enabled for voltage reconciliation.

SYNTAX

```
status set_variation
  [-supply supply_net]
  [-tolerance {vboth | vlow vhigh}]
```

ARGUMENTS

-supply *supply_net*

This option takes either one or more supply net names. This option is not mandatory.

-tolerance {*vboth* | *vlow* *vhigh*}

This option takes either one or two values. The value can be either integer or floating point value. It defines the maximum allowed tolerance undershoot and tolerance overshoot. This option is mandatory.

If only one value is specified for this option, tool will consider the same value for both tolerance undershoot and tolerance overshoot.

If two values are specified for this option, then tool will consider first value as tolerance undershoot and the second value as tolerance overshoot.

DESCRIPTION

This command allows the user to specify tolerance levels of supplies in the current design. The tolerance range is the range within which voltage equivalence checks are relaxed for supplies that belong to the block that is enabled for voltage reconciliation.

The default value of tolerance level is 0, which means no relaxation while performing voltage equivalence checks.

If option **-supply** is not specified, then the tolerance levels are considered as global. Such global tolerance levels apply to all the supplies in the design.

If option **-supply** is specified, then the tolerance levels are considered as supply specific. Such tolerance levels apply to only those supply nets listed in the command. If both global tolerance level and supply specific tolerance levels are specified, supply specific tolerance levels gets higher precedence.

This is not a override command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to specify single global tolerance using set_variation command.

```
prompt> set_variation -tolerance 0.1
```

The following example shows how to specify both undershoot and overshoot global tolerance levels using set_variation command.

```
prompt> set_variation -tolerance {0.1 0.2}
```

The following example shows how to specify single supply specific tolerance using set_variation command.

```
prompt> set_variation -supply {VDD BLK/VDD} -tolerance {0.1}
```

The following example shows how to specify both undershoot and overshoot supply specific tolerance levels using set_variation command.

```
prompt> set_variation -supply {PDT.primary.power} -tolerance {0.1 0.2}
```

SEE ALSO

set_verification_priority

Sets the **verification_priority** attribute on specified designs, cells, or references, indicating the level of optimization during **compile_ultra**.

SYNTAX

```
status set_verification_priority
    -all
    [-high]
    [-low]
    object_list
```

Data Types

object_list list

ARGUMENTS

-all

Sets the attribute on all designs (equivalent to [**get_designs ***]).

-high

Sets the verification priority level. This option maps to the low effort of the optimization effort level.

-low

Sets the verification priority level for Formality runtime.

object_list

Specifies a list of cells, references, or designs on which the attribute is to be set.

DESCRIPTION

This command sets the **verification_priority** attribute on the specified objects. During **compile_ultra**, the optimizations of the design with the attribute are adjusted depending on the verification priority level so that the potential for hard verification is reduced. It primarily adjusts the optimizations on datapath logic. Ungrouping of DesignWare components in the design with the attribute is disabled. It also identifies CRC logic in the design and isolates it by creating the new hierarchy. The attribute is not transitive to its subdesigns. Design Compiler does not ungroup cells or designs on which the **verification_priority** attribute is set.

When the attribute is set on a synthetic operator, such as an adder or a multiplier, the resource sharing and the datapath extraction is not performed on the operator. The DesignWare hierarchy of the operator is preserved, except that the size of the DesignWare is small.

When the **verification_priority** is set to 'low', the tool will identify the Designware operators that drives many other operators, and avoid extracting datapath blocks that have large number of primary input. This option does not affect any other optimization or ungroup.

You can use the **remove_verification_priority** command to remove the **verification_priority** attribute.

EXAMPLES

In the following example, the **verification_priority** attribute is set to **medium** on the *U1* cell:

```
prompt> set_verification_priority U1
```

If the **verification_priority** attribute is specified on a reference object, cells using that reference are not ungrouped. In this example, all instances of ADDER in the current design are not ungrouped:

```
prompt> set_verification_priority [get_references ADDER]
```

SEE ALSO

[compile\(2\)](#)
[current_design\(2\)](#)
[hdlin_verification_priority\(3\)](#)
[remove_verification_priority\(2\)](#)

set_verification_top

SYNTAX

```
status set_verification_top
```

ARGUMENTS

None

DESCRIPTION

This command is a part of the recommended Synopsys verification setup (SVF) creation flow.

This recommended flow is also called the Guide Hierarchical Map (GHM) flow because it improves how complex hierarchy transformations are handled in the verification guidance.

For more information on this flow, see the **hdlin_enable_hier_map** man page.

This command requires that the **hdlin_enable_hier_map** application variable was set to **true** prior to reading any RTL files.

If you attempt some post-design-read command that would modify the design, but you have forgotten to run the **set_verification_top** command, the tool issues a GHM-003 error. Any subsequent attempts to run the **compile** or **compile_ultra** command will also fail.

EXAMPLES

The following script shows the correct command ordering for this recommended flow.

```
# Specify SVF output file
prompt> set_svf ./guidance/top.svf

# Enable GHM flow
prompt> set_app_var hdlin_enable_hier_map true

# Read design files
prompt> analyze -format sverilog {sub.sv top.sv}
prompt> elaborate top
prompt> current_design top

# Issue this command after reading last RTL file and before
# other commands that can modify netlist
prompt> set_verification_top
```

SEE ALSO

`hdlin_enable_hier_map(3)`
`hdlin_ignore_ghm_errors(3)`

set_via_ladder_candidate

Specify via ladder candidates for optimization.

SYNTAX

```
status set_via_ladder_candidate
  library_pin
  -ladder_name ladder_name
```

Data Types

```
library_pin  collection
ladder_name   string
```

ARGUMENTS

library_pin

Specifies library pin on which to set via ladder candidates.

This is a required option.

-ladder_name ladder_name

Specifies the name of the via ladder to set on library pin.

This is a required option.

DESCRIPTION

This command sets the list of via ladder candidates on library pins for via ladder optimization.

If the variable *spg_enable_via_ladder_opto* is turned on for via ladder optimization, the compile will infer via ladders on pins to improve the timing based on the via ladder candidates on their library pins.

The priority of via ladder candidates follows their order on library pin, the first via ladder with timing improvement has higher priority.

EXAMPLES

The following command shows setting typical via ladders on pins.

```
prompt> set_via_ladder_candidate [get_lib_pin slow/CLKBUFX20/Y] -ladder_name VL1_2 -cell_spacing {200.000 220.000}
```

SEE ALSO

`report_via_ladder_candidates(2)`
`spg_enable_via_ladder_opto(3)`

set_via_ladder_constraints

Attaches ordered via ladder lists to specified instances of logical pins.

SYNTAX

```
status set_via_ladder_constraints
  -pins pin_names
    via_ladder_list
```

Data Types

<i>pin_names</i>	collection
<i>via_ladder_list</i>	list

ARGUMENTS

-pins *pin_names*

Specifies the name of the logical pins to set via ladder constraints.

This is a required option.

via_ladder_list

Specifies the ordered via ladder list to be attached to the specified logical pins.

A via ladder is a physical structure of connected vias and wires that is placed on top of a standard cell pin as a special connecting device. A via ladder can have, for example, two rows of via1, four columns of via2, and one row of via3 connected with a metal4 wire.

A named via ladder is defined by set of rules in the technology file.

This is a required argument.

DESCRIPTION

This command sets the list of via ladder names as via ladder constraints for specified pins. During RC extraction the first appropriate via ladder from the list will be used for RC estimation on the specified pin.

EXAMPLES

The following command shows setting typical via ladders on pins

```
prompt> set_via_ladder_constraints -pins [get_pins */Z] {VL3_3 VL3_2 ABC DE}
```

SEE ALSO

`remove_via_ladder_constraints(2)`
`report_via_ladder_constraints(2)`

set_via_ladder_rules

Sets via ladder rules for the design.

SYNTAX

```
status set_via_ladder_rules
  -master_pin_map masterpin_ladders_list
  -master_pin_map_file file
  -default_ladders via_ladders_list
  -all_instances_of cell_master_pin_list
  -all_clock_outputs true | false
  -all_clock_inputs true | false
  -all_pins_driving port_list
  -remove_all_rules
```

Data Types

<i>masterpin_ladders_list</i>	string
<i>file</i>	string
<i>cell_master_pin_list</i>	string
<i>port_list</i>	port names or collection

ARGUMENTS

-master_pin_map masterpin_ladders_list

Specifies what type of ladder(s) should be used on an instance of given cell_master/pin if it is to get a ladder. Format of masterpin_ladders_list is {{cell_master/pin {via_ladder_list}}...}. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a warning.

-master_pin_map_file file

Specifies file name to provide entries for -master_pin_map option. Format of file entry is same as needed in option-
master_pin_map. master_pin_map entries can be provided with both the options together. In case of clash, entry in file will be
given priority. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a
warning.

Design Compiler topographical mode does not support this option.

-default_ladders via_ladders_list

Specifies what ladder to use if a cell/pin requires a ladder based on a rule, but it is not defined in the master_pin_map list. Format of via_ladders_list is {VL1 VL2 ...}.

Design Compiler topographical mode does not support this option.

-all_instances_of cell_master_pin_list

Specifies that anytime an instance of this cell master/pin is used, a ladder is to be created automatically. Format of cell_master_pin_list is {cell_master1/pin1 cell_master2/pin2 ...}. The cell_master should be a library cell, entries where cell_master is not a library cell would be ignored with a warning.

Design Compiler topographical mode does not support this option.

-all_clock_outputs true | false

Specifies that all output pins on clock nets get a ladder. Default values is false.

Design Compiler topographical mode does not support this option.

-all_clock_inputs true | false

Specifies that all input pins on clock nets get a ladder. Default values is false.

Design Compiler topographical mode does not support this option.

-all_pins_driving port_list

Specifies that all pins driving one of the ports in the collection gets a ladder.

Design Compiler topographical mode does not support this option.

-remove_all_rules

If this option is specified, all the rules will be removed.

DESCRIPTION

This command sets via ladder rules for the block. These rules will be used by zroute to automatically update via ladders as the design changes. Instance/pin specifications set with via ladders constraints commands will remain, and can/should still be used for fixed/non-changing cells. These rules are more valuable for dynamically changing cells. If both an instance specific constraint and a rule exist, the instance constraint should apply.

This command returns 1 if succeeded, 0 otherwise.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information if there is no scenario dependency for the options.

EXAMPLES

The following examples associate via ladder 'VP1' with library pin 'BUFFD10/Z' and 'VP2' with 'INVD8/ZN'

```
prompt> set_via_ladder_rules -master_pin_map { {lib/BUFFD10/Z {VP1}} {lib/INVD8/ZN {VP2}} }
```

1

SEE ALSO

```
remove_via_ladder_rules(2)
report_via_ladder_rules(2)
set_via_ladder_constraints(2)
remove_via_ladder_constraints(2)
report_via_ladder_constraints(2)
```

set_voltage

Applies an operating voltage to a list of supply net or internal supply port objects.

SYNTAX

```
status set_voltage
  max_voltage
  [-min min_voltage]
  -object_list supply_objects
```

Data Types

<i>max_voltage</i>	float
<i>min_voltage</i>	float
<i>supply_objects</i>	collection

ARGUMENTS

max_voltage

Specifies the operating voltage for the maximum (worst) case.

-min min_voltage

Specifies the operating voltage for the minimum (best) case.

-object_list supply_objects

Specifies the supply nets and internal supply ports that have the operating voltages specified in this command.

DESCRIPTION

Defines the operating voltage on the supply nets and their corresponding power nets so that the parts of the design powered by these supply nets or power nets are timed and optimized at the specified voltage.

It is an error if supply nets do not have any voltage set on them.

To see the operating voltages of the supply nets, use the **report_supply_net** command.

The objects can also be supply ports that correspond to the internal PG pins of low-power macros with fine-grain switch cells. The internal PG pins must satisfy the following conditions:

- It belongs to a macro cell whose **switch_cell_type** attribute has a value of "fine_grain".
- The pin's **direction** attribute has a value of "internal".
- The pin's **pg_type** attribute has a value of "internal_power" or "internal_ground".

- The pin has a **switch_function** attribute.
- The pin has a **pg_function** attribute.

If there is no voltage set on the supply port, the voltage value is picked from the voltage name of its corresponding internal PG pin, as defined in the Liberty file of the macro.

A voltage can be set on the supply port if its internal PG pin derives a different voltage than the primary voltage for the macro. This voltage is then used for linking and timing calculation purposes.

To see the operating voltages of the supply ports, use the **report_supply_port** command.

The operating voltage of a supply object, once defined, can only be overridden with another **set_voltage** command.

If voltage ranges are specified for a power net, the operating voltages of the power net must fall within one of the specified ranges. Furthermore, the minimum voltage must fall within the same range as the maximum voltage.

The operating voltage of a power net, once defined, can only be overridden with another **set_voltage** command. It can also be cleared by using the **reset_design** command.

Multicorner-Multimode Support

This command applies to the current scenario only.

EXAMPLES

The following example shows a typical usage of the **set_voltage** command.

This example creates a power domain named CNTL that has two supply nets, sn1 and sn2. Both supply nets are assigned a worst case voltage of 0.9. A worst case voltage of 0.9 is also set on the supply port corresponding to the internal VDDPI PG pin of the ram macro cell, which has a fine-grain switch. The definition for the VDDPI pin in the Liberty file is

```
pg_pin(VDDPI) {  
    voltage_name : VDD;  
    direction : internal;  
    pg_type : internal_power;  
    switch_function : "CTRL";  
    pg_function : "VDDP";  
}
```

where VDD is a voltage value defined in the voltage map; CTRL is a switch-pin that controls the fine-grain switch of the macro; and VDDP is a PG pin of type primary_power.

The following commands perform these assignments:

```
prompt> create_power_domain CNTL  
1  
prompt> create_supply_net sn1 -domain CNTL  
1  
prompt> create_supply_net sn2 -domain CNTL  
1  
prompt> set_voltage 0.9 -object_list {sn1 sn2}  
1  
prompt> set_voltage 0.9 -object_list {ram/VDDPI}  
1
```

SEE ALSO

```
create_supply_net(2)
create_power_domain(2)
set_domain_supply_net(2)
connect_supply_net(2)
report_supply_net(2)
report_power_domain(2)
```

set_voltage_model

Sets the voltage model for the specified library.

SYNTAX

```
status set_voltage_model  
  library_name  
  [-voltage {voltage_name voltage_value}]
```

Data Types

<i>library_name</i>	string
<i>voltage_name</i>	string
<i>voltage_value</i>	float

ARGUMENTS

library_name

Specifies the name of the library for which to define the voltage model.

-voltage {*voltage_name* *voltage_value*}

Sets the voltage name and value pair for the specified library. You can specify this option multiple times in a single run of the command.

DESCRIPTION

The **set_voltage_model** command updates the voltage map of the library. If the voltage is already defined in the library, the new value overrides the old value. If the voltage is not defined, the new definition is added to the library voltage map.

EXAMPLES

The following example defines the voltage model for a single-rail library.

```
prompt> set_voltage_model standard_lib \  
  -voltage {VDD 1.2} \  
  -voltage {VSS 0.0}
```

The following example defines the voltage model for a multiple-rail library.

```
prompt> set_voltage_model standard_lib \  
  -voltage {VDD 1.2} \  
  -voltage {VSS 0.0}
```

```
-voltage {VDD 1.2} \
-voltage {VSS 0.0} \
-voltage {VDD_BACK 0.7}
```

set_vsdc

Generates a setup information file in V-SDC format for efficient compare point matching in formal verification tools.

SYNTAX

Boolean **set_vsdc**
 filename
 [-append]
 [-off]

ARGUMENTS

filename

Names the file into which verification setup information will be recorded. You must specify a file name unless the *-off* option is specified.

-append

Appends to the specified file. If another verification setup file is already open then it will be closed before opening the specified file. If *-append* is not used then **set_vsdc** will overwrite the named file, if it exists.

-off

Stops recording verification setup information to the currently-open file. To resume recording into the same file, you must re-issue the **set_vsdc** command with the *-append* option.

DESCRIPTION

This command causes Design Compiler to start recording setup information for formal verification tools. (If you are using Formality, the Synopsys formal verification product, you should use the **set_svf** command, instead.) The V-SDC file that is produced may be used by some verification tools during the matching step to facilitate the alignment of compare points. By using the automatically-generated V-SDC file, the user is relieved of the time-consuming and error-prone process of entering the setup information manually.

The V-SDC file is a series of Tcl commands stored in plain-text format.

The V-SDC file is used to account for name changes that occur during synthesis as a result of running commands such as group, ungroup, uniquify and change_names. Also, certain operations performed by the compile command perform operations that are recorded in the V-SDC file.

Once this command is issued, Design Compiler will begin recording all relevant operations. Because information is buffered internally, the file may not be complete until recording is stopped. Recording is stopped by running "set_vsdc -off" or by exiting dc_shell. Running **set_vsdc** with a new file name will write out and close the original V-SDC file before starting the new one.

This command returns a Boolean value indicating whether **set_vsdc** succeeded (true) or not (false).

EXAMPLES

The following example shows a typical invocation of the command

```
prompt> set_vsdc my_design.vsd़
```

In the following example the verification setup information is appended to the existing V-SDC file, barfile.vsd़.

```
prompt> set_vsdc -append barfile.vsd़
```

set_watermark_configuration

Sets the default watermark configuration for the current design.

SYNTAX

```
status set_watermark_configuration
  [-parameters parameter_list]
  [-exec_name executable_name]
  [-location instance_path_name]
  [-exclude_cells cell_list]
```

Data Types

parameter_list	list
executable_name	string
cell_list	list

ARGUMENTS

-parameters *parameter_list*

Specifies list of parameters to watermark logic insertion.

Here is syntax of parameter.

<parameter_name>:<parameter_value>

These parameters are applied to watermark logic insertion in **insert_security command**.

-exec_name *executable_name*

Specifies leaf level executable name of performer tool that inserts watermark logic into the design.

Complete path name of the executable is inferred from path environment in **insert_security command**.

-location *instance_path_name*

Specifies instance name into which watermark logic is inserted in **insert_security command**.

Specified instance name should be a hierarchical instance name.

-exclude_cells *cell_list*

Specifies list of cells of current design which are excluded from watermark logic in **insert_security command**.

These cells can be leaf level cells or hierarchical cells.

Complete path name of cells should be specified.

Simple regular expressions that contain * are also accepted.

DESCRIPTION

This command specifies the default watermark configuration to be used for watermark logic insertion by the **insert_security** command.

Use the **reset_watermark_configuration** command to reset the current watermark configuration of the design.

EXAMPLES

The following example specifies watermark as executable name for gate level watermark logic insertion and associated parameters.

```
prompt> set_watermark_configuration -exec_name watermark \
    -parameters { copyright_text:synopsys hash:enable ratio:.2 \
    input_fsm_width:3 output_fsm_width:3 num_states:12 \
    unused_transitions:2 random_transitions:enable }
Accepted watermark configuration for design '...'.
1
```

SEE ALSO

insert_security(2)
reset_watermark_configuration(2)

set_wire_load

Sets the wire loading model for the current design or for the specified cluster or ports.

SYNTAX

```
int set_wire_load
  [-mode mode_name]
  [-size value]
  [-library library_name]
  [-cluster cluster_name]
  [-selection_group group_name]]
  [-min]
  [-max]
  [-name model_name]
  [object_list]
```

Data Types

mode_name	string
value	float
library_name	string
cluster_name	string
group_name	string
model_name	string
object_list	string

ARGUMENTS

-mode mode_name

Specifies the mode to use to handle hierarchical wire load models; overrides the default mode, which is discussed in the DESCRIPTION section. Allowed values are *top*, *enclosed* or *segmented*.

-size value

Specifies the minimum block area of the design and all its subdesigns, to use when selecting the appropriate wire load. When you specify a *mode_name* of *enclosed*, the **-size** option can be supplied to control the automatic wire load selection based on block area for this design and for all of its subdesigns.

-library library_name

Specifies the name of the library that contains the desired wire load model.

-cluster cluster_name

Specifies the name of a cluster associated with the current design, to which this wire load model is to be assigned.

-selection_group group_name

Specifies the name of the selection group to use when determining the wire load model based on design or cluster area, when the **auto_wire_load_selection** variable is set to true. This option is required only when the library has more than one selection group

defined and the default group defined in the library is not the desired group.

You can define a selection group for a design or for a cluster, but not for a port list. This option is supported only for the *enclosed* wire load mode, specified using the **-mode** option.

-min

Specifies which model to use for minimum delay analysis: use the wire load model or use the selection group. You cannot use the **-min** option to set a different wire load mode or minimum block size, because both minimum and maximum delay analysis always use the same values for these parameters.

-max

Specifies which model to use for maximum delay analysis: the wire load model or the selection group. Any model set for minimum delay analysis is not affected.

-name *model_name*

Specifies the wire load model to use. The model must be defined in the specified library or in one of the libraries in the **link_library** or the **local_link_library**.

object_list

Collection of objects that use the wire load model.

DESCRIPTION

This command has been obsoleted and is replaced by **set_wire_load_model**, **set_wire_load_mode**, **set_wire_load_selection_group**, and **set_wire_load_min_block_size**.

In its simplest usage, the **set_wire_load** command specifies a wire load model for the top-level design. This model is applied to all nets in that design, both top-level and those under the hierarchy.

You can use this command to set a port's external **wire_load_model**. The wire load model set on a port overrides the wire load model of the design for the net connected to that port.

You also can use this command to set a cluster's **wire_load_model**.

If no wire load model is specified for a design, a default is selected. Design Compiler searches the first library on the link path (or the first library in the design's **local_link_library**) for a default wire load to use. If the library has **wire_load_selection** tables, the cell area of the current design is used to automatically select the appropriate wire load model from the appropriate **wire_load_selection** table. If the library has more than one table, it typically specifies that one of the tables is the default (by setting the **default_wire_selection_group** attribute). You can override this value by using the **-selection_group** option. If you did not supply the **-min_block_size** option, the cell area of the design is assumed to be at least as large as the value specified for this option when selecting the appropriate **wire_load** to use. If there are no **wire_load_selection** tables, a **default_wire_load** is used if there is one in the library. If the library has neither of the aforementioned, no wire load model is used.

The **report_design** command displays the wire loading model and mode for the current design, and the libraries to which the current design is linked. The **report_clusters** command shows the wire load associated with any particular cluster, while the use of the **report_wire_load** command can provide a more detailed report on the **wire_load_models** associated with either a design or cluster. The **report_lib** command shows the wire loading models that are defined in the specified library, as well as any **wire_load_selection** tables that might be defined there. The you can use **report_port** command to display the **wire_load_model** of the ports of a design.

To specify distinct wire load models for various hierarchical cells in the top-level design, specify wire load models on the designs referenced by these hierarchical cells, because wire load models are reference-specific and not instance-specific. You must also ensure that the **wire_load_mode** of the topmost design is not *top*; otherwise, the wire load models selected for lower-level blocks in the design are ignored. The same holds true when specifying a wire load model on a cluster; that is, the wire load mode of the top-level design must not be mode *top*, or these annotations are ignored.

If you don't specify a **wire_load_model_mode** for a design, a default **wire_load_model_mode** is searched for in the first library in the link path during **compile**. If that library does not have a default **wire_load_model_mode**, *top* is assumed. You can override a mode by using the **-mode** option. If the mode for the top-level design is *top*, the wire load model on subdesigns and subclusters has no affect,

and the top-level wire load model is used to compute wire capacitance for all hierarchical or top-level nets within a top-level design. If the first library in the link path during **compile** has a `wire_load_selection` table, and if the mode is *top* and no wire load has been explicitly set for the topmost design, a wire load model is automatically selected based on the total cell area of the design, and is used for all designs in the hierarchy. For designs with an area smaller than the minimum specified, the `-min_block_size` option can set a minimum area to influence which wire load is selected.

If the mode for the top-level design is either enclosed or *segmented*, wire load models on subdesigns and subclusters are used to calculate wire capacitance in nets inside these blocks. If a wire load model is not specified for a subdesign, and if the first library in the link path contains a `wire_load_selection` table, the **compile** command automatically selects a wire load model to use based on the cell area of the subdesign. If you don't define a `wire_load_selection` table, the wire load model of the parent design or cluster is used. If the top-level mode is enclosed or segmented, the wire load model of the subdesign is not set by **characterize** unless the subdesign does not have a wire load.

If the model mode is enclosed, the wire load model of the smallest design that encloses a net completely is used to calculate the wire capacitance of that net. The number of pins on the net equals the number of leaf pins on the net.

If a model mode is segmented, a net is broken into segments; one segment within each hierarchical design. The wire capacitance of a net is the sum of wire capacitances on each segment. When calculating the wire capacitance of each segment, the hierarchical boundary pins are included in the total pin count for that segment. The segmented mode is not supported for `wire_load_models` on clusters.

Hierarchical wire load models are explained previously in terms of wire capacitance, but the wire resistance and wire area are also calculated according to these rules.

With the `-min` option, you can use **set_wire_load** to specify a different wire load model or wire load selection group to use for minimum delay analysis. Unless explicitly specified, minimum delay analysis uses the same wire loads that maximum delay analysis uses. Different wire loads for minimum delay analysis can be set on designs, ports, or clusters. It is not possible to specify a different wire load mode or a different minimum block size for minimum delay analysis only. In these cases these same value is always used for both minimum and maximum analysis.

Wire area is always calculated using the same wire loads used for maximum delay analysis.

Wire loading models contain all the information required by **compile** to estimate interconnect wiring delays. Following is an example of a wire loading model definition, as it appears in the source text of a library.

```
wire_load("90x90") {
    resistance : 0 ;
    capacitance : 1 ;
    area : 0 ;
    slope : 1.64 ;
    fanout_length( 1 , 1.9 ) ;
    fanout_length( 2 , 2.8 ) ;
    fanout_length( 3 , 4.7 ) ;
}
```

The name of this model is "90x90". The fields in this model are defined as follows:

resistance

The resistance per unit-length of interconnect wire.

capacitance

The capacitance per unit-length of interconnect wire.

area

The net-area per unit-length of interconnect wire.

fanout_length (fanout1, length1)

These pairs of numbers specify a lookup table that the design and dft compilers use to estimate the length of interconnect wire being driven by a cell with a given fanout. You must specify at least one of these pairs (with *fanout* = 1), and can specify as many additional pairs as necessary to characterize the desired fanout-length behavior. Linear interpolation between the two nearest pairs is used to estimate any points that are not in the lookup table.

slope

This value is used to characterize linear fanout or length behavior beyond the last pair specified in the lookup table.

To remove a wire load model from a design, use the **set_wire_load** command with no parameters, or use the **reset_design** command.

EXAMPLES

The following example sets the wire load model on the top-level design, on which there is no **local_link_library** set.

```
prompt> report_lib tech_lib
```

Wire Loading Model:

Name	Library	Res	Cap	Area	Slope	Fanout	Length
05x05	tech_lib	0.0000	1.0000	0.0000	0.1860	10	0.3900
10x10	tech_lib	0.0000	1.0000	0.0000	0.3110	1	0.5300

```
prompt> link_library = {tech_lib.db}
prompt> set_wire_load "10x10"
```

In the following example, the **-library** option specifies a wire load model of "10x10" from the library "my_lib.db".

```
prompt> set_wire_load "10x10" -library my_lib.db
```

The following example sets wire load model "10x10" on the subdesign "LOW" to be used for maximum and minimum delay analysis. Then, the wire load model is set to "20x20" and the wire load model mode is set to *enclosed* for the top-level design "TOP". Finally a different wire load model "20x20MIN" is set at the top level to be used for minimum delay analysis only.

```
prompt> current_design LOW
prompt> set_wire_load "10x10"
prompt> current_design TOP
prompt> set_wire_load "20x20" -mode enclosed
prompt> set_wire_load "20x20MIN" -min
```

The following example sets no wire load model on the subdesign "LOW", leaving it to be selected based on its cell area. Then, the wire load model is set to "20x20" and the wire load model mode is set to *enclosed* for the top-level design "TOP", with a **-min_block_size** argument specifying to assume (in this case, LOW) a block size of at least 200.0 for all subdesigns.

```
prompt> current_design LOW /* no wire-load set now */
prompt> current_design TOP
prompt> set_wire_load "20x20" -mode enclosed -min_block_size 200.0
```

The following example sets wire load model "10x10" on the cluster 'CACHE'. Then, the wire load model is set to "20x20" and the wire load model mode is set to *enclosed* for the top-level design "TOP".

```
prompt> current_design TOP
prompt> set_wire_load -cluster CACHE "10x10"
prompt> set_wire_load "20x20" -mode enclosed
```

The following sequence of commands describes the external fanout of a port.

```
prompt> set_wire_load -port_list find(port, "O1") "default_wl"  
prompt> set_load -fanout_number 5 find(port, "O1")
```

The following example sets the selection group for the current design.

```
prompt> current_design TOP  
prompt> set_wire_load -selection_group 2layermetal
```

set_wire_load_min_block_size

Sets the wire load **min_block_size** attribute on the current design.

SYNTAX

```
int set_wire_load_min_block_size  
    size
```

Data Types

size float

ARGUMENTS

size

A positive value in the units of the technology library, that specifies the minimum block area of the design and all its subdesigns, to use when selecting the appropriate wire load.

DESCRIPTION

You can use this command only if the **wire_load_model_mode** attribute has been set to *enclosed* using the **set_wire_load_mode** command.

Sets the wire load minimum block area for the current design and all its subdesigns. By default, the cell area of the design is assumed to be at least as large as the value specified for this option when selecting the appropriate wire load to use in **set_wire_load_model** command. For designs with an area smaller than the minimum specified, this command can set a minimum area to influence which wire load is selected. If there are no **wire_load_selection** tables, a **default_wire_load** is used if there is one in the library. If the library has neither of the aforementioned, no wire load model is used.

EXAMPLES

The following example sets no wire load model on the subdesign "LOW", leaving it to be selected based on its cell area. Then, the wire load model is set to "20x20" and the wire load model mode is set to *enclosed* for the top-level design "TOP", with a-**min_block_size** argument specifying to assume a block size of at least 200.0 for all subdesigns (in this case, LOW).

```
prompt> current_design LOW /* no wire-load set now */  
prompt> current_design TOP  
prompt> set_wire_load_mode enclosed
```

```
prompt> set_wire_load_min_block_size 200.0
prompt> set_wire_load_model -name "20x20"
```

set_wire_load_mode

Sets the **wire_load_model_mode** attribute on the current design, specifying how wire load models are to be used to calculate wire capacitance in nets.

SYNTAX

```
status set_wire_load_mode  
      mode_name
```

Data Types

mode_name string

ARGUMENTS

mode_name

Specifies the value with which to set the **wire_load_model_mode** attribute, thus specifying the mode to be used to handle hierarchical wire load models. Allowed values are as follows:

- The value of *top* (the default) specifies that the wire capacitance of all nets is calculated using the wire load model set on the top-level design.
- The value of *enclosed* specifies that the wire capacitance of each net is calculated using the wire load model set on the smallest subdesign that completely encloses that net. You must specify this mode in order to use the **set_wire_load_min_block_size** commands.
- The value of *segmented* specifies that for each net that crosses hierarchical subdesigns, the wire capacitance is calculated for each segment of the net based on the wire load model set on the subdesign that contains that segment. The total wire capacitance of the net is the sum of the wire capacitances of its segments.

DESCRIPTION

The **set_wire_load_mode** command sets the **wire_load_model_mode** attribute on the current design, specifying how hierarchical wire load models are to be used to calculate wire capacitance of nets in the current design. If you use the **set_wire_load_min_block_size** command to set the **min_block_size** attribute and execute this command to set the *mode_name* to be different from *enclosed*, the **min_block_size** attribute is canceled.

The **report_design** command displays the wire loading model and mode for the current design, and the libraries to which the current design is linked.

To specify distinct wire load models for various hierarchical cells in the top-level design, specify wire load models on the designs referenced by these hierarchical cells; wire load models are reference-specific and not instance-specific. You must also ensure that the **wire_load_model_mode** attribute of the topmost design is not *top*; otherwise, the wire load models selected for lower-level blocks in the design are ignored.

If you do not specify a **wire_load_model_mode** for a design, **compile** searches for a default **wire_load_model_mode** in the first library in the **link_path**. If that library does not have a default **wire_load_model_mode**, *top* is the default. If the mode for the top-level design is *top*, the wire load model on subdesigns and subclusters has no effect, and the top-level wire load model is used to compute wire capacitance for all hierarchical or top-level nets within a top-level design.

If the mode for the top-level design is either *enclosed* or *segmented*, wire load models on subdesigns and subclusters are used to calculate wire capacitance in nets inside these blocks. When the **auto_wire_load_selection** variable is *true*, if a wire load model is not specified for a subdesign, and if the first library in the **link_path** contains a **wire_load_selection** table, the **compile** command automatically selects a wire load model based on the cell area of the subdesign. If you do not define a **wire_load_selection** table, the wire load model of the parent design or cluster is used. If the top-level mode is *enclosed* or *segmented*, the wire load model of the subdesign is not set by **characterize** unless the subdesign does not have a wire load. When the **auto_wire_load_selection** variable is *false*, if a wire load model is not specified for a subdesign, no wire load model is selected.

If the model mode is *enclosed*, the wire load model of the smallest design that encloses a net completely is used to calculate the wire capacitance of that net. The number of pins on the net equals the number of leaf pins on the net.

EXAMPLES

The following example sets the **wire_load_mode** attribute to *enclosed* for the top-level design named TOP:

```
prompt> current_design TOP  
prompt> set_wire_load_mode enclosed
```

set_wire_load_model

Sets the **wire_load_attach_name** attribute on designs, ports, hierarchical cells of current design, for selecting a wire load model to use in calculating wire capacitance.

SYNTAX

```
status set_wire_load_model
  -name model_name
  [-library lib]
  [-min] [-max]
  [object_list]
```

Data Types

model_name string
object_list collection

ARGUMENTS

-name *model_name*

Specifies the name of the wire load model to be used. The model must be defined in the library or in one of the libraries in the **link_library** (including the **local_link_library**). This is a required option.

-library *lib*

Specifies the library that contains the desired wire load model. This is either a library or a collection. The first library in the collection that contains the wire load model is selected.

-min

Indicates that the wire load model or selection group is to be used for minimum delay analysis only. You cannot use the **-min** option to set a different wire load mode or minimum block size, because both minimum and maximum delay analysis always use the same values for these parameters.

-max

Indicates that the wire load model or selection group is to be used for maximum delay analysis only. Any model set for minimum delay analysis is not affected.

object_list

Specifies a list of ports, designs, and/or cells, to which this wire load model is to be assigned. By default, the current design is assigned the wire load model.

DESCRIPTION

The **set_wire_load_model** command sets the **wire_load_attach_name** attribute on the specified ports, designs, or cells specified in the object list, or on the current design, for selecting a wire load model to use in calculating wire capacitance. Issuing the command without options specifies a wire load model for the top-level design. The **-name** option is required.

When a design is specified, this wire load model is applied to all nets in the design at the top level and those under the hierarchy. If cells are specified, they are searched in the current design. The wire load model set on a cell overrides the wire load model of the design for the cell.

You can use this command to set a port's external wire load model. The wire load model set on a port overrides the wire load model of the design for the net connected to that port.

If no wire load model is specified for a design, a default is selected. The tool searches the first library on the link path (or the first library in the design's **local_link_library**) for a default wire load model to use. When the **auto_wire_load_selection** attribute is set to true, if the library has **wire_load_selection** tables, the cell area of the current design is used to automatically select the appropriate wire load model from the appropriate **wire_load_selection** table. If the library has more than one table, it typically specifies that one of the tables is the default (by setting the **default_wire_selection_group** attribute). You can override this value by using the **set_wire_load_selection_group** command. If you did not set the minimum block size by using the **set_wire_load_min_block_size** command, the cell area of the design is assumed to be at least as large as the value specified for this option when selecting the appropriate wire load to use. If there are no **wire_load_selection** tables, a **default_wire_load** is used if there is one in the library. If the library has neither of the aforementioned, no wire load model is used.

When the **auto_wire_load_selection** attribute is set to false, and no *model_name* is specified, no wire load model is used.

The **report_design** command displays the wire load model and mode for the current design, and the libraries to which the current design is linked. The **report_wire_load** command provides a more detailed report on the wire load models associated with a design.

The **report_lib** command shows the wire load models that are defined in the specified library, as well as any **wire_load_selection** tables that are defined. You can use the **report_port** command to display the wire load model of the ports of a design.

You can specify instance-specific wire load models for hierarchical cells in the current design. The wire load models on the designs referenced by these hierarchical cells are not changed.

If you specify wire load model on subdesigns, you must ensure that the wire load mode of the top design is not **top**; otherwise, the wire load models selected for lower-level blocks in the design are ignored.

If you do not specify a wire load mode for a design, the tool searches for a default wire load mode in the first library in the link path during **compile**. If that library does not have a default wire load mode, **top** is assumed. You can override a mode by using the **set_wire_load_mode** command. For a definition of the **top**, **enclosed**, and **segmented** values of the **wire_load_model_mode** attribute, and an explanation of how a default wire load model is selected, see the man page for the **set_wire_load_mode** command.

Wire resistance and wire area are also calculated according to the rules for wire capacitance.

With the **-min** option, you can use the **set_wire_load_model** command to specify a different wire load model to use for minimum delay analysis. Unless explicitly specified, minimum delay analysis uses the same wire loads that maximum delay analysis uses. You can set different wire loads for minimum delay analysis on designs or ports. You cannot specify a different wire load mode or a different minimum block size for minimum delay analysis only. In these cases these same value is always used for both minimum and maximum analysis.

Wire area is always calculated by using the same wire loads used for maximum delay analysis.

Wire loading models contain all the information required by **compile** to estimate interconnect wiring delays. The following is an example of a wire loading model definition, as it appears in the source text of a library.

```
wire_load("90x90") {
    resistance : 0 ;
    capacitance : 1 ;
    area : 0 ;
    slope : 1.64 ;
    fanout_length( 1 , 1.9 ) ;
    fanout_length( 2 , 2.8 ) ;
    fanout_length( 3 , 4.7 ) ;
}
```

The name of this model is 90x90. The fields in this model are defined as follows:

resistance

The resistance per unit length of interconnect wire.

capacitance

The capacitance per unit length of interconnect wire.

area

The net-area per unit length of interconnect wire.

fanout_length (fanout1, length1)

These pairs of numbers specify a lookup table that the tools use to estimate the length of interconnect wire being driven by a cell with a given fanout. You must specify at least one of these pairs (with fanout = 1), and can specify as many additional pairs as necessary to characterize the desired fanout length behavior. Linear interpolation between the two nearest pairs is used to estimate any points that are not in the lookup table.

slope

This value is used to characterize linear fanout or length behavior beyond the last pair specified in the lookup table.

To remove a wire load model from a design, use the **remove_wire_load_model** command, or use the **reset_design** command.

EXAMPLES

The following example sets the wire load model on the top-level design, on which there is no **local_link_library** set:

```
prompt> report_lib tech_lib
```

```
.
```

Wire Loading Model:

Name	Library	Res	Cap	Area	Slope	Fanout	Length
05x05	tech_lib	0.0000	1.0000	0.0000	0.1860	10	0.3900
10x10	tech_lib	0.0000	1.0000	0.0000	0.3110	1	0.5300

```
.
```

```
prompt> link_library = {tech_lib.db}
prompt> set_wire_load_model -name "10x10"
```

In the following example, the **-library** option specifies a wire load model of 10x10 from the **my.lib.db** library:

```
prompt> set_wire_load_model -name "10x10" -library my.lib.db
```

The following example sets the 10x10 wire load model on the subdesign named **LOW** to be used for maximum and minimum delay analysis. Then, the wire load model is set to 20x20 and the wire load model mode is set to **enclosed** for the top-level design **TOP**. Finally, a different wire load model named **20x20MIN** is set at the top level to be used for minimum delay analysis only.

```
prompt> current_design LOW
prompt> set_wire_load_model -name "10x10"
prompt> current_design TOP
prompt> set_wire_load_mode enclosed
prompt> set_wire_load_model -name "20x20"
prompt> set_wire_load_model -name "20x20MIN" -min
```

The following example sets no wire load model on the **LOW** subdesign, leaving it to be selected based on its cell area. Then, the wire load model is set to 20x20 and the wire load model mode is set to **enclosed** for the **TOP** top-level design, with a **-min_block_size** option specifying to assume a block size of at least 200.0 for all subdesigns (in this case, **LOW**).

```
prompt> current_design LOW /* no wire-load set now */
prompt> current_design TOP
prompt> set_wire_load_mode enclosed
prompt> set_wire_load_min_block_size 200.0
prompt> set_wire_load_model -name "20x20"
```

The following sequence of commands describes the external fanout of a port:

```
prompt> set_wire_load_model [get_ports O1] "default_wl"
prompt> set_port_fanout_number 5 [get_ports O1]
```

Assume U1, U2, and U3 are 3 cells in the design named TOP, and all of them are instances of a subdesign named LOW. The following commands set the 10x10 wire load model on LOW and the 20x20 wire load model on U1 and U2:

```
prompt> current_design TOP
prompt> set_wire_load_model -name "10x10" LOW
prompt> set_wire_load_model -name "20x20" {U1 U2}
```

set_wire_load_selection_group(2)
auto_wire_load_selection(3)
link_library(3)

set_wire_load_selection_group

Specify a selection group to use for determining a wire load model to be assigned to designs and cells or to a specified cluster.

SYNTAX

```
int set_wire_load_selection_group  
  [-library lib] [-min]  
  [-max]  
  group_name [object_list]
```

Data Types

group_name string
object_list list

ARGUMENTS

-library *lib*

Specifies the library from which to select the wire load model. This is either a library name or a collection. The first library in the collection that contains the wire load model is selected.

-min

Specifies to use the selection group for minimum delay analysis only. You cannot use the **-min** option to set a different wire load mode or minimum block size, because both minimum and maximum delay analysis always use the same values for these parameters.

-max

Specifies to use the selection group for maximum delay analysis. Any model set for minimum delay analysis is not affected.

group_name

Specifies the name of the selection group to use to determine the wire load model based on area.

object_list

Specifies a list of designs and/or cells, to which the wire load model selection group attributes are to be assigned. If the *object_list* is not specified, the current design is assigned the attributes.

DESCRIPTION

This command sets the **wire_load_model_selection_group** attribute to *group_name*, and the **wire_load_model_selection_group_lib** attribute to the first library in *lib* that contains the group, on the designs and cells specified in *object_list* or on the specified cluster of current design. If none of them is specified, current design is assigned the attributes. You can

define a selection group for designs, cells, or a cluster, but not for ports.

The area of the specified selection group is used to determine the wire load model for designs and cells, or cluster. It is supported only for the *enclosed* wire load model mode, which you specify using the **set_wire_load_mode** command. This command has an effect only when the variable **auto_wire_load_selection** is *true*.

To view the wire load associated with a specific cluster, use the **report_clusters** command. For a more detailed report on the wire load models associated with either a design or a cluster, use the **report_wire_load** command. To view the wire loading models defined in a library, as well as any **wire_load_selection** tables that might be defined there, use the **report_lib** command.

With the **-min** option, you can use this command to specify a wire load selection group to use for minimum delay analysis. Unless explicitly specified, minimum delay analysis uses the same wire loads as does maximum delay analysis. Different wire loads for minimum delay analysis can be set on designs, cells, or clusters. You cannot specify a different wire load mode or a different minimum block size for minimum delay analysis only. In these cases, the same value is always used for both minimum and maximum analysis.

Wire area is always calculated based on the wire loads used for maximum delay analysis.

EXAMPLES

The following example sets the selection group for a sub-design LOW and a hierarchical cell U1/U2 in the top design.

```
prompt> current_design TOP  
prompt> set_wire_load_selection_group 2layermetal {LOW U1/U2}
```

The following example sets the selection group for the current design.

```
prompt> current_design TOP  
prompt> set_wire_load_selection_group 2layermetal
```

integer	threshold_value
port_name	string
threshold_value	integer
mask_bound	pin or port
mode_name	string

mode_list list
cell_list list

ARGUMENTS

-class core_wrapper | shadow_wrapper

Specifies the name of the class to which the wrapper configuration applies.

This option is required.

-style dedicated | shared

Specifies the wrapper cell style to be used for core-wrapping the current design.

The default is **dedicated** in the simple and delay test wrapper flows; the default is **shared** in the maximized reuse flow.

-core core_list

Specifies the list of core cells to which the configuration applies.

The default is to apply the configuration to the current design, rather than applying it to specific cells.

-dedicated_cell_type WC_D1 | WC_D1_S | none

Specifies the cell type to be used for dedicated wrapper cells when core-wrapping the current design.

The default is **WC_D1** for cells without a SAFE value and **WC_D1_S** for cells with a SAFE value.

-shared_cell_type WC_S1 | WC_S1_S | none

Specifies the cell type to be used for shared wrapper cells when core-wrapping the current design.

The default is **WC_S1** for cells without a SAFE value and **WC_S1_S** for cells with a SAFE value.

-dedicated_design_name design_name

Specifies the name of the wrapper cell design to be used for dedicated wrapper cells when core-wrapping the current design.

The specified design must be previously specified with the **define_dft_design** command.

There is no default for this option.

-shared_design_name design_name

Specifies the name of the wrapper cell design to be used for shared wrapper cells when core-wrapping the current design.

The specified design must be previously specified with the **define_dft_design** command.

There is no default for this option.

-register_io_implementation swap | in_place

Specifies the implementation to be used for synthesizing shared wrapper cells when core-wrapping the current design.

The default is **swap** in the simple and delay test wrapper flows; the default is **in_place** in the maximized reuse flow.

-use_dedicated_wrapper_clock true | false

Specifies if a dedicated wrapper clock should be used for shared wrapper cells added by core wrapping.

The default is **false**.

-safe_state 0 | 1 | none

Specifies the safe state value to be used for wrapper cells added by core wrapping.

The default is **none**.

-delay_test true | false

Specifies if additional wrapper test modes that are used for delay testing should be created by core wrapping. In these additional wrapper test modes, all wrapper chains contain either input wrapper cells or output wrapper cells. Wrapper chains containing input wrapper cells and wrapper chains containing output wrapper cells are controlled by different wrapper shift enables.

The default is **false**.

-max_length integer

Specifies the maximum length of a wrapper chain in all wrapper modes. Wrapper chain lengths in scan compression modes are not controlled by this option.

The default is that wrapper chain length is not controlled this option.

-chain_count integer

Specifies the maximum number of wrapper chains in all wrapper modes. The number of wrapper chains in scan compression modes are not controlled by this option.

There is no default for this option; it has no effect unless explicitly set.

When you do not use either the **-max_length** or **-chain_count** option, the wrapper chain length or number of wrapper chains are controlled by the **-max_length** and **-chain_count** options of the **set_scan_configuration** command.

-mix_cells true | false

Specifies if wrapper cells for input or output ports can be mixed in a wrapper chain.

If this option is set to **false**, all wrapper cells in a wrapper chain are either associated with input ports or output ports but not both.

If this option is set to **true**, input and output wrapper cells can be mixed in the same wrapper chain.

The default is **true** in the simple and delay test wrapper flows; the default is **false** in the maximized reuse flow.

-input_shift_enable port_name

Specifies the wrapper shift enable port for wrapper chains that contain only wrapper cells for input ports.

The *port_name* argument must be defined as a **wrp_shift** DFT signal.

There is no default for this option.

-output_shift_enable port_name

Specifies the wrapper shift enable port for wrapper chains that contain only wrapper cells for output ports.

The *port_name* argument must be defined as a **wrp_shift** DFT signal.

There is no default for this option.

-maximize_reuse enable | disable

Specifies that the tool can reuse I/O registers in the fanin or fanout cone of ports as shared wrapper cells. These I/O registers do not need to be on the sensitive path of the ports; any combinational logic is allowed between the ports and the I/O registers.

Dedicated wrapper cells are not added to ports that are not register bounded.

Dedicated wrapper cells are added to ports that are connected to clock gating cells or registers inside a DFT model.

Currently the tool expects to see the netlist of a DFT model in addition to the model as the model does not show the complete association of pins to the registers inside the model. If netlist is not loaded for a model cell, the tool assumes that the model has only combinational logic.

When a dedicated wrapper cell is added to a port that is connected to I/O registers, a user-specified clock is used for the dedicated wrapper cell. In the absence of such a specification, the most used clock domain of I/O registers is used as the clock of the dedicated wrapper cell. If no such clock is found, a dedicated wrapper clock is used.

If an I/O register is common to both an input port and a output port, the I/O register is classified as an input I/O register.

These I/O registers are also used as normal scan cells in internal_scan mode.

When the **-maximize_reuse** option is enabled, the tool sets the following options automatically:

- style shared
- register_io_implementation in_place
- mix_cells false
- use_system_clock_for_dedicated_wrp_cells enable

The default of this option is **disable**.

-reuse_threshold threshold_value

Specifies the maximum number of I/O registers that can be reused as shared wrapper cells in the maximized reuse flow.

This option is applicable only when the **-maximize_reuse** option is set to **enable**.

When the number of I/O registers detected for a port exceeds the specified threshold value, a dedicated wrapper cell is added to the port.

The default is 1. If the option is set to 0, all I/O registers associated with a port are reused as shared wrapper cells.

-depth_threshold threshold_value

Specifies the maximum combinational depth of I/O registers that can be reused as shared wrapper cells for a port in the maximized reuse flow.

This option is applicable only when the **-maximize_reuse** option is set to **enable**.

The combinational logic depth is defined as the maximum number of combinational logic levels, including buffers and inverters, between a port and an associated I/O register. For a given port, if the combinational logic depth of any associated I/O register exceeds this value, a dedicated wrapper cell is added to the port.

There is no default for this option. When not specified, the check is not performed and all I/O registers associated with a port are reused as shared wrapper cells, subjective to other checks.

-use_system_clock_for_dedicated_wrp_cells enable | disable

Controls whether the tool uses the system clock of I/O registers of the port as the clock for the dedicated wrapper cell.

When a dedicated wrapper cell is added to a port and this option is enabled, the tool uses the system clock of I/O registers of the port as the clock for the dedicated wrapper cell.

If the port is connected to a single I/O register and the tool adds a dedicated wrapper cell to the port, the clock of the associated I/O register is used as the clock for the dedicated wrapper cell.

The default wrapper clock is used for a dedicated wrapper cell if the associated port is not connected to any I/O registers.

The tool issue an error if more than one I/O register is found for a port and all of these I/O registers do not use the same clock domain and you did not specify any clock for the port. The command is terminated in such a case.

If you specify a clock for such a port, the tool treats the error as a warning and uses the specified clock as the clock for the dedicated wrapper cell.

The default is **disable** in the simple and delay test wrapper flows; the default is **enable** in the maximized reuse flow.

-end_of_chain_logic enable | disable

Controls whether the tool adds end-of-chain logic to all wrapper chains of all modes. Here is the description of the logic added to wrapper chains when this option is enabled.

All wrapper chains are driven with the following logic:

```
masked_wsi = (~wse & wrapper_mode & input_mask_bound) | wsi
```

The following logic is added to all wrapper chain outputs:

```
masked_wso = ((~wse & wrapper_mode & input_mask_bound) | output_mask_bound) | wso
```

where

wse	- wrapper chain scan enable
wrapper_mode	- the test mode in which the wrapper chain is active
wsi	- wrapper chain's original scan input
masked_wsi	- wrapper chain's masked(new) scan input
wso	- wrapper chain's original scan output
masked_wso	- wrapper chain's masked(new) scan output

The default is **disable** so that no end-of-chain logic is added to wrapper chains.

-input_mask_bound mask_bound

Specifies the mask bound to be used in the end-of-chain logic added by the tool for wrapper chain inputs.

The logic added is described in the **-end_of_chain_logic** description. The mask bound can be a pin or a port.

This option is effective only if the **-end_of_chain_logic** option is enabled.

There is no default for this option.

-output_mask_bound mask_bound

Specifies the mask bound to be used in the end-of-chain logic added by the tool for wrapper chain outputs.

The logic added is described in the **-end_of_chain_logic** description. The mask bound can be a pin or a port.

This option is effective only if the **-end_of_chain_logic** option is enabled.

There is no default for this option.

-hier_wrapping enable | disable

Enables or disables hierarchical wrapping.

Hierarchical wrapping is supported only when the **-maximize_reuse** option is enabled and there is only one scan mode synthesized in DFT insertion.

When hierarchical wrapping is enabled, the following core wrapping functionality is used:

All input wrapper cells are stitched into one or more input wrapper chains, controlled by an input shift-enable signal.

All output wrapper cells are stitched into one or more output wrapper chains, controlled by an output shift-enable signal.

Separate input and output control signals are used for the following wrapper control signal types:

- Wrapper shift signal
- Wrapper capture signal (if the input or output wrapper chains include a dedicated wrapper cell)
- SAFE mode enable signal (if the input or output wrapper chains include a wrapper cell that drives a SAFE value)

There is no wrapper mode logic added to the design.

The default is **disable**.

-use_separate_wrapper_chain_controls enable | disable

Specifies whether to use separate control signals for each wrapper chain.

This option is used in the hierarchical wrapping flow to create cores with increased wrapper chain reclassification flexibility. Hierarchical wrapping is enabled by the **-hier_wrapping** option.

When this option is set to the default of **disable**, the tool uses the minimum set of wrapper control signals needed for all wrapper chains.

When this option is set to **enable**, the tool uses separate signals for each individual input and output wrapper chain for the following wrapper control signal types:

- Wrapper shift signal
- Wrapper capture signal (if the wrapper chain includes a dedicated wrapper cell)
- SAFE mode enable signal (if the wrapper chain includes a wrapper cell that drives a SAFE value)

When you use separate control signals for each wrapper chain, the tool can independently reclassify each wrapper chain when the core is integrated at a higher level. This can be useful when some wrapper chains communicate with logic within the integration level (so that the wrapper chain could be reclassified as a standard scan chain) and some communicate with logic outside the integration level (so that the wrapper chain should remain as a wrapper chain).

This option has no effect when the **-hier_wrapping** option is set to its default of **disable**. For more information about wrapper chain classification, see the description for the **-hier_wrapping** option.

-shift_enable port_name

Specifies the wrapper shift enable port for wrapper chains.

This option is applicable only when the **-mix_cells** option is set to **true**.

The *port_name* argument must be defined as a **wrp_shift** DFT signal.

If the option is not specified, the tool uses one of the wrapper shift signals. If no wrapper shift signal is specified, the tool creates a wrapper shift signal.

-test_mode mode_name

Specifies the test mode to which the specification applies.

Only the following options can be specified with this option when the value of the option is not **all**:

-max_length
-chain_count
-mix_cells
-input_shift_enable
-output_shift_enable
-shift_enable

The values of all other options are taken from the wrapper configuration specification for the **all** mode.

The default is **all** (the specification applies to all modes).

-create_only_wrapper_modes mode_list

Specifies that only wrapper test modes with the specified usages should be created.

This option is used for analog/mixed-signal designs that do not require any inward-facing wrapper modes. By default, the tool creates both inward-facing and outward-facing wrapper modes. Valid argument values to restrict mode creation are:

- {**wrp_of**} - Creates only outward-facing wrapper modes. This provides only outward-facing wrapper functionality for analog/mixed-signals cores.
- {**wrp_of wrp_safe**} - Creates both outward-facing wrapper modes and safe wrapper modes. This can be used to also create a safe mode for the block that drives constant output values with no scan requirements.

The default is an empty list ({ }), which deactivates the option so that the tool creates both inward-facing and outward-facing wrapper modes.

-add_wrapper_cells_to_power_domains enable | disable

Enables or disables the addition of dedicated wrapper cells to associated power domain hierarchies.

This option has no effect if there are no power domains in the design or no dedicated wrapper cells are added during wrapper insertion.

When this option is enabled, the tool identifies the hierarchy in which a dedicated wrapper cell is added by using the following method.

If the port of the dedicated wrapper cell is connected to an I/O register, the top-level hierarchy of the power domain of the I/O register is used as the location for the dedicated wrapper cell.

If no I/O register is found for the port of the dedicated wrapper cell, the tool checks if the port is connected to a CTL modeled instance. If so, the top-level hierarchy of the power domain of the CTL modeled instance is used as the location for the dedicated wrapper cell.

If neither I/O register nor CTL modeled instance is found to be connected to the port of the dedicated wrapper cell, the top-level hierarchy of the first connected gate is used as the location for the dedicated wrapper cell.

If the I/O register or CTL modeled instance or the gate connected to the port of the dedicated wrapper cell does not have a power domain, the dedicated wrapper cell is added to the top-level hierarchy.

When this option is enabled, no additional hierarchy is created for dedicated wrapper cells added to the design.

When this option is enabled, any user-specified wrapper logic location (**set_dft_location ...**) is ignored.

The default is **disable** so that dedicated wrapper cells are added to the user-specified wrapper logic location if specified (**set_dft_location ...**) or to the top-level hierarchy.

-gate_dedicated_wrapper_cell_clk enable | disable

Enables or disables gating of the clock of all dedicated wrapper cells synthesized during wrapper insertion.

When this option is enabled, the clock of all dedicated wrapper cells is gated with simple combinational logic such that the clock is off in all test modes in which dedicated wrapper cell is not active.

For example, the clock of dedicated wrapper cells is off in mission_mode and internal_scan test modes.

The default is **disable** so that the clock of the dedicated wrapper cells is not gated.

-gate_cells none | existing_cg | all

Controls whether clock-gating logic is inserted or modified to reduce power consumption in core wrapping modes.

This feature implements the following behavior for integrated clock-gating cells:

- In EXTEST (outward-facing) modes, clocks to core register cells are disabled.
- In SAFE mode, clocks to both core register cells and wrapper cells are disabled.

When this option is set to **existing_cg**, the tool modifies only existing integrated clock-gating cells. Both the functional and test enable pin connections are modified.

When this option is set to **all**, the tool modifies existing integrated clock-gating cells, and it also inserts integrated clock-gating cells for more aggressive power reduction. (You must set the **test_icg_p_ref_for_dft** and **test_icg_n_ref_for_dft** application variables to specify the rising-edge and falling-edge ICG library cells to insert, respectively.)

The default is **none**, which disables the feature.

-hold_mux_for_shared_wrapper_cells enable | disable

Enables or disables a hold MUX for shared wrapper cells when the **-maximize_reuse** option is enabled.

When a hold MUX is added, shared wrapper cells hold the state when the cell is not in shift mode in test operation.

The default is not to add a hold MUX to shared wrapper cells.

This option has no effect when the **-maximize_reuse** option is disabled.

-no_dedicated_wrapper_cells enable | disable

When this option is set to **enable**, dedicated wrapper cells are not added to chains for the specified wrapper test mode.

The default is **disable** so that dedicated wrapper cells are added to chains for the specified wrapper test mode.

-feedthrough_chains enable | disable

Specifies whether feedthrough chains are created in transparent modes.

When this option is set to **disable**, feedthrough chains are not created in transparent modes. In this case, you no longer need to use dedicated wrapper scan I/Os for the core's outward-facing modes. The resulting core contains no feedthrough chains, and it can be integrated in top-level designs that do not have a top-level codec.

The default is **enable**, which creates feedthrough chains in transparent modes. This ensures that the core can be integrated in top-level designs that have a top-level codec.

This option affects only transparent test modes, which are defined with the **-transparent_mode_of** option of the **define_test_mode** command.

-input_wrapper_cells cell_list

Specifies additional scan cells to be classified as output-related registers to include in the input wrapper chain. The input is accepted as a simple list. Wildcards and collections are not supported.

This option is not cumulative; new specifications overwrite previous specifications. Specify an empty list to remove a previous specification.

This option is applicable only when the **-maximize_reuse** option is set to **enable**.

-output_wrapper_cells cell_list

Specifies additional scan cells to be classified as input-related registers to include in the output wrapper chain. The input is accepted as a simple list. Wildcards and collections are not supported.

This option is not cumulative; new specifications overwrite previous specifications. Specify an empty list to remove a previous specification.

This option is applicable only when the **-maximize_reuse** option is set to **enable**.

DESCRIPTION

This command specifies the default configuration to be used by the core wrapper or shadow wrapper application.

Use the **reset_wrapper_configuration** command to reset the current wrapper configuration of the design.

EXAMPLES

The following example specifies that the the WC_D1_S cell is to be used as dedicated wrapper cell, WC_S1_S to be used as shared wrapper cell with safe value 0 in core wrapping.

```
prompt> set_wrapper_configuration -class core_wrapper \
    -dedicated_cell_type WC_D1_S -shared_cell_type WC_S1_S \
    -safe_state 0
```

Accepted wrapper configuration for design '...' for mode all_dft.

1

```
prompt> set_wrapper_configuration -class core_wrapper \
    -style shared -register_io_implementation in_place -mix_cells false \
    -maximize_reuse enable -reuse_threshold 4
```

```
Accepted wrapper configuration for design '...' for mode all_dft.  
1  
  
prompt> define_test_mode WINTEST -usage wrp_if  
Defining test mode WINTEST in view existing_dft  
Defining test mode WINTEST in view spec  
Current test mode is 'WINTEST'.  
1  
  
prompt> define_test_mode WEXTEST -usage wrp_of  
Defining test mode WEXTEST in view existing_dft  
Defining test mode WEXTEST in view spec  
Current test mode is 'WEXTEST'.  
1  
  
prompt> set_wrapper_configuration -class core_wrapper \  
-test_mode all -maximize_reuse enable \  
-reuse_threshold 4 -mix_cells false  
Accepted wrapper configuration for design '...' for mode all_dft.  
1  
  
prompt> set_wrapper_configuration -class core_wrapper \  
-test_mode WINTEST -chain_count 4  
Accepted wrapper configuration for design '...' for mode WINTEST.  
1  
  
prompt> set_wrapper_configuration -class core_wrapper \  
-test_mode WEXTEST -mix_cells true -chain_count 1  
Accepted wrapper configuration for design '...' for mode WEXTEST.  
1
```

set_zero_interconnect_delay_mode

Forces the timer to ignore the contribution on a timing path from any wire capacitance in the design.

SYNTAX

```
status set_zero_interconnect_delay_mode
      [true | false]
```

ARGUMENTS

true | false

Enables the zero interconnect delay mode when set to **true**. Disables the zero interconnect delay mode when set to **false**. If no value is specified, the default is **true**.

DESCRIPTION

This command enables or disables the zero interconnect delay mode. The zero interconnect delay mode forces the timer to ignore contributions on a timing path from any wire capacitance in a design. It forces all wire capacitance to be as trivial as 0, regardless of the wire load model used in the design or any back-annotated capacitance on a wire. Disabling the mode allows the timer to consider the wire capacitance as it did before enabling the mode.

The command is used primarily in preplacement and postplacement steps to assess design and constraint feasibility. When the mode is enabled, the design is analyzed with only cell delay and the capacitance of the pin load on all wires in the design to determine if the design can meet timing goals. It also helps when debugging potential missing timing exceptions in the constraints. Zero interconnect delay mode must not be used in the final implementation step.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

setenv

Sets the value of a system environment variable.

SYNTAX

```
string setenv
      variable_name new_value
```

Data Types

<i>variable_name</i>	string
<i>new_value</i>	string

ARGUMENTS

variable_name

Names of the system environment variable to set.

new_value

Specifies the new value for the system environment variable.

DESCRIPTION

The **setenv** command sets the specified system environment *variable_name* to the *new_value* within the application. If the variable is not defined in the environment, the environment variable is created. The **setenv** command returns the new value of *variable_name*. To develop scripts that interact with the invoking shell, use **getenv** and **setenv**.

Environment variables are stored in the Tcl array variable **env**. The environment commands **getenv**, **setenv**, and **printenv** are convenience functions to interact with this array.

The **setenv** command sets the value of a variable only within the process of your current application. Child processes initiated from the application using the **exec** command after a usage of **setenv** inherit the new variable value. However, these new values are not exported to the parent process. Further, if you set an environment variable using the appropriate system command in a shell you invoke using the **exec** command, that value is not reflected in the current application.

EXAMPLES

The following example changes the default printer.

```
prompt> getenv PRINTER
```

```
laser1
prompt> setenv PRINTER "laser3"
laser3
prompt> getenv PRINTER
laser3
```

SEE ALSO

[exec\(2\)](#)
[getenv\(2\)](#)
[printenv\(2\)](#)
[printvar\(2\)](#)
[set\(2\)](#)
[sh\(2\)](#)
[unset\(2\)](#)

sh

Executes a command in a child process.

SYNTAX

string **sh**

ARGUMENTS

The **sh** command has no arguments.

DESCRIPTION

This is very similar to the **exec** command. However, file name expansion is performed on the arguments. Remember that quoting and grouping is in terms of Tcl. Arguments which contain spaces will need to be grouped with double quotes or curly braces. Tcl special characters which are being passed to system commands will need to be quoted and/or escaped for Tcl. See the examples below.

EXAMPLES

This example shows how you can remove files with a wildcard.

```
prompt> ls aaa*
aaa1    aaa2    aaa3
prompt> sh rm aaa*
prompt> ls aaa*
Error: aaa*: No such file or directory
      Use error_info for more info. (CMD-013)
```

This example shows how to grep some files for a regular expression which contains spaces and Tcl special characters:

```
prompt> exec cat test3.out
blah blah blah
blah blah blah c blah
input [1:0] A;
output [2:0] B;
prompt>
prompt> sh egrep -v {[ ]+c[ ]+} test3.out
blah blah blah
prompt>
```

```
prompt> sh egrep {t[ ]+[]} test3.out
input [1:0] A;
output [2:0] B;
```

SEE ALSO

[exec\(2\)](#)

sh_list_key_bindings

Displays all the key bindings and edit mode of current shell session. This variable is for use in Tcl mode only.

SYNTAX

int **sh_list_key_bindings** [*-nosplit*]

ARGUMENTS

-nosplit

Indicates that lines are not to be split when column fields overflow.

DESCRIPTION

The **sh_list_key_bindings** command displays current key bindings and the edit mode. To change the edit mode, command **set_cle_options** can be used on the shell.

The text CTRL+K is read as `Control+K' and describes the character produced when the k key is hit while the Control key is depressed.

The text META+K is read as `Meta+K' and describes the character produced when the Meta key is depressed, and the k key is hit. The Meta key is labeled ALT on many keyboards. On keyboards with two keys labeled ALT (usually to either side of the space bar), the ALT on the left side is generally set to work as a Meta key. The ALT key on the right may also be configured to work as a Meta key or may be configured as some other modifier, such as a Compose key for typing accented characters.

If you do not have a Meta or ALT key, or another key working as a Meta key, the identical keystroke can be generated by typing ESC first, and then typing k. Either process is known as metatyping the k key.

In vi mode, typing ESC will change the edit mode to alternate (command) mode. Alternate key bindings work only in vi alternate (command) mode.

In vi mode, if arrow keys are used while in input mode then the mode will be automatically changed to alternate (command). Arrow keys should not be used to move around in the line while in input mode. If there is any mistake has been made while entering text in input mode, first press ESC to return to alternate mode and then relocate the cursor to the position where the error was made.

shell_is_dcnxt_shell

Determines if the shell was invoked in DCNXT mode.

SYNTAX

status **shell_is_dcnxt_shell**

ARGUMENTS

The **shell_is_dcnxt_shell** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in DCNXT mode. The command returns 1 if the shell is in DCNXT mode, or a 0 otherwise.

EXAMPLES

The following example shows how to check if shell was invoked in DCNXT:

```
prompt> if { [shell_is_dcnxt_shell] } { \
    echo "You invoked dc_shell in DCNXT mode" \
} else { \
    echo "You are not in DCNXT mode" \
}
```

shell_is_in_exploration_mode

Determines if the shell was invoked in DC Explorer.

SYNTAX

status **shell_is_in_exploration_mode**

ARGUMENTS

The **shell_is_in_exploration_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in DC Explorer. The command returns 1 if the shell is in DC Explorer, or a 0 otherwise.

EXAMPLES

The following example shows how to check if shell was invoked in DC Explorer:

```
prompt> if { [shell_is_in_exploration_mode] } { \
    echo "You invoked de_shell in DC Explorer" \
} else { \
    echo "You are not in DC Explorer" \
}
```

shell_is_in_ndm_mode

Determines if the Design Compiler shell is in NDM mode.

SYNTAX

status **shell_is_in_ndm_mode**

ARGUMENTS

The **shell_is_in_ndm_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in NDM mode. The command returns 1 if the shell is in NDM mode or 0 if it is in Milkyway mode

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to check the mode in which the shell has been invoked:

```
prompt> if { [shell_is_in_ndm_mode] } { \
    echo "You invoked dc_shell in NDM mode" \
} else { \
    echo "You invoked dc_shell in Milkyway mode" \
}
```

shell_is_in_topographical_mode

Determines if the Design Compiler shell was invoked in topographical mode.

SYNTAX

status **shell_is_in_topographical_mode**

ARGUMENTS

The **shell_is_in_topographical_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in topographical mode. The command returns 1 if the shell is in topographical mode, or a 0 otherwise.

EXAMPLES

The following example shows how to check the mode in which the shell has been invoked:

```
prompt> if { [shell_is_in_topographical_mode] }{ \
    echo "You invoked dc_shell in Topographical mode" \
} else { \
    echo "You invoked dc_shell in normal mode" \
}
```

SEE ALSO

[dc_shell\(1\)](#)

shell_is_in_xg_mode

Determines if the shell is in XG mode.

SYNTAX

status **shell_is_in_xg_mode**

ARGUMENTS

The **shell_is_in_xg_mode** command has no arguments.

DESCRIPTION

This command is used to check if the shell is in XG mode. The command returns 1 if shell is in XG mode, or 0 otherwise. For use in Tcl-based dc_shell only. Since XG is the only mode, this command will be obsoleted in the future.

EXAMPLES

The following example shows how to determine the mode in which the shell has been invoked:

```
prompt> if { [shell_is_in_xg_mode] } { \
    echo "You invoked dc_shell in XG mode" \
} else { \
    echo "You invoked dc_shell in normal mode" \
}
```

sim_assertion_control

This is a simulation command.

SYNTAX

```
string sim_assertion_control
  [-elements element_list]
  [-exclude_elements exclude_list]
  [-domain domain_name]
  [-model model_name]
  [-controlling_domain controlling_domain_name]
  [-control_expr boolean_expression]
  [-type type]
  [-transitive transitive]
```

Data Types

element_list	set
exclude_list	set
domain_name	string
model_name	string
controlling_domain_name	string
type	string
transitive	Boolean

ARGUMENTS

Synthesis tool does not evaluate the arguments.

DESCRIPTION

This is a simulation command. It is ignored as it does not have functional impact in the synthesis tool. **save_upf** will not write out this command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

SEE ALSO

simplify_constants

Propagates constants and other information in the current design.

SYNTAX

```
status simplify_constants
      [-boundary_optimization]
```

ARGUMENTS

-boundary_optimization

Indicates that **simplify_constants** is to propagate information across all hierarchical boundaries in the design. Use the **set_boundary_optimization** command to perform boundary optimization on a particular set of subdesigns.

DESCRIPTION

This command propagates constants and unconnected information inside each module of the current design and simplifies the logic. When **-boundary_optimization** is used, this information is propagated across all boundaries.

EXAMPLES

In the following example, using library A, the constants are propagated in the current design:

```
prompt> link_library = {A}
prompt> target_library = {A}
prompt> read_file -format verilog my_design.v
prompt> current_design
prompt> simplify_constants
```

SEE ALSO

```
compile(2)
set_boundary_optimization(2)
set_logic_one(2)
set_logic_zero(2)
```

set_unconnected(2)

size_cell

Relinks leaf cells to a new library cell that has the required drive strength (or other properties).

SYNTAX

```
collection size_cell
  cell_object
  lib_cell_object
```

Data Types

```
cell_object      list
lib_cell_object  string
```

ARGUMENTS

cell_object

Specifies the leaf cell to be relinked. Each cell must be in scope; that is, the cell must be at or below the current instance.

lib_cell_object

Specifies the library cell objects to which the specified cell is to be linked. In this case, each object is either a named library cell or a library cell collection. The library specified cells must be logical equivalent to the library cell that is to be relinked.

DESCRIPTION

The **size_cell** command changes the drive strength (or other properties) of a leaf cell by relinking it to a new library cell that has the required properties. Like all other netlist editing commands, all of the arguments of the **size_cell** command must succeed for a successful command run. If any argument fails, the netlist remains unchanged. The **size_cell** command returns the collection of cells sized if successful and a NULL string if unsuccessful. Each cell in *cell_list* must be in scope; that is, the cell must be at or below the current instance.

The *lib_cell* that is being swapped in must conform to the following restrictions:

- *lib_cell* must be functionally compatible with the current library cell to which the cells in *cell_list* are linked.
- *lib_cell* cannot be the same as the current library cell of any of the cells in *cell_list*.
- *lib_cell* must have the same pin count and pin directions as the current library cell of the cells in *cell_list*. The **size_cell** command matches *lib_cell* by its pin numbers.

You can get a list of library cells that are compatible with a given cell using the **get_alternative_lib_cells** command.

The **size_cell** command is for leaf cells only. The **size_cell** command is optimized for incremental timing and does not do a full timing update.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, an attempt to size a cell fails because the target is not functionally equivalent. After finding a compatible library cell, the second attempt succeeds.

```
prompt> size_cell o_reg1 class/NR4P
Error: Could not size 'o_reg1' ('FD2') with 'NR4P'. (NLE-009)
```

```
prompt> get_alternative_lib_cells o_reg1
{class/FD2P}
```

```
prompt> size_cell o_reg1 class/FD2P
Information: Sizing cell 'o_reg1' with lib cell 'class/FD2P'
{o_req1}
```

SEE ALSO

`get_alternative_lib_cells(2)`
`get_libs(2)`
`get_lib_cells(2)`

sizeof_collection

Returns the number of objects in a collection.

SYNTAX

```
int sizeof_collection  
  [-categorize]  
  collection1
```

Data Types

collection1 collection

ARGUMENTS

-categorize

Return 0, 1, 2 indicating if the collection has 1, or or more than 1 item.

collection1

Specifies the collection for which to get the number of objects. If the empty collection (empty string) is used for the *collection1* argument, the command returns 0.

DESCRIPTION

The **sizeof_collection** command is an efficient mechanism for determining the number of objects in a collection.

EXAMPLES

The following example from PrimeTime shows a simple way to find out how many objects matched a particular pattern and filter in the **get_cells** command.

```
prompt> echo "Number of hierarchical cells: \  
?      [sizeof_collection \  
?          [filter_collection [get_cells * -hier \  
?              "is_hierarchical == true"]]]"  
Number of hierarchical cells is: 10
```

The following example from PrimeTime shows what happens when the argument for the **sizeof_collection** command results in an empty collection.

```
prompt> set s1 [get_cells *]  
{u1 u2 u3}  
prompt> set ssize [filter_collection $s1 "area < 0"]  
prompt> echo "Cells with area < 0: [sizeof_collection $ssize]"  
Cells with area < 0: 0  
prompt> unset s1
```

SEE ALSO

[collections\(2\)](#)
[filter_collection\(2\)](#)

sort_collection

Sorts a collection based on one or more attributes, resulting in a new, sorted collection. The sort is ascending by default.

SYNTAX

```
collection sort_collection
  [-descending]
  [-dictionary]
  [-limit value_count]
  collection
  criteria
```

Data Types

<i>value_count</i>	int
<i>collection</i>	string
<i>criteria</i>	list

ARGUMENTS

-descending

Indicates that the collection is to be sorted in reverse order. By default, the sort proceeds in ascending order.

-dictionary

Sort strings dictionary order. For example "a30" would come after "a4".

-limit *value_count*

Only return the first unique values from the primary sort key.

collection

Specifies the collection to be sorted.

criteria

Specifies a list of one or more application or user-defined attributes to use as sort keys.

DESCRIPTION

You can use the **sort_collection** command to order the objects in a collection based on one or more attributes. For example, to get a collection of leaf cells increasing alphabetically, followed by hierarchical cells increasing alphabetically, sort the collection of cells using the *is_hierarchical* and *full_name* attributes as *criteria*.

The *criteria* can specify an attribute on another object. The other object must be available as an attribute on this object. For example, if you had a collection of net shapes, you can sort the objects by net using *owner_net.name* for instance.

In an ascending sort, Boolean attributes are sorted with those objects first that have the attribute set to *false*, followed by the objects that have the attribute set to *true*. In the case of a sparse attribute, objects that have the attribute come first, followed by the objects that do not have the attribute.

Sorts are ascending by default. You can specify ascending or descending order on a per attribute basis. You do this by adding a suffix to the attribute name in the sort criteria. The '-' means sort descending and '+' means sort ascending. If no suffix is specified than the default order ascending unless the *-descending* option is used.

The *-limit* option limits the size of the returned collection by choosing the first unique values from the primary sort criteria. For example using a limit of 1 will return all the objects with the smallest (or biggest if descending) value according to the primary sort key.

EXAMPLES

The following example from PrimeTime sorts a collection of cells based on hierarchy, and adds a second key to list them alphabetically. In this example, cells i1, i2 and i10 are hierarchical, and o1 and o2 are leaf cells. Because the *is_hierarchical* attribute is a Boolean attribute, those objects with the attribute set to *false* are listed first in the sorted collection.

```
prompt> set zc [get_cells {o2 i2 o1 i1 i10}]
{o1 i2 o1 i1 i10}
prompt> set zsort [sort_collection $zc {is_hierarchical full_name}]
{o1 o2i1 i10 i2}
prompt> set zsort [sort_collection -dictionary $zc {is_hierarchical full_name}]
{o1 o2 i1 i2 i10}
prompt> set zsort [sort_collection -dictionary $zc {area- full_name}]
{i10 o1 o2 i1 i2 i10}
prompt> set zsort [sort_collection -dictionary $zc {area- full_name} -limit 1]
{i10 o1}
```

SEE ALSO

[collections\(2\)](#)

source

Read a file and evaluate it as a Tcl script.

SYNTAX

```
string source
      [-echo] [-verbose] [-continue_on_error] file
```

Data Types

file string

ARGUMENTS

-echo

Echoes each command as it is executed. Note that this option is a non-standard extension to Tcl.

-verbose

Displays the result of each command executed. Note that error messages are displayed regardless. Also note that this option is a non-standard extension to Tcl.

-continue_on_error

Don't stop script on errors. Similar to setting the shell variable sh_continue_on_error to true, but only applies to this particular script.

file

Script file to read.

DESCRIPTION

The **source** command takes the contents of the specified *file* and passes it to the command interpreter as a text script. The result of the source command is the result of the last command executed from the file. If an error occurs in evaluating the contents of the script, then the **source** command returns that error. If a return command is invoked from within the file, the remainder of the file is skipped and the source command returns normally with the result from the return command.

By default, source works quietly, like UNIX. It is possible to get various other intermediate information from the source command using the **-echo** and **-verbose** options. The **-echo** option echoes each command as it appears in the script. The **-verbose** option echoes the result of each command after execution.

NOTE: To emulate the behavior of the dc_shell **include** command, use both of these options.

The file name can be a fully expanded file name and can begin with a tilde. Under normal circumstances, the file is searched for based only on what you typed. However, if the system variable sh_source_uses_search_path is set to "true", the file is searched for

based on the path established with the `search_path` variable.

The **source** command supports several file formats. The *file* can be a simple ascii script file, an ascii script file compressed with gzip, or a Tcl bytecode script, created by TclPro Compiler. Some applications also supported encrypted files. The **-echo** and **-verbose** options are ignored for encrypted formatted files.

EXAMPLES

This example reads in a script of aliases:

```
prompt> source -echo aliases.tcl
alias q quit
alias hv {help -verbose}
alias include {source -echo -verbose}
prompt>
```

SEE ALSO

`search_path(3)`
`sh_source_uses_search_path(3)`
`sh_continue_on_error(3)`

split_register_bank

Splits a multibit register bank into smaller multibit registers or single-bit registers.

SYNTAX

```
status split_register_bank
  bank_name
  -lib_cells list_of_lib_cells
```

Data Types

<i>bank_name</i>	string
<i>list_of_lib_cells</i>	list

ARGUMENTS

bank_name

Specifies the name of the register bank that needs to be split, as specified in the **create_register_bank** command that created the register bank.

-lib_cells list_of_lib_cells

Specifies the list of smaller multibit registers or single-bit registers used to replace the multibit register bank, in sequential order of usage, repeated as needed to replace the full number of bits in the bank. Specifying the library name with the cell name (for example, mylib/mreg1) is mandatory in the Design Compiler tool and optional in the IC Compiler tool.

DESCRIPTION

The **split_register_bank** command splits a multibit register bank into smaller multibit registers or single-bit registers. The original register bank is removed from the netlist and replaced by smaller multibit registers or single-bit registers.

The order of the library cells specified by using the **-lib_cells** option determines the pin connection order of the split banks.

The total bit-width of all the listed split banks should equal the bit-width of the original bank. If the total bit-width is too large, some registers of the split banks are not used, and the pins of the unused registers are left dangling.

If a pin in the original bank does not have a corresponding pin in the split bank, the tool disconnects the pin and issues a warning message.

In the Design Compiler tool, you can use the **create_register_bank** and **split_register_bank** commands only before scan insertion. If you want to use these commands after scan insertion, use them later in the IC Compiler tool.

Multicorner-Multimode Support

In designs with multiple scenarios, to properly transfer scenario-specific information during splitting operations, you must activate all

scenarios before you run the **split_register_bank** commands.

EXAMPLES

The following example splits a 6-bit register bank into two smaller 3-bit register banks:

```
prompt> split_register_bank reg_6_bit_inst \
           -lib_cells { mylib/REG_3_BIT mylib/REG_3_BIT }
```

SEE ALSO

[create_register_bank\(2\)](#)

ssf_version

Check the SSF version.

SYNTAX

```
string ssf_version
      [version]
```

Data Types

version String

ARGUMENTS

version

The SSF version string, such as "1.0". The tool checks if this version is currently supported.

DESCRIPTION

This command checks if the specified version is currently supported. If no argument is passed in, the tool will return the currently supported version string.

EXAMPLES

The following **ssf_version** command checks if version "1.0" is supported.

```
prompt> ssf_version 1.0
SSF version 1.0 is supported
```

1

The SSF file "out.ssf" written by the **save_ssf** command contains the command "ssf_version 1.0".

SEE ALSO

[save_ssf\(2\)](#)

start_icc2

Launches an IC Compiler II floorplanning session from within Design Compiler Graphical or DC Explorer physical mode.

SYNTAX

```
int start_icc2
    -f file_name
    [-check_only]
    [-verbose]
```

Data Types

file_name string

ARGUMENTS

-f *file_name*

Allows you to run a batch script. This optional argument allows batch processing of a specified file. Make sure that the batch script has a quit command specified at the end of the file or it will wait for user input in the `icc2_shell`.

-check_only

Performs the startup checks and issues errors, if any.

-verbose

Prints out verbose messages, if any.

DESCRIPTION

The **start_icc2** command launches an IC Compiler II session from within Design Compiler Graphical or DC Explorer physical mode, allowing you to create or modify floorplans using the IC Compiler II tool.

Use the **set_icc2_options** command to set the IC Compiler II specific options, such as the executable and the IC Compiler II reference libraries. Use the **report_icc2_options** command to report the **set_icc2_options** command settings. Then, use the **start_icc2** command to launch the IC Compiler II session.

Note: Do not use the **start_icc2** and **start_icc_dp** commands in the same Design Compiler session.

EXAMPLES

In the following example, the **start_icc2** command launches the IC Compiler II session using settings specified by the **set_icc2_options** command:

```
prompt> set_icc2_options -ref_libs "lib1.ndm lib2.ndm" -icc2_executable  
/my_executable_location/icc2_shell  
1  
prompt> start_icc2
```

The following example performs startup checks and issues an error due to missing IC Compiler II settings:

```
prompt> start_icc2 -check_only  
Error: Missing set_icc2_options information. (DCT-158)  
0
```

SEE ALSO

`compile_ultra(2)`
`set_icc2_options(2)`
`report_icc2_options(2)`

start_icc2_dp

Launches an IC Compiler II floorplanning session from within Design Compiler Graphical.

SYNTAX

```
int start_icc2_dp
    -f file_name
    [-check_only]
    [-verbose]
```

Data Types

file_name string

ARGUMENTS

-f *file_name*

Allows you to run a batch script. This optional argument allows batch processing of a specified file. Make sure that the batch script has a quit command specified at the end of the file or it will wait for user input in the icc2_shell.

-check_only

Performs the startup checks and issues errors, if any.

-verbose

Prints out verbose messages, if any.

DESCRIPTION

The **start_icc2_dp** command launches an IC Compiler II session from within Design Compiler Graphical , allowing you to create or modify floorplans using the IC Compiler II tool.

Use the **set_icc2_options** command to set the IC Compiler II specific options, such as the executable and the IC Compiler II reference libraries. Use the **report_icc2_options** command to report the **set_icc2_options** command settings. Then, use the **start_icc2_dp** command to launch the IC Compiler II session.

Note: Do not use the **start_icc2_dp** and **start_icc_dp** commands in the same Design Compiler session.

EXAMPLES

In the following example, the **start_icc2_dp** command launches the IC Compiler II session using settings specified by the **set_icc2_options** command:

```
prompt> set_icc2_options -ref_libs "lib1.ndm lib2.ndm" -icc2_executable  
/my_executable_location/icc2_shell  
1  
prompt> start_icc2_dp
```

The following example performs startup checks and issues an error due to missing IC Compiler II settings:

```
prompt> start_icc2_dp -check_only  
Error: Missing set_icc2_options information. (DCT-158)  
0
```

start_icc_dp

Launches the floorplan exploration session from Design Compiler Graphical.

SYNTAX

```
int start_icc_dp
    -f      file_name
    -check_only flag
    -verbose flag
```

Data Types

```
file_name   string
flag        flag
```

ARGUMENTS

-f *file_name*

Allows batch processing.

This optional argument allows batch processing of a file specified. Make sure that the batch file has a quit command specified at the end of the file or it will wait for user input in icc_shell.

-check_only *flag*

Performs the start up checks and issues errors, if any.

-verbose *flag*

Prints out verbose messages, if any.

DESCRIPTION

This command launches the floorplan exploration session from Design Compiler Graphical. Use the **set_icc_dp_options** command to set the design planning options, and use the **report_icc_dp_options** command to report the **set_icc_dp_options** settings. Then, use **start_icc_dp** to begin the floorplan exploration session.

EXAMPLES

```
prompt> start_icc_dp
```

```
prompt> start_icc_dp -check_only
```

streaming_dft_planner

Provides visualization of the current DFTMAX Ultra architecture.

SYNTAX

```
status streaming_dft_planner
      [-show flow | elements | all]
      [-preview_output file_name]
```

DESCRIPTION

This command provides a visualization of the currently configured DFTMAX Ultra architecture. The visualization is based on the current DFT (scan and on-chip clocking (OCC) controller) configuration.

You can modify the DFT configuration and rerun this command as many times as needed until you are satisfied with the architecture.

For more information on the data provided in the planning report, see SolvNet article 2150838, "Understanding The Streaming DFT Planner Report."

This command does not perform any synthesis or optimization tasks.

ARGUMENTS

-show flow | elements | all

Generates the specified report types.

You must specify one of the following values:

- The **flow** argument displays a report that focuses on scan chain lengths and compression ratios. This view summarizes the DFT architecture. It is useful for length-balancing multiple codecs.
This is the default.
- The **elements** argument displays a report that shows more detail about the elements within the scan chains. It shows information such as clock and polarity information, lock-up latches, retiming registers, and test clock waveform information. This view shows how the clock edges interact in the compression architecture, and it shows why lock-up latches and retiming registers are inserted.
- The **all** argument displays both the **flow** and **elements** reports.

-preview_output *file_name*

Specifies the name of the output text file to write the DFT preview information to. This file contains the output that the **preview_dft -show all** command would create, but without the need (and extra runtime) of running the command after the **streaming_dft_planner** command.

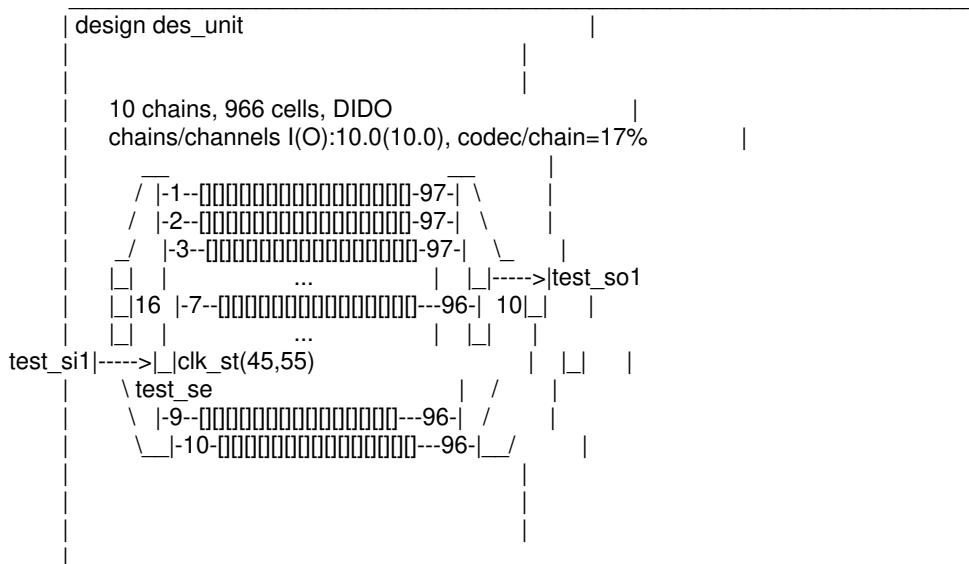

EXAMPLES

The following example displays a **flow** visualization for a TDI flow design:

```
prompt> streaming_dft_planner
      or
prompt> streaming_dft_planner -show flow
```

Running Streaming Compression DFT Planner (version 1.0)

Compression DFT Flow for test mode: ScanCompression_mode

Streaming Compression DFT Flow Information

```
DFT Flow:          TDI
Base scan mode:   Internal_scan
Base scan mode chains: 1
Base scan mode maximum shift length: 966
```

```
Compression mode maximum shift length: 113
Codec shift penalty (codec/chain): 17%
Target input compression: 8.55X (w.r.t. Internal_scan)
Target output compression: 8.55X (w.r.t. Internal_scan)
```

The following example displays an **elements** visualization for a TDI flow design:

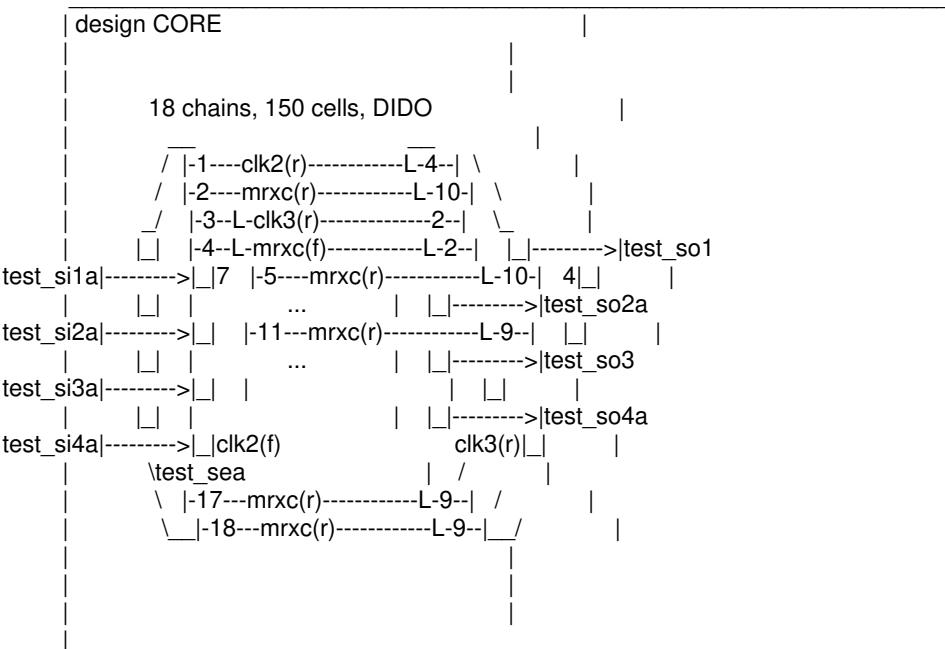

```
prompt> streaming_dft_planner -show elements
```

Running Streaming Compression DFT Planner (version 1.0)

Compression DFT Elements for test mode: ScanCompression_mode

```
=====

```

sub_designs_of

Gets the subdesigns according to the options.

SYNTAX

```
collection sub_designs_of
  [-hierarchy]
  [-in_partition | -partition_only]
  [-dt_only | -ndt_only]
  [-multiple_instances | -single_instances]
  [-names_only]
  design
```

ARGUMENTS

-hierarchy

Returns all subdesigns in the hierarchy of the specified design. By default, only the children of the specified design are returned.

-in_partition

Returns only subdesigns that are part of the partition containing the specified design.

This option and the **-partition_only** option are mutually exclusive.

-partition_only

Looks only at subdesigns that are compile partitions (subdesigns that have the **in_partition** attribute set). Specifically, it returns the direct child compile partitions of the specified design (even if they are more than one level away). With the **-hierarchy** option, it returns all compile partitions in the hierarchy below the specified design.

This option and the **-in_partition** option are mutually exclusive.

-dt_only

Returns only subdesigns that are at least instantiated once with the **dont_touch** attribute set.

This option and the **-ndt_only** option are mutually exclusive.

-ndt_only

Returns only subdesigns that are at least instantiated once with the **dont_touch** attribute not set.

This option and the **-dt_only** option are mutually exclusive.

-multiple_instances

Returns only subdesigns that are instantiated multiple times.

This option and the **-single_instances** option are mutually exclusive.

-single_instances

Returns only subdesigns that are instantiated once.

This option and the **-multiple_instances** option are mutually exclusive.

-names_only

Returns a list of design names, instead of a collection.

design

Specifies the design whose subdesigns will be returned.

DESCRIPTION

The **sub_designs_of** command returns a collection of subdesigns of the specified design (or a Tcl list of design names if the **-names_only** option is specified). By default, the command returns the hierarchical children of the specified design. You can return all subdesigns in the hierarchy by specifying the **-hierarchy** option. In addition, you can filter the results in the following ways:

- subdesigns that are the top-level of a partition (-partition_only)
- subdesigns within the partition that contains the specified design (-in_partition)
- subdesigns that are at least instantiated once with the **dont_touch** attribute set (-dt_only)
- subdesigns that are instantiated at least once with the **dont_touch** attribute not set (-ndt_only)
- subdesigns that have multiple instances (-multiple_instances)
- subdesigns that have a single instance (-single_instances)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

SEE ALSO

[get_attribute\(2\)](#)
[report_partitions\(2\)](#)
[set_attribute\(2\)](#)
[set_compile_partitions\(2\)](#)
[set_dont_touch\(2\)](#)
[sub_instances_of\(2\)](#)

sub_instances_of

Gets the subinstances according to the options.

SYNTAX

```
collection sub_instances_of
  [-hierarchy]
  [-in_partition] [-partition_only]
  [-dt_only] [-ndt_only]
  [-of_references reference_list]
  [-master_instance]
  [-names_only]
  design
```

ARGUMENTS

-hierarchy

Returns all subinstances in the hierarchy of the specified design.

By default, only the children of the specified design are returned.

-in_partition

Returns only subinstances that are part of the partition that contains the specified design.

This option and the **-partition_only** option are mutually exclusive.

-partition_only

Looks only at subinstances that are the top-level designs of compile partitions (subdesigns that have the **in_partition** attribute set). Specifically, it returns the instances that reference the next direct child compile partitions below the specified design (even if the instances are more than one level of hierarchy away). With the **-hierarchy** option, it returns all compile partition instances in the hierarchy below the specified design.

This option and the **-in_partition** option are mutually exclusive.

-dt_only

Returns only subinstances that have the **dont_touch** attribute set.

This option and the **-ndt_only** option are mutually exclusive.

-ndt_only

Returns only subinstances that do not have the **dont_touch** attribute set.

This option and the **-dt_only** option are mutually exclusive.

-of_references reference_list

Specifies the reference designs whose instances will be returned.

By default, the **sub_instances_of** command returns instances for all reference designs.

-master_instance

Returns only the master instance when a design has multiple instances.

By default, the **sub_instances_of** command returns all instances of a multiply instantiated design.

-names_only

Returns a list of instance names, instead of a collection.

design

Specifies the design whose subinstances will be returned.

DESCRIPTION

This command returns a collection of instances of the specified design (or a Tcl list of instance names, if the **-names_only** option is specified). By default, it returns only the direct children of the design, if the **-hierarchy** option is specified, all instances of the entire design subtree are returned. If the **-master_only** option is specified, it will return only one instance for multiply instantiated designs. It will pick the master instance (i.e. the one that has the **MasterInstance** attribute set). If none of the qualifying instances (according to the other options) is the master instance, any instance of that design will be returned.

In addition, you can filter the results in the following ways:

- subinstances that are the top-level of a partition (**-partition_only**)
- subinstances within the partition that contains the specified design (**-in_partition**)
- subinstances that have the **dont_touch** attribute set (**-dt_only**)
- subinstances that do not have the **dont_touch** attribute set (**-ndt_only**)
- instances of certain designs (**-of_references**)

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

suppress_icc2_message

Disables printing of one or more IC Compiler II informational or warning messages during ICC2Link.

SYNTAX

```
string suppress_icc2_message
      [message_list]
```

Data Types

message_list list

ARGUMENTS

message_list

A list of messages to suppress.

DESCRIPTION

The **suppress_icc2_message** command provides a mechanism to disable the printing of IC Compiler II messages during the ICC2Link. You can suppress only informational and warning messages. The result of **suppress_icc2_message** is always the empty string.

The command takes effect only if **set_icc2_options -silent** is specified.

Please use the command carefully else it may mask some real issues by suppressing the specified messages.

EXAMPLES

```
prompt> set_icc2_options -silent
prompt> suppress_message SEL-004
```

SEE ALSO

[set_icc2_options\(2\)](#)

suppress_message

Disables printing of one or more informational or warning messages.

SYNTAX

```
string suppress_message
      [message_list]
```

Data Types

message_list list

ARGUMENTS

message_list

A list of messages to suppress.

DESCRIPTION

The **suppress_message** command provides a mechanism to disable the printing of messages. You can suppress only informational and warning messages. The result of **suppress_message** is always the empty string.

A given message can be suppressed more than once. So, a message must be unsuppressed (using **unsuppress_message**) as many times as it was suppressed in order for it to be enabled. The **print_suppressed_messages** command displays the currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to suppress the CMD-029 message:

```
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
prompt> suppress_message CMD-029
prompt> unalias q*
prompt>
```

SEE ALSO

`print_suppressed_messages(2)`
`unsuppress_message(2)`

translate

Translates a design from one technology to another.

SYNTAX

```
int translate
    [-preserve_structure]
```

SYNTAX

```
int translate
    [-preserve_structure]
```

ARGUMENTS

-preserve_structure

Specifies that the structure of a design is to be preserved during **translate**. The default is false.

DESCRIPTION

The **translate** command translates all components of the current design to components found in the target library. If the current design is hierarchical, all subdesigns below the current design are translated. With this command, designs are converted from one technology to another while preserving as much of the original gate structure as possible. Each cell in the design is replaced with a functionally-equivalent cell from the target library. If no corresponding cell is found, the cell is converted to a Synopsys generic logic form. The replacement cell selection is influenced by preferring or disabling specific library cells using the **set_prefer** and **set_dont_use** commands, and by specifying the types of registers using the **set_register_type** command.

The target libraries are specified by the **target_library** variable. The **local_link_library** of the top-level design is set to **target_library** after the design is linked.

The **translate** command does not operate on cells or designs that have the **dont_touch** attribute. After the translation process, cells that are not successfully translated are reported.

EXAMPLES

In the following example, a design is translated from library *A* to library *B*.

```
prompt> link_library = {A}  
prompt> read -f edif test.edif  
prompt> target_library = {B}  
prompt> translate
```

SEE ALSO

uniquify(2)
target_library(3)

unalias

Removes one or more aliases.

SYNTAX

string **unalias**
 patterns

ARGUMENTS

patterns

Specifies the patterns to be matched. This argument can contain more than one pattern. Each pattern can be the name of a specific alias to be removed or a pattern containing the wildcard characters * and %, which match one or more aliases to be removed.

DESCRIPTION

The **unalias** command removes aliases created by the **alias** command.

EXAMPLES

The following command removes all aliases.

```
prompt> unalias *
```

The following command removes all aliases beginning with f, and the alias rt100.

```
prompt> unalias f* rt100
```

SEE ALSO

[alias\(2\)](#)

ungroup

Removes a level of hierarchy.

SYNTAX

```
status ungroup
  cell_list | -all
  [-prefix prefix_name]
  [-flatten]
  [-simple_names]
  [-soft]
  [-small n]
  [-force]
  [-start_level n]
  [-all_instances]
```

Data Types

<i>cell_list</i>	list
<i>prefix_name</i>	string
<i>n</i>	integer

ARGUMENTS

cell_list

Specifies a list of cells in the current design that are to be ungrouped. The contents of these cells are brought up to the same level as the cells. You must specify either *cell_list* or **-all** but not both.

-all

Indicates that all cells in the current design or current instance are to be ungrouped. You must specify either **-all** or *cell_list* but not both.

-prefix *prefix_name*

Specifies the prefix to use in naming ungrouped cells. The default naming style is as follows:

cell_being_ungrouped/old_cell_name{number}

To provide a vestige of the former hierarchy, omit this option when using the **-flatten** option.

-flatten

Indicates that the specified cell and all of its subcells are to be exploded recursively until all levels of hierarchy are removed.

-simple_names

Indicates that simple, nonhierarchical names are to be used for cells that are ungrouped. Unless this option is used, cells are given default hierarchical names. With this option, cells maintain their original names.

-soft

Indicates that the **group_name** attribute is to be removed on the specified cells. With the **-soft** and **-flatten options**, the **group_name** attribute is removed recursively down the hierarchy of the selected cells. The **group_name** attribute specifies cell grouping constraints for layout placement tools.

-small n

Causes all subdesigns with less than the number of leaf cells specified by *n* to be ungrouped. This option implies the **-all** option.

-force

Causes all **dont_touch** hierarchical cells to be flattened. The **dont_touch** attribute is inherited by their leaf cells. This option can only be used when either **-all** or **cell_list** is specified.

-start_level n

Causes all hierarchical cells that are at the level specified by *n* to be flattened. This option implies the **-flatten** option. The level value can be 1, 2, 3, and so on. Specifying a value of 1 for **-start_level** flattens the cells from the current design. Specifying a value of 2 causes the top-level blocks to be maintained and all cells in each of the top-level blocks to be flattened. The current instance cannot be set when this option is used. This option cannot be used with the **-small** option.

-all_instances

Enables the command to accept instance cells that are not unique in the object list.

DESCRIPTION

Removes a single level of hierarchy from the current design by exploding the contents of the specified cell or cell instance in the current design.

Any cells that are marked **dont_touch** are left undisturbed. Black boxes are also not collapsed. Clock gates inserted by Power Compiler are not collapsed by default. To do that, set the **power_cg_flatten** variable to TRUE before running **ungroup**.

New cell names are created by concatenating *prefix_name* with original cell names. If the resulting name is not unique, the new unique name is similar to the following:

<prefix_name>cell<number>

If the design contains instances (leaf cells) and only part of the design hierarchy needs to be ungrouped, use **current_instance** to set the instance before ungrouping the cells within that design instance. Alternatively, you can use the full hierarchical name of the cell instance. When **current_instance** is defined, it must be unique and when cell instance is used, the parent must be unique. This restriction prevents design inconsistency.

If you do not specify a prefix, the default is as follows:

cell_being_ungrouped/old_cell_name{number}

If there are dangling nets in the design, they are removed by **ungroup**.

If timing derate is defined for the cell being ungrouped, the derates are pushed down to the lower-level cells if they or their library cells do not have the corresponding derates. This can cause timing inconsistency in the timing report before and after the ungrouping.

Use the **-all_instances** option when any cell in the object list is an instance in the lower hierarchy and its parent cell is not unique. All similar instance cells under the same parent design are ungrouped. The current design does not have to be changed in order to ungroup the instance cells in the lower design hierarchy. If none of the cells in the object list is an instance in the lower hierarchy, or if its parent cell is unique, the **-all_instances** option is not required.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information. However, in order to preserve constraints and attributes for

inactive scenarios, the tool automatically activates inactive scenarios before the hierarchy is changed and deactivates them before the command returns. Due to the overhead, if there are many ungroup commands in the script, it is more runtime efficient to activate inactive scenarios once before the **ungroup** command executions and deactivate them after all the **ungroup** command executions finish.

EXAMPLES

The following example ungroups a specified list of cells:

```
prompt> ungroup {u1 u2 u3}
```

The following example ungroups a specific cell and specifies the prefix to be used:

```
prompt> ungroup {u1} -prefix "U1:"
```

The following example completely removes the hierarchy of two cells:

```
prompt> ungroup {u1 u2} -flatten
```

The following example completely collapses the hierarchy of the current design:

```
prompt> ungroup -all -flatten
```

The following example ungroups all cells in the design except u1:

```
prompt> set_dont_touch {u1}
```

```
prompt> ungroup -all
```

The following example hierarchically removes cell grouping constraints destined to drive layout placement tools without modifying the design hierarchy:

```
prompt> ungroup -soft -flatten
```

The following example ungroups all cells under the instance A/B/C:

```
prompt> current_instance A/B
```

```
prompt> ungroup C
```

The following example flattens all cells starting at level 2:

```
prompt> ungroup -start_level 2
```

The following example ungroups the cell instance MID1/BOT1/FOO1 and MID1/BOT1/FOO2. MID1/BOT1 is a unique instantiation of design BOT.

```
prompt> ungroup {MID1/BOT1/FOO1 MID1/BOT1/FOO2}
```

set_active_scenarios(2)

uniquify

Removes the multiply instantiated hierarchy in the current design by creating a unique design for each cell instance.

SYNTAX

```
status uniquify
  [-force]
  [-base_name base_name]
  [-cell cell_list]
  [-reference design_name]
  [-new_name new_design_name]
  [-dont_skip_empty_designs]
```

Data Types

<i>base_name</i>	string
<i>cell_list</i>	list
<i>design_name</i>	string
<i>new_design_name</i>	string

ARGUMENTS

-force

Renames instances even if they are already unique or are assigned the **dont_touch** attribute. The top-level design and the ILMs are not renamed.

-base_name *base_name*

Specifies the base name to be used instead of the original design name for new designs.

-cell *cell_list*

Specifies a list of cells for which unique designs are to be generated. Unique designs are generated even if the referenced design is already unique, or if the **dont_touch** attribute is set on the cell or its reference. The cells specified in *cell_list* must be in the current design hierarchy.

-reference *design_name*

Specifies the name of a design that is referenced by cells for which unique designs are to be created. Unique designs are created even if the referenced design is already unique, or if the **dont_touch** attribute is set on the cells or reference. Only cells in the current design that reference the given design are considered.

-new_name *new_design_name*

Specifies the name for a single cell specified in the **-cell** option.

-dont_skip_empty_designs

Creates unique designs even for black box designs. Without this option, the **uniquify** command does not modify black box designs.

DESCRIPTION

The **uniquify** command removes the multiply instantiated hierarchy in the current design by creating a unique design for each cell instance. The command initiates a search for designs referenced in the hierarchy of the current design and generates new, uniquely named designs for all instances that have the same name. If the **dont_touch** attribute is set on a cell, reference, or design, a new design is not created for that cell or any cell with that reference or design.

The **uniquify** command links the current design before it executes. If the link fails, the **uniquify** command aborts and issues an error message.

If a new design is generated, it is copied from the original design, and placed in the same file as the current design. The new design is named according to the **uniquify_naming_style** variable. The default of this variable is %s_%d, where %s is replaced by the original design name unless the **-base_name** option is specified, and %d is replaced by the smallest integer that forms a name not used by any other design in memory. The cell reference is updated to use the new design name.

After the **uniquify** command executes, all designs in the hierarchy of the current design have unique names. However, some names might conflict with designs on disk if the current design is a submodule of another design. In this case, you must resolve these conflicts before integrating the designs. One way to resolve conflicts is to use the **uniquify** command with different values of the **uniquify_naming_style** variable.

When a cell instance is used with the **-cell** option, the complete path to that instance is uniquified (all the parent instances are uniquified if they are not already unique).

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates uniquely named designs for all cells and designs in the hierarchy of the current design that have non-unique names, unless a cell or reference has the **dont_touch** attribute set.

```
prompt> uniquify
```

In the following example, a new design "ADDER1" is created for cell "U4" in the current design.

```
prompt> uniquify -cell U4 -new_name ADDER1
```

In the following example, new designs are created with the base name "X" for all cells starting with "U" in the current design.

```
prompt> uniquify -cell [get_cells U*] -base_name X
```

The following example forces all designs in the hierarchy of the current design to be renamed using the **uniquify_naming_style** variable.

```
prompt> set uniquify_naming_style "joe_%s_%d"
```

```
prompt> uniquify -force
```

The following example uniquifies the instance mid1 and mid1/bot1. Though the argument to uniquify command is mid1/bot1 since the design mid corresponding to mid1 is not unique, mid1 is also uniquified.

```
prompt> uniquify -cell mid1/bot1
```

unset_power_guide

Unsets an existing power guide to be just like an exclusive movebound.

SYNTAX

```
unset_power_guide  
[power_guide_list]
```

Data Types

power_guide_list collection

ARGUMENTS

power_guide_list

Unsets the selected power guides.

DESCRIPTION

This command unsets the given power guides. If no specific name is given, all existing power guides will be unset. They will be in design just like an exclusive movebound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows the flow of the **unset_power_guide** command. In it, if the given power guide AO_WELL exists in the design it will be unset.

```
prompt> unset_power_guide AO_WELL
```

SEE ALSO

`create_bounds(2)`

```
create_voltage_area(2)
set_power_guide(2)
```

unsetenv

Removes a system environment variable.

SYNTAX

```
string unsetenv
      variable_name
```

Data Types

variable_name string

ARGUMENTS

variable_name

Specifies the name of the environment variable to remove.

DESCRIPTION

The **unsetenv** command searches the system environment for the specified environment variable and removes it from the environment.

If the variable is not defined in the environment, the command returns a Tcl error. The command is catchable.

Environment variables are stored in the **env** Tcl array variable. The **unsetenv** command is a convenience function to interact with this array. It is equivalent to the **unset ::env(*variable_name*)** command.

The application inherits the initial values for the environment variables from its parent process (that is, the shell from which you invoked the application). If you remove the variable using the **unsetenv** command, you remove the variable value in the application and in any new child processes you initiate from the application using the **exec** command. However, the variable is still set in the parent process.

See the man pages for the **set** and **unset** commands for information about working with non-environment variables.

EXAMPLES

In the following example, the **unsetenv** command removes the DISPLAY variable from the environment:

```
prompt> getenv DISPLAY
host:0
prompt> unsetenv DISPLAY
prompt> getenv DISPLAY
```

Error: can't read "::env(DISPLAY)": no such variable
Use error_info for more info. (CMD-013)

SEE ALSO

catch(2)
exec(2)
printenv(2)
set(2)
unset(2)
setenv(2)
getenv(2)

unsuppress_message

Enables printing of one or more suppressed informational or suppressed warning messages.

SYNTAX

```
string unsuppress_message
      [messages]
```

Data Types

messages list

ARGUMENTS

messages

A list of messages to enable.

DESCRIPTION

The **unsuppress_message** command provides a mechanism to re-enable the printing of messages which have been suppressed using **suppress_message**. You can suppress only informational and warning messages, so the **unsuppress_message** command is only useful for informational and warning messages. The result of **unsuppress_message** is always the empty string.

You can suppress a given message more than once. So, you must unsuppress a message as many times as it was suppressed in order to enable it. The **print_suppressed_messages** command displays currently suppressed messages.

EXAMPLES

When the argument to the **unalias** command does not match any existing aliases, the CMD-029 warning message displays. This example shows how to re-enable the suppressed CMD-029 message. Assume that there are no aliases beginning with 'q'.

```
prompt> unalias q*
prompt> unsuppress_message CMD-029
prompt> unalias q*
Warning: no aliases matched 'q*' (CMD-029)
```

SEE ALSO

`print_suppressed_messages(2)`
`suppress_message(2)`

update_bounds

Updates an existing bound by adding or removing objects.

SYNTAX

```
int update_bounds
  [-name bound_name]
  [-bound bound_object]
  [-add]
  [-remove]
  cell_list
```

ARGUMENTS

-name *bound_name*

Specifies the name of the bound.

-bound *bound_object*

Specifies the bound object. You can specify the bound object directly or by using the **get_bounds** command. You cannot specify more than one bound object.

-add

Adds cells to the bound.

-remove

Removes cells from the bound.

cell_list

Specifies the list of cells to be attached to the bound. If a cell is a hierarchical cell, the bound is also applied to all cells in the subdesigns.

DESCRIPTION

The **update_bounds** command enables you to add cells to or remove cells from an existing move bound or group bound.

For a bound, you can change the floorplan by adding cells within the bound or readjust the utilization by removing cells from the bound. If you add new objects to an existing bound, the placer uses them during coarse placement. When objects are removed from a bound, the placer assumes that the objects are no longer constrained by placement bounds.

When adding objects to a bound, an error occurs if the specified objects are already in a bound. Similarly when removing objects from a bound, an error occurs if the objects do not belong to the same bound.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example creates a bound named my_bound with the **create_bounds** command. Next, it adds cells to the my_bound bound, and then it removes a cell from the my_bound bound.

```
prompt> create_bounds -name "my_bound" -coord {100 100 200 200} INSTN_1
prompt> update_bounds -name "my_bound" -add {INSTN_2 INSTN_3}
prompt> update_bounds -bound [get_bounds my_bound] -remove INSTN_3
```

SEE ALSO

`create_bounds(2)`
`remove_bounds(2)`
`report_bounds(2)`
`get_bounds(2)`

update_cross_probing_files

Updates the paths of the cross-probed files.

SYNTAX

```
status update_cross_probing_files
  [-search_path paths]
  [-original_file file1]
  [-new_file file2]
  [-write_script_only output_file]
  [-force]
  [-verbose]
```

Data Types

<i>paths</i>	list
<i>file1</i>	string
<i>file2</i>	string
<i>output_file</i>	string

ARGUMENTS

-search_path *paths*

By default, the **search_path** variable is used to search for files when the tool updates the cross-probed files. If this option is specified, the tool uses the *paths* specified with this option instead.

When search paths are used, the first matching file found will be used as the replacement file. In general, a file is considered a match if its basename matches the original file and the file content is identical as determined by the tool.

-original_file *file1* -new_file *file2*

Updates only one cross-probed file. The **-original_file** and **-new_file** options must be used together. The existing cross-probed file, *file1*, in the cross-probing database will be updated to the new file specified by *file2*. For the update to be successful,

- (1) The *file1* argument needs to be an existing file in the set of cross-probed files as listed by the **report_cross_probing_files** command.
- (2) The basename of the file in *file1* and *file2* need to match unless the **-force** option is used.
- (3) The calculated checksum value of *file2* needs to match the one stored in the database for *file1*.

-write_script_only *output_file*

Specifies not to update the paths of the cross-probed files but writes the commands to a file. The file can be examined, modified if necessary, and then sourced as a Tcl script.

-force

Updates all cross-probed files (even the file paths are fine) if you specify this option without the **-original_file** and **-new_file** options. Without this option, the command updates files that do not have an OK status as reported by the **report_cross_probing_files** command.

When you specify the **-original_file** and **-new_file** options, the **-force** option allows the command to update the cross-probed file

paths even if the basenames are different.

-verbose

Specifies to use verbose mode. The command prints out additional information messages.

DESCRIPTION

In order for GUI cross-probing functionality to work, the files that are stored in the database must be valid. If the design has been moved to a different location or cross-probed files have been moved to a different disk location, the paths that are stored in the database need to be updated accordingly. Running this command updates these paths.

To get a list of all cross-probed files and each file status, run the **report_cross_probing_files** command.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses the **-search_path** option with the **update_cross_probing_files** command:

```
prompt> report_cross_probing_files
```

```

SEE ALSO

[report_cross_probing_files\(2\)](#)

update_floorplan

Updates the floorplan when reading a floorplan script file generated by the **write_floorplan** command.

SYNTAX

```
int update_floorplan
```

DESCRIPTION

A floorplan script file is created by the **write_floorplan** command. The **update_floorplan** command is included in this script file.

You use the **read_floorplan** command to read the floorplan script file created by the **write_floorplan** command. During this process, any existing floorplan information is removed and replaced by the floorplan information in the script file.

EXAMPLES

The following example writes out the floorplan information to a script file named top.fp.

```
prompt> write_floorplan -all top.fp
```

The following example reads the floorplan information in the top.fp script file and applies it to the design.

```
prompt> read_floorplan top.fp
```

SEE ALSO

write_floorplan(2)
read_floorplan(2)

update_lib

Reads in a specified library file and uses it to update an existing technology, synthetic, or symbol library.

SYNTAX

```
int update_lib  
    [-overwrite] [-permanent] library_name file_name [-no_warnings]
```

Data Types

<i>library_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-overwrite

Indicates that a group declared in *file_name* is to overwrite any group in *library_name* that has the same name. Only groups added by **update_lib** or **model** can be overwritten. If **-force** is specified, some library-level groups(wire_load, power_supply and operating_conditions) included in the original library can be modified. The other groups included in the original library and groups added with **-permanent** cannot be modified.

-permanent

Indicates that groups declared in *file_name* are to be stored in the library in such a way that they cannot be overwritten.

library_name

Specifies the name of the library to be updated. The library must be resident in memory.

file_name

Specifies the name of the file in which one or more new groups are listed. The syntax of this file is the same as that expected by **read_lib**, except that the file contains only library level groups without the library() {} group definition.

-no_warnings

Indicates that all messages of severity 'warning' are to be suppressed. The default is to issue all warning messages. Warning messages can identify serious library problems; use this flag sparingly.

DESCRIPTION

Reads in a library file and adds the groups declared in that file to the library specified. Groups are added to the library as if entered at the end of the original text of the library.

Only library-level group statements are added to a library. Library level functions or attributes are not accepted(some library-level

attributes can be an exception, as described in the "-force" section).

The library can be a technology, symbol, or synthetic library. Only groups normally found in a library of that type are accepted. For example, you cannot add a symbol group to a technology library. For technology libraries, the delay model and technology associated with the original library must be the same used by new group(s).

If Library Compiler finds any errors while processing a group, it does not add that group to the library. Legal groups are added. The update operation does not fail if there are illegal groups intermixed with legal groups.

If you update a library with a wire_load group describing a wire load model in use by the current design, the wire load model of the current design is reset.

library_name can have a simple or a complex file name. A simple file name has no directory specification, which in UNIX means that it does not contain a "/" (slash). Simple filenames such as **test.lib** or **library.db** must be found in a directory listed in the **search_path**.

A complex file name has a directory specification, which in UNIX means that it contains a slash. Relative or complex filenames such as **./test.lib**, or **~synopsys/dc/test.lib** are not included in the **search_path**.

For details on library file syntax, refer to the *Library Compiler Reference Manual*. If you do not have a Library Compiler License, function statements and state information are ignored when you attempt to update technology library files. You do not need a Library Compiler License to update symbol library files.

Do not use **update_lib** on the synthetic library **standard.sldb**, because its parts are licensed differently from user parts.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, the library file **add_ms.lib**, which contains technology information in Synopsys technology library entry format, is added to the library **cmos**:

```
prompt> update_lib cmos add_ms.lib
```

In the following example, the library file **new_wire_load.lib**, which contains a new **wire_load** group for a technology library, is added to the library **cmos**. Any **wire_load**(s) in the library that have identical names are overwritten if they are not permanent groups. In addition, all warning messages are suppressed with the **-no_warnings** flag.

```
prompt> update_lib -overwrite cmos new_wire_load.lib -no_warnings
```

In the following example, the library file **ramgen.lib**, which contains a black box cell description of a RAM cell, is added to the library **cmos**. The **-permanent** flag indicates that the new cell cannot be overwritten.

```
prompt> update_lib -permanent cmos ramgen.lib
```

SEE ALSO

read_lib(2)
write_lib(2)

update_lib_model

Updates the library to conform to the PG pin library syntax. This command gets the PG information either from reference library FRAM view or from specific Tcl commands. The library voltage, PG pin of the cell, and related PG pin of the cell pin are updated.

SYNTAX

```
status update_lib_model  
  -reference_mode FRAM | TCL  
  [library_name]
```

ARGUMENTS

-reference_mode FRAM | TCL

Sets the reference mode from where the power and ground pin information is read.

If set to **FRAM**, the command gets the power and ground pin information from the FRAM view of each library cell. When you use this mode, either the Milkyway design library must contain the reference library set or the **mw_reference_library** variable must be set to the reference library.

If set to **TCL**, you must define the voltage and PG pin reference by using the following commands: **update_lib_voltage_model**, **update_lib_pg_pin_model**, and **update_lib_pin_model**.

If the library to be updated uses the old PG syntax, the voltage value is used from the power_supply attachment and rail_connection is used to define the related PG pins.

This is a required option.

library_name

Specifies the library to be converted.

If you do not specify this option, all libraries in the link library or target library set are updated.

DESCRIPTION

The **update_lib_model** command updates the specified library to a Liberty PG pin library. The library can be a non-PG library or it can use the old PG syntax. The reference base for the PG pin definition and association can be either the FRAM reference libraries or the settings from the **update_lib_voltage_model**, **update_lib_pg_pin_model**, and **update_lib_pin_model** commands.

EXAMPLES

The following example sets the voltage map for the library named standard_lib and updates the library to a Liberty PG pin library.

```
prompt> update_lib_voltage_model standard_lib \
           -voltage {VDD 1.2} -voltage {VSS 0.0}
prompt> update_lib_model -reference_mode TCL standard_lib
```

The following example uses a reference library to update all the libraries in the link library and target library set.

```
prompt> update_lib_model -reference_mode FRAM
```

SEE ALSO

[mw_reference_library\(3\)](#)

update_lib_pg_pin_model

Defines the power and ground pin model for a library cell.

SYNTAX

```
status update_lib_pg_pin_model
  cell_name
  -pg_pin_name pin_names
  [-pg_voltage_name voltage_names]
  [-pg_pin_type pin_types]
  [-pg_pin_direction pin_directions]
  [-pg_physical_connection physical_connections]
  [-pg_related_bias_pin related_bias_pin]
```

Data Types

<i>cell_name</i>	string
<i>pin_names</i>	list
<i>voltage_names</i>	list
<i>pin_types</i>	list
<i>pin_directions</i>	list
<i>physical_connections</i>	list

ARGUMENTS

cell_name

Specifies the name of the library cell for which to update the power and ground pins.

The format of the *cell_name* argument is [*library_name*]/*cell_name*. If you do not specify the library name, the PG pin model applies to all libraries.

-pg_pin_name *pin_names*

Specifies the names of the power and ground pins of the library cell.

This is a required argument.

-pg_voltage_name *voltage_names*

Specifies the voltage name of the corresponding power or ground pin of the library cell. The voltage names are defined in the library voltage map by using the **update_lib_voltage_model** command.

There must be a one-to-one correspondence between the voltage names specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_pin_type *pin_types*

Specifies the pin type for each pin specified in the **-pg_pin_name** option. Valid values are primary_power, primary_ground, backup_power, backup_ground, internal_power, internal_ground, pwell, nwell, deeppwell, and deepnwell.

There must be a one-to-one correspondence between the pin types specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_pin_direction *pin_directions*

Specifies the direction for each pin specified in the **-pg_pin_name** option. Valid values are input, output, inout, and internal.

There must be a one-to-one correspondence between the pin directions specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_physical_connection *physical_connections*

Specifies the type of physical connection used for each pin specified in the **-pg_pin_name** option. Valid values are device_layer and routing_pin.

There must be a one-to-one correspondence between the connection types specified in this option and the pins specified in the **-pg_pin_name** option.

-pg_related_bias_pin *related_bias_pin*

Specifies the related bias pin for each pin specified in the **-pg_pin_name** option.

There must be a one-to-one correspondence between the related bias pins specified in this option and the pins specified in the **-pg_pin_name** option.

DESCRIPTION

The **update_lib_pg_pin_model** command defines the power and ground pin model for a library cell. The model is later used by the **update_lib_model** command. If the power or ground pin already exists, the new specification overrides the old one. Otherwise, a new power or ground pin is created for the library cell.

EXAMPLES

The following example defines the power and ground pin model for the LIB1/CELL1 library cell.

```
prompt> update_lib_pg_pin_model LIB1/CELL1 -pg_pin_name {VDD VSS} \
           -pg_voltage_name {VDDL VSS} -pg_pin_type {primary_power primary_ground}
```

SEE ALSO

`update_lib_voltage_model(2)`
`update_lib_pin_model(2)`
`update_lib_model(2)`

update_lib_pin_model

Sets the pin map for the specified library cell.

SYNTAX

```
status update_lib_pin_model
  cell_name
  -pins list_of_pins
  [-related_power_pin list_of_pins]
  [-related_ground_pin list_of_pins]
  [-related_bias_pin list_of_pins]
  [-power_down_function power_down_func]
```

Data Types

<i>cell_name</i>	string
<i>list_of_pins</i>	list
<i>power_down_func</i>	string

ARGUMENTS

cell_name

Specifies the name of the library cell for which to set the pin map.

The format for specifying the cell name is *library_name/cell_name*. If you omit the library name, the pin map applies to all libraries.

This is a required argument.

-pins *list_of_pins*

Specifies the names of the pins being mapped. You can specify one or more pins.

This is a required argument.

-related_power_pin *list_of_pins*

Specifies the related power pin for each pin specified in the **-pins** option. There must be a one-to-one correlation between the pins specified in this option and those specified the **-pins** option.

-related_ground_pin *list_of_pins*

Specifies the related ground pin for each pin specified in the **-pins** option. There must be a one-to-one correlation between the pins specified in this option and those specified the **-pins** option.

-related_bias_pin *list_of_pins*

Specifies the related bias pin for each pin specified in the **-pins** option. There must be a one-to-one correlation between the pins specified in this option and those specified the **-pins** option.

-power_down_function *power_down_func*

Specifies the power down function for each pin specified in the *-pins* option. There must be a one-to-one correlation between the pins specified in this option and those specified the **-pins** option.

DESCRIPTION

The **update_lib_pin_model** command sets the pin map for the specified library cell. The pin map is used by the **update_lib_model** command.

If a pin map already exists for the specified library cell, the new specifications overrides the old one. Otherwise, a new pin map is created for the cell.

EXAMPLES

The following example sets the pin map for the CELL1 cell in the LIB1 library.

```
prompt> update_lib_pin_model LIB1/CELL1 -pins {A B} \
           -related_power_pin {VDD VDD} -related_ground_pin {VSS VSS}
```

SEE ALSO

`update_lib_voltage_model(2)`
`update_lib_pg_pin_model(2)`
`update_lib_model(2)`

update_lib_voltage_model

Sets the voltage model for the specified library.

SYNTAX

```
status update_lib_voltage_model  
    library_name  
    [-voltage {voltage_name voltage_value}]
```

Data Types

<i>library_name</i>	string
<i>voltage_name</i>	string
<i>voltage_value</i>	float

ARGUMENTS

library_name

Specifies the name of the library for which to define the voltage model.

-voltage {*voltage_name* *voltage_value*}

Sets the voltage name and value pair for the specified library. You can specify this option multiple times in a single run of the command.

DESCRIPTION

The **update_lib_voltage_model** command sets the voltage map for the specified library. The map is used later during the **update_lib_model** command.

EXAMPLES

The following example defines the voltage model for a single-rail library.

```
prompt> update_lib_voltage_model standard_lib \  
    -voltage {VDD 1.2} \  
    -voltage {VSS 0.0}
```

The following example defines the voltage model for a multiple-rail library.

```
prompt> update_lib_voltage_model standard_lib \  
    -voltage {VDD 1.2} \  
    -voltage {VSS 0.0}
```

```
-voltage {VDD 1.2} \
-voltage {VSS 0.0} \
-voltage {VDD_BACK 0.7}
```

SEE ALSO

`update_lib_model(2)`
`update_lib_pg_pin_model(2)`
`update_lib_pin_model(2)`

update_timing

Updates timing information on the current design.

SYNTAX

status **update_timing**

ARGUMENTS

This command has no arguments.

DESCRIPTION

Updates timing for the current design. Timing information is obsoleted when environmental information, such as arrival times or loads, is changed. The **update_timing** command is used to update this information after these changes are made.

Timing information is automatically updated in the current design when **compile** or **translate** is used or when reports that display timing information are used. So, for most cases, the **update_timing** command is not needed. However, there are instances when timing might not be current (such as if **set_attribute** is incorrectly used instead of **set_drive** to set a drive value).

Note that this command does not automatically identify and define clocks in the design. These should be defined by using the **create_clock** command.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

This example updates timing for the current design.

```
prompt> update_timing
```

SEE ALSO

[compile\(2\)](#)

```
create_clock(2)
set_drive(2)
translate(2)
```

upf_version

Accepts and preserves a UPF version string.

SYNTAX

```
string upf_version
      [version]
```

Data Types

version String

ARGUMENTS

version

The UPF version string, such as "2.1". The tool accepts the string without checking.

DESCRIPTION

This command accepts and preserves a string that describes the UPF version number. The command always returns the string "IEEE-1801".

This command does not have any effect aside from preserving the entered string. When you use the **save_upf** command, the command is written to the UPF file exactly as originally entered.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following **upf_version** command saves the UPF version string "2.1".

```
prompt> upf_version 2.1
IEEE-1801
...
prompt> save_upf out.upf
1
```

The UPF file "out.upf" written by the **save_upf** command contains the command "upf_version 2.1".

SEE ALSO

`save_upf(2)`

use_interface_cell

Specifies how to map the isolation, level-shifter, and enable level-shifter cells belonging to the specified isolation and/or level-shifter strategy.

SYNTAX

```
string use_interface_cell
  interface_implementation_name
  -strategy list_of_isolation_level_shifter_strategies
  -domain power_domain
  -lib_cells lib_cells
  [-force_function]
  [-port_map port_map_list]
```

Data Types

interface_implementation_name	string
list_of_isolation_level_shifter_strategies	list
power_domain	string
lib_cells	list

ARGUMENTS

interface_implementation_name

Specify the name of the interface cell implementation strategy.

-domain *power_domain*

Specifies the name of the power domain name to which the strategy/strategies belongs.

-lib_cells *lib_cells*

Specifies a list of the target library cells to be used for the isolation mapping.

DESCRIPTION

This command defines how the **compile** command performs the mapping of isolation, level-shifter, or enable level-shifter cells.

EXAMPLES

In the following example, the isolation cells belonging to the strategy named ISO1 will be mapped to the isocell1 library cell with the highest priority, and level-shifter cells belonging to the strategy LS1 will be mapped to the levshicell1 library cell with the highest priority:

```
prompt> use_interface_cell my_interface -domain PD1 -strategy {ISO1 LS1} \
-lib_cells {isocell1 levshicell1} \
-port_map {{VDD sn1} {VSS gnd}}
```

SEE ALSO

`set_isolation(2)`
`set_level_shifter(2)`

use_test_model

Specifies the subdesigns that will use test model information during DRC and DFT insertion.

SYNTAX

```
status use_test_model
  [-true design_list]
  [-false design_list]
```

ARGUMENTS

-true *design_list*

Specifies the set of designs for which test models are to be used. This is the default.

-false *design_list*

Specifies the set of designs for which test models are not to be used.

DESCRIPTION

This command is used to specify whether or not DFT Compiler uses Core Test Language (CTL) test model information during DRC and DFT insertion for the specified subdesigns.

The default is to use test models for all designs where test model information is available. When a previously DFT-inserted subdesign contains test model information, such as when it is loaded from a .ddc file, DFT Compiler automatically uses the stored test model information for subsequent DFT operations. The use of test models improves the capacity and runtime of the tool.

When test models are disabled for a subdesign, DFT Compiler ignores the test model information describing complex test logic. However, any test-ready attributes on scan flip-flops are still considered. If the design contains only standard scan chains, DFT Compiler will restitch the chains according to the top-level scan requirements.

You should use caution when disabling test models for a design containing complex test logic, such as core wrapping, on-chip clocking (OCC) controllers, or any type of scan compression. When test models are disabled, these complex structures are no longer meaningful to DFT Compiler, and are simply treated as part of the existing design logic.

EXAMPLES

The following example specifies that test models should not be used for the des3 and des4 designs. Test models will be used for all other designs in memory.

```
prompt> use_test_model -false {des3 des4}
```

SEE ALSO

`reset_design(2)`

which

Locates a file and displays its pathname.

SYNTAX

```
string which
      filename_list
```

Data Types

```
filename_list    list
```

ARGUMENTS

filename_list

List of files to locate.

DESCRIPTION

Displays the location of the specified files. This command uses the search_path to find the location of the files. This command can be a useful prelude to read_db or link_design, because it shows how these commands expand filenames. The **which** command can be used to verify that a file exists in the system.

If an absolute pathname is given, the command searches for the file in the given path and returns the full pathname of the file.

EXAMPLES

The following examples are based on the following search_path.

```
prompt> set search_path "/u/foo /u/foo/test"
```

The following command searches for the file name foo1 in the search_path.

```
prompt> which foo1
/u/foo/foo1
```

The following command searches for files foo2, foo3.

```
prompt> which {foo2 foo3}
/u/foo/test/foo2 /u/foo/test/foo3
```

The following command returns the full pathname.

```
prompt> which ~/test/designs/sub_design.db  
/u/foo/test/designs/sub_design.db
```

SEE ALSO

[read_db\(2\)](#)
[search_path\(3\)](#)

while

Loop execution control structure.

SYNTAX

```
return_val while
```

ARGUMENTS

The **while** command has no arguments.

DESCRIPTION

This command iteratively executes commands based on the value of an evaluated *expression*. The format of the **while** statement is similar to that used in the C programming language.

The *expression* is evaluated upon execution. While the *expression* evaluates to a non-zero value, the *loop-statement-block* executes, then the condition *expression* is evaluated again. When the *expression* evaluates to zero, the loop exits.

The return value of the **while** statement is the return value of the last statement executed. If no statements execute, the return value is 0.

The **break** and **continue** commands modify the standard execution of the **while** statement. See the man pages for the **break** and **continue** commands for more information.

The output of the **while** statement can be redirected to a file. This file contains the output of any of the statements executed in the body of the **while** statement. For more information on file redirection, refer to the Tcl documentation.

EXAMPLES

The following example prints squared values from 0 to 10.

```
set p 0
while {$p <= 10} {
    echo "$p squared is: [expr $p * $p]"; incr p
}
```

SEE ALSO

[break\(2\)](#)
[if\(2\)](#)

win_select_objects

Creates a collection of objects equivalent to a graphical selection operation.

SYNTAX

```
string win_select_objects
  [-slct_targets slct_bus]
  [-slct_targets_operation operation]
  [-create_slct_buses]
  [-root instance]
  [-within rectangle
    | -line line
    | -at point
    | -radius r | -again_at]
  [-intersect]
  [-index i]
  [-visible]
```

Data Types

<i>slct_bus</i>	string
<i>operation</i>	string
<i>instance</i>	string

ARGUMENTS

-slct_targets *slct_bus*

Specifies the name of a selection bus to store the result in. By default the result of this command is returned in a collection. If this option is specified selection bus *slct_bus* is used instead. *slct_bus* is also returned as result of the command.

-slct_targets_operation *operation*

Specifies which operation should be used when storing the result in selection bus *slct_bus*. This is only allowed if you specify the -slct_targets option. Legal operations are clear, add and remove.

-create_slct_buses

Specifies that a new selection bus is created and used to store the result in. Using this option is equivalent to first creating a selection bus using the create_selection_bus command and then providing the created selection bus to option -slct_targets.

-root *instance*

Specifies a string for the instance whose component design objects and hierarchy are to be examined against the specified region criteria.

-within *rectangle*

Collects design objects lying within the specified rectangle.

-line *line*

Collects design objects intersected by specified line.

-at *point*

Collects design objects whose bounding box contains the specified point.

-radius *r*

Specifies a radius for points specified by the **-at** option. It is applicable only for **_pins** and **_ports**.

-again_at

Reapplies the previous **-at** option, but returns a previously-matched design object.

-intersect

Collects design objects intersecting with specified rectangle. Without this option, the command collects design objects contained in the specified rectangle.

-index *i*

For point select (-at option) specifies a specific object index to select. Similar to running **-again_at**.

-visible

Select objects marked as visible with **win_set_select_class** command.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

win_set_select_class(2)
win_set_filter(2)

win_set_filter

Sets a filter to apply to objects selected by the **win_select_objects** command.

SYNTAX

```
int win_set_filter
  -class class_name
  [-filter expression]
  [-layer list]
  [-user_filter true | false]
  [-user_filter_cmd tcl_cmd]
  [-highlighted_only true | false]
  [-expand_cell_types list]
  [-visible]
  -part parts
  -stop_level level
  -z_level level
  [-start_level level]
```

ARGUMENTS

-class *class_name*

Specifies a single class name for which the filter is to apply.

-filter *expression*

Specifies a filter expression that an object must satisfy to be returned by the **win_select_objects** command. The expression argument must be a Boolean expression based on attributes of the specified class. If this option is not specified, the filter is cleared.

-layer *list*

Specifies a layer number list that an object must satisfy to be returned by the **win_select_objects** command. If this option is not specified, the layer filter is cleared.

-user_filter true | false

Enables user supplied filter command.

-user_filter_cmd *tcl_cmd*

Specifies a tcl command for filtering.

-highlighted_only true | false

Specifies that only highlighted objects can be selected.

-expand_cell_types *list*

Specifies cell types for searching design objects down the hierarchy when the search level is greater than 0. This has no effect on types that is not supported or objects that are not collectable.

-visible

Specified filters are for visible objects. By default the filters are for selectable objects.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

[win_select_objects\(2\)](#)
[win_set_select_class\(2\)](#)

win_set_select_class

Sets the design objects to be collected by the **win_select_objects** command.

SYNTAX

```
string win_set_select_class
  {-all | class_names}
  [-visible]
```

ARGUMENTS

-all

Selects all classes. The **-all** option and the *class_names* option are mutually exclusive.

class_names

Specifies a list of design objects. The **-all** option and the *class_names* option are mutually exclusive.

-visible

Specified classes are for visible objects. By default the classes are for selectable objects.

DESCRIPTION

This command is for use by the graphics window(s) for logging interactive, graphical selection operations to the command log for later playback. You are advised not to use this command directly. Use of this command other than by graphics windows may cause unexpected results from selection operations.

SEE ALSO

[win_select_objects\(2\)](#)
[win_set_filter\(2\)](#)

write

Alias for the **write_file** command.

DESCRIPTION

The **write** command has been renamed **write_file**. The **write** command is provided so that older scripts will run correctly, but it is recommended that you use the command's actual name, **write_file**.

See the **write_file** man page for information about this command.

SEE ALSO

[write_file\(2\)](#)

write_app_var

Writes a script to set the current variable values.

SYNTAX

```
string write_app_var
    -output file
    [-all | -only_changed_vars]
    [pattern]
```

Data Types

file string
pattern string

ARGUMENTS

-output *file*

Specifies the file to which to write the script.

-all

Writes the default values in addition to the current values of the variables.

-only_changed_vars

Writes only the changed variables. This is the default when no options are specified.

pattern

Writes the variables that match the specified *pattern*. The default is "*".

DESCRIPTION

The **write_app_var** command generates a Tcl script to set all application variables to their current values. By default, variables set to their default values are not included in the script. You can force the default values to be included by specifying the **-all** option.

EXAMPLES

The following is an example of the **write_app_var** command:

```
prompt> write_app_var -output sh_settings.tcl sh*
```

SEE ALSO

[get_app_var\(2\)](#)
[report_app_var\(2\)](#)
[set_app_var\(2\)](#)

write_bsd_rtl

Writes the RTL for the configured boundary-scan design into an output file.

SYNTAX

```
status write_bsd_rtl
      [-output output_file_name]
      [-format verilog]
      [-all]
      [-tap]
      [-bsr]
```

Data Types

output_file_name string

ARGUMENTS

-output *output_file_name*

Specifies the name of the boundary-scan output RTL file to write. If only a base name is given without a directory path, the files are written in the current directory. This option is required.

-format verilog

Selects the format for the output RTL file. The only allowed value is **verilog**, which is the default.

-all

Specifies that all boundary-scan logic modules are to be written to the specified output file. This is the default.

-tap

Specifies that the TAP controller and its submodules should be written to a separate file. A file with `tap_` prefixed to the specified output file name (for example, `tap_rtl_file.v`) is written for the TAP controller modules. The remaining boundary-scan modules are written to the file specified with the **-output** option.

-bsr

Specifies that the boundary-scan register (BSR) and its submodules should be written to a separate file. A file with `bsr_` prefixed to the specified output file name (for example, `bsr_rtl_file.v`) is written for the BSR modules. The remaining boundary-scan modules are written to the file specified with the **-output** option.

DESCRIPTION

The **write_bsd_rtl** command writes the configured boundary-scan design to an output Verilog RTL file. This file can be used for

simulation.

The Verilog RTL file can be simulated along with the patterns, as well as analyzed statically with the **check_bsd** command.

The **-tap** and **-bsr** options control how the modules are written to different output RTL files, but they do not affect the actual logic structure of the boundary-scan design.

EXAMPLES

The following example commands write a boundary-scan configured RTL file for a design. Both commands are equivalent.

```
prompt> write_bsd_rtl -format verilog -all -output rtl_file.v
prompt> write_bsd_rtl -output rtl_file.v
```

The following example writes a boundary-scan configured RTL file for a design. The TAP controller and its submodules are written to the tap_rtl_file.v file. The BSR chain and its submodules are written to the bsr_rtl_file.v file. The remaining modules are written to the rtl_file.v file.

```
prompt> write_bsd_rtl -format verilog \
           -tap -bsr -output rtl_file.v
```

SEE ALSO

[current_design\(2\)](#)
[insert_dft\(2\)](#)
[create_bsd_patterns\(2\)](#)
[write_test\(2\)](#)

write_bsdl

Generates the boundary-scan description language (BSDL) file for a boundary-scan design.

SYNTAX

```
int write_bsdl
  [-naming_check VHDL | BSDL | none]
  [-output file_name]
  [-effort low | medium | high]
```

Data Types

file_name string

ARGUMENTS

-naming_check VHDL | BSDL | none

Specifies the type of naming checks to perform on the design. *VHDL* (the default) checks for both VHDL and BSDL reserved words; *BSDL* checks for BSDL reserved words only. *none* disables all naming checks.

-output *file_name*

Specifies the name of the output BSDL file. The default is *top_level_design_name.bsdl*.

-effort low | medium | high

Controls the effort used to search for implemented instructions if the boundary-scan database has not been previously built by the **check_bsd**, **insert_dft**, or **read_bsdl** command and the tool must infer the implemented instructions. For more information, see the man page for the **check_bsd** command.

DESCRIPTION for all modes

Generates the BSDL file for a boundary-scan design. If the boundary-scan database was not previously built by the **check_bsd**, **insert_dft**, or **read_bsdl** command, the command performs an implicit compliance check before proceeding. If a valid port-to-pin map exists for the boundary-scan design and if no errors occurred during compliance checking, the **write_bsdl** command generates the BSDL output file for the boundary-scan design.

You can change the default suffix name, **bsdl**, by setting the **test_bsdl_default_suffix_name** variable with another suffix name.

By default, the BSDL file line length is 74 characters per line. You can specify a different line length using the **test_bsdl_max_line_length** variable. The specified maximum line length should not be less than 50 or more than 132. If you specify a line length outside this range, **write_bsdl** uses the default instead.

EXAMPLES

The following example generates the BSDL output file test.bsd for a boundary-scan design while performing BSDL naming checks on the identifiers used in the design.

```
prompt> write_bsdl -naming_check BSDL -out test.bsd
```

[remove_pin_map\(2\)](#)
[set_bsd_compliance\(2\)](#)
[test_bsdl_default_suffix_name\(3\)](#)
[test_bsdl_max_line_length\(3\)](#)

write_cell_expansion

Writes the cell expansion data, including the area, width, and height of each cell that is expanded.

SYNTAX

```
int write_cell_expansion  
    output_file_name
```

Data Types

output_file_name string

ARGUMENTS

output_file_name

Specifies the name of the output expansion data file. This is a required argument.

DESCRIPTION

The **write_cell_expansion** command writes the cell expansion data to a file. Cell expansion data includes the area, width, and height of each cell that is expanded. The data can be used for better congestion correlation between the Design Compiler Graphical tool and the IC Compiler and IC Compiler II tools.

EXAMPLES

The following example writes out a cell expansion file from the existing design.

```
prompt> write_cell_expansion out.exp
```

SEE ALSO

`read_cell_expansion(2)`

write_collection

Output a machine readable report of attribute values for elements in a collection.

SYNTAX

```
write_collection
  collection
  [-file filename]
  [-format format]
  [-max_rows value_count]
  [-columns attribute_list]
  [-metadata]
```

Data Types

<i>collection</i>	string
<i>filename</i>	string
<i>format</i>	string
<i>value_count</i>	int
<i>attribute_list</i>	list

ARGUMENTS

collection

Specifies the collection on which to report. The collection may be homogeneous or heterogeneous. If the collection is very large, you may want to use the **-max_rows** option to limit the size of your output.

-file *filename*

This option indicates the name of the file to which the data is written.

-format *format*

This option accepts one of the following valid argument values: "csv" | "tsv". If the option is omitted, the default format is "csv", or command separated values. The argument "tsv" produces a tab separated values formatted data.

-max_rows *value_count*

This option indicates how many rows of data to include in the output. This number indicates the number of collection elements on which data is output.

-columns *attribute_list*

Indicates the set of attributes for which to output values, and their order in the output.

The special attribute name "object_class" may be used to include the element object class names, such as "cell" or "net", in the output.

If the option is omitted, then the object names and object class (or type) names are output by default.

-metadata

This option indicates that a meta data section should be included in the output.

DESCRIPTION

This command outputs tabular data of attribute values for elements of the given collection. The attribute values in the output are determined by the list of attributes given to the **-columns** option. The columns in the tabular report will be ordered by the order of attributes in the list. The command **list_attributes** may be called to view a list of attributes defined for an object class.

If the collection is large, the output size may be limited by indicating a **-max_rows** value. The commands **filter_collection** and **sort_collection** may be called to filter and sort a collection based on some criteria prior to creating a report for the collection elements.

By default, the output file omits the meta data section. If **-metadata** option is present, the output initiates with the meta data section which contains information such as the file generation timestamp, the product name and version and column data types. Some consumers of csv/tsv files benefit from the extra information in the meta data while other consumers do not handle it well.

EXAMPLES

The following example from IC Compiler II writes the full_name and area values of cells in a collection to a comma separated values (CSV) file named "cell_area.db".

```
prompt> set cells [get_cells U*]
prompt> write_collection $cells -columns {full_name area} \
    -file cell_area_pins.db
```

The next example outputs the same values to a tab separated values (TSV) file.

```
prompt> write_collection $cells -columns {full_name area} \
    -format "tsv" -file cell_area_pins.db
```

The next examples limits the output to a CSV file to the first 10 objects in the collection.

```
prompt> write_collection $cells -columns {full_name area} \
    -file cell_area_pins.db -max_rows 10
```

The next example first sorts the original collection of cells by the area attribute value in descending order, limiting the resulting collection to the top 10 area values. The example then outputs the full_name and area values to a CSV file named top_10_areas.db.

```
icc2_shell set sorted_cells [sort_collection -dictionary \
    $cells {area- full_name} -limit 10]
prompt> write_collection $cells -columns {full_name area} \
    -file top_10_areas.db
```

The next example writes a sorted collection as in the above example but further limits the output to the first 10 objects in the collection. Note that this command may produce an output that is different from the above example. Limiting the sort to the first 10 values may produce a collection with more than 10 objects since multiple objects may share the same area value.

```
icc2_shell set sorted_cells [sort_collection -dictionary \
    $cells {area- full_name} -limit 10]
prompt> write_collection $sorted_cells -columns {full_name area} \
    -file first_10_objects_by_area.db -max_rows 10
```

The next example outputs to a CSV file which will include the meta data section.

```
prompt> write_collection $cells -columns {full_name area} \
    -format "csv" -file cell_area_pins.db -metadata
```

`sort_collection(2)`
`report_collection(2)`

write_def

Writes the physical data of the specified design to a file in DEF format. To ensure that the names match in the DEF and Verilog files, run the **change_names -rules verilog** command before saving the design.

SYNTAX

```
status write_def
  -output output_file_name
  [-version def_version]
  [-unit conversion_factor]
  [-compressed]
  [-rows_tracks_gcells]
  [-vias]
  [-all_vias]
  [-nondefault_rule]
  [-lef lef_file_name]
  [-regions_groups]
  [-components]
  [-macro]
  [-fixed]
  [-placed]
  [-pins]
  [-blockages]
  [-specialnets]
  [-notch_gap]
  [-pg_metal_fill]
  [-nets]
  [-routed_nets]
  [-diode_pins]
  [-floating_metal_fill]
  [-scanchain]
  [-no_legalize]
  [-verbose]
```

Data Types

```
output_file_name      string
def_version          real
conversion_factor    integer
lef_file_name        string
```

ARGUMENTS

-output *output_file_name*

Specifies the name of the DEF file written by the **write_def** command. This is a required argument.

-version *def_version*

Specifies the version of DEF to be written. Valid *def_version* values are 5.3, 5.4, 5.5, 5.6, 5.7 and 5.8.

Note: The Design Compiler tool writes out DEF files in versions 5.7 and 5.8 only, irrespective of this option setting other than 5.7 and 5.8. The default is 5.8.

-unit conversion_factor

Specifies the value used in the DEF UNITS DISTANCE MICRONS statement of the DEF file. Valid values for conversion factor are 100, 200, 400, 800, 1000, 2000, 4000, 8000, 10000 and 20000. The values 10000 and 20000 are supported in DEF 5.6. The values 400, 800, 4000 8000 are only supported in DEF 5.8.

If this option is not used, the **write_def** command first checks if the .db representation stores a unit value from a previously read DEF file. If not, the default is 1000.

-compressed

Writes a compressed DEF file in gzip format.

-rows_tracks_gcells

Includes the ROW, TRACK and GCELLGRID sections in the output DEF file. This option can be combined with options for writing out other DEF sections.

-vias

Includes the VIAS section in the output DEF file. This option can be combined with options for writing out other DEF sections.

-all_vias

Includes all vias in the technology file, as well as those present in the design, in the output DEF file. By default, only vias present in the design are written out.

-nondefault_rule

Includes the NONDEFAULTRULES section in the output DEF file, version 5.6 and later. (The NONDEFAULTRULES syntax is not supported in DEF version 5.5 and earlier.)

-lef lef_file_name

Writes the rotated vias and design-specified nondefault rule to the specified LEF file.

-regions_groups

Includes the REGIONS and GROUPS sections in the output DEF file. This option can be combined with options for writing out other DEF sections.

-components

Includes the COMPONENTS section in the output DEF file. This option can be combined with options for writing out other DEF sections.

-macro

Includes only macro cells in COMPONENTS section; excludes standard cells. By default, both macro cells and standard cells are included in the COMPONENTS section.

-fixed

Includes only fixed cells in the COMPONENTS section. By default, all fixed, cover, placed, and unplaced cells are included in the COMPONENTS section.

-placed

Includes only fixed and placed cells in the COMPONENTS section. By default, all fixed, cover, placed, and unplaced cells are included in the COMPONENTS section.

-pins

Includes the PINS section in the output DEF file. This option can be combined with options for writing out other DEF sections.

-blockages

Includes the BLOCKAGES section in the output DEF file. This option can be combined with options for writing out other DEF sections.

-specialnets

Includes the SPECIALNETS section in the output DEF file. This option can be combined with options for writing out other DEF sections. To include notch/gap and PG metal fill as well, use the "-notch_gap" and "-pg_metal_fill" options.

-notch_gap

Includes notch/gap in the SPECIALNETS section.

-pg_metal_fill

Includes PG metal fill in SPECIALNETS section.

-nets

Includes the NETS section in the output DEF file.

-routed_nets

Includes only routed nets in the SPECIALNETS and NETS sections. By default, all nets are included in the SPECIALNETS and NETS sections.

-diode_pins

Includes the diode (extra) pins in the NETS section.

-floating_metal_fill

Includes floating metal fill in the FILLS section.

-scanchain

Includes the SCANCHAINS section in the output DEF file. This option can be combined with options for writing out other DEF sections.

-no_legalize

Prevents name legalization from being performed. Name legalization escapes DEF special characters that do not actually have special meaning. Escaping the special character causes its special meaning to be ignored by the DEF reader. For example, if a component name contains bus bit characters, the bus bit characters are escaped because it is not really a bus. By default, legalization is performed.

-verbose

Reports warning and information messages, in addition to error messages. By default, only error messages are reported.

DESCRIPTION

The **write_def** command writes the physical design data for the specified design in memory to a file in DEF format.

The **write_def** command uses the current design from the open Milkyway design library. You need to open the Milkyway design before you use the **write_def** command.

By default, the command writes out all sections of the DEF file. However, if you use any one or more of the following options, the command writes out only the specified sections: **-rows_tracks_gcells**, **-vias**, **-regions_groups**, **-components**, **-macro**, **-fixed**, **-placed**, **-pins**, **-blockages**, **-specialnets**, **-nondefault_rule**, **-nets**, **-routed_nets**, **-diode_pins**, **-scanchain**, **-notch_gap**, **-floating_metal_fill**, and **-pg_metal_fill**.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example writes out the file "out.def" from the currently open Milkyway design.

```
prompt> write_def -lib my_lib -topdesign my_top_design -output out.def
```

SEE ALSO

[open_mw_lib\(2\)](#)

write_design_lib_paths

Writes into a file the paths to which design libraries are mapped.

SYNTAX

```
status write_design_lib_paths
  [-filename file_name]
  [-dc_setup]
```

Data Types

file_name string

ARGUMENTS

-filename *file_name*

Specifies the file to which design library information is to be written. If **-dc_setup** is specified, the default file to which the data is written is **.synopsys_dc.setup** in the current working directory. If **-dc_setup** is not specified, the default file to which the data is written is determined by setting the **design_library_file** variable.

-dc_setup

Indicates that the *file_name* is to be written in **.synopsys_dc.setup** format. By default, the file is written in **synopsys_vss.setup** format (the format used by the Synopsys simulator). If **-dc_setup** is specified, the file written contains **define_design_lib** commands. The **-dc_setup** option changes the default *file_name* value to **.synopsys_dc.setup** in the current working directory.

DESCRIPTION

This command writes into a file the paths to which design libraries are mapped. The format is either **.synopsys_vss.setup** or **.synopsys_dc.setup**. The **write_design_lib_paths** command does not modify an existing file. If the file to which paths are written already exists, **write_design_lib_paths** fails.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

In the following example, **write_design_lib_paths** writes the current design library paths:

```
prompt> write_design_lib_paths -file ~/.synopsys_dc.setup -dc_setup
```

SEE ALSO

[analyze\(2\)](#)
[define_design_lib\(2\)](#)
[elaborate\(2\)](#)
[get_design_lib_path\(2\)](#)
[read_file\(2\)](#)
[report_design_lib\(2\)](#)

write_environment

Writes the variable settings and constraints for the specified cells or designs.

SYNTAX

```
return_val write_environment
[-cells cell_list] [-designs design_list]
[-format dcsh | dctl]
[-output file_name]
[-suffix suffix]
[-environment_only]
[-constraints_only]
[-no_lib_info]
[-compress]
[-consistency]
[-script]
```

Data Types

<i>cell_list</i>	string
<i>design_list</i>	string
<i>file_name</i>	string
<i>suffix</i>	string

ARGUMENTS

-cells *cell_list*

The list of instances for which the environment is to be created. This option and the **-designs** option are mutually exclusive. You can specify one or the other or neither. If you specify neither, the command writes the environment for the current design.

-designs *design_list*

The list of designs for which the environment is to be created. This option and the **-cells** option are mutually exclusive. You can specify one or the other or neither. If you specify neither, the command writes the environment for the current design.

-format dcsh | dctl

Specifies the format for the constraints file.

If you do not specify a format, the command uses Tcl format.

-output *file_name*

Specifies the output file name. If you specify the file name, this command generates a single file that contains the requested information. If you do not specify an output file name, this command creates an output file for each partition named *partition_name.suffix*, where the suffix value is determined by the **-suffix** option. When the *file_name* ends with the .gz extension, the output file will be written out in gzip format.

-suffix *suffix*

Specifies the output file suffix used by this command when you do not specify the file name. The default suffix is "env."

-environment_only

Writes out only the variable settings. By default, both the variable settings and the constraints are written.

-constraints_only

Writes out only the constraints. By default, both the variable settings and constraints are written.

-no_lib_info

Specifies not to include attributes that come from library cells. By default, instances inherit attributes from their reference library cells.

-compress

Writes a compressed output file in gzip format.

-consistency

Writes out variables, attributes, constraints, and so on, for consistency checking. When this option is specified, the **-output** option needs to be specified also.

-script

Writes out the IC Compiler environment in a setup script in Design Compiler in topographical mode. The script includes variables settings, attributes, constraints, and so on. The script ensures that the most updated physical environment is used for additional Design Compiler Graphical runs and helps ensure good correlation of Design Compiler Graphical to IC Compiler post-placement results.

When the **-script** option is specified, the **-output** option must be specified also.

The **-consistency** and **-script** options are mutually exclusive; you can use only one.

DESCRIPTION

For each specified design, this command writes out the following information:

- Settings for all variables whose settings have changed since the session began
- Design constraints
- Attributes inherited from the reference library cells

You can exclude information using the **-constraints_only**, **-environment_only**, and **-no_lib_info** options.

By default, an output file is generated for each design. You can generate a single output file by using the **-output** option.

Multicorner-Multimode Support

This command uses information from the current scenario only.

SEE ALSO

[derive_constraints\(2\)](#)

write_file

Writes a design netlist or schematic from memory to a file.

SYNTAX

```
int write_file
  [-format output_format]
  [-hierarchy]
  [-no_implicit]
  [-output output_file_name]
  [-scenarios scenario_list]
  [-library library_name]
  [-include_anchor_cells]
  [-exclude_references reference_names]
  [-pg]
  [design_list]
```

Data Types

<i>output_format</i>	string
<i>output_file_name</i>	string
<i>scenario_list</i>	list
<i>library_name</i>	string
<i>reference_names</i>	list
<i>design_list</i>	list

ARGUMENTS

-format *output_format*

Specifies the output format of the design. Supported output formats and their descriptions are as follows:

- ddc** - Synopsys internal database format (the default format)
- verilog** - IEEE Standard Verilog
- svsim** - SystemVerilog netlist wrapper
- vhdl** - IEEE Standard VHDL

Specifying **-format svsim** causes the tool to write out only the netlist wrapper, not the gate-level design under test (DUT). To write out the gate-level DUT use **-format verilog**. For further information see the *SystemVerilog User Guide*.

-hierarchy

Writes out all the designs in the hierarchy, starting from the designs specified in *design_list*. If *design_list* is not specified, the current design's hierarchy is written. If a design hierarchy is not completely linked, the unresolved design references are not written out.

If the output format is ddc, block abstractions are not written out unless *design_list* consists of a single design that is the top of the block abstraction's hierarchy. Alternatively, *design_list* can be left empty if the current design is the top of the block abstraction's hierarchy. The **-hierarchy** and **-output** options are required when writing block abstractions to a .ddc file.

-no_implicit

Specifies not to write (save) the synthetic design hierarchy that is implicitly created during the optimization of the design. By default, the command writes designs created in the hierarchy through the use of synthetic libraries even if you do not use the **-hierarchy** option.

-output *output_file_name*

Specifies a single file into which designs are to be written. By default, the command writes each design into a separate file named *design.suffix*, where *design* is the name of each design (with a full UNIX path) and *suffix* is the default suffix for the specified format. The default format suffixes and their descriptions are as follows:

.ddc - ddc
.v - verilog
.sv - svsim
.vhd - vhdl

The **-output** option is required if the output format is .ddc and a block abstraction hierarchy is being written.

-scenarios *scenario_list*

Lists scenarios whose constraints should be included in the output file. This option applies to ddc format only. By default, the command includes all scenarios.

-library *library_name*

Writes the Synopsys database format object to the specified library.

-include_anchor_cells

Includes anchor cells created during linking (if any) when generating Verilog output. These are, by default, filtered out in Verilog output. This option is supported only by DC Explorer.

-exclude_references *reference_names*

Specifies the reference cell names, separated by space characters, for which all cell instances must not be written. The **-exclude_references** option can only be used with the **-format verilog** option.

-pg

Includes PG nets and ports in Verilog output. If the RTL was read with the **dc_allow_rtl_pg** variable set to **true**, the data obtained from the original RTL is used. Otherwise, PG connections will be inferred from the design's UPF specification, if present. For more information, see the Design Compiler User Guide and the Power Compiler User Guide. The **-pg** option can only be used with the **-format verilog** option.

design_list

Lists the designs or design files to be written. If *design_list* is omitted, the current design is used as the design list.

Block abstractions are only written to .ddc files when exactly one design is specified, or the current design is inferred, and that design is the top design of a block abstraction hierarchy.

For other output formats, such as .v, if both block abstractions and non-block abstractions exist in the design list, only the non-block abstractions are written out. However, if only block abstractions exist in the design list, the block abstractions are written out.

Designs are not removed from memory after they have been written; to remove a design from memory, use the **remove_design** command.

DESCRIPTION

This command saves the designs from memory to disk. If a design is modified in the tool, you must use the **write_file** command to save the design.

Multicorner-Multimode Support

When writing in ddc format, constraint data for all scenarios is saved by default. You can use the **-scenarios** option to specify a list of scenarios that should be saved.

EXAMPLES

The following examples show how to save designs in ddc format.

This example shows how to write out all designs in the current hierarchy. Since no output file is specified, each design is written to a separate file using the design name as the base of the file name:

```
prompt> write_file -hierarchy
Writing ddc file 'top.ddc'
Writing ddc file 'mid.ddc'
Writing ddc file 'bot.ddc'
```

This example shows how to save all designs in the current hierarchy to a single file:

```
prompt> write_file -hierarchy -output ~bill/dc/designs.ddc
Writing ddc file '/home/bill/dc/designs.ddc'
```

This example shows how to specify a list of designs to be saved:

```
prompt> write_file {ADDER MULT16}
Writing ddc file 'ADDER.ddc'
Writing ddc file 'MULT16.ddc'
```

This example shows another use of the **-hierarchy** option. All designs in the hierarchies of designs A and B are written to a single file:

```
prompt> write_file -hierarchy -output ~bill/dc/two_hiers.ddc {A B}
Writing ddc file '/home/bill/dc/two_hiers.ddc'
```

The following example shows how to specify designs by listing the design file name instead of the design names themselves. (Use **list_designs -show_file** to see the design names associated with each file.) It writes all designs that are associated with the top.ddc file.

```
prompt> write_file top.ddc
Writing ddc file 'top.ddc'.
Writing ddc file 'mid.ddc'.
Writing ddc file 'bot.ddc'.
```

The following example shows how to resolve an ambiguous file name. It is possible to have multiple designs in memory with the same name if they are associated with different files. To resolve the ambiguity you must specify the design in the form *file_name:design_name*. Use the absolute path to the file to avoid possible file name conflicts. In the following example, the design name "top" is ambiguous, and the ambiguity is resolved by using the file name:

```
prompt> write_file -output new.ddc top
Error: 'top' doesn't specify a unique design
Please use complete specification: full_file_name:design_name (UID-13)
prompt> write_file -output new.ddc /home/bill/dc/top.ddc:top
Writing ddc file 'new.ddc'
```

SEE ALSO

```
change_names(2)
define_name_rules(2)
create_block_abstraction(2)
view_write_file_suffix(3)
dc_allow_rtl_pg(3)
```

write_floorplan

Writes a Tcl script that contains detailed floorplanning information for the specified design. This file can be used to re-create elements of the floorplan.

SYNTAX

```
status write_floorplan
  [-all]
  [-create_bound]
  [-no_bound]
  [-no_create_boundary]
  [-no_placement_blockage]
  [-no_route_guide]
  [-no_voltage_area]
  [-placement {placement_info_types} [-create_terminal]]
  [-preroute]
  [-user_shape]
  [-net_shape]
  [-row]
  [-pin_guide]
  [-track]
  [-def_version def_version]
  [-def_units conversion_factor]
  file_name
  [-format format]
```

Data Types

<i>placement_info_types</i>	keyword
<i>def_version</i>	real
<i>conversion_factor</i>	integer
<i>file_name</i>	string

ARGUMENTS

-all

Writes all floorplan information to the Tcl script. You can combine the **-all** option with the **-no_bound**, **-no_create_boundary**, **-no_placement_blockage**, **-no_route_guide**, and **-no_voltage_area** options to prevent writing certain types of information. The **-create_terminal** option is ignored and always enabled when using the **-all** option. The **-all** option writes user and net shapes on metal layers that are written by the **-user_shape** and **-net_shape** options.

-create_bound

Writes **create_bounds** commands instead of **update_bounds** commands for bound objects. This option has no effect if you specify the **-no_bound** option. By default, the command writes **update_bounds** commands to the Tcl script.

-no_bound

Prevents the writing of bound information to the Tcl script. By default, bound information is written.

-no_create_boundary

Prevents the writing of boundary information to the Tcl script. By default, the command writes boundary information.

-no_placement_blockage

Prevents the writing of placement blockage information to the Tcl script. By default, the command writes placement blockage information.

-no_route_guide

Prevents the writing of route guide information to the Tcl script. By default, the command writes route guide information.

-no_voltage_area

Prevents the writing of voltage area information to the Tcl script. By default, the command writes voltage area information.

-placement {*placement_info_types*}

Writes the specified placement information to the output file. Valid placement values are: **io**, **hard_macro**, **soft_macro**, and **terminal**. You can specify one or more of these values. The **io** keyword causes the command to write I/O pads. The **soft_macro** keyword causes the command to write black box cells because they are considered soft macros. The **hard_macro** keyword causes the command to write hard macro placements.

The **terminal** keyword causes the command to write pins. When you use the **-placement terminal** option, you should also use the **-create_terminal** option.

By default, the command does not write placement information.

-create_terminal

Writes **remove_terminal** and **create_terminal** commands to the Tcl script. The command writes **create_terminal** commands for terminals if there are pins in the design.

To use this option, you must also use the **-placement {terminal}** option.

-preroute

Writes preroute information to the Tcl script. By default, the command does not write preroute information.

-user_shape

Writes the user shapes created on metal layers by the **create_user_shape** command to the Tcl script. By default, the command does not write these user shapes.

-net_shape

Writes the net shapes created on metal layers by the **create_net_shape** command to the Tcl script. By default, the command does not write these net shapes.

-row

Writes row information to the Tcl script. By default, the command does not write row information.

-pin_guide

Writes pin guide information to the Tcl script. By default, the command does not write pin guide information.

-track

Writes track information to the Tcl script. By default, the command does not write track information.

-def_version *def_version*

Specifies the version of DEF to be written. This option is valid only with "-format icc2" Valid *def_version* values are 5.3, 5.4, 5.5, 5.6, 5.7 and 5.8. The default is 5.8.

Note: The Design Compiler tool writes out DEF files in versions 5.7 and 5.8 only, irrespective of this option setting other than 5.7

and 5.8.

-def_units conversion_factor

Specifies the value used in the DEF UNITS DISTANCE MICRONS statement of the DEF file. This option is valid only with "-format icc2". Valid values for conversion factor are 100, 200, 400, 800, 1000, 2000, 4000, 8000, 10000 and 20000. The values 400, 800, 4000 and 8000 are only supported in DEF 5.8.

file_name

Specifies the name of the file to which the floorplan information is written.

-format format

Enables writing floorplan files in IC Compiler II format.

By default, the **write_floorplan** command writes floorplan files in Design Compiler format.

When you specify the **-format icc2** option, all the other **write_floorplan** command options are ignored.

DESCRIPTION

This command writes a Tcl script file that contains floorplan information for the current or user-specified design. You restore the floorplan information by reading the generated file with the **read_floorplan** command.

The **write_floorplan** command writes commands relative to the top of the design, regardless of the current instance. The generated Tcl script must be read from the top of the design.

By default, the command writes floorplan information only for the top-level design. The information includes the boundary data and information on the following objects: bounds, placement blockages, route guides, and voltage areas.

When you specify the **-format icc2** option, the **write_floorplan** command writes out the floorplan files in Tcl and DEF format into a folder named by the *file_name* argument. The folder contains a main floorplan.tcl script file, which you can use to load the floorplan in IC Compiler II. The script

- Uses the **read_def** command to load the floorplan.def file
- Sources commands to read the generated Tcl format files
- Uses the remaining settings or constraints that are not captured in the DEF or individual generated Tcl files

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following commands validate the name of the current design, write the floorplan to a file named top.fp, and restore the floorplan by reading it.

```
prompt> write_floorplan -placement {io std_cell hard_macro} \
           -row top.fp
1
prompt> read_floorplan top.fp
```

The following example writes out a floorplan in IC Compiler II format into the folder named my_fp.

```
prompt> write_floorplan -format icc2 my_fp
```

1

This floorplan information is restored in IC Compiler II by sourcing the floorplan.tcl file.

```
prompt> source my_fp/floorplan.tcl
```

SEE ALSO

[read_floorplan\(2\)](#)

write_icc2_files

Writes the files needed to load the design in IC Compiler II.

SYNTAX

```
status write_icc2_files
  -output dir_name
  [-force]
  [-golden_upf upf_files]
  [-pg]
  [-environment_only]
  [-scenarios scenario_list]
  [-golden_floorplan golden_floorplan_file]
  [-def_version def_version]
  [-def_units conversion_factor]
```

Data Types

<i>dir_name</i>	string
<i>upf_files</i>	list
<i>scenario_list</i>	list
<i>golden_floorplan_file</i>	string
<i>def_version</i>	real
<i>conversion_factor</i>	integer

ARGUMENTS

-output *dir_name*

Specifies the name of the directory in which to write the design and script files.

-force

Overwrites the existing directory. By default, the command fails if the directory already exists or it has no permission to create directory.

-golden_upf *upf_files*

Specifies the golden UPF file that is used in IC Compiler II. This is a required option only in the golden UPF flow, and this options is required to not use in the non-golden UPF flow.

-pg

Includes PG nets and ports in the Verilog output.

-environment_only

Only the *desing_name.setting.tcl* file is written in the output directory.

-scenarios *scenario_list*

Specifies a list of scenarios to save. By default, the command includes all scenarios.

-golden_floorplan *golden_floorplan_file*

Specifies the name of the golden floorplan file to use.

-def_version *def_version*

Specifies the version of DEF to be written. Valid *def_version* values are 5.3, 5.4, 5.5, 5.6, 5.7 and 5.8. The default is 5.8.

Note: The Design Compiler tool writes out DEF files in versions 5.7 and 5.8 only, irrespective of this option setting other than 5.7 and 5.8.

-def_units *conversion_factor*

Specifies the value used in the DEF UNITS DISTANCE MICRONS statement of the DEF file. Valid values for conversion factor are 100, 200, 400, 800, 1000, 2000, 4000, 8000, 10000 and 20000. The values 400, 800, 4000 and 8000 are only supported in DEF 5.8.

DESCRIPTION

The **write_icc2_files** command writes the design files and Tcl scripts for the current design to load the design data into IC Compiler II. Files are written into the directory specified by the **-output** option. The written files include the following, if the data is present:

- Netlist in Verilog format
- Propagate backward SAIF
- Tcl floorplan and DEF files
- Design's power intent as a UPF command script
- Scan chain information in SCANDEF format
- Constraints in SDC format
- Timing contexts (scenarios)

In addition, the **write_icc2_files** command writes the following:

- The Design Compiler settings in IC Compiler II format
- The top-level script to load all data generated in IC Compiler II

The **write_icc2_files** command saves the design data for the current design, using the design name to name the generated files.

Use the top-level script, *design_name.icc2_script.tcl* to load all the design data. The script loads design data in the correct order.

The **write_icc2_files** command writes a directory, *design_name.MCMM*, which contains timing contexts (scenarios) in a format that can be read into IC Compiler II to create and populate the same set of scenarios as specified in Design Compiler.

In the golden UPF mode, the command writes out the supplemental UPF file and the name mapping file. The top-level script includes *load_upf* commands to load the golden files specified by the **-golden_upf** option. If the **-pg** option is not specified, in the golden UPF mode, the supplemental UPF file generated by **write_icc2_files** will contain exception power connections derived by the tool.

The scripts generated by the **write_icc2_files** command do not include scripts for library creation in IC Compiler II. You need to create a library that is consistent with the library used in Design Compiler and then source the top-level script. In the same way, constraints set on the library cell are not included. You need to apply them in IC Compiler II.

When used in conjunction with the **set_host_options** command, the **write_icc2_files** command uses up to the user-specified number of CPU cores on the same computer for parallel execution. See the description of the **-max_cores** option in the **set_host_options** man page for more information.

EXAMPLES

The following example writes the design files to be loaded in IC Compiler II in the `icc2_files` directory for the current design:

```
prompt> write_icc2_files -output icc2_files
```

Next, in IC Compiler II, use the `design_name.icc2_script.tcl` file to load all the design files, after creating the library

```
prompt> source icc2_files/my_design.icc2_script.tcl
```

SEE ALSO

```
write_floorplan(2)

save_upf(2)
write_saif(2)
write_scan_def(2)
enable_golden_upf(3)
```

write_lib

Writes a compiled library to disk as a Synopsys .db file.

SYNTAX

```
int write_lib  
    library_name  
    [-format db]  
    [-output file_name]  
    [-names_file file_list]
```

Data Types

<i>library_name</i>	string
<i>file_name</i>	string

ARGUMENTS

library_name

In the Synopsys .db file format, the *library_name* argument specifies the name of the technology or symbol library to be written.

-format db

Specifies the external format of the specified library. Only the .db file format is supported.

-output *file_name*

Specifies an output file name or path name for the library.

DESCRIPTION

The **write_lib** command saves a compiled technology or symbol library to the disk.

If you specify the **-output** option, the command writes out the .db file using the specified path and file name. By default, the command writes out the .db file in the current directory as *library_name.db*.

Note: This command overwrites any existing file without issuing a warning.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows how to read and write a logic library.

```
prompt> read_lib my_lib.lib  
prompt> write_lib my_lib
```

The following example shows how to write a logic library to a specified file.

```
prompt> write_lib my_lib -output ~synopsys/test/test.db
```

The following example shows a name-mapping file called lib.names, and its usage.

Design	Type	Old Name	New Name
lib	reference	NR2	nr2
NR2	pin A	a	
NR2	pin B	b	
NR2	pin Z	z	
lib	reference	HO22	aoi2
HO22	pin I1	a	
HO22	pin I2	b	
HO22	pin I3	c	
HO22	pin O1	z	

NR2	pin A	a
NR2	pin B	b
NR2	pin Z	z
HO22	pin I1	a
HO22	pin I2	b
HO22	pin I3	c
HO22	pin O1	z

write_lib_specification_model

Writes the PG pin library conversion-specification commands in the output file.

SYNTAX

```
status write_lib_specification_model
      output_file_name
```

ARGUMENTS

output_file_name

Specifies the output file in which all the commands have to be written out.

DESCRIPTION

The **write_lib_specification_model** command writes out the library update commands and specification commands to the output file. The output file is in Tcl format. This command also writes the **update_lib_model** command to the output file. When the FRAM reference library is not available, the output file written by this command can be sourced to generate a PG pin library.

EXAMPLES

The following command writes the library conversion specification commands to a file named library.tcl.

```
prompt> write_lib_specification_model library.tcl
```

SEE ALSO

`update_lib_voltage_model(2)`

`set_voltage_model(2)`
`set_pg_pin_model(2)`
`set_pin_model(2)`
`set_always_on_cell(2)`
`set_retention_cell(2)`

```
set_level_shifter_cell(2)
set_isolation_cell(2)
set_power_switch_cell(2)
```

write_link_library

Writes shell commands to save the current link library settings for design instances.

SYNTAX

```
int write_link_library
  [-full_path_lib_names] [-nosplit]
  [-full_path_lib_names] [-nosplit]
  [-output file_name]
  [-target target]
```

Data Types

<i>file_name</i>	string
<i>target</i>	string

ARGUMENTS

-full_path_lib_names

Writes library names with full pathnames. The default is to write only the library name without the path.

-nosplit

Indicates that lines are not to be split when column fields overflow. This is most useful for diffing on previous scripts or for post-processing the script.

-output *file_name*

Writes the script to the specified file. By default, the command writes shell commands to standard output.

-target *target*

Specifies the target to write out scripts. The only valid value is **ptsh**.

DESCRIPTION

This command writes a script of shell commands. It is used to recreate link library settings for each instance in the design.

The redirection operator (>) can be used to redirect the output of this command to a disk.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example shows output redirected to a file named *output.tcl* and uses the full pathname for output for the link libraries.

```
prompt> write_link_library -output output.tcl \
    -full_path_lib_names
```

SEE ALSO

[link_library\(3\)](#)

write_milkyway

Writes out the design to Milkyway database format.

SYNTAX

```
status write_milkyway
  -output filename
  [-overwrite]
  [-scenario scenario_list]
```

Data Types

<i>filename</i>	string
<i>scenario_list</i>	list

ARGUMENTS

-output *filename*

Specifies the design file name to be written. For example, the following design files are under the CEL view in the *design_lib* Milkyway design library:

```
design_lib/CEL/design1_pre_route:1
design_lib/CEL/design1_pre_route:2
design_lib/CEL/design1_post_route:1
```

The *design1_pre_route* and *design1_post_route* are the *filename* arguments. The 1 and 2 after the colons (:) are the version numbers of the file names. This is a required argument.

-overwrite

Overwrites the existing version of the design under the CEL view. This option does not increment the version of the existing file name specified in the **-output** option.

-scenario *scenario_list*

Specifies a list of scenarios to save.

DESCRIPTION

The **write_milkyway** command writes the design into the Milkyway database. The command writes the hierarchical netlist and synthesis constraints. If floorplan, placement, and routing data exists, this information is also written into the Milkyway design library. If the specified Milkyway design library does not exist, the library is created by **write_milkyway**. This command does not write a design in the Milkyway database if the design is not unqualified or not mapped.

The **write_milkyway** command requires that a variable be set to specify where to find the Milkyway design library. The

mw_design_library variable must be set before using the **write_milkyway** command:

```
prompt> set mw_design_library <string>
```

The directory name can be a relative name or an absolute name. For a single session, only one Milkyway design library can be accessed. You cannot read or write to different Milkyway design libraries.

Internally, this command writes the design to a CEL view in the Milkyway design library. The exception is when the current design is an Interface Logic Model (ILM), in which case this command writes it to the ILM view. The UNIX structure of the sample the Milkyway design library (CEL/ILM view) is as follows:

```
my_design_lib/          (Milkyway design library)
my_design_lib/CEL/      (CEL view)
my_design_lib/CEL/design1_john:1 (John's CEL data for design1)
my_design_lib/CEL/design1_mike:1 (Mike's CEL data for design1)
my_design_lib/ILM/      (ILM view)
my_design_lib/ILM/design1_john:1 (John's ILM data for design1)
```

Assume the **mw_design_library** variable is set to *my_design_lib*. The UNIX file called *my_design_lib/CEL/design1_john:1* is created when you run the following command:

```
prompt> write_milkyway -output design1_john
```

EXAMPLES

In the following example, the contents of the design are written to the *MW_DESIGN_LIB* design library. The saved design file is called *RISC_CORE*.

```
prompt> set mw_design_library MW_DESIGN_LIB
prompt> write_milkyway -output RISC_CORE
```

In the following example, an ILM is created and saved to the ILM view in the *mw_design_library MW_DESIGN_LIB*. The **write_milkyway** command saves to the ILM view because the design in-memory after the **create_ilm** command is an Interface Logic Model.

```
prompt> set mw_design_library MW_DESIGN_LIB
prompt> create_ilm -physical
prompt> write_milkyway -output RISC_CORE
```

SEE ALSO

mw_design_library(3)

write_multibit_components

Writes out a set of **create_multibit** command statements that if executed will allow the user to re-create the current set of multibit components of the design.

SYNTAX

```
status write_multibit_components  
    [-output output_file_name]
```

Data Types

output_file_name string

ARGUMENTS

DESCRIPTION

The **write_multibit_components** command allows the user to preserve the multibit components through an ASCII interface when a DDC flow cannot be used and an ASCII flow approach is needed.

The command will output a set of **create_multibit** commands for the user to source them after reading the netlist in ASCII format.

This command is not needed in DDC flow, as the multibit components are preserved in the DDC file.

SEE ALSO

[create_multibit\(2\)](#)
[remove_multibit\(2\)](#)
[identify_register_banks\(2\)](#)

write_multibit_guidance_files

Writes out the mapping guidance files for the input map file and the register group file that can be used for placement-based multibit mapping in Design Compiler Graphical and IC Compiler.

SYNTAX

```
status write_multibit_guidance_files  
  [-prefix prefix_of_output_file_names]
```

Data Types

prefix_of_output_file_names string

ARGUMENTS

-prefix *prefix_of_output_file_names*

Specifies the prefix for the mapping guidance file names. The default prefix is multibit_guidance.

DESCRIPTION

The **write_multibit_guidance_files** command identifies the multibit registers that are available in the target and link libraries and the single-bit registers that can be replaced by the multibit registers based on the functional information of the library cells.

The **write_multibit_guidance_files** command uses the same process as the **identify_register_banks** command to identify the multibit and single-bit registers and then generates the following guidance files based on the functional information of the library cells:

- multibit_guidance.input_map (input map file)
 - multibit_guidance.register_group (register group file)

Examine these files to see which multibit cells are available in the library and which single-bit cells can be replaced by multibit cells.

If you do not need to change the way these files define multibit mapping, you do not need to specify the input map file and the register group file when you run the **identify_register_banks** command. In this case, Design Compiler automatically uses the guidance from the files generated by the **write_multibit_guidance_files** command.

To change the way multibit mapping is performed, modify these guidance files and provide additional multibit mapping guidance. You must specify the modified files when you run the **identify_register_banks** command in Design Compiler Graphical.

To use these guidance files in IC Compiler, specify them with the **set_banking_guidance_strategy** command.

See the **identify_register_banks** command man page for the mapping guidance files format.

SEE ALSO

`identify_register_banks(2)`

write_mw_lib_files

Writes the technology, or plib, or reference control file of the Milkyway library.

SYNTAX

```
status_value write_mw_lib_files
  [-technology]
  [-reference_control_file]
  [-stream_layer_map_file file_format]
  -output file_name
  [libName]
```

Data Types

<i>file_format</i>	string
<i>file_name</i>	string
<i>libName</i>	string

ARGUMENTS

-technology

Writes the technology information of the specified Milkyway library into a new text file in .tf format. To write the technology information from a Milkyway library other than the one currently open, you must first close the open Milkyway library.

These options are mutually exclusive: **-technology**, **-plib**, **-reference_control_file**, and **-stream_layer_map_file**.

-reference_control_file

Writes the reference control file of the specified Milkyway library into a new text file. The Milkyway reference control file is a list of Milkyway libraries referenced by the design library.

-stream_layer_map_file *file_format*

Writes a layer mapping file of the specified Milkyway library into a new text file. The *file_format* argument must be one of the following:

- * **in** for the stream-in layer mapping file
- * **out** for the stream-out layer mapping file
- * **starrc** for the StarRC layer mapping file
- * **all** for all of the above layer mapping files

-output *file_name*

Specifies the name of the new text file written by the command.

libName

Specifies the name of the Milkyway library from which to obtain the .tf technology information, .plib physical library information, reference control file, or layer mapping information.

DESCRIPTION

Writes a specified type of information obtained from a specified Milkyway library into an ASCII text file.

You must use exactly one of the following options to specify the type of information to write: **-technology**, **-plib**, **-reference_control_file**, or **-stream_layer_map_file**.

The command returns 1 for success or 0 for failure.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following command writes the .tf technology file of the Milkyway library named my_mw_lib. The new text file created is named my_tech.tf.

```
prompt> write_mw_lib_files -technology -output my_tech.tf  
prompt> my_mw_lib  
Technology file data dumped to my_tech.tf completely.  
1
```

The following command writes out the stream-out layer mapping file of the Milkyway library named my_mw_lib. The new text file created is named my_layer_map.out.

```
prompt> write_mw_lib_files -stream_layer_map_file out \  
-output my_layer_map.out my_mw_lib  
1
```

SEE ALSO

[create_mw_lib\(2\)](#)
[set_mw_lib_reference\(2\)](#)
[set_mw_technology_file\(2\)](#)

write_parasitics

Writes parasitics in SPEF format or as a Tcl script that contains **set_load** and **set_resistance** commands.

SYNTAX

```
status write_parasitics
  [-output file_name]
  [-format reduced]
  [-min]
  [-ratio ratio_number]
  [-script]
```

Data Types

<i>file_name</i>	string
<i>ratio_number</i>	float

ARGUMENTS

-output *file_name*

Specifies the name of the output file to which parasitics for the current design are written.

If you do not specify this option, the parasitics are written to a file named *design_name.format_name*, where *design_name* is the name of the current design.

-format reduced

Specifies to write the parasitics in reduced SPEF format.

-min

Writes parasitics for the minimum operating condition. By default, the parasitics are written for the maximum operating conditions.

-ratio *ratio_number*

Specifies the ratio used when writing the pie model description for every driver in the net. The ratio specified by this command must be in the range 0.0 - 1.0. By default, the nets in reduced format are generated with a ratio equal to 0.5. The capacitor closest to the driver is 0.5 (the ratio value) times the total net capacitance in the pie model description.

-script

Writes out **set_load** and **set_resistance** commands instead of an SPEF file.

DESCRIPTION

This command writes parasitics for the current design to a disk file.

Multicorner-Multimode Support

This command uses information from all active scenarios.

EXAMPLES

The following example writes parasitics in reduced SPEF format to a file named top.reduced.

If there are minimum and maximum operating conditions, parasitics for both conditions are written.

```
prompt> write_parasitics -format reduced -output top
```

[set_resistance\(2\)](#)

write_physical_constraints

Writes the script of Tcl commands to export the current physical constraint settings. This command is supported only in topographical mode. Note: The **write_physical_constraints** command is now aliased to the **write_floorplan** command. You should use the **write_floorplan** command instead.

SYNTAX

```
status write_physical_constraints
      -output tcl_file
      [-no_site_row]
      [-pre_route]
```

Data Types

tcl_file string

ARGUMENTS

-output *tcl_file*

Specifies the name of the file to which the physical constraints are written. This argument is required.

-no_site_row

Indicates that site rows commands are not dumped in the output file. By default, site row commands are written out to the output file.

-pre_route

Writes pre-routes to the output file. By default, pre-routes are not written to the output file.

DESCRIPTION

The **write_physical_constraints** command generates a script file containing the Tcl commands used to set the physical constraints that have been applied to the design. The script file is saved in the file specified with the **-output** option.

You can use the generated script file to reapply the physical constraints at a later time by the **read_floorplan** command.

The **write_physical_constraints** command writes commands relative to the top of the design, regardless of the current instance. The output file it writes must be read from the top of the design.

By default, the physical constraints information is written only for the top-level design and includes the boundary information, as well as the following objects: bounds, placement blockages, route guides, plan groups, and voltage areas.

For the physical constraints of pre-routes, the corresponding command is **create_net_shape**. In order to write out the commands, specify the **-pre_route** option.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example command writes the physical constraints into the file named script.tcl:

```
prompt> write_physical_constraints -output script.tcl
```

SEE ALSO

`extract_physical_constraints(2)`
`report_physical_constraints(2)`

write_qtm_model

Writes the Quick Timing Model (QTM) file.

SYNTAX

```
string write_qtm_model
    -out_dir output_qtm_directory
    [-text]
```

Data Types

output_qtm_directory string

ARGUMENTS

-out_dir *output_qtm_directory*

Specifies the name of the output QTM directory

-text

To write out text format file for the QTM model in addition to the .db format file.

DESCRIPTION

This command writes out the QTM model file in Synopsys .db format.

If the *-text* option is provided then the QTM model file is written out in text format also.

This command writes out all the QTM Model(s) in the internal QTM database with different names in one output directory. You must provide the output directory as a command-line option.

The name of the QTM Model is given in **create_qtm_model** command. The name of the output QTM Model file is derived from the QTM Model Name. The output QTM Model file name is <ModelName>.qtm.db.

This command writes out the in-memory .db to on-disk .db file. This command runs slower than **save_qtm_model** command and requires disk I/O. Usually, this command is expected to be called once at the end of an ICC session to get a final version of the QTM model.

For a more detailed description about QTM please refer to the *ICC Design Planning User Guide*.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example writes the QTM Model **adder** in internal QTM database in directory **qtm** as **adder.qtm.db**. This will generate a file **./qtm/adder.qtm.db**.

```
prompt> write_qtm_model -out_dir qtm
```

SEE ALSO

`create_qtm_model(2)`
`save_qtm_model(2)`

write_rp_groups

Writes out the relative placement constraints for the specified relative placement groups.

SYNTAX

```
collection write_rp_groups
  rp_groups | -all
  [-hierarchy]
  [-quiet]
  [-nosplit]
  [-output filename]
  [-create]
  [-leaf]
  [-keepout]
  [-instance]
  [-include]
```

Data Types

rp_groups list or collection
filename string

ARGUMENTS

rp_groups

Specifies the relative placement groups to be written out to the script.

This option is mutually exclusive with the **-all** option.

-all

Specifies that all relative placement groups are to be written out to the generated script.

This option cannot be used with either the *rp_groups* argument or the **-hierarchy** option.

-hierarchy

Specifies that all relative placement groups within the hierarchy of the groups in *rp_groups* are to be written out. By default, subgroups are not written out.

This option is mutually exclusive with the **-all** option.

-quiet

Turns off informational messages that would otherwise be issued if no groups are written.

-nosplit

Specifies not to split long commands into multiple lines. The default is to split long commands into multiple lines.

-output *filename*

Specifies that the script is to be written to *filename*. The default is to write to standard output.

-create

Specifies that the **create_rp_group** commands are included in the generated script.

-leaf

Specifies that the **add_to_rp_group -leaf** commands are included in the generated script.

-keepout

Specifies that the **add_to_rp_group -keepout** commands are included in the generated script.

-instance

Specifies that the **add_to_rp_group -hierarchy -instance** commands are included in the generated script.

-include

Specifies that the **add_to_rp_group -hierarchy** commands (without **-instance**) are included in the generated script.

DESCRIPTION

The **write_rp_groups** command writes the relative placement constraints for the specified relative placement groups. You can use the generated commands to re-create the relative placement groups and their items on the same designs.

When you specify any of the **-create**, **-leaf**, **-keepout**, **-instance**, and **-include** options, the generated script generated contains only the commands related to the specified options. If you do not specify any of these options, all commands are output to the generated script.

The command returns a collection that contains the relative placement groups that are written out. If no objects are written out, the empty string is returned.

Relative placement usage is available with Design Compiler Ultra.

Multicorner-Multimode Support

This command has no dependency on scenario-specific information.

EXAMPLES

The following example uses **write_rp_groups** to re-create relative placement groups after their removal:

```
prompt> get_rp_groups
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> write_rp_groups -all -output my_groups.tcl
{mul::grp_mul ripple::grp_ripple example3::top_group}

prompt> remove_rp_groups -all -quiet
1

prompt> get_rp_groups
Error: Can't find objects matching '*'. (UID-109)
```

```
prompt> source my_groups.tcl
{example3::top_group}

prompt> get_rp_groups
{example3::top_group ripple::grp_ripple mul::grp_mul}
```

SEE ALSO

[add_to_rp_group\(2\)](#)
[create_rp_group\(2\)](#)
[remove_rp_groups\(2\)](#)

write_rtl_load

Writes a script of RTL load commands for the current design.

SYNTAX

```
int write_rtl_load
  [-format dctcl | dcsh]
  [-output file_name]
```

Data Types

file_name string

ARGUMENTS

-format *dctcl | dcsh*

Specifies that the script is to be written in dctcl or dcsh mode. By default, the script is written in the format of the mode from which this command is executed.

-output *file_name*

Specifies that the script is to be written to the specified file. If **-output** is not specified, the script is written to standard output.

DESCRIPTION

The **write_rtl_load** command writes a script of **set_rtl_load** commands. You can use this command to display the RTL loads on the current design, or to write a **set_rtl_load** script file to apply to another design.

By default, the **write_rtl_load** command writes commands to standard output. The **-output** option redirects the output to the specified disk file.

EXAMPLES

In the following example, the RTL loads of the current design are written to the file test.scr.

```
prompt> write_rtl_load -output test.scr
```

In the following example, the RTL loads of the current design are written in dcsh format to standard output.

```
prompt> write_rtl_load
```

SEE ALSO

`set_rtl_load(2)`
`write_script(2)`

write_safety_register_data

Writes a script file for creating safety register rules and groups.

SYNTAX

```
status write_safety_register_data  
-output filename
```

Data Types

filename string

ARGUMENTS

-output *filename*

The name of the output text file where the script for generating rules and groups will be written out. If the file already exists, it will be overwritten.

DESCRIPTION

Writes out a Tcl script file containing commands for creating the safety_register_rules and safety_register_groups. This information can be used in tools in downward flow which do not accept the same database format. The file will be written in ASCII text format and will contain the commands like create_safety_register_rule and create_safety_register_group.

EXAMPLES

The following example writes out a script file which can be sourced in another tool to re-create the safety data.

```
prompt> write_safety_register_data -output ./create_safety_data.tcl
```

SEE ALSO

create_safety_register_rule(2)
set_safety_register_rule(2)
create_safety_register_group(2)

write_saif

Writes a backward Switching Activity Interchange Format (SAIF) file.

SYNTAX

```
status write_saif
  -output file_name
  [-instances instances]
  [-no_hierarchy]
  [-rtl]
  [-propagated]
  [-exclude_sdpd]
```

Data Types

<i>file_name</i>	string
<i>instances</i>	list

ARGUMENTS

-output *file_name*

Specifies the name of the output SAIF file, if the *file_name* ends with the .gz extension, the output file is written in gzip format.

-instances *instances*

Specifies an optional list of instances for which the SAIF file is generated. If this argument is not specified, then the SAIF file is generated for the current instance.

-no_hierarchy

This flag specifies that the SAIF file contains switching activity information for only the top-level design objects. When this flag is not specified, **write_saif** generates a SAIF file containing switching activity information for all the objects in the hierarchy.

-rtl

Specifies that the generated SAIF file contains the switching activity for the synthesis invariant objects. These are the design ports, hierarchical cell pins, and outputs of sequential and tri-state cells. When this option is used on an unmapped design, the generated SAIF file is similar to one generated by RTL simulation flow using an RTL SAIF file. The generated SAIF file can then be read correctly into the synthesized design. If this option is not used when writing a SAIF file for an unmapped design, then the generated SAIF file might not be read correctly after the design has been synthesized, although it can be read correctly on the unmapped design. Note that the -rtl_direct of the **read_saif** command should not be used when reading SAIF files generated by **write_saif**.

-propagated

Propagates the user-annotated switching activity to estimate the switching activity of unannotated objects, and generates a SAIF file containing both the annotated and estimated switching activity. When this option is not specified, the **write_saif** command generates a SAIF file containing the user-annotated switching activity only.

-exclude_sdpd

Excludes state dependent static probabilities and state dependent or path dependent toggle rates from the SAIF file.

DESCRIPTION

The **write_saif** command generates a backward SAIF file containing the design switching activity information.

The **write_saif** command can generate both user-annotated and propagated switching activity information. If you specify the **-propagated** option, the command propagates the switching activity information and generates a SAIF file with both user-annotated and propagated switching activity. If you do not specify the **-propagated** option, the command generates only the user-annotated switching activity.

The top-level instance name in the generated SAIF file is the current design name. This name needs to be specified as the instance name when reading the SAIF file with the **read_saif** command.

When you specify the **-exclude_sdpd** option, the SAIF file contains only the following simple switching activity information: the toggle rate and static probability of the design nets, ports, and cell pins that are not connected to nets.

Note, the related clock information cannot be included in the SAIF file. The toggle rates in the SAIF file are converted to be relative to the synthesis time unit automatically.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example creates a SAIF file containing user-annotated switching activity information on all design objects.

```
prompt> write_saif -output design.saif
```

The following example creates a compressed SAIF file in gzip format containing user-annotated switching activity information on all design objects.

```
prompt> write_saif -output design.saif.gz
```

The following example creates a SAIF file containing both user-annotated and propagated switching activity information.

```
prompt> write_saif -output design.saif -propagated
```

The following example creates a SAIF file on a synthesized design object, and reads in the same file.

```
prompt> write_saif -output design.saif
prompt> reset_switching_activity
prompt> read_saif -input design.saif -instance top
```

The following example generates a SAIF file with user-annotated and propagated switching activity, but does not contain state-dependent and path-dependent information.

```
prompt> write_saif -output design.saif -propagated -exclude_sdpd
```

The following example generates an RTL SAIF file from an unmapped design and read in the file.

```
prompt> write_saif -output rtl.saif -rtl
prompt> reset_switching_activity
prompt> compile
prompt> read_saif -input rtl.saif -instance top
```

write_scan_def

Generates SCANDEF scan chain information for performing scan chain reordering in the physical implementation flow.

SYNTAX

```
int write_scan_def
    [-output def_file]
    [-expand_elements list_of_cells]
```

ARGUMENTS

-output *def_file*

Specifies the name of the SCANDEF output file to create for the physical implementation tool. The default name is *current_design.def*, in the current directory.

-expand_elements *list_of_cells*

Specifies a list of CTL-modeled cell instances whose scan segments must be treated as 'flat' fully visible segments when generating the SCANDEF file.

The default behavior of SCANDEF generation is to treat all cell instances with CTL test model information as black boxes, which are represented in the SCANDEF by the "BITS" construct. When a CTL-modeled cell is specified with this option, the scan chain contents of the cell are included in the SCANDEF file.

DESCRIPTION

The **write_scan_def** command generates scan chain information in SCANDEF format. It is a post-DFT command, intended for use after scan chains are inserted into the design.

Reordering of scan chains in physical implementation tools, such as IC Compiler, requires information about the scan chains that exist in the design. This is because there can be aspects of the scan chains, such as lock-up latches, clock-mixing, or user-defined scan paths or scan segments, that must be considered during reordering. The SCANDEF information describes these scan chain ordering requirements.

The **write_scan_def** command writes the SCANDEF information to the file specified by the **-output** option, or to the default file name if the option is not specified. The command also annotates the SCANDEF information to the current design in memory. If you write the design out in .ddc format, the SCANDEF information is included in the .ddc file. In this case, IC Compiler does not need the SCANDEF file written to disk, but you can use the file for reference.

Generating SCANDEF in a Hierarchical DFT Flow

For any DFT-inserted cores in the design that contain CTL test model information, the **write_scan_def** command abstracts the contents of the core cell with the "BITS" construct. This prevents reordering inside the cell, which is desired behavior for hard and soft macros that are frozen during top-level optimization.

To include ("expand") the contents of DFT-inserted cores, specify the list of core instances with the **-expand_elements** option. These cores must themselves contain SCANDEF information, which is accomplished in the core-level run by using the **write_scan_def** command, then writing out the core design in .ddc or .ctlddc format. If a core does not contain SCANDEF information, DFT Compiler issues a warning:

Warning: SCANDEF information for design instance %s is not available. NETLIST information is available. SCANDEF for design instance %s will be expanded using netlist information.

In this case, DFT Compiler expands the core scan chains by exploring the core netlist structure. Basic reordering requirements such as clock mixing are inferred, but any user-applied core-level scan constraints (such as scan group or scan path definitions) are lost.

EXAMPLES

The following example writes out a SCANDEF file named HUNSLEY.def for the current design HUNSLEY, using the default SCANDEF generation options.

```
prompt> current_design HUNSLEY
prompt> create_test_protocol
prompt> dft_drc
prompt> insert_dft
prompt> dft_drc
prompt> write_scan_def
prompt> check_scan_def
```

The following example writes out a SCANDEF file named HUNSLEY.def that includes the scan elements inside cores CORE1 and CORE2.

```
prompt> current_design HUNSLEY
prompt> create_test_protocol
prompt> dft_drc
prompt> insert_dft
prompt> dft_drc
prompt> write_scan_def -output scan.def \
    -expand_elements [list CORE1 CORE2]
prompt> check_scan_def
```

SEE ALSO

```
create_test_protocol(2)
dft_drc(2)
preview_dft(2)
insert_dft(2)
set_scan_configuration(2)
check_scan_def(2)
```

write_script

Writes shell commands to save the current settings.

SYNTAX

```
int write_script
    [-hierarchy]
    [-no_annotated_check] [-no_annotated_delay] [-no_cg]
    [-full_path_lib_names] [-nosplit]
    [-format dctcl | dcsh]
    [-include loop_breaking]
    [-output file_name]
```

ARGUMENTS

-hierarchy

Writes commands for all designs in the hierarchy.

-no_annotated_check

Indicates that **set_annotated_check** commands are not to be written. By default, annotation commands are written to standard output. Use this option to avoid creating a very large script for designs that contain a large amount of annotated information. Annotated timing checks can be written to a file using the **write_timing** command.

-no_annotated_delay

Indicates that **set_annotated_delay** commands are not to be written. By default, annotation commands are written to standard output. Use this option to avoid creating a very large script for designs that contain a large amount of annotated information. Annotated delays can be written to a file using the **write_timing** command.

-no_cg

Indicates that Power Compiler clock gating attributes are not to be written. By default, **set_attribute** commands are written to standard output for all relevant clock gating attributes. Use this option if clock gate information is not needed for later flow.

-full_path_lib_names

Indicates that library names are to be written with full pathnames. The default is to write only the library name, without the path.

-nosplit

Indicates that lines are not to be split when column fields overflow. This is most useful for doing diffs on previous scripts, or for post-processing the script.

-format dctcl | dcsh

Indicates that the script is to be written in Tcl mode or dcsh mode.

-include loop_breaking

Writes the **set_disable_timing** commands for internally disabled timing arcs.

-output *file_name*

Indicates that the script is to be written to the specified file.

DESCRIPTION

The **write_script** command writes a script of dc_shell commands. This command is used to recreate the attributes on the current design.

By default, the **write_script** command writes dc_shell commands to standard output. User-defined attributes are not supported. Some of the commands whose constraints are written out by **write_script** are listed below. (This is not a complete list.)

```
create_clock
group_path
set_annotated_check
set_annotated_delay
set_boundary_optimization
set_connection_class
set_disable_timing
set_dont_retime
set_dont_touch
set_dont_touch_network
set_drive
set_driving_cell

write_sdc

Writes out a script in Synopsys Design Constraints (SDC) format.

SYNTAX

```
int write_sdc
  file_name
  [-nosplit]
  [-version sdc_version]
```

Data Types

file_name string

ARGUMENTS

file_name

Specifies the name of the file to which the SDC script is to be written.

-nosplit

Indicates that lines are not to be split when column fields overflow. This is most useful when comparing previous script files with the UNIX diff command, or for post-processing the script.

-version *sdc_version*

Specifies the version of SDC to write. Allowed values are **1.2**, **1.3**, **1.4**, **1.5**, **1.6**, **1.7**, **1.8**, **1.9**, **2.0**, **2.1** and **latest** (the default).

DESCRIPTION

The **write_sdc** command writes out a script file in the latest Synopsys Design Constraints (SDC) format. This script contains commands that can be used with PrimeTime or with Design Compiler. SDC is also licensed by external vendors through the Tap-in program. SDC-formatted script files are read into PrimeTime or Design Compiler using the **read_sdc** command.

By default, the script is written as simple text. Also, by default the latest version of SDC is written. Some earlier versions of SDC can be written using the **-version** option.

SDC is a subset of the commands already supported by Design Compiler, Physical Compiler, IC Compiler, Astro, Jupiter, and PrimeTime. Of the commands supported in the latest SDC version, the following may be written by **write_sdc**. Those added for versions 1.3 and later are noted.

General Purpose Commands:

expr
list

set

Object Access Functions:

all_clocks
all_inputs
all_outputs
all_registers (1.7)

set_port_fanout_number
set_resistance
set_wire_load_min_block_size
set_wire_load_mode
set_wire_load_model
set_wire_load_selection_group

```

Like **write_script**, the **write_sdc** command writes out commands relative to the top of the design, regardless of the current instance. SDC files written by **write_sdc** must be read in from the top of the design.

For a complete guide to using SDC with Synopsys applications, see the *Using the Synopsys Design Constraints Format Application Note* which is available through SolvNET at <http://solvnet.synopsys.com>.

The usage of some of the supported commands is restricted when reading SDC. In some cases, some options are not allowed. The **write_sdc** command supports the restricted usage by restricting what is written. The following restrictions apply for SDC Version 1.3:

- For **set_driving_cell**, the **-min** and **-max** options are not supported.
- For **set_port_fanout_number**, the **-min** and **-max** options are not supported.

When the hierarchy has been partially flattened, embedded hierarchy separators can make names ambiguous. It is not clear which hierarchy separator characters are part of the name, and which are real separators. Beginning with SDC Version 1.2, hierarchical names can be made non-ambiguous using the **set_hierarchy_separator** SDC command and/or the **-hsc** option available on the **get_cells**, **get_lib_cells**, **get_lib_pins**, **get_nets**, and **get_pins** SDC object access commands. By default, PrimeTime and Design Compiler write an SDC file using these features to create non-ambiguous names. It is considered best practice to write SDC files that contain names that are not ambiguous. However, if you are using a third-party application that does not fully support SDC 1.2 or later (that is, it does not support the non-ambiguous hierarchical names features of SDC), then you can suppress these features by setting **sdc_write_unambiguous_names** variable to **true**.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following command writes the SDC script to the file named *top.sdc*:

```

prompt> write_sdc top.sdc
1

```

SEE ALSO

`read_sdc(2)`
`write_script(2)`
`sdc_write_unambiguous_names(3)`

write_sdf

Writes a Standard Delay Format (SDF) back-annotation file.

SYNTAX

```
string write_sdf
  [-version sdf_version] [-significant_digits digits]
  [-instance inst_name]
  file_name
```

Data Types

<i>sdf_version</i>	string
<i>inst_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-version *sdf_version*

Selects which SDF version to use. Supported SDF versions are 1.0 or 2.1. SDF 2.1 is the default.

-significant_digits *digits*

Specifies the number of digits to the right of the decimal point that are reported. Allowed values are from 0 through 13; the default is 3. Using this option overrides the value set by the variable **report_default_significant_digits**.

-instance *inst_name*

Specifies that the SDF is to be written only for the instance named *inst_name*.

file_name

Specifies the name of the SDF file to write.

DESCRIPTION

Writes leaf cell pin-to-pin timing information to a disk file. Timing information is written in SDF format using version v1.0 or v2.1. The timing file contains data associated with the netlist from which it is created.

Use **write_sdf** only when the instance names in the design agree with the naming conventions of the system to which the timing file is written.

Timing information can be written in multiples of ns, ps, and us. The time unit in the SDF file is the time unit specified in the technology library and is written in the timing file under 'timescale'. If there is no time unit in the library, the unit is assumed to be a multiple of nanoseconds.

Multicorner-Multimode Support

This command uses information from the current scenario only.

EXAMPLES

The following example writes timing information for the design **MULT16** to a disk file called mult16.sdf, using SDF version 2.1.

```
prompt> write_sdf -version 2.1 mult16.sdf
```

[set_annotated_delay\(2\)](#)
[remove_annotated_check\(2\)](#)
[remove_annotated_delay\(2\)](#)
[report_annotated_check\(2\)](#)
[report_annotated_delay\(2\)](#)
[report_default_significant_digits\(3\)](#)

write_tech_file

Write a technology file from the current library.

SYNTAX

```
status write_tech_file
  [-library lib_name]
  file_name
```

Data Types

<i>lib_name</i>	string
<i>file_name</i>	string

ARGUMENTS

-library *lib_name*

Library from which the technology file to be written, default is current lib.

file_name

The output technology file name.

DESCRIPTION

The **write_tech_file** command writes out a technology file from the user specified library. If there is no library specified, the default is current library.

This command is supported in Design Compiler NXT topographical mode.

EXAMPLES

The following example dump out a technology file "tcb90g.tf" from the current library.

```
prompt> write_tech_file tcbn90g.tf
```

SEE ALSO

`create_lib(2)`
`read_tech_file(2)`

write_test

Formats the test patterns for the current design into one or more test vector files.

SYNTAX

```
status write_test
  [-output output_vector_file_name]
  [-capture_cycle]
  -format stil | wgl_serial | verilog
  [-multiple_pattern_counter list]
  [-multiple_signature list]
  [-multiple_seed list]
  [-multiple_occ list]
```

Data Types

output_vector_file_name string

ARGUMENTS

-output *output_vector_file_name*

Specifies as output the name of the path and base file name for the test program files. By default, test program files are written in the current directory, using the current design name as the base file name.

-capture_cycle *binary_word*

Specifies the self-test capture clock pattern to use. See the "Autonomous Self-Test Operation" section for details.

The valid values are **01** or **10** for a single capture pulse, and **11** for two capture pulses. (The tool zero-pads the capture pattern to the **set_dft_clock_controller -cycles_per_clock** value, if needed.) The default is a single capture pulse. This option requires that OCC clock weights also be configured.

-format **stil** | **wgl_serial** | **verilog**

Selects the format for the output test program. Valid values for *test_program_format* are as follows:

- Specifying **stil** generates STIL patterns.
- Specifying **wgl_serial** generates patterns in serial WGL format.
- Specifying **verilog** generates a Verilog RTL testbench.

DESCRIPTION

The **write_test** command writes out a test pattern file for the current design.

Test patterns can be written for the following:

- Boundary-scan logic
- Autonomous self-test (DFTMAX LogicBIST self-test)

Boundary-Scan Test Patterns

For boundary-scan logic, the **write_test** command writes the test patterns generated for the current design by the **create_bsd_patterns** command into a series of test program files suitable for running on automated test equipment (ATE) or simulators.

The output test program is intended as input to manufacturing ATE. The program specifies the stimuli to be applied to a fabricated chip and specifies the responses that a fully working chip generates. If during the testing process, the chip does not generate the correct responses when the stimuli are applied, the chip is faulty and should be discarded.

By default, all test vectors are placed into a single test program file.

The organization of the test program, in terms of the precise boundary scan test sequence employed, is determined by the boundary scan test protocol for the design inferred by the **create_bsd_patterns** command.

By default, the values used for the 4 timing options are those specified in the test protocol file for the design. In the protocol inferred by the **create_bsd_patterns** command, the default timing values are controlled by the environment variables: **test_default_period**, **test_bsd_default_strobe**, **test_bsd_default_delay**, and **test_bsd_default_bidir_delay**. In addition, the timing of any clock signals can again be specified in a test protocol file or can be specified directly by using the **set_dft_signal** command.

Autonomous Self-Test Operation

For designs with LogicBIST self-test, the **write_test** command writes patterns that perform autonomous self-test. The patterns load the signature value into the PRPG, run autonomous self-test to completion, then measure the resulting signature value against the expected value.

The self-test logic uses the following values to control its operation:

- Seed value
- Signature value
- Pattern counter
- Shift counter (number of shift cycles in each pattern)
- Capture clock mask

By default, the testbench takes no special action for these values. Constant-driven values are driven according to their value. Port-driven values require that the desired values be forced externally using simulator commands or options.

However, if you have implemented self-test logic (in the current design or within a core) that is controlled by DFT-inserted IEEE 1500 logic, the **write_test** command allows you to specify these values, and the testbench loads or compares the values through the IEEE 1500 interface as needed.

Autonomous self-test patterns can be written only in the STIL format.

EXAMPLES

The following example writes out a test program for a design named *HUNSLEY* using the STIL format:

```
prompt> current_design HUNSLEY
prompt> write_test -format stil
Getting test program from design.
Writing test patterns to file HUNSLEY.stil.
1
```

The following example creates a Verilog RTL testbench:

```
prompt> write_test -format verilog
Getting test program from design.
Writing native Verilog test bench to file HUNSLEY_verilog_test.v.
1
```

The following example writes a self-test testbench for a LogicBIST self-test design:

```
prompt> write_test -format stil -output selftest \
    -seed 101110000000111111 \
    -signature 011011000100011110 \
    -shift_counter 101000 \
    -pattern_counter 1110 \
    -capture_cycle 11
...Getting test program from design.
...Writing test patterns to file selftest.stil.
1
```

write_test_model

Writes a test model file.

SYNTAX

```
int write_test_model
  [-format ctl | ddc]
  [-names verilog | verilog_single_bit]
  [-output model_file]
  [-inclusive]
  [-design design_name]
```

Data Types

model_file string
design_name string

ARGUMENTS

-format *ctl* | *ddc*

Specifies the format of the test model file. When **ddc** is specified, the CTL test model information and an interface-only representation of the design are written out to a file. When **ctl** is specified, an ASCII CTL test model file is written out to a file. The default format is **ddc**.

-names *verilog* | *verilog_single_bit*

Specifies the form of the names used in the ASCII CTL model. By default, names are not changed from internal representation. Names can be modified as Verilog names or as Verilog names compatible with the usage of the **verilogout_single_bit** environment variable. In all cases the internal representation is not changed.

-output *model_file*

Specifies the name of the output test model file. By default, the output file name is *design_name.format*.

-inclusive

Expands the include statement when writing out an ASCII CTL file. By default, the included contents are written out to separate files.

-design *design_name*

Specifies the name of the design for which the test model is written. The default is the current design.

DESCRIPTION

The **write_test_model** command writes a test model file to disk.

When **-format ddc** is specified, a test model for the specified design is written out as a .ddc file. This file contains test model information, as well as an interface-only representation of the design. This file can be used to satisfy link requirements for instantiations of that design. The **write_test_model** command does not write out any netlist information for the specified design. If you need both the test model information as well as the full netlist, you should use the **write -format ddc** command instead.

When **-format ctl** is specified, a test model is written to an ASCII CTL file. The ASCII CTL format is primarily used for exporting test models outside of a Synopsys environment. The **write_test_model** command does not modify the version of the design that is in memory.

The **write_test_model** command is insensitive to the **test_stil_netlist_format** application variable.

EXAMPLES

The following example writes out a test model file in .ddc format:

```
prompt> write_test_model -format ddc -output ALARM_SM_2.ddc
Writing test model file
'/home/felixng/DFTC/dft_tutorial/ctl/ ALARM_SM_2.ddc'...
1
```

The following example writes out a test model file in CTL format:

```
prompt> write_test_model -format ctl -output ./ctl/ALARM_SM_2.ctl
Writing test model file
'/home/felixng/DFTC/dft_tutorial/ctl/ALARM_SM_2.ctl'...
1
```

[read_test_model\(2\)](#)
[remove_test_model\(2\)](#)
[report_test_model\(2\)](#)
[write\(2\)](#)

write_test_protocol

Writes a STIL test protocol file.

SYNTAX

```
int write_test_protocol
  [-design design_name]
  [-output file_name]
  [-test_mode mode_name]
  [-instruction instruction_name]
  [-names format_name]
  [-disable_codecs decompressor_list]
```

Data Types

<i>design_name</i>	string
<i>file_name</i>	string
<i>mode_name</i>	string
<i>format_name</i>	string
<i>decompressor_list</i>	list

ARGUMENTS

-design *design_name*

Specifies the design name for which the STIL test protocol is written. The default is the current design.

-output *file_name*

Specifies the name of the text file to which the STIL test protocol is written. If a *file_name* is not specified, the file is named *current_design_name.spf*.

-test_mode *mode_name*

Specifies the test mode from which the STIL protocol is generated.

-instruction *instruction_name*

Specifies that a STIL protocol file should be written for the specified JTAG instruction implemented by BSD Compiler. This option can be used after the **insert_dft** or **check_bsd** commands have been run.

-names *format_name*

Specifies the form of the names used in the STIL protocol. Valid values for *format_name* are as follows:

- The value of **dc_shell** instructs DFT Compiler to write a STIL protocol where the design objects are not changed.
- The value of **verilog** instructs DFT Compiler to write a STIL protocol where the names of the design objects follow the naming rules of the Verilog format. Vectored ports are allowed.
- The value of **verilog_single_bit** instructs DFT Compiler to write a STIL protocol where the names of the design objects follow

the naming rules of the Verilog format. The STIL protocol file will not contain vectored ports, but it will have single bit ports.

Names can be unchanged from internal representation (the default). They can be modified as Verilog names or as Verilog names compatible with the usage of the **verilogout_single_bit** environment variable. In all cases, the internal representation is not changed. This option takes effect only in conjunction with **-test_mode** options, when Hierarchical Scan Synthesis is used. In all other cases, the form of the names is determined by the setting of the **test_stil_netlist_format** variable.

-disable_codecs decompressor_list

Specifies the codecs to be disabled in the test protocol. The default is not to disable any codecs.

Codecs are referenced by decompressor name. You can disable any set of codecs, provided at least one codec is active in the design across all DFT partitions.

If you are using IEEE 1500 test-mode control, this command writes a test protocol that automatically configures the TMCDR codec selection bits as needed.

If you are not using IEEE 1500 test-mode control, this command assumes that you are modifying the test protocol and/or netlist to disable the specified codecs, and it issues a TEST-1473 information message to remind you of this.

This option can only be used for codecs that have codec controls. To insert codecs with codec controls, use the **-shared_codec_controls** option of the **set_scan_compression_configuration** command.

DESCRIPTION

The **write_test_protocol** command outputs the STIL test protocol from memory to disk in text format. This allows you to customize the test protocol.

The scan test protocol formally defines the process by which a design is tested, so the sequence of scan-in vectors, parallel vectors, and scan-out vectors is performed for each test pattern. The protocol defined for a design is used to drive scan test and design rule checking.

If a *file_name* is not specified with the **-output** option, the file is named *current_design_name.spf*.

If the **-test_mode** option is used, the protocol for the specified test mode is written out.

when an OCC (On-Chip Clocking) controller block is present in the design, the protocols for both the "PLL clocks bypassed" and "PLL clocks non-bypassed" modes will be included in the same protocol file.

If the **-instruction** option is used, the protocol is generated for the specified JTAG instruction implemented by BSD Compiler. The instruction name corresponds to the name given to the **set_bsd_instruction** command. This option can be used after one of the following commands has been successfully run:

- **insert_dft**, with BSD synthesis enabled
- **check_bsd**

EXAMPLES

The following example writes a test protocol to the **newUPC1.spf** file:

```
prompt> write_test_protocol -output newUPC1.spf
Writing test protocol file 'newUPC1.spf'...
```

The following example writes a test protocol with two codecs disabled:

```
prompt> write_test_protocol -test_mode MY_COMP \
    -output MY_COMP.spf \
```

```
-disable_codecs { \
  {sub1:sub_1_U_decompressor_ScanCompression_mode \
  sub2:sub_2_U_decompressor_ScanCompression_mode}
```

Writing test protocol file 'MY_COMP.spf'...

The following example writes a test protocol for the **UPC1** design to the default file named **UPC1.spf**:

```
prompt> write_test_protocol
Writing test protocol file 'UPC1.spf'...
```

The following example writes a test protocol for the scan-through-TAP (STT) JTAG instruction:

```
prompt> set_bsd_instruction STT -register STT_REG -code 1101
...
prompt> write_test_protocol -instruction STT -output BSD_STT.spf
Writing test protocol file 'BSD_STT.spf'...
```

write_timing_context

Writes Scenarios constraints and configuration for the current design

SYNTAX

```
status write_timing_context
  -output directory
  [-scenarios scenario_list]
  [-format icc2]
  [-nosplit]
```

ARGUMENTS

-scenarios *scenario_list*

Specifies a list of active and inactive Scenarios for which the timing context will be written for loading in IC Compiler II

-format *icc2*

Specifies for which target tool the timing contexts are to be written. Currently, only the icc2 format is supported.

-nosplit

This argument behaves the same as the -nosplit argument of the **write_script** command.

DESCRIPTION

This command writes a directory containing timing contexts (Scenarios) in a format that may be read into IC Compiler II in order to create and populate the same set of Scenarios as specified in IC Compiler. The output directory will contain a timing context constraint file for each of the specified (or all) Scenarios and scripts to create and populate the IC Compiler II modes, corners and scenarios. The directory structure of the constraint directory created by **write_timing_context** is the same as written by the IC Compiler II **write_script** command

top.tcl - Mode, Corner and Scenario creation and population script.

design.tcl - Scenario-independant timing constraints

scenario_Scen1.tcl - Scenario-specific constraints for the Scenario Scen1

scenario_Scen2.tcl - Scenario-specific constraints for the Scenario Scen2

Multicorner-Multimode Support

By default, this command uses information from all scenarios

EXAMPLES

The following example uses the **write_timing_context** command to create a constraint directory suitable for use in IC Compiler II.

```
icc> get_scenarios -setup true -active true;  
Func::COLD Func::HOT  
  
icc> write_timing_context -format icc2 -nosplit -verbose -output CONS4ICC2 -scenarios [get_scenarios -setup true -active true];  
  
icc.2> open_block netlist;  
icc.2> source CONS4ICC2/top.tcl;  
icc.2> get_object_names [get_scenarios -filter setup&&active];  
Func::HOT Func::COLD
```
